4. In the Oracle Console, edit the VCN's security rules to enable ingress TCP and UDP traffic on ports 4500 and 500 like you did for the AWS security groups and network ACLs. You can use the AWS Libreswan VM public IP address instead of 0.0.0.0/0 if it's a persistent public IP. Also open all protocols and ports for ingress traffic from the AWS VPC CIDR (10.0.0.0/16). Remember: Security lists are associated with a subnet, so edit the security
Networking

list associated with each subnet that needs to communicate with the AWS VPC. Or, if you're using VCN network security groups, edit the rules in the relevant NSGs.

5. In the Oracle Console, edit the VCN’s route tables to add a rule that has the AWS VPC CIDR (10.0.0.0/16) as the destination CIDR block and the DRG you created earlier as the target. Remember: Route tables are associated with a subnet, so edit the route table associated with each subnet that needs to communicate with the AWS VPC. The following screenshot shows the route table for the VCN with an added route for the AWS VPC CIDR.

Task 3: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- `${cpeLocalIP}`: The IP address of your Libreswan device.
- `${cpePublicIpAddress}`: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from `${cpeLocalIP}`.
- `${oracleHeadend1}`: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${oracleHeadend2}`: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${vti1}`: The name of the first VTI used. For example, vti1.
- `${vti2}`: The name of the second VTI used. For example, vti2.
- `${sharedSecret1}`: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${sharedSecret2}`: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${vcnCidrNetwork}`: The VCN IP range.

Task 4: Set up the configuration file: `/etc/ipsec.d/oci-ipsec.conf`

Libreswan configuration uses the concept of left and right to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the conn in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **Left**: Your local Libreswan CPE
- **Right**: The Oracle VPN headend

Use the following template for your `/etc/ipsec.d/oci-ipsec.conf` file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.
Important:
If your CPE is behind a 1–1 NAT device, uncomment the `leftid` parameter and set it equal to the `${cpePublicIpAddress}`.

```plaintext
conn oracle-tunnel-1
  left=${cpeLocalIP}
  # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
  right=${oracleHeadend1}
  authby=secret
  leftsubnet=0.0.0.0/0
  rightsubnet=0.0.0.0/0
  auto=start
  mark=5/0xffffffff # Needs to be unique across all tunnels
  vti-interface=${vti1}
  vti-routing=no
  ikev2=no # To use IKEv2, change to ikev2=insist
  ike=aes_cbc256-sha2_384;modp1536
  phase2alg=aes_gcm256;modp1536
  encapsulation=yes
  ikelifetime=28800s
  salifetime=3600s

conn oracle-tunnel-2
  left=${cpeLocalIP}
  # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
  right=${oracleHeadend2}
  authby=secret
  leftsubnet=0.0.0.0/0
  rightsubnet=0.0.0.0/0
  auto=start
  mark=6/0xffffffff # Needs to be unique across all tunnels
  vti-interface=${vti2}
  vti-routing=no
  ikev2=no # To use IKEv2, change to ikev2=insist
  ike=aes_cbc256-sha2_384;modp1536
  phase2alg=aes_gcm256;modp1536
  encapsulation=yes
  ikelifetime=28800s
  salifetime=3600s
```

Task 5: Set up the secrets file: `/etc/ipsec.d/oci-ipsec.secrets`

Use the following template for your `/etc/ipsec.d/oci-ipsec.secrets` file. It contains two lines per IPSec connection (one line per tunnel).

```plaintext
${cpePublicIpAddress} ${ipAddress1}: PSK "${sharedSecret1}"
${cpePublicIpAddress} ${ipAddress2}: PSK "${sharedSecret2}"
```

Task 6: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service with the following command.

```plaintext
Important:
Restarting the Libreswan service may impact existing tunnels.
```

```
service ipsec restart
```
**Task 7: Configure IP routing**

Use the following `ip` command to create static routes that send traffic to your VCN through the IPSec tunnels. If you're logged in with an unprivileged user account, you might need to use `sudo` before the command.

```
<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static routes created with the IP route command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.</td>
</tr>
</tbody>
</table>
```

```
ip route add ${VcnCidrBlock} nexthop dev ${vti1} nexthop dev ${vti2}
ip route show
```

**Verification**

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see [VPN Connect Metrics](#) on page 3164.

If you have issues, see [VPN Connect Troubleshooting](#) on page 3166.

**Checking the Libreswan Status**

Check the current state of your Libreswan tunnels by using the following command:

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you're using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

**Checking the Tunnel Interface Status**

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as tcpdump with the interfaces.

Here's an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>
vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
   inet6 2001:db8::1 prefixlen 64 scopeid 0x20<link>
      tunnel txqueuelen 1000 (IPIP Tunnel)
      RX packets 0 bytes 0 (0.0 B)
      RX errors 0 dropped 0 overruns 0 frame 0
      TX packets 0 bytes 0 (0.0 B)
      TX errors 10 dropped 0 overruns 0 carrier 10 collisions 0

vti02: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
   inet6 2001:db8::2 prefixlen 64 scopeid 0x20<link>
      tunnel txqueuelen 1000 (IPIP Tunnel)
      RX packets 0 bytes 0 (0.0 B)
```

Networking

| RX errors 0 dropped 0 overruns 0 frame 0 |
| TX packets 0 bytes 0 (0.0 B)          |
| TX errors 40 dropped 0 overruns 0 carrier 40 collisions 0 |

Here's an example of the `ip link show` output:

```
ip link show
<output trimmed>

9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
   state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.1.2.3 peer 192.168.0.51

10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
    state UNKNOWN mode DEFAULT group default qlen 1000
    link/ipip 10.1.2.3 peer 192.168.0.49
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.

**Network Performance**

The content in the sections below apply to **Category 7** and **Section 3.c** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation. You can download a PDF from the Oracle Cloud Infrastructure Service Level Agreement page.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for network throughput between instances in the same availability domain in a virtual cloud network (VCN). You might think of this as a measurement of LAN performance.

**Important:**

This SLA applies only to bare metal instances.

To meet the SLA, the network throughput for instances within the same availability domain and VCN must be at least 90% of the stated maximum for at least 99.9% of the billing month. Network throughput is measured in megabits per second (Mbps) or gigabits per second (Gbps).

For the stated maximum bandwidth by instance shape, see the "Network Bandwidth" column in the "Shape" tables.

**Testing Methodology**

Launch two bare metal instances in the same availability domain and VCN. Install and run the `iperf3` utility, with one instance as server and the other as client. Look at the `iperf3` bandwidth results to determine your VCN's network throughput.

1. Launch two bare metal instances in the same availability domain in a single VCN. Designate one as the server and the other as the client. For launch instructions, see Creating an Instance on page 695.
2. Install `iperf3` on both instances. Example Linux command:
   ```bash
   sudo yum install -y iperf3
   ```
3. Enable communication to the server instance on TCP port 5201 (for `iperf3`):
   a. For the subnet that the server instance is in, add a rule to the subnet's security list to allow stateless ingress traffic on TCP port 5201 from any source IP address (0.0.0.0/0) and any source port. For instructions, see
To update rules in an existing security list on page 2853. If you are instead using network security groups (NSGs) with the instance, add the rule to the instance's NSG.

b. On the instance itself, open the firewall to allow iperf3 traffic. Example Linux commands:

```
Caution:
For instances with an iSCSI boot volume, the following --reload command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.
```

```
sudo firewall-cmd --zone=public --permanent --add-port 5201/tcp
sudo firewall-cmd --reload
```

4. Start the iperf3 test:
   a. On the server instance, run iperf3 in server mode. Example Linux command:

```
iperf3 -s
```

   b. On the client instance, run iperf3 in client mode and specify the private IP address of the server instance. Example Linux command:

```
iperf3 -c <server_instance_private_ip_address>
```

5. Look at the iperf3 results on the client instance. The network throughput between the two instances is shown under "Bandwidth" in the last five lines of the client's iperf3 test output. For example:

```
- - - - - - - - - - - - - - - - - - - - - - - - -
[ ID] Interval         Transfer      Bandwidth        Retr
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec  752
 sender
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec
 receiver
iperf Done.
```

Frequently Asked Questions

Q: My VCN isn't meeting the bandwidth SLA. What should I do?
A: Ensure that the CPU on the instance isn't loaded heavily with other services or applications. Confirm with a utility such as `top` to look at the average CPU utilization. It should be less than one.

Q: Can I use the preceding iperf instructions to test performance between hosts that are not in the same availability domain, or between a host in the VCN and a host in the on-premises network?
A: Yes. The instructions can be used to test performance between any two endpoints. For accurate results, when transferring data outside an availability domain, you must add `--parallel 5` at the end of the client connection command.

Networking Metrics

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

There are multiple Monitoring service metric namespaces related to networking resources.

For instance connectivity:

- `oci_vcn`: Metrics related to `VNICs`. See VNIC Metrics on page 3321.

For cloud connectivity:
Networking

- **oci_fastconnect**: Metrics related to *FastConnect*. See *FastConnect Metrics* on page 3236.
- **oci_vpn**: Metrics related to an *IPSec VPN connection*. See *VPN Connect Metrics* on page 3164.
- **oci_service_gateway**: Metrics related to a *service gateway*. See *Service Gateway Metrics* on page 3325.

**VNIC Metrics**

You can monitor the health, capacity, and performance of your Networking service VNICs by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_vcn` (the Networking service).

Resources: virtual network interface cards (VNICs).

**Overview of Metrics for an Instance and Its Network Devices**

If you're not already familiar with the different types of metrics available for an instance and its storage and network devices, see *Compute Instance Metrics* on page 788.

**Overview of Metrics: oci_vcn**

Each Compute instance has one or more Networking service *VNICs*. A VNIC connects the instance to a subnet in a virtual cloud network (VCN). A given VNIC controls how the instance communicates with endpoints inside the VCN (other instances) and endpoints outside the VCN (hosts on the internet, in your on-premises network, in another VCN, and so on).

With the Networking service metrics (in metric namespace `oci_vcn`), you can get this information for a VNIC:

- **Traffic to and from the network**: Per-VNIC traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of your instances
- **Packets dropped due to security list violations**: Per-VNIC drops (dropped packets), which can help you identify changes in traffic caused by security list changes

The following diagram illustrates the general concept. A given instance resides in a subnet within a VCN that has one or more gateways to communicate with other networks. The instance is enlarged to show its VNIC, which the instance uses to communicate with the network. In this context, the term network means both the other instances in the VCN and hosts outside the VCN available through the gateways.

The VNIC receives traffic from the network and sends traffic to the network. The Networking service drops packets according to security list rules you set up for the instance's subnet. Traffic coming to the VNIC from the network is measured after the Networking service drops the packets that violate the subnet's security list rules. Traffic leaving the VNIC is measured before the Networking service drops the packets that violate the subnet's security list rules.
Networking

The Compute service separately reports network-related metrics as measured on the instance itself and aggregated across all the attached VNICs. Those metrics are available in the oci_computeagent metric namespace. For more information, see Compute Instance Metrics on page 788.

Raw Data Point Frequency

For every 1-minute interval, the Networking service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, 1-hour (60-minute), and 1-day intervals. Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the 1h or 1d interval values are supported. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

- The mean for each 5-minute interval is calculated over five raw data points.
The mean for each 60-minute interval is calculated over 60 raw data points.

**Required IAM Policy**

When writing an IAM policy for viewing VNIC metrics, it's important to remember that:

- The VNIC and the VNIC's metrics (emitted by the `oci_vcn` metric namespace) reside in the subnet's compartment, and not the instance's compartment.
- The VNIC attachment (which is an object different from the VNIC itself) resides in the instance's compartment.

If the instance and subnet are in the same compartment, these details aren't so important when you write the IAM policy.

**Minimum required policy for getting VNIC metrics**

The following policy contains the one statement required to get VNIC metrics, which are part of the `oci_vcn` metric namespace.

If you're using the Console, this policy lets you go to the Monitoring tab in the Console and view the metrics for one or more VNICs in the specified compartment. The policy uses an example group called VnicMetricReaders. The condition at the end (`where target.metrics.namespace='oci_vcn'`) allows the group to view only the metrics in the `oci_vcn` metric namespace.

Allow group VnicMetricReaders to read metrics in compartment `<subnet_compartment>` where target.metrics.namespace='oci_vcn'

**Policy for viewing a VNIC's details and metrics in the Console**

The following policy lets you view an instance in the Console, click through to a specific VNIC, and then view that VNIC's details and metrics.

Allow group VnicMetricReaders to read metrics in compartment `<subnet_compartment>` where target.metrics.namespace='oci_vcn'

Allow group VnicMetricReaders to read instance-family in compartment `<instance_compartment>`

Allow group VnicMetricReaders to inspect virtual-network-family in compartment `<subnet_compartment>`

The second and third statements let you view the instance's details and the VNIC's details, respectively.

**Available Metrics: oci_vcn**

The metrics listed in the following table are automatically available for any VNIC on any instance you create. You do not need to enable monitoring on the instance to get these metrics for the VNIC or VNICs on the instance.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimension:

**RESOURCEID**

The *OCID* of the VNIC.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>VnicEgressDropsSecurityList</td>
<td>Egress Packets Dropped by Security List</td>
<td>packets</td>
<td>Packets sent by the VNIC, destined for the network, dropped due to security rule violations.</td>

<td>packets</td>
<td>Packets sent from the VNIC to the network, before drops.</td>
<td></td>
</tr>
</tbody>
</table>

* The Compute service separately reports network-related metrics as measured on the instance itself and aggregated across all the attached VNICs. Those metrics are available in the oci_computeagent metric namespace. For more information, see Compute Instance Metrics on page 788.

**Tips for Working with VNIC Metrics**

Here are some tips to help you use VNIC metrics.

**Default Metric Charts for One VNIC Versus Multiple VNICs**

The default charts for VNIC metrics use these default settings:

- Time range = the last hour
- Interval = 1 minute
- Statistic displayed: Sum
- Aggregation of metric streams = not selected (which means each VNIC is displayed as a separate line on the chart)

You can view the default charts with data for only a single VNIC by viewing the VNIC's details in the Console. When looking at a single VNIC, these statistics are the most useful: sum, mean, max, and min.

You can view the default charts with data for multiple VNICs by going to the Service Metrics page in the Console. Select the necessary compartment and metric namespace (oci_vcn) at the top of the page. For all the charts, you can either show each VNIC as a separate line, or show a single line that aggregates the data for all the VNICs in your selected compartment. To aggregate the data, select the check box for Aggregate Metric Streams.

When viewing aggregated data, you can use the P90 - P99.9 statistics to help identify typical behavior of your instance fleet and outliers. To view these statistics over an even larger number of data points, expand the chart's start and end time (for example, view the last 7 days instead of the last hour), and set the interval to 1 hour.

For general information about how to work with and modify the default metric charts, see Using the Console on page 2672 in the Monitoring documentation.
Alarms for VNIC Metrics

You can set up alarms for a given metric. For VNICs, an alarm makes the most sense for the egress security list drops metric (VnicEgressDropsSecurityList). In a normal situation, you shouldn't have egress security list drops. If you do, it might be due to one of the following causes:

- An application is behaving in an unexpected manner
- Your security list is incorrectly configured

In either case, an alarm is warranted.

Using the Console

To view default metric charts for a single VNIC

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance to view its details.
3. Under Resources, click Attached VNICs.
4. Click the VNIC to view its details.
5. Under Resources, click Metrics.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for multiple VNICs

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the VNICs you're interested in. Remember that a given VNIC resides in its subnet's compartment.
3. For Metric Namespace, select oci_vcn.

The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

Tip:

If the compartment has multiple VNICs, the charts default to show a separate line for each VNIC. By selecting the check box for Aggregate Metric Streams on the right side of the page, you can show a single line aggregated across all the VNICs.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Service Gateway Metrics

You can monitor the health, capacity, and performance of your service gateways by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

This topic describes the metrics emitted by the metric namespace oci_service_gateway.

Resources: Service gateways
Overview of Metrics: oci_service_gateway

A service gateway is used to enable on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

The available metrics help you determine quickly if your service gateway is up, how much data is flowing through the gateway, and if packets are being dropped for unexpected errors.

- Traffic to and from the service gateway: Per-gateway traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of the gateway.
- Packets dropped: Per-gateway drops (dropped packets), which can help you identify changes in traffic caused by issues such as gateway misconfiguration or unrecognized packet protocol.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_service_gateway

The metrics listed in the following table are automatically available for each service gateway that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes one or more of the following dimensions:

- **RESOURCEID**: The OCID of the service gateway.
- **DROPTYPE**: The type of packet drop:
  - sgwDisabledDrops: Packets dropped because the service gateway is disabled.
  - sgwMtuExceededDrops: Packets dropped because the Maximum Transmission Unit (MTU) has been exceeded.
  - sgwServiceDestUnknown: Packets dropped because of an unknown or incorrect service destination.
  - sgwTtlExpiryDrops: Packets dropped because the TTL (Time To Live) value in the IPv4 header of the packet has expired.
  - sgwMisconfigurationDrops: Packets dropped because the gateway service moniker is misconfigured. For example, the gateway's associated route table points to a different CIDR service than the one specified in the gateway configuration.
  - sgwUnknownProtocolDrops: Packets dropped because the protocol in the IPv4 header of the packet is not recognized.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>packetsToService</td>
<td>Packets to Service</td>
<td>Packets</td>
<td>The number of packets successfully sent from the service gateway toward Oracle services.</td>
<td>resourceId</td>
</tr>
<tr>
<td>packetsFromService</td>
<td>Packets from Service</td>
<td>Packets</td>
<td>The number of packets successfully sent from the service gateway toward customer instances.</td>
<td></td>
</tr>
<tr>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Dimensions</td>
<td></td>
</tr>
<tr>
<td>--------------------</td>
<td>------</td>
<td>-------------</td>
<td>------------</td>

</tr>
<tr>
<td>sgwDropsToService</td>
<td>Packets</td>
<td>The number of packets dropped while sending packets from the service gateway toward Oracle services.</td>
<td>resourceId, dropType</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

To view default metric charts for all service gateways in a compartment:

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. In Compartment, select the compartment you're interested in.
3. For Metric Namespace, select oci_service_gateway.
4. The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

By default, the charts show a separate line for each resource in the compartment.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Troubleshooting**

These topics cover some common issues and how to address them:

- Hanging Connection on page 3327
- Subnet or VCN Deletion on page 3334
- Redundancy Remedies on page 3336
- VPN Connect Troubleshooting on page 3166
- FastConnect Troubleshooting on page 3241

**Hanging Connection**

This topic covers one of the most common issues seen with communications between your cloud network and on-premises network: a hanging connection, even though you can ping hosts across the connection.

**Summary of Problem and Solutions**

**Symptom:** Your virtual cloud network (VCN) is connected to your existing on-premises network via an IPSec VPN, or Oracle Cloud Infrastructure FastConnect. Hosts on one side of the connection can ping hosts on the other side, but the connection hangs. For example:

- You can SSH to a host across the connection, but after you log in to the host, the connection hangs.
• You can start a Virtual Networking Computing (VNC) connection, but the session hangs.
• You can start an SFTP download, but the download hangs.

General problem: Path Maximum Transmission Unit Discovery (PMTUD) is probably not working on one or both sides of the connection. It must be working on both sides of the connection so that both sides can know if they're trying to send packets that are too large for the connection and adjust accordingly. For a brief overview of Maximum Transmission Unit (MTU) and PMTUD, see Overview of MTU on page 3329 and Overview of PMTUD on page 3330.

Solutions for fixing PMTUD:

1. **Ensure that your hosts are configured to use PMTUD:** If the hosts in your on-premises network don't use PMTUD (that is, if they don't set the Don't Fragment flag in the packets), they have no way to discover if they're sending packets that are too large for the connection. Your instances on the Oracle side of the connection use PMTUD by default. Do not change that configuration on the instances.

2. **Ensure both the VCN security lists and the instance firewalls allow ICMP type 3 code 4 messages:** When PMTUD is in use, the sending hosts receive a special ICMP message if they send packets that are too large for the connection. Upon receipt of the message, the host can dynamically update the size of the packets to fit the connection. However, your instances can't receive these important ICMP messages if both the security lists for the subnet in the VCN and the instance firewalls aren't configured to accept them.

   Tip:
   
   If you're using stateful security list rules (for TCP, UDP, or ICMP traffic), you don't need to ensure that your security list has an explicit rule to allow ICMP type 3 code 4 messages because the Networking service tracks the connections and automatically allows those messages. Stateless rules require an explicit ingress security list rule for ICMP type 3 code 4 messages. Confirm that the instance firewalls are set up correctly.

3. **Ensure that your router honors the Don't Fragment flag:** If the router doesn't honor the flag and thus ignores the use of PMTUD, it sends fragmented packets to the instances in the VCN, which is bad (see Why Avoid Fragmentation? on page 3329). The VCN's security lists are most likely configured in such a way that they recognize only the initial fragment, and the remaining ones are dropped, causing the connection to hang. Instead, your router should use PMTUD and honor the Don't Fragment flag to determine the correct size of unfragmented packets to send through the connection.

The parts of the solution are numbered and called out in red italics in the following diagram. It shows an example scenario with your on-premises network connected to your VCN over an IPSec VPN.
Keep reading for a brief overview of MTU and PMTUD, and how to check if PMTUD is working on both sides of the network connection.

**Why Avoid Fragmentation?**

You may be wondering why you want to avoid fragmentation. First, it adversely affects the performance of your application. Fragmentation requires reassembly of the fragments and retransmission if fragments are lost. Reassembly and retransmission require time and CPU resources.

Second, only the first fragment contains the source and destination port information. This means that firewalls or your VCN's security lists will probably drop the other packets, because they are typically configured to evaluate the port information. For fragmentation to work with your firewalls and security lists, you would have to configure them to be more permissive than usual, which is not desirable.

**Overview of MTU**

The communications between any two hosts across an Internet Protocol (IP) network use packets. Each packet has a source and destination IP address and a payload of data. Every network segment between the two hosts has a *Maximum Transmission Unit (MTU)* that represents the number of bytes that a single packet can carry.

The standard internet MTU size is 1500 bytes. This is also true for most home networks and many corporate networks (and their Wi-Fi networks). Some data centers, including those for Oracle Cloud Infrastructure, can have a larger MTU. The Compute instances use an MTU of 9000 by default. On a Linux host, you can use the `ifconfig` command to display the MTU of the host's network connection. For example, here's the `ifconfig` output from an Ubuntu instance (the MTU is highlighted in red italics):

```
ifconfig
ens3 Link encap:Ethernet HWaddr 00:00:00:00:00:01
inet addr:10.0.6.9 Bcast:10.0.6.31 Mask:255.255.255.224
inet6 addr: 2001:db8::/32 Scope:Link
UP BROADCAST RUNNING MULTICAST
MTU: 9000
Metric: 1
```

For comparison, here's the output from a machine connected to a corporate network:

```
ifconfig
en0: flags=8863<UP,BROADCAST,SMART,RUNNING,SIMPLEX,MULTICAST>

mtu 1500
```

Notice that its MTU is the more typical 1500 bytes.

If the host is connected through a corporate VPN, the MTU is even smaller, because the VPN tunnel must encapsulate the traffic inside an IPsec packet and send it across the local network. For example:

```
ifconfig
utun0: flags=81d1<UP,POINTOPOINT, RUNNING, NOARP, PROMISC, MULTICAST>

mtu 1300
```

How do the two hosts figure out how large of a packet they can send to each other? For many types of network traffic, such as HTTP, SSH, and FTP, the hosts use TCP to establish new connections. During the initial three-way handshake between two hosts, they each send the *Maximum Segment Size (MSS)* for how large their payload can be. This is smaller than the MTU. (TCP runs inside the Internet Protocol (IP), which is why it's referred to as TCP/IP. Segments are to TCP what packets are to IP.)
Networking

Using the `tcpdump` application, you can see the MSS value shared during the handshake. Here's an example from `tcpdump` (with the MSS highlighted in red italics):

```
12:11:58.846890 IP 192.168.0.25.22 > 10.197.176.19.58824: Flags [S.], seq 2799552952, ack 2580095593, win 26844, options [mss 1260, sackOK,TS val 44858491 ecr 1321638674,nop,wscale 7], length 0
```

The preceding packet is from an SSH connection to an instance from a laptop connected to a corporate VPN. The local network the laptop uses for its internet connection has an MTU of 1500 bytes. The VPN tunnel enforces an MTU of 1300 bytes. Then when the SSH connection is attempted, TCP (running inside the IP connection) tells the Oracle Cloud Infrastructure instance that it supports TCP segments that are less than or equal to 1260 bytes. With a corporate VPN connection, the laptop connected to the VPN typically has the smallest MTU and MSS compared to anything it's communicating with across the internet.

A more complex case is when the two hosts have a larger MTU than some network link between them that is not directly connected to either of them. The following diagram illustrates an example.

The example shows two servers, each directly connected to its own routed network that supports a 9000-byte MTU. The servers are in different data centers. Each data center is connected to the internet, which supports a 1500-byte MTU. An IPSec VPN tunnel connects the two data centers. That tunnel crosses the internet, so the inside of the tunnel has a smaller MTU than the internet. In this diagram, the MTU is 1380 bytes.

If the two servers try to communicate (with SSH, for example), during the three-way handshake, they agree on an MSS around 8960. The initial SSH connection might succeed, because the maximum packet sizes during the initial SSH connection setup are usually less than 1380 bytes. When one side tries to send a packet larger than the smallest link between the two endpoints, Path MTU Discovery (PMTUD) becomes critical.

**Overview of PMTUD**

Path MTU Discovery is defined in RFC 1191. It works by requiring the two communicating hosts to set a Don't Fragment flag in the packets they each send. If a packet from one of these hosts reaches a router where the egress (or outbound) interface has an MTU smaller than the packet length, the router drops that packet. The router also returns an ICMP type 3 code 4 message to the host. This message specifically says "Destination Unreachable, Fragmentation Needed and Don't Fragment Was Set" (defined in RFC 792). Effectively the router tells the host: "You told me not to fragment packets that are too large, and this one's too large. I'm not sending it." The router also tells the host the maximum size packets allowed through that egress interface. The sending host then adjusts the size of its outbound packets so they're smaller than the value the router provided in the message.

Here's an example that shows the results when an instance tries to ping a host (203.0.113.2) over the internet with an 8000-byte packet and the Don't Fragment flag set (that is, with PMTUD in use). The returned ICMP message is highlighted in red italics:

```
ping 203.0.113.2 -M do -s 8000
PING 203.0.113.2 (203.0.113.2) 8000(8028) bytes of data.
```
Networking

From 10.0.0.2 icmp_seq=1
Frag needed and DF set (mtu = 1500)

The response is exactly what's expected. The destination host is across the internet, which has an MTU of 1500 bytes. Even though the sending host's local network connection has an MTU of 9000 bytes, the host can't reach the destination host with the 8000-byte packet and gets an ICMP message accordingly. PMTUD is working correctly.

For comparison, here's the same ping, but the destination host is across an IPSec VPN tunnel:

ping 192.168.6.130 -M do -s 8000
PING 192.168.0.130 (192.168.0.130) 8000(8028) bytes of data.
From 192.0.2.2 icmp_seq=1 Frag needed and DF set
(mtu = 1358)

Here the VPN router sees that to send this packet to its destination, the outbound interface is a VPN tunnel. That tunnel goes across the internet, so the tunnel must fit inside the internet's 1500-byte MTU link. The result is that the inside of the tunnel only allows packets up to 1360 bytes (which the router then lowered to 1358, which can make things more confusing).

Finding Where PMTUD Is Broken

If PMTUD isn't working somewhere along the connection, you need to figure out why and where. Typically it's because the ICMP type 3 code 4 packet (from the router with the constrained link that can't fit the packet) never gets back to the sending host. This can happen if there's something blocking that kind of traffic between the host and the router. And it can happen on either side of the VPN tunnel (or other constrained MTU link).

Try Pinging From Each Side of the Connection

To troubleshoot the broken PMTUD, you must determine if PMTUD is working on each side of the connection. In this scenario, let's assume the connection is an IPSec VPN.

How to ping: Like in Overview of PMTUD on page 3330, ping a host on the other side of the connection with a packet that you know is too large to fit through the VPN tunnel (for example, 1500 bytes or larger). Depending on which operating system the sending host uses, you might need to format the ping command slightly different to ensure the Don't Fragment flag is set. For both Ubuntu and Oracle Linux, you use the -M flag with the ping command.

Here's information about the -M flag:

-M pmtudisc_opt
Select Path MTU Discovery strategy. pmtudisc_option may be either do (prohibit fragmentation, even local one), want (do PMTU discovery, fragment locally when packet size is large), or dont (do not set DF flag).

Here's an example ping (with the -M flag and the resulting ICMP message highlighted in red italics)

ping
-M do
-s 1500 192.168.6.130
PING 192.168.0.130 (192.168.0.130) 1500(1528) bytes of data.
From 10.0.0.2 icmp_seq=1
Frag needed and DF set (mtu = 1358)
**Good: PMTUD is working**

If the result includes the line "From x.x.x.x icmp_seq=1 Frag needed and DF set (mtu = xxxx)", then PMTUD is working on that side of the tunnel. Note that the source address of the ICMP message is the public IP address of the tunnel the traffic is trying to go out (for example 203.0.113.13 in the preceding Ubuntu example).

Also, ping from the other side of the connection to confirm PMTUD is working from that side. Both sides of the connection must recognize that there is a tunnel between them that can't fit the large packets.

**Bad: If you're testing your side of the connection and the ping succeeds**

If you're sending the ping from a host in your on-premises network, and the ping succeeds, that probably means your edge router is not honoring the Don't Fragment flag. Instead the router is fragmenting the large packet. The first fragment reaches the destination host, so the ping succeeds, which is misleading. If you try to do more than just ping, the fragments after the first get dropped, and the connection will hang.

**Verify that your router configuration honors the Don't Fragment flag.** The router's default configuration is to honor it, but someone might have changed the default.

**Bad: If you're testing the VCN side of the connection and you don't see the ICMP message**

When testing from the VCN side of the connection, if you don't see the ICMP message in the response, there is probably something dropping the ICMP packet before it reaches your instance.

There could be two issues:

- **Security list:** The Networking security list could be missing an ingress rule that allows ICMP type 3 code 4 messages to reach the instance. This is an issue only if you're using stateless security list rules. If you're using stateful rules, your connections are tracked and the ICMP message is automatically allowed without needing a specific security list rule to allow it. If you're using stateless rules, ensure that the subnet the instance is in has a security list with an ingress rule that allows ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port. For more information, see Security Lists on page 2850, and specifically To update rules in an existing security list on page 2853.

- **Instance firewall:** The instance's firewall rules (set in the OS) could be missing a rule that allows ICMP type 3 code 4 messages to reach the instance. Specifically for a Linux instance, ensure that iptables or firewalld is configured to allow the ICMP type 3 code 4 messages.

**Avoiding the Need for PMTUD**

Oracle recommends using PMTUD. However, in some situations it's possible to configure servers so they don't need to rely on it. Consider the case of the instances in your VCN communicating across an IPSec VPN to hosts in your on-premises network. You know the range of IP addresses for your on-premises network. You can add a special route to your instances that specifies the maximum MTU to use when communicating with hosts in that address range. The instance-to-instance communication within the VCN still uses an MTU of 9000 bytes.

The following information shows how to set that route on a Linux instance.

The default route table on the instance typically has two routes: the default route (for the default gateway), and a local route (for the local subnet). For example:

```
ip route show
default via 10.0.6.1 dev ens3
10.0.6.0/27 dev ens3 proto kernel scope link src 10.0.6.9
```

You can add another route that points to the same default gateway, but with the address range of the on-premises network and a smaller MTU. For example, in the following command, the on-premises network is 1.0.0.0/8, the default gateway is 10.0.6.1, and the maximum MTU size is 1300 for packets being sent to the on-premises network.

```
ip route add 1.0.0.0/8 via 10.0.6.1 mtu 1300
```

The updated route table looks like this:

```
ip route show
```

```
Within the VCN, the instance-to-instance communication continues to use 9000 MTU. However, communication to the on-premises network uses a maximum of 1300. This example assumes there's no part of the connection between the on-premises network and VCN that uses an MTU smaller than 1300.

**Important:**
The preceding commands do not persist if you reboot the instance. You can make the route permanent by adding it to a configuration file in the OS. Oracle Linux, for example, uses an interface-specific file called `/etc/sysconfig/network-scripts/route-<interface>`. For more information, see the documentation for your variant of Linux.

**VCN Troubleshooting**

**Breaking API Changes**
If anyone in your organization implements a regional subnet, be aware that you may need to update any client code that works with Networking service subnets and private IPs. There are possible breaking API changes. For more information, see the regional subnet release note.

**DNS Resolver Endpoints**
Network security groups (NSGs) act as a virtual firewall for your DNS resolver endpoints. An NSG consists of a set of ingress and egress security rules that apply only to the associated DNS resolver endpoints.

**Secondary IP Address**
If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**DNS in Your VCN**
You use the Domain Name Server DHCP option to specify the DNS Type for the associated subnet. If you change the option's value, either restart the DHCP client on the instance or reboot the instance. Otherwise, the change does not get picked up until the DHCP client refreshes the lease (within 24 hours).

By default, the Internet and VCN Resolver does not let instances resolve the hostnames of hosts in your on-premises network connected to your VCN by IPSec VPN connection or FastConnect. That functionality can be achieved either by using a custom resolver or by configuring the VCN's private DNS resolver.

**Requirements for DNS Labels and Hostnames**
- VCN and subnet labels: Max 15 alphanumeric characters and must start with a letter. **Notice that hyphens and underscores are NOT allowed.** The value cannot be changed later.
- Hostnames: Max 63 characters and must be compliant with RFCs 952 and 1123. The value can be changed later.

Don't confuse the DNS label or hostname with the friendly name you can assign to the object (that is, the *display name*), which doesn't have to be unique.

**Firewalls**
Your instances running Oracle-provided Linux images or Windows images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:
- The rules in the network security groups that the instance is in
• The rules in the security lists associated with the instance's subnet
• The instance's OS firewall rules

For more information, see Oracle-Provided Images on page 629.

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, or Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding --reload command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

**Subnet or VCN Deletion**

This topic covers reasons why deletion of a subnet or VCN might fail.

Remember:

• To delete a VCN, it must first be empty and have no related resources or attached gateways (for example: no internet gateway, dynamic routing gateway, and so on).
• To delete a VCN's subnets, they must first be empty.

**Delete All Option**

The Console has an easy "Delete all" process that deletes a VCN and its related Networking resources (subnets, route tables, security lists, sets of DHCP options, internet gateway, and so on). If the VCN is attached to a dynamic routing gateway (DRG), the attachment is deleted, but the DRG remains.

The "Delete All" process deletes one resource at a time and takes a minute or two. A progress report is displayed to show you what's been deleted so far.

Before using the "Delete All" process, verify there are no instances, load balancers, DB systems, or orphaned mount targets in any of the subnets. For more information, see Subnet or VCN Deletion on page 3334.

If there are still resources in any subnet, or if you don't have permission to delete a particular Networking resource, the "Delete All" process stops and an error message is displayed. Any resources deleted up to that point cannot be restored. You might need to contact your tenancy administrator to help you delete any remaining resources.

**The Subnet Isn't Empty**

The most common reason a subnet (and thus a VCN) can't be deleted is because the subnet contains one or more of these resources:

• Load balancer
• Mount target
• DB system

**Note:**

When you create one of the preceding resources, you specify a VCN and subnet for it. The relevant service creates at least one VNIC in the subnet and attaches the VNIC to the resource. The service manages the VNICs on your behalf, so they are not readily apparent to you in the Console. The VNIC enables the resource to communicate with other resources over the network. Although this documentation commonly talks about the resource itself being in the subnet, it's actually the resource's attached VNIC. This documentation uses the term *parent resource* to refer to this type of resource.

If the subnet is empty when you try to delete it, its state changes to TERMINATING briefly and then to TERMINATED.
Networking

If the subnet is not empty, you instead get an error indicating that there are still resources that you must delete first. The error includes the OCID of a VNIC that is in the subnet (there could be more, but the error returns only a single VNIC’s OCID).

You can use the Oracle Cloud Infrastructure command line interface (CLI) or another SDK or client to call the GetVnic operation with the VNIC OCID. The response includes the VNIC’s display name. Depending on the type of parent resource, the display name can indicate which parent resource the VNIC belongs to. You can then delete that parent resource, or you can contact your administrator to determine who owns the resource. When the VNIC’s parent resource is deleted, the attached VNIC is also deleted from the subnet. If there are remaining VNICs in the subnet, repeat the process of determining and deleting each parent resource until the subnet is empty. Then you can delete the subnet.

For example, if you're using the CLI, use this command to get information about the VNIC:

```bash
oci network vnic get --vnic-id <VNIC_OCID>
```

Load balancer example

Here is an example CLI response for a VNIC that belongs to a load balancer. The display name shows the load balancer's OCID:

```json
{
  "data": {
    "availability-domain": "fooD:PHX-AD-1",
    "compartment-id": "ocid1.compartment.oc1..<unique_id_1>",
    "defined-tags": {},
    "display-name": "VNIC for LB ocid1.loadbalancer.oc1.phx.<unique_id_2>",
    "freeform-tags": {},
    "hostname-label": null,
    "id": "ocid1.vnic.oc1.phx.<unique_id_3>",
    "is-primary": false,
    "lifecycle-state": "AVAILABLE",
    "mac-address": "00:00:17:00:BB:CA",
    "private-ip": "10.0.0.6",
    "public-ip": null,
    "skip-source-dest-check": false,
    "subnet-id": "ocid1.subnet.oc1.phx.<unique_id_4>",
    "time-created": "2019-05-11T04:28:31.950000+00:00"
  },
  "etag": "5d8213fa"
}
```

File Storage example

Here's an example for a VNIC that belongs to a File Storage mount target:

```json
"display-name": "fss-<integer>",
```

Although the display name does not include an OCID, the fss characters indicate that the resource is for the File Storage service.

Database example

Here's an example of the display name for a VNIC that belongs to a DB system:

```json
"display-name": "ocid1.dbnode.oc1.phx.<unique_id>",
```

A Network Security Group Isn’t Empty

Another reason a VCN can't be deleted is because it contains a one or more network security groups (NSGs) that are not yet empty. To delete an NSG, it must not contain any VNICs (or parent resources with VNICs). You can
determine what parent resources are in an NSG by using either the Console or REST API. For more information, see To delete an NSG on page 2849.

There Are Resources in Compartments You Don't Have Access To

You might not be able to see all the resources in a subnet or VCN. This is because subnets and VCNs can contain resources in multiple compartments, and you might not have access to all the compartments. For example, the subnet might contain instances that your team manages but also DB systems that another team manages. Another example: The VCN might have security lists or a gateway in a compartment that another team manages. You might need to contact your tenancy administrator to help you determine who owns the resources in the subnet or VCN.

Redundancy Remedies

Oracle recommends setting up a redundant connection between your on-premises network and virtual cloud network (VCN) for high availability. This topic gives background and links to other topics that describe how to resolve some common redundancy issues with that connection.

About the DRG and Redundant Connections

When you connect your on-premises network to a virtual cloud network (VCN) in Oracle Cloud Infrastructure, you use a dynamic routing gateway (DRG). A DRG is a virtual representation of highly available hardware (physical routers) on the edge of the Oracle Cloud Infrastructure network. You attach a DRG to the VCN, and the DRG is the termination point for the connections from your on-premises network to that VCN. If you have multiple VCNs in your tenancy, each has its own DRG. A VCN can be attached to only a single DRG, and a DRG can be attached to only a single VCN.

A single DRG can have multiple connections to it from your on-premises network, which allows redundancy. Those connections could be the same type or different types. Here are the two types:

- FastConnect
- VPN Connect

For example, you might use FastConnect, but also set up VPN Connect to use as backup when FastConnect is temporarily unavailable because of maintenance. Or, you might have two VPN tunnels, with one as primary and the second as failover.

For high availability, the multiple connections to a DRG must not terminate on a single physical router in Oracle's edge network. If they do, your overall connection to Oracle Cloud Infrastructure is disrupted whenever Oracle performs maintenance on that router.

How to Identify and Fix a Redundancy Issue

You might have a redundancy issue in which a DRG in your tenancy has multiple on-premises connections that terminate on a single physical Oracle router. Or you might have only a single connection with no redundancy.

If you do, the Console displays an alert message when you view the DRG's details, or when you view the details of one of the connections (for example, the IPSec connection). The alert message includes a link to one of the following topics, which explain how to fix the particular issue:

- Case 1: Multiple FastConnect virtual circuits
- Case 2: FastConnect and VPN Connect
- Case 3: Multiple IPSec connections
- Case 4: Single FastConnect virtual circuit
- Case 5: Single IPSec connection with only a single tunnel
**Redundancy Remedy: Case 1**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You have redundant FastConnect virtual circuits that connect your on-premises network to a VCN. However, both of those virtual circuits terminate on the same Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

Depending on your situation, there are two possible ways to fix the problem.

*If You Are Using an Oracle Partner*

The following diagram illustrates the issue.

**Before the fix:**

In this case, you have multiple FastConnect virtual circuits, each using a different Oracle partner (called X and Y in the diagram). Each partner has two physical connections to Oracle, and each goes to a different Oracle router (called A and B in the diagram).

The problem is that both virtual circuits happen to terminate on the same Oracle router (router A in the diagram).

**After the fix:**

To fix the problem, work with one of the partners to establish a new virtual circuit that goes to the *other* Oracle router (router B in the diagram). When that new secondary virtual circuit is up and running, delete the old secondary virtual circuit (in the diagram, the one on physical connection Y-A).

*If You Are Using a Third-Party Provider or Colocated with Oracle*

The following diagram illustrates the issue.

**Before the fix:**
In this case, you have two physical connections (*cross-connect groups*), and both go to the same Oracle router (router A in the diagram).

**After the fix:**

---
To fix the problem, one of your physical connections must go to a different router (B in the diagram). To do that, set up a new physical connect (cross-connect group) in the Oracle Console. During setup, specify the proximity of that connection to other FastConnect connections in that location. For example, the following image shows how to request that your secondary cross-connect group is created on a different router than your primary connection in that FastConnect location (called MyConnection-1).

After you’ve worked to set up the cabling in the data center, and the new secondary cross-connect group is up and running, you can create a new virtual circuit on that cross-connect group. When the virtual circuit is up and running, confirm that failover works between the primary and new secondary cross-connect group. Then you can terminate the old virtual circuit and old cross-connect group.

**Redundancy Remedy: Case 2**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You have a FastConnect virtual circuit that connects your on-premises network to a VCN. For redundancy you use VPN Connect, but with only a single active IPSec tunnel. Both the FastConnect virtual circuit and the IPSec tunnel terminate on the *same* Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

**How to Fix the Issue**

The following diagram illustrates the issue.
Before the fix:

In this case, you have a FastConnect virtual circuit and VPN Connect as backup. Notice that each VPN Connect consists of two IPSec tunnels, and Oracle automatically provisions each tunnel on a different Oracle router. However, you must configure your CPE so that both tunnels are up/active.

The problem is that:
- Only one of the two IPSec tunnels is up/active.
- The one IPSec tunnel that is up terminates on the same Oracle router as the virtual circuit.

Notice that some CPEs only support one IPSec tunnel being up/active to a given destination.

After the fix:

If your CPE supports having two IPSec tunnels up/active to the same destination, configure the second tunnel to also be up/active. Oracle recommends configuring them both to use BGP dynamic routing for the IPSec tunnels.

If your CPE supports only a single active IPSec tunnel to a given destination, configure the other IPSec tunnel to be up. Then switch the original IPSec tunnel to be down/inactive. The following diagram illustrates that setup. Also, if your CPE supports BGP dynamic routing, configure the tunnel to use it instead of static routing.
Redundancy Remedy: Case 3

This topic describes one of several redundancy issues that you might be alerted to in the Console.

Summary of the Issue

You have redundant VPN Connect connections that connect your on-premises network to a VCN. Although each connection consists of two IPSec tunnels, only one tunnel per connection is up/active, and both of those tunnels terminate on the same Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

How to Fix the Issue

The following diagram illustrates the issue.

Before the fix:

In this case, you have a primary connection and a secondary connection as backup. Notice that each VPN Connect consists of two IPSec tunnels, and Oracle provisions each on a different Oracle router. However, you must configure your CPE so that both tunnels are up/active.

The problem has two parts:

- In each connection, only one of the two IPSec tunnels is up/active.
- Both of the tunnels that are up/active terminate on the same Oracle router.
Some CPEs only support one IPSec tunnel being up/active to a given destination.

After the fix:

If your CPE supports having two IPSec tunnels up/active to the same destination, configure the second tunnel to also be up/active. Oracle recommends configuring all tunnels to use BGP dynamic routing.

If your CPE supports only a single active IPSec tunnel to a given destination, then for one of the connections only, switch which of the two IPSec tunnels is configured to be up. The following diagram illustrates that setup. Oracle recommends configuring both tunnels to use BGP dynamic routing.

Redundancy Remedy: Case 4

This topic describes one of several redundancy issues that you might be alerted to in the Console.

Summary of the Issue

You use FastConnect to connect your on-premises network to a VCN. Although you might have multiple virtual circuits in this connection, only one of them is up (the BGP status is UP). Your connection to Oracle is at risk when routine maintenance is performed on the Oracle router.

You can fix the problem in one of two possible ways.

Option A: Use a Second Virtual Circuit

The details of the fix depend on your situation.
If You Are Using an Oracle FastConnect Partner

The following diagram illustrates the issue.

**Before the fix:**

![Diagram showing a single FastConnect virtual circuit up.]

In this case, you have only a single FastConnect virtual circuit that is up.

**After the fix:**

![Diagram showing two FastConnect virtual circuits up, each to a different Oracle router.]

After the fix, you have two FastConnect virtual circuits that are up, each to a different Oracle router. Some partners give you an option to specify which physical location to use for each virtual circuit. Other partners automatically use a different physical connection for the secondary virtual circuit.

If You Are Using a Third-Party Provider or Colocated with Oracle

The following diagram illustrates the issue.

**Before the fix:**

![Diagram showing a single virtual circuit to a third-party provider or colocated with Oracle.]

After the fix, you have two FastConnect virtual circuits that are up, each to a different Oracle router. Some partners give you an option to specify which physical location to use for each virtual circuit. Other partners automatically use a different physical connection for the secondary virtual circuit.
Networking

In this case, you have only a single FastConnect virtual circuit that is up.

**After the fix:**

To fix the problem, set up a secondary physical connection to Oracle. It must go to a different router (B in the diagram). To do that, set up a new physical connect (cross-connect group) in the Oracle Console. During setup, specify the proximity of that connection to other FastConnect connections in that location. For example, the following
Networking

image shows how to request that your secondary cross-connect group is created on a different router than your primary connection in that FastConnect location (called MyConnection-1).

After you've worked with the data center to have the cabling set up, and the new secondary cross-connect group is up and running, you can create a new virtual circuit on that cross-connect group. Confirm that failover works between the primary and new secondary cross-connect group.

Option B: Use VPN Connect with Both Tunnels Up/Active

This option is recommended if your CPE supports having two IPSec tunnels up/active to the same destination. The details of the fix depend on your situation.

If You Are Using an Oracle Partner

The following diagram illustrates the issue.

Before the fix:

In this case, you have only a single FastConnect virtual circuit that is up.

After the fix:
Here you set up VPN Connect as backup. You must configure your CPE so that both IPSec tunnels are up/active. Oracle automatically provisions each tunnel on a different Oracle router. Therefore, the secondary tunnel (to router B in the diagram) will be available when Oracle performs maintenance on the virtual circuit's router (router A in the diagram). Oracle recommends configuring both tunnels to use BGP dynamic routing.

If You Are Using a Third-Party Provider or Colocated with Oracle

The following diagram illustrates the issue.

Before the fix:

In this case, you have only a single FastConnect virtual circuit that is up.
After the fix:

Here you set up VPN Connect as backup. You must configure your CPE so that both IPSec tunnels are up/active. Oracle automatically provisions each tunnel on a different Oracle router. Therefore, the secondary tunnel (to router B in the diagram) will be available when Oracle performs maintenance on the virtual circuit's router (router A in the diagram). Oracle recommends configuring both tunnels to use BGP dynamic routing.

**Redundancy Remedy: Case 5**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You use VPN Connect to connect your on-premises network to a VCN. Although Oracle provisions two IPSec tunnels for the connection, only one of them is up/active. Your connection to Oracle is at risk when routine maintenance is performed on the Oracle router.

**How to Fix the Issue**

The following diagram illustrates the issue.

**Before the fix:**

Notice that a VPN Connect consists of two IPSec tunnels, and Oracle automatically provisions each on a different Oracle router.

**After the fix:**
If your CPE supports having two IPSec tunnels up/active to the same destination, configure the second tunnel to also be up/active. Oracle recommends configuring both tunnels to use BGP dynamic routing.
Chapter 27

Notifications

This chapter explains how to use the Notifications service.

Notifications Overview

The Oracle Cloud Infrastructure Notifications service broadcasts messages to distributed components through a publish-subscribe pattern, delivering secure, highly reliable, low latency and durable messages for applications hosted on Oracle Cloud Infrastructure and externally. Use Notifications to get notified when event rules are triggered or alarms are breached, or to directly publish a message.

How Notifications Works

The Notifications service enables you to set up communication channels for publishing messages using topics and subscriptions. When a message is published to a topic, the Notifications service sends the message to all of the topic's subscriptions.

When a subscriber's endpoint does not acknowledge receipt of the message, the Notifications service retries delivery. This situation can occur when the endpoint is offline. For example, the email server for an email address may be down.

Delivery retry details

Notifications retries delivery following these steps until either (a) acknowledgement is received or (b) the subscription's retry duration is over. By default, the retry duration is two hours.

1. Immediate retry.
2. Exponential backoff retry for the period of the subscription's retry duration, using the following timing:
   a. 1 minute
   b. 2 minutes
   c. 4 minutes
   d. 8 minutes
   e. 16 minutes
   f. 32 minutes
3. Discarding of the message at the end of the retry duration.

You can change the retry duration for a subscription. For instructions using the Console, see To update the retry duration for a subscription on page 3363. For the API, use the following operation: UpdateSubscription.

Notifications Concepts

The following concepts are essential to working with Notifications.

message

The content that is published to a topic. Each message is delivered at least once per subscription. Every message sent out as email contains a link to unsubscribe from the related topic.
**Friendly formatting**: Select friendly formatting to increase human readability of messages.

Supported subscription protocols:

- **Email**

Supported message types:

- Service connector messages (when Notifications is the target service)
  
  See service connector message examples and steps to select friendly formatting for existing service connectors.

subscription

An endpoint for a *topic*. Published *messages* are sent to each subscription for a *topic*.

Supported subscription protocols:

- **Email**:
  
  Sends an email message when you publish a *message* to the subscription's parent *topic*.
  
  Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
  
  Some message types allow friendly formatting.

- **Function**:
  
  Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

- **HTTPS (Custom URL)**:
  
  Sends specified information when you publish a *message* to the subscription's parent *topic*.

- **PagerDuty**:
  
  Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

- **Slack**:
  
  Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.
  
  Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

- **SMS**:
  
  Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

  **Note:**
  
  SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.

  Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Country or region</td>
<td>ISO code</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>
</tr>
<tr>
<td>Chile</td>
<td>CL</td>
</tr>
<tr>
<td>China</td>
<td>CN</td>
</tr>
<tr>
<td>Costa Rica</td>
<td>CR</td>
</tr>
<tr>
<td>Croatia</td>
<td>HR</td>
</tr>
<tr>
<td>Czechia</td>
<td>CZ</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
<tr>
<td>Germany</td>
<td>DE</td>
</tr>
<tr>
<td>Hungary</td>
<td>HU</td>

<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>
topic

A communication channel for sending messages to the subscriptions in the topic. Each topic name is unique across the tenancy.

Note:
Messages sent out as email by the Oracle Cloud Infrastructure Notifications service are processed and delivered through Oracle resources in U.S.-based regions.

Flow of Message Publication

Notifications publishes messages when event rules are triggered, alarms are breached, service connectors run, or someone directly publishes a message.

Event rules

Notifications sends event messages when rules are triggered. The event message is sent to the topic specified in the rule. For example, a message might be configured for new databases. See Managing Rules for Events on page 1801.

Alarms

Notifications sends alarm messages when alarms are breached. The alarm message is sent to the topic specified in the alarm. For example, an alarm message might be configured for high CPU usage. See Managing Alarms on page 2719.

Service connectors

Notifications sends service connector messages when service connectors are running. The service connector message is sent to the topic specified in the service connector. For example, a service connector might be configured to send usage logs. See Managing Service Connectors on page 3754.
Notifications

Direct publication

Notifications sends *messages* when you (or a service or app) publish the messages directly. The message is sent to the *topic* you specify. See Publishing Messages on page 3365.

Availability

The Notifications service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Service Comparison for Sending Email Messages

Consider the following service features when deciding whether to use the Notifications service or the Email Delivery service to send your email messages. For more information about Email Delivery, see Overview of the Email Delivery Service on page 1738.

<table>
<thead>
<tr>
<th>Service Feature</th>
<th>Notifications service</th>
<th>Email Delivery service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires confirmation before sending email.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Allows email decorations, such as signatures.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Allows raw email messages.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Supports MIME attachments.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Supports special handling for failed email delivery.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Priced for small messages (less than 32 KB, with a 64-KB limit).</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
### Service Feature

<table>
<thead>
<tr>
<th>Notifications service</th>
<th>Email Delivery service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priced for large messages (greater than 32 KB, with a 2-MB limit)</td>
<td>No</td>
</tr>
</tbody>
</table>

### Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

### Moving Topics and Subscriptions to a Different Compartment

You can move topics and subscriptions from one compartment to another. When you move a topic to a new compartment, its associated subscriptions remain in their existing compartment. The same consideration applies when moving a subscription: its associated topic remains in its existing compartment.

After you move the topic or subscription to the new compartment, inherent policies apply immediately and affect access to the moved topic or subscription through the Console. For more information, see To move a resource to a different compartment on page 2444.

**Important:**

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service on page 2322.

### Ways to Access Notifications

You can access the Notifications service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

**Console:** To access Notifications using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.

**API:** To access Notifications through API, use Notifications API.

### Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.
Administrators: For common policies that give groups access to Notifications, see Allow a group to manage topics on page 2158, Allow a group to manage topic subscriptions on page 2158, and Allow a group to publish messages to topics on page 2158.

## Limits on Notifications

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

### Limits for publishing messages (PublishMessage operation)

All limits are per tenancy.

<table>
<thead>
<tr>
<th>Limit type</th>
<th>Limit amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message size per request</td>
<td>64KB</td>
</tr>
<tr>
<td>Message delivery rate per endpoint for HTTP-based protocols (endpoints that begin with &quot;http:&quot; or &quot;https:&quot;), Message delivery rate per endpoint for Email protocol</td>
<td>60 messages per minute</td>
</tr>
<tr>
<td>Messages per minute (also known as Transactions Per Minute, or TPM)</td>
<td>10 messages per minute</td>
</tr>
<tr>
<td>Messages per minute (also known as Transactions Per Minute, or TPM)</td>
<td>60 per topic</td>
</tr>
</tbody>
</table>

### Best Practices for Your Subscriptions and Topics

This topic covers best practices related to subscriptions and topics.

#### Prevent Processing of Duplicate Items

As depicted at Flow of Message Publication on page 3353, an event, alarm, or direct publication can trigger a message. The Notifications service then sends the message to many types of subscriptions, including email, HTTPS endpoints, and functions.

Depending on your goals, you may want to prevent your system from processing duplicate messages from a given message trigger. This situation is especially relevant when messages are sent to function subscriptions, which can result in double invocations. (For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 3366.)

To prevent your system from processing duplicate messages, write code that de-duplicates received messages by using identifiers specific to the trigger:

- For any message, consider using a custom de-dupe key entered in the body of the message.
- For alarm-triggered messages, use a combination of dedupekey and timestampEpochMillis from the alarm message.
- For event-triggered messages, use eventID from the event message.
- For directly published messages, use x-oci-ns-messageid in the header (provided by Notifications).

For handling duplicate requests sent to Oracle Cloud Infrastructure API endpoints, see Retry Token on page 4372.

For related troubleshooting information, see Troubleshooting Notifications on page 3385.

### Managing Topics and Subscriptions

This section describes how to manage topics and their subscriptions.

A topic is a communication channel for sending messages to its subscriptions. A topic can have zero, one, or multiple subscriptions that are notified whenever a message is published to a topic.
Notifications

Prerequisites
IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. For Functions, you must have `FN_INVoke` permission against the function to be able to add the function as a subscription to a topic. To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2088.

If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview on page 3350.

Creating Automation with Functions and Events
You can create automation by publishing messages to function subscriptions. For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 3366.

You can create also automation based on state changes of your topics and subscriptions (Notifications resources) by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Using the Console
To create a topic
1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Click Create Topic at the top of the topic list.
3. In the Create Topic dialog box, configure your topic.
   - Name: Required. Specify a friendly name for the topic. It must be unique across the tenancy; validation is case-sensitive. Avoid entering confidential information.
   - Description: Optional. Enter a description for the topic. Avoid entering confidential information.
4. Click Create.

To delete a topic
1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. For the topic you want to delete, click the Actions icon (three dots), and then click Delete.
3. Confirm when prompted.

To update the description for a topic
1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Click the name of the topic you want to update.
3. On the topic detail page, next to Description, click the edit icon.
4. Edit the description.
5. Click the save icon.

To move a topic to a different compartment
Associated subscriptions remain in their current compartments. For more information, see Moving Topics and Subscriptions to a Different Compartment on page 3355.

Note:
To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about
permissions for Notifications resources, see Details for the Notifications Service on page 2322.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. In the Scope section, select a compartment.
3. Find the topic in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

**To create a subscription**

**Note:**
While new subscriptions must be created in the same compartment as the topic, you can move them to different compartments after creating them.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click Create Subscription.
4. In the Create Subscription dialog box, configure your subscription for the protocol you want:

   **Email subscription**
   Sends an email message when you publish a message to the subscription's parent topic.
   
   Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
   
   Some message types allow friendly formatting.
   
   • **Protocol:** Select Email.
   • **Email:** Type an email address.

   **Function subscription**
   Runs the specified function when you publish a message to the subscription's parent topic. For example, runs a function to resize VMs when an associated alarm is triggered.

   **Note:**
   You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.

   The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 3387.
Confirmation is not required for function subscriptions.

- **Subscription Protocol**: Select Function.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and
password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Protocol**: Select HTTPS (Custom URL).
- **URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Protocol**: Select PagerDuty.
- **URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Protocol**: Select Slack.
- **URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub.</td>
</tr>
</tbody>
</table>
SMS messages sent by unsupported services are dropped. **Troubleshoot dropped messages.**

Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>
</tr>
<tr>
<td>Chile</td>
<td>CL</td>
</tr>
<tr>
<td>China</td>
<td>CN</td>
</tr>
<tr>
<td>Costa Rica</td>
<td>CR</td>
</tr>
<tr>
<td>Croatia</td>
<td>HR</td>
</tr>
<tr>
<td>Czechia</td>
<td>CZ</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
<tr>
<td>Germany</td>
<td>DE</td>
</tr>
<tr>
<td>Hungary</td>
<td>HU</td>
</tr>
<tr>
<td>India</td>
<td>IN</td>
</tr>
<tr>
<td>Ireland</td>
<td>IE</td>
</tr>
<tr>
<td>Israel</td>
<td>IL</td>
</tr>
<tr>
<td>Japan</td>
<td>JP</td>
</tr>
<tr>
<td>Lithuania</td>
<td>LT</td>
</tr>
<tr>
<td>Mexico</td>
<td>MX</td>
</tr>
<tr>
<td>Netherlands</td>
<td>NL</td>
</tr>
<tr>
<td>New Zealand</td>
<td>NZ</td>
</tr>
<tr>
<td>Norway</td>
<td>NO</td>
</tr>
<tr>
<td>Philippines</td>
<td>PH</td>
</tr>
<tr>
<td>Poland</td>
<td>PL</td>
</tr>
<tr>
<td>Portugal</td>
<td>PT</td>
</tr>
<tr>
<td>Romania</td>
<td>RO</td>
</tr>
<tr>
<td>Saudi Arabia</td>
<td>SA</td>
</tr>
<tr>
<td>Singapore</td>
<td>SG</td>
</tr>
<tr>
<td>South Africa</td>
<td>ZA</td>
</tr>
<tr>
<td>South Korea</td>
<td>KR</td>
</tr>
<tr>
<td>Spain</td>
<td>ES</td>
</tr>
</tbody>
</table>
### Notifications

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sweden</td>
<td>SE</td>
</tr>
<tr>
<td>Switzerland</td>
<td>CH</td>
</tr>
<tr>
<td>Ukraine</td>
<td>UA</td>
</tr>
<tr>
<td>United Arab Emirates</td>
<td>AE</td>
</tr>
<tr>
<td>United Kingdom</td>
<td>GB</td>
</tr>
<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

- **Protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format.

Example SMS endpoints:

- Phone Number (E.164 format): +14255550100

5. **Click Create**.

The subscription has been created.

Subscriptions using protocols that require confirmation, such as Email, remain in "Pending" status until confirmation is received. For these subscriptions, a subscription confirmation URL is sent. For detailed steps, see To confirm a subscription on page 3362.

### To confirm a subscription

Confirmation is not required for function subscriptions.

Navigate to the confirmation URL that is sent to the subscription's endpoint and follow the provided instructions.

Some protocols provide confirmation URLs in unique ways:

- **HTTPS (Custom URL)**: You can find the confirmation URL in the request header or body of the subscription confirmation message (request of content-type: "application/json") that is sent to the endpoint.

  - In the request header, see the value of the X-OCI-NS-ConfirmationURL field.

  **Example request header**:

  ```
  "X-OCI-NS-SignatureVersion":"1.0"
  "X-OCI-NS-Signature":"<example-signature>"
  "X-OCI-NS-SigningCertURL":"<example-url>"
  "X-OCI-NS-TopicOcid":"ocid.compartment.oc1..<unique_ID>"
  "X-OCI-NS-Timestamp":"2019-04-19T21:26:00.310+0000"
  "X-OCI-NS-MessageId":"<unique_ID>"
  "X-OCI-NS-TopicName":"mytopic"
  "X-OCI-NS-MessageType":"SubscriptionConfirmation"
  "X-OCI-NS-ConfirmationURL":"<exampleConfirmationURL>"
  "X-OCI-NS-SubscriptionId":"ocid1.onssubscription.oc1.phx.<unique_ID>"
  ```
Notifications

"X-OCI-NS-State":"Pending"

- In the request body, see the value of the ConfirmationURL key.

Example ConfirmationURL key and value (request body):

"ConfirmationURL":"<exampleConfirmationURL>"

- PagerDuty: Incident titled "Oracle Notification Service Subscription Confirmation". For more information, see the PagerDuty documentation for Oracle Cloud Infrastructure.

- Slack: Message sent to Slack channel containing the text "To confirm the subscription".

- SMS: Message sent to phone number containing the text "REPLY 'CONFIRM <short-topic-id>' to confirm subscription."

  <short-topic-id> is the short code of the topic that the SMS subscription was added to. The short code is used to identify the topic in messages sent to SMS subscriptions. Each short code contains six case-insensitive alphanumeric characters.

To resend a subscription confirmation

The ability to resend subscription confirmations is only applicable for pending subscriptions.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. For the subscription you want to resend the confirmation for, click the Actions icon (three dots), and then click Resend Confirmation.

To update the retry duration for a subscription

The retry duration is part of the delivery policy for the subscription. By default, Notifications retries delivery of a message for up to two hours.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. For the subscription you want to update, click the Actions icon (three dots), and then click Update Delivery Policy.
3. In the Update Delivery Policy dialog box, click the edit icon for Max Retry Duration in Minutes, type the new value, and then click the save icon.

To move a subscription to a different compartment

The associated topic remains in its current compartment. For more information, see Moving Topics and Subscriptions to a Different Compartment on page 3355.

Note:

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service on page 2322.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. In the Scope section, select a compartment.
3. Find the subscription in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.
To delete a subscription (unsubscribe)

Note:
Every message sent out as email contains a link to unsubscribe from the related topic.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. For the subscription you want to delete, click the Actions icon (three dots), and then click Delete.
3. Confirm when prompted.

Managing Tags for a Topic or Subscription

You can apply tags to your resources, such as topics and subscriptions, to help you organize them according to your business needs. You can apply tags at the time you create a topic or subscription, or you can update the topic or subscription later with the tags you want. For general information about applying tags, see Resource Tags on page 211.

To manage tags for a topic

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Choose the Compartment that contains the topic you want to tag, and then click the topic's name.
3. Click the Tags tab to view or edit existing tags, or click Add Tags to add new ones.

For more information, see Resource Tags on page 211.

To manage tags for a subscription

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Choose the Compartment that contains the subscription you want to tag, and then click the name of the topic that has the subscription.
3. For the subscription you want to tag, click the Actions icon (three dots), and then click Add Tags.
   To view or edit existing tags, click the Actions icon (three dots), and then click View Tags.

For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage topics:

- CreateTopic
- GetTopic
- ListTopics
- UpdateTopic
- ChangeTopicCompartment
- DeleteTopic

Use these API operations to manage subscriptions:

- CreateSubscription
- GetSubscription
- ListSubscriptions
- UpdateSubscription
- ChangeSubscriptionCompartment
Publishing Messages

This topic describes how to publish messages directly using the Notifications service. You can manually enter the message content or allow a service or app to programmatically define the message content.

Each message is broadcast to all subscriptions in the specified topic. Every message sent out as email contains a link to unsubscribe from the related topic.

Message delivery rate limits per endpoint: 60 messages per minute for HTTP-based protocols. (HTTP-based protocols use URL endpoints that begin with "http:" or "https:".) 10 messages per minute for Email protocol.

Prerequisites

• IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview on page 3350.

• Before you can publish a message, you need a topic with at least one subscription. See Managing Topics and Subscriptions on page 3356.

Creating Automation with Functions and Events

You can create automation by publishing messages to function subscriptions. For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 3366.

You can create also automation based on state changes of your topics and subscriptions (Notifications resources) by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Using the Console

To publish a message

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. On the Topics page, for the topic you want, click the Actions icon (three dots), and then click Publish Message.
3. In the Publish Message dialog box, fill in the fields:

• Title: Enter the title you want to send.

Rendering of the title by protocol

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>
Notifications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Message**: Enter the content you want to send.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message size limit per request: 64KB.</td>
</tr>
</tbody>
</table>

4. Click **Publish**.

For troubleshooting information related to published messages, see *Message not received* on page 3386.

**Using the API**

For information about using the API and signing requests, see *REST APIs* on page 4368 and *Security Credentials* on page 179. For information about SDKs, see *Software Development Kits and Command Line Interface* on page 4225.

Use these API operations to publish messages:

- PublishMessage

**Scenarios**

Here are a few basic scenarios to help you understand the Notifications service and generally how the components work together.

- **Scenario A: Automatically Resize VMs** on page 3366
- **Scenario B: Send Alarm Messages to Slack and SMS** on page 3373

**Scenario A: Automatically Resize VMs**

This topic explains how to set up automatic resizing for virtual machines (VMs) that exceed memory.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.</td>
</tr>
</tbody>
</table>

This scenario involves writing a **function** to resize VMs and creating an **alarm** that sends a message to that function. When the alarm fires, the Notifications service sends the **alarm message** to the destination topic, which then fans out to the topic's subscriptions. In this scenario, the topic’s subscriptions include the function as well as your email address and an SMS phone number. The function is invoked on receipt of the alarm message.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at <em>Function not invoked or run</em> on page 3387.</td>
</tr>
</tbody>
</table>
Notifications

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring, Notifications, and Functions. You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic. To resize VMs, the function must be authorized to update Compute instances. To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2088.

Task 1: Create and Authorize Your Function

Once you create your function to resize VMs using your preferred SDK and authorize your function to access VMs (include the function in a dynamic group and grant that dynamic group access), all other scenario steps can be completed in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

For more information about authorizing functions to access other Oracle Cloud Infrastructure resources, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2088.

Function code sample

```
import io
import json
import oci
from fdk import response

def increase_compute_shape(instance_id, alarm_msg_shape):
    signer = oci.auth.signers.get_resource_principals_signer()
    compute_client = oci.core.ComputeClient(config={}, signer=signer)
    current_shape = compute_client.get_instance(instance_id).data.shape
    print("INFO: current shape for Instance {0}: {1}".format(instance_id,current_shape), flush=True)
    if current_shape != alarm_msg_shape:
        sign
```
Notifications

```python
def increase_compute_shape(instance_id, shape):
    # improve the logic below to handle more scenarios, make sure the shapes you select are available in the region and AD
    if current_shape == "VM.Standard1.1":
        new_shape = "VM.Standard2.1"
    elif current_shape == "VM.Standard2.1":
        new_shape = "VM.Standard2.2"
    else:
        return "Instance {0} cannot get a bigger shape than its current shape {1}".format(instance_id, current_shape)
    print("INFO: new shape for Instance {0}: {1}".format(instance_id, new_shape), flush=True)
    try:
        update_instance_details = oci.core.models.UpdateInstanceDetails(shape=new_shape)
        resp = compute_client.update_instance(instance_id=instance_id,
                                               update_instance_details=update_instance_details)
        print(resp, flush=True)
    except Exception as ex:
        print('ERROR: cannot update instance {}'.format(instance_id), flush=True)
        raise
    return "The shape of Instance {} is updated, the instance is rebooting...".format(instance_id)

def handler(ctx, data: io.BytesIO=None):
    alarm_msg = {}
    message_id = func_response = ""
    try:
        headers = ctx.Headers()
        message_id = headers["x-oci-ns-messageid"]
    except Exception as ex:
        print('ERROR: Missing Message ID in the header', ex, flush=True)
        raise
    print("INFO: Message ID = ", message_id, flush=True)
    # the Message Id can be stored in a database and be used to check for duplicate messages
    try:
        alarm_msg = json.loads(data.getvalue())
        print("INFO: Alarm message: ")
        print(alarm_msg, flush=True)
    except (Exception, ValueError) as ex:
        print(str(ex), flush=True)
    if alarm_msg["type"] == "OK_TO_FIRING":
        if alarm_msg["alarmMetaData"][0]["dimensions"]:
            alarm_metric_dimension = alarm_msg["alarmMetaData"][0]["dimensions"][0]  #assuming the first dimension matches the instance to resize
            print("INFO: Instance to resize: ", alarm_metric_dimension["resourceId"], flush=True)
            func_response = increase_compute_shape(alarm_metric_dimension["resourceId"],
                                                   alarm_metric_dimension["shape"])
        else:
            print('ERROR: There is no metric dimension in this alarm message', flush=True)
            func_response = "There is no metric dimension in this alarm message"
    else:
        print('INFO: Nothing to do, alarm is not FIRING', flush=True)
        func_response = "Nothing to do, alarm is not FIRING"
return func_response
```

Oracle Cloud Infrastructure User Guide
return response.Response(
    ctx,
    response_data=func_response,
    headers={"Content-Type": "application/json"}
)

Include your function in a dynamic group

Find and note your function OCID (format is ocid1.fnfunc.ocl.iad.exampleuniqueID), then specify the following rule in the relevant dynamic group:

```
resource.id = '<function-ocid>'
```

Create a policy to grant the dynamic group access to VMs (Compute instances)

Add the following policy:

```
allow dynamic-group <dynamic-group-name> to use instances in tenancy
```

Task 2: Create the alarm, topic, and subscriptions

You can create the alarm, topic, and subscriptions in the Console, CLI, or API.

Using the Console

This section walks through creating the alarm, topic, and subscriptions using the Console. Your function must be deployed.

Note:

Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see Troubleshooting Notifications on page 3385.

Create the alarm, topic, and function subscription

This example walks through using the Console to create an alarm that sends a message to run the function when high memory usage is detected. During this process, you'll create a topic that references your function. You can add the SMS and email subscriptions later.

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. Click Create alarm.
3. On the Create Alarm page, under Define alarm, set up your threshold:

   - Metric description:
     - Compartment: (select the compartment that contains your VM)
     - Metric Namespace: oci_computeagent
     - Metric Name: MemoryUtilization
     - Interval: 1m
     - Statistic: Max
   - Trigger rule:
     - Operator: greater than
     - Value: 90
     - Trigger Delay Minutes: 1
4. Select your function under **Notifications, Destinations**:
   - **Destination Service**: Notifications Service
   - **Compartment**: (select the *compartment* where you want to create the topic and associated subscriptions)
   - **Topic**: Click **Create a topic**

   **Note:**
   If you already created your topic and function subscription, you can select that topic here instead of creating a new one.

   - **Topic Name**: Alarm Topic
   - **Subscription Protocol**: Function
   - **Function Compartment**: (select the *compartment* that contains your function)
   - **Function Application**: (select the application that contains your function)
   - **Function**: (select your function)

5. Click **Save alarm**.

Add an SMS subscription

This example walks through using the Console to add an SMS subscription to the topic you created when you set up the alarm.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, set up your SMS subscription:
   - **Protocol**: Select SMS.
   - **Country**: Select the country for the phone number.
   - **Phone Number**: Enter the phone number, using E.164 format.

   Example SMS endpoints:
   - **Phone Number (E.164 format)**: +14255550100

5. Click **Create**.

   The SMS subscription has been created and a subscription confirmation message is sent to the specified phone number. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new SMS subscription, follow the instructions in the received confirmation message. (Look for the message containing the phrase "REPLY 'CONFIRM" followed by your topic name.)

Add an email subscription (optional)

This example walks through using the Console to add an optional email subscription to the topic you created when you set up the alarm.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, set up your email subscription:
   - **Protocol**: Select Email.
   - **Email**: Type an email address.
5. Click Create.
   The email subscription has been created and a subscription confirmation URL is sent to the specified email
   address. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new email subscription, open your email and navigate to the confirmation URL.

Using the CLI

This section walks through creating the topic, subscriptions, and alarm using the CLI. Your function must be
deployed.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on
page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

1. Create the topic
   Open a command prompt and run the oci ons topic create command:
   
   ```shell
   oci ons topic create --name "Alarm Topic" --compartment-id "<compartment-ocid>"
   ```

2. Add the subscriptions
   To this topic, add subscriptions referencing your function OCID, an SMS phone number, and an optional email
   address.
   
   • Create a function subscription: Open a command prompt and run the oci ons subscription create command:
     
     ```shell
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "ORACLE_FUNCTIONS" --subscription-endpoint "<function-ocid>"
     ```
   
   • Create an SMS subscription: Open a command prompt and run the oci ons subscription create command:
     
     ```shell
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SMS" --subscription-endpoint "<sms-endpoint>"
     ```
   
   • Create an email subscription (optional): Open a command prompt and run the oci ons subscription create command:
     
     ```shell
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
     ```

3. Create the alarm
   Create an alarm that defines the memory threshold and references this topic as the destination: Open a command
   prompt and run the oci monitoring alarm create command:
   
   ```shell
   oci monitoring alarm create --display-name "VM Memory Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --metric-name "oci_computeagent" --query-text "MemoryUtilization[1m].max() > 90" --severity "CRITICAL" --destinations "<topic-ocid>" --is-enabled true
   ```

For help with troubleshooting, see Troubleshooting Notifications on page 3385.

Using the API

This section walks through creating the topic, subscriptions, and alarm using the API. Your function must be
deployed.
Notifications

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:

1. **CreateTopic**: Create a topic.

   **Example CreateTopic request**

   ```
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "name": "Alarm Topic",
     "compartmentId": "<compartment_OCID>"
   }
   ```

2. **CreateSubscription**: To this topic, add subscriptions referencing your function OCID, SMS phone number, and an optional email address.

   **Example CreateSubscription request: Function**

   ```
   POST /20181201/subscriptions
   Host: cp.notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "topicId": "<topic_OCID>",
     "compartmentId": "<compartment_OCID>",
     "protocol": "ORACLE_FUNCTIONS",
     "endpoint": "<function_OCID>"
   }
   ```

   **Example CreateSubscription request: SMS**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "topicId": "<topic_OCID>",
     "compartmentId": "<compartment_OCID>",
     "protocol": "SMS",
     "endpoint": "<sms-endpoint>"
   }
   ```

   **Example CreateSubscription request: Email**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "topicId": "<topic_OCID>",
     "compartmentId": "<compartment_OCID>",
     "protocol": "EMAIL",
     "endpoint": "john.smith@example.com"
   }
   ```

3. **CreateAlarm**: Create an alarm that defines the memory threshold and references this topic.

   **Example CreateAlarm request**

   ```
   POST /20180401/alarms
   Host: telemetry.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   }
   ```
Notifications

```
"displayName": "VM Memory Alarm",
"compartmentId": "<compartment_OCID>",
"metricCompartmentId": "<compartment_OCID>",
"namespace": "oci_computeagent",
"query": "MemoryUtilization[1m].max() > 90",
"severity": "CRITICAL",
"destinations":
[
   "<topic_OCID>
],
"isEnabled": true
}
```

For help with troubleshooting, see Troubleshooting Notifications on page 3385.

**Scenario B: Send Alarm Messages to Slack and SMS**

This topic explains how to set up automatic notifications to a Slack channel and an SMS phone number when alarms are triggered.

**Caution:**

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

This scenario involves setting up a Slack endpoint for a channel and creating an alarm that sends a message to both that channel and an SMS phone number. When the alarm fires, the Notifications service sends the alarm message to the destination topic, which then fans out to the topic's subscriptions. In this scenario, the topic's subscriptions include the Slack channel and SMS phone number as well as your email address.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring and Notifications.

**Task 1: Set up your Slack endpoint**

Create an incoming webhook to your Slack app.

Example of an incoming webhook to a Slack app (equivalent to the Slack endpoint for your subscription): `https://hooks.slack.com/services/T00000000/B0000000/XXXXXXXXXXXXXXXXXXXXXXXX`

Once you set up your Slack endpoint, you can complete all other scenario steps in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.
**Task 2: Create the alarm, topic, and subscriptions**

You can create the alarm, topic, and subscriptions in the Console, CLI, or API.

*Using the Console*

This section walks through creating the alarm, topic, and subscriptions using the Console.

**Note:**

Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see *Troubleshooting Notifications* on page 3385.

Create the alarm, topic, and Slack subscription

This example walks through using the Console to create an alarm that sends a message to Slack when a high CPU usage is detected. During this process, you'll create a topic that references your Slack channel (Slack endpoint, including the webhook token). You can add the SMS and email subscriptions later.

1. Open the navigation menu. Under *Solutions and Platform*, go to *Monitoring* and click *Alarm Definitions*.
2. Click *Create alarm*.
3. On the *Create Alarm* page, under *Define alarm*, set up your threshold:
   - **Metric description**:
     - **Compartment**: (select the *compartment* that contains your VM)
     - **Metric Namespace**: `oci_computeagent`
     - **Metric Name**: `CpuUtilization`
     - **Interval**: `1m`
     - **Statistic**: `Count`
   - **Trigger rule**:
     - **Operator**: `greater than`
     - **Value**: `90`
     - **Trigger Delay Minutes**: `1`
4. Add your Slack endpoint under *Notifications, Destinations*:
   - **Destination Service**: *Notifications Service*
   - **Compartment**: (select the *compartment* where you want to create the topic and associated subscriptions)
   - **Topic**: Click *Create a topic*
     **Note:**
     If you already created your topic and Slack subscription, you can select that topic here instead of creating a new one.
     - **Topic Name**: Alarm Topic
     - **Subscription Protocol**: Slack
     - **URL**: Your Slack endpoint, including the webhook token.
5. Click *Save alarm*.
6. Confirm your new Slack subscription: Navigate to the confirmation URL that is sent to the Slack channel. (Look for the message containing the phrase "To confirm the subscription".)

Add an SMS subscription

This example walks through using the Console to add an SMS subscription to the topic you created when you set up the alarm.

1. Open the navigation menu. Under *Solutions and Platform*, go to *Application Integration* and click *Notifications*.
2. Click the name of the topic that you want to add the subscription to.
   
   Example: "Alarm Topic" (assuming you used the suggested topic name when creating the topic in the alarm).

3. On the topic detail page, click Create Subscription.

4. In the Create Subscription dialog box, set up your SMS subscription:
   
   - **Protocol**: Select SMS.
   - **Country**: Select the country for the phone number.
   - **Phone Number**: Enter the phone number, using E.164 format.

   Example SMS endpoints:
   
   - Phone Number (E.164 format): +14255550100

5. Click Create.
   
   The SMS subscription has been created and a subscription confirmation message is sent to the specified phone number. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new SMS subscription, follow the instructions in the received confirmation message. (Look for the message containing the phrase "REPLY CONFIRM" followed by your topic name.)

Add an email subscription (optional)

This example walks through using the Console to add an optional email subscription to the topic you created when you set up the alarm.

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.

2. Click the name of the topic that you want to add the subscription to.

   Example: "Alarm Topic" (assuming you used the suggested topic name when creating the topic in the alarm).

3. On the topic detail page, click Create Subscription.

4. In the Create Subscription dialog box, set up your email subscription:

   - **Protocol**: Select Email.
   - **Email**: Type an email address.

5. Click Create.

   The email subscription has been created and a subscription confirmation URL is sent to the specified email address. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new email subscription, open your email and navigate to the confirmation URL.

Using the CLI

This section walks through creating the topic, subscriptions, and alarm using the CLI.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

1. **Create the topic**

   Open a command prompt and run the oci ons topic create command:

   ```bash
   oci ons topic create --name "Alarm Topic" --compartment-id "<compartment-ocid>"
   ```
2. **Add the subscriptions**

To the topic you just created in the previous step, add subscriptions referencing your Slack endpoint (including the webhook token) and an optional email address and SMS phone number.

- **Create a Slack subscription:** Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SLACK" --subscription-endpoint "<slack-endpoint>"
  ```

- **Create an SMS subscription:** Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SMS" --subscription-endpoint "<sms-endpoint>"
  ```

- **Create an email subscription (optional):** Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
  ```

3. **Create the alarm**

Create an alarm that defines the CPU threshold and references this topic as the destination: Open a command prompt and run the `oci monitoring alarm create` command:

```bash
oci monitoring alarm create --display-name "VM Memory Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --namespace "oci_computeagent" --query-text "CPUUtilization[1m].count() > 90" --severity "CRITICAL" --destinations "<topic-ocid>" --is-enabled true
```

For help with troubleshooting, see Troubleshooting Notifications on page 3385.

**Using the API**

This section walks through creating the topic, subscriptions, and alarm using the API.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:

1. **CreateTopic:** Create a topic.

   **Example CreateTopic request**

   ```
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "name": "Alarm Topic",
   "compartmentId": "<compartment_OCID>"
   }
   ```
2. **CreateSubscription**: To this topic, add subscriptions referencing your Slack channel and optionally your email address and SMS phone number.

**Example CreateSubscription request: Slack**

```plaintext
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "SLACK",
  "endpoint": "<slack-endpoint>
}
```

**Example CreateSubscription request: SMS**

```plaintext
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "SMS",
  "endpoint": "<sms-endpoint>
}
```

**Example CreateSubscription request: Email**

```plaintext
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "EMAIL",
  "endpoint": "john.smith@example.com"
}
```

3. **CreateAlarm**: Create an alarm that defines the CPU threshold and references this topic.

**Example CreateAlarm request**

```plaintext
POST /20180401/alarms
Host: telemetry.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "displayName": "CPU Alarm",
  "compartmentId": "<compartment_OCID>",
  "metricCompartmentId": "<compartment_OCID>",
  "namespace": "oci_computeagent",
  "query": "CPUUtilization[1m].count() > 90",
  "severity": "CRITICAL",
  "destinations":
  ["<topic_OCID>"],
  "isEnabled": true
}
```

For help with troubleshooting, see [Troubleshooting Notifications](#) on page 3385.
Scenario C: File Jira Tickets for Reminders

This topic explains how to file automatic Jira tickets whenever maintenance reminder events occur. In this scenario, whenever a reminder for upcoming database maintenance comes from Oracle Cloud Infrastructure, a Jira ticket is created for your on-call engineer.

This scenario involves writing a function to file Jira tickets (and creating a secret to store your Jira credentials), adding that function and optional email as subscriptions to a topic, and creating a rule that sends messages to that topic when maintenance reminder events occur (see Database Service: Autonomous Container Database Event Types on page 1849). The message fans out to the topic's subscriptions, which includes a group email address in addition to the function. The function is invoked on receipt of the message.

Everything but the function can be set up in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Note:
The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 3387.

For more information about this scenario, see Automated Jira Ticketing using OCI Events, Notifications, and Functions and the associated GitHub repository.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Events, Notifications, and Functions. You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic. To access your Jira credentials, the function must be authorized to read secrets. This scenario walks through steps to provide this authorization.

Task 1: Store your Jira credentials in a secret

You can create a secret in the Console, CLI, or API. You'll reference this secret later, when creating your function.
**Using the Console**

**To create the secret for your Jira credentials**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create a secret.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create a secret.
   - Create a new vault for the secret by following the instructions in **To create a new vault**, and then click the name of the vault.
4. Click **Secrets**, and then click **Create Secret**.
5. In the **Create Secret** dialog box, choose a compartment from the **Create in Compartment** list. (Secrets can exist outside the compartment the vault is in.)
6. Click **Name**, and then enter a name to identify the secret. Avoid entering confidential information.
   
   Example name: `jira_auth_plain_text`

7. Click **Description**, and then enter a brief description of the secret to help identify it. Avoid entering any confidential information in this field.
   
   Example description: `jira_auth_plain_text`

8. Choose the master encryption key that you want to use to encrypt the secret contents while they're imported to the vault. (The key must belong to the same vault.)
9. For **Secret Type Template**, select **Plain-Text**.
10. Click **Secret Contents**, and then enter your Jira credentials in the following format, with a colon separating your login email from your auth token:

    `<your-jira-cloud-login-email>:<your-jira-cloud-auth-token>`

11. Click **Create Secret**.
12. Note the secret **OCID** for use in your function code to securely fetch the secret.

For more information about creating secrets using the Vault service, see **To create a new secret** on page 4008.

**Using the CLI**

**To create the secret using the CLI**

Create a secret storing your Jira credentials: Open a command prompt and run the `oci vault secret create-base64` command:

```
oci vault secret create-base64 --compartment-id <compartment_OCID>  
--secret-name <secret_name> --vault-id <vault_OCID> --  
description <secret_description_text> --key-id <encryption_key_OCID> --  
secret-content-content <base64_encoded_secret_content> --secret-content-  
name <unique_content_name>
```

Avoid entering confidential information.

For more information about managing secrets using the CLI, see **Using the Command Line Interface (CLI)** on page 4013.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **CreateSecret** operation.

**Example CreateSecret request**

```
POST /20180608/secrets
Host: <managementEndpoint>
<authorization and other headers>
```
Notifications

{ "vaultId": "<vault_OCID>",
"compartmentId": "<compartment_OCID>",
"secretName": "jira_auth_plain_text",
"description": "jira_auth_plain_text",
"keyId": "<key_OCID>",
"secretContent": {
   "content": "<base64_encoded_secret_contents>",
   "contentType": "BASE64"
}
}

For more information about managing secrets using the API, see Using the API on page 4018.

**Task 2: Create the function**

This section provides the code sample for creating your function and covers steps to authorize the function to access your Jira credentials in the secret created using the Vault service.

**Function code sample**

The following code sample is for a function to file Jira tickets.

Add your secret OCID in the line that includes `getSecretForOcid`.

For instructions on creating and deploying functions, see Creating and Deploying Functions on page 2063.

```java
public String handleRequest(CloudEvent cloudEvent) {
   // Json body of Cloud event from Oracle Event Service in serialized into
   // cloudEvent object by Fn SDK implicitly
   System.err.println("Inside Java jira function with input as " +
   cloudEvent.getEventType() + " +
   cloudEvent.getData().getResourceName());

   String response = jiraCreateTicket(cloudEvent);
   if (response != null) return response;
   return null;
}

private String jiraCreateTicket(CloudEvent cloudEvent) {
   try {
      //create jira ticket body as per CloudEvent
      String jsonBodyJira = getJiraApiBody(cloudEvent);

      String jiraCloudEndpoint = System.getenv().get("JIRA_CLOUD_URL");
      String ocidForSecretForJiraAuthToken =
      System.getenv().get("JIRA_CLOUD_SECRET_OCID");
      String jiraAuthToken =
      getSecretForOcid(ocidForSecretForJiraAuthToken); // base64 encoded form of
      <YourJiraUsername:YourJiraAuthToken>

      // actual REST call to JIRA cloud
      OkHttpClient client = new OkHttpClient().newBuilder()
         .build();
      MediaType mediaType = MediaType.parse("application/json");
      RequestBody body = RequestBody.create(mediaType, jsonBodyJira);
      Request request = new Request.Builder()
         .url(jiraCloudEndpoint)
         .method("POST", body)
         .addHeader("Accept", "application/json")
         .addHeader("Content-Type", "application/json")
      
   } catch (

```
.addHeader("Authorization", "Basic " + jiraAuthToken)
    .build();
    Response response = client.newCall(request).execute();
    return response.body().string();
}

return null;

**Authorize your function to access secrets**

Use a dynamic group to grant your function the ability to read secrets. Your function must have this authorization to access your Jira credentials, which are stored in the secret you created earlier.

**To authorize your function to access secrets (Console)**

1. Find and note your function **OCID** (format is ocid1.fnfunc.ocl.iad.exampleuniqueID).
2. Include your function in a dynamic group: In the relevant **dynamic group**, specify the following rule:

   ```
   resource.id = '<function-ocid>'
   ```

   Alternatively, you can create a dynamic group that includes all functions:

   ```
   ALL{resource.type='fnfunc', resource.compartment.id='<compartment_OCID>'}
   ```

3. Grant the dynamic group access to secrets: Add the following **policy**:

   ```
   allow dynamic-group <dynamic-group-name> to read secret-family in tenancy
   ```

To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see [Accessing Other Oracle Cloud Infrastructure Resources from Running Functions](#).

For more information about dynamic groups, see [Managing Dynamic Groups](#).

**Task 3: Create the topic, subscriptions, and rule**

This section walks through creating a topic, adding your function and optional email as subscriptions, and creating the rule that sends a message whenever the Database service emits an event for a database maintenance reminder. Your function must be deployed.

Everything can be set up in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

For more information about managing topics and subscriptions, see [Managing Topics and Subscriptions](#). For more information about managing rules, see [Managing Rules for Events](#).

**Using the Console**

To create the topic

This section walks through creating the topic you'll use for the subscriptions and rule.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click **Create Topic** at the top of the topic list.
3. In the **Create Topic** dialog box, configure your topic.

   • **Name**: Required. Specify a friendly name for the topic. It must be unique across the tenancy; validation is case-sensitive. Avoid entering confidential information.
     
     Example: Maintenance Topic
   
   • **Description**: Optional. Enter a description for the topic. Avoid entering confidential information.

4. Click **Create**.

   For help with troubleshooting, see *Troubleshooting Notifications* on page 3385.

**To create the function subscription**

This section walks through adding your function as a subscription to the topic. Your function must be deployed.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.

2. Click the name of the topic that you want to add the subscription to.

   Example: "Maintenance Topic" (assuming you used the suggested topic name when creating the topic).

3. On the topic detail page, click **Create Subscription**.

4. In the **Create Subscription** dialog box, configure your function subscription:

   **Note:**

   The function must be deployed. You must have **FN_INVOCATION** permission against the function to be able to add the function as a subscription to a topic.

   The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at *Function not invoked or run* on page 3387.

   Confirmation is not required for function subscriptions.

   • **Subscription Protocol**: Select **Function**.

   • **Function Compartment**: Select the compartment containing your function.

   • **Function Application**: Select the application containing your function.

   • **Function**: Select your function.

5. Click **Create**.

   The subscription has been created.

   For help with troubleshooting, see *Troubleshooting Notifications* on page 3385.

**To create an email subscription**

This section walks through adding an optional email subscription to your topic.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.

2. Click the name of the topic that you want to add the subscription to.

   Example: "Maintenance Topic" (assuming you used the suggested topic name when creating the topic).

3. On the topic detail page, click **Create Subscription**.

4. In the **Create Subscription** dialog box, set up your email subscription:

   • **Protocol**: Select **Email**.

   • **Email**: Type an email address.

5. Click **Create**.

   The email subscription has been created and a subscription confirmation URL is sent to the specified email address. The subscription remains in "Pending" status until it has been confirmed.
6. To confirm your new email subscription, open your email and navigate to the confirmation URL.
   For more information, see To confirm a subscription on page 3362.

   For help with troubleshooting, see Troubleshooting Notifications on page 3385.

To create the rule

This section walks through creating the rule that sends a message to the topic whenever the Database service emits an event for a database maintenance reminder.

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click Create Rule.

   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   • Display Name: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
     Example: Maintenance Reminder
   • Description: Specify a description of what the rule does. You can change this description later. Avoid entering confidential information.
     Example: Sends messages to Maintenance Topic
4. In Rule Conditions, create a filter for database reminder events:
   • For Service Name, select Database.
   • In Event type, select Autonomous Container Database – Maintenance Reminder.
5. In Actions, select the topic you previously created:
   a. Select Notifications.
   b. Select the Notifications Compartment.
   c. Select the Topic that you previously created.
6. Click Create Rule.

Using the CLI

This section walks through creating the topic, subscriptions, and rule using the CLI. Your function must be deployed.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

1. Create the topic

   Open a command prompt and run the oci ons topic create command:

   ```bash
   oci ons topic create --name "Maintenance Topic" --compartment-id "<compartment-ocid>"
   ```
2. **Add the subscriptions**

To the topic you just created in the previous step, add subscriptions referencing your function **OCID** and an optional email address.

- Create a function subscription: Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "ORACLE_FUNCTIONS" --subscription-endpoint "<function-ocid>
  ```

- Create an email subscription: Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "maintenance.team@example.com"
  ```

3. **Create the rule**

Create a rule that is triggered by maintenance reminders and references this topic as the destination:

- Create a file, **action.json**, that contains the following, referencing your topic created previously:

  ```json
  {
  "actions": [
  {
  "actionType": "ONS",
  "description": "string",
  "isEnabled": true,
  "topicId": "<topic_OCID>"
  }
  ]
  }
  ```

- Open a command prompt and run the `oci events rule create` command:

  ```bash
  oci events rule create --display-name <friendly_name> --is-enabled true --condition "{"eventType": ["com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder"]}" --compartment-id <compartment_OCID> --actions file://action.json
  ```

For more information about creating rules using the CLI, see To create a rule on page 1811.

For help with troubleshooting, see Troubleshooting Notifications on page 3385.

**Using the API**

This section walks through creating the topic, subscriptions, and rule using the API. Your function must be deployed.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:

1. **CreateTopic**: Create a topic.

   **Example CreateTopic request**

   ```
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "name": "Maintenance Topic",
   "compartmentId": "<compartment_OCID>"
   }
   ```
2. **CreateSubscription**: To this topic, add subscriptions referencing your function OCID and an optional email address.

**Example CreateSubscription request: Function**

```
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "topicId": "<topic_OCID>",
    "compartmentId": "<compartment_OCID>",
    "protocol": "ORACLE_FUNCTIONS",
    "endpoint": "<function_OCID>"
}
```

**Example CreateSubscription request: Email**

```
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "topicId": "<topic_OCID>",
    "compartmentId": "<compartment_OCID>",
    "protocol": "EMAIL",
    "endpoint": "maintenance.team@example.com"
}
```

3. **CreateRule**: Create a rule that is triggered by maintenance reminders and references this topic as the destination.

**Example CreateRule request**

```
POST /20181201/rules
Host: events.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "displayName": "Maintenance Reminder",
    "condition": {
        "eventType": "com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder",
        "compartmentId": "<compartment_OCID>",
        "isEnabled": true,
        "actions": [
            {
                "actionType": "ONS",
                "topicId": "<topic_OCID>",
                "isEnabled": true
            }
        ]
    }
}
```

For help with troubleshooting, see [Troubleshooting Notifications](#) on page 3385.

**Troubleshooting Notifications**

This topic covers troubleshooting techniques for Notifications.
Message not received

Tip:
Assess alarms and messages using their unique identifiers. See Prevent Processing of Duplicate Items on page 3356. To view the format used by alarm messages, see Message format and examples on page 2661.

Check these items:

• **Alarm firing transition:** If the message is a result of a firing alarm, then view the history of the alarm. Note times for any transition to a firing state. You'll use noted times for comparison to metrics for your topic ("Publication and delivery").

To view history for your alarm
1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. On the Alarm Definitions page, click the alarm that you want to view history for.
3. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.

• **Publication and delivery:** Note times for messages published to your topic as well as messages delivered to your topic. Compare to times of the firing alarm or other inciting incident.

To view timing of published and delivered messages for your topic
1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Choose the Compartment that contains your topic, and then click the topic's name.
3. In the Resources menu, click Metrics.
   
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Notifications. For more information about the emitted metrics, see Available Metrics: oci_notification on page 3389.
4. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.
5. Review the following metric charts:
   - Published Messages Total Count
   - Delivered Messages Count

• **Service permissions (alarm messages):** If your topic is in an Oracle Platform Services managed compartments (named "ManagedCompartmentForPaas"), then the Monitoring service may not have permissions to use it, and alarm messages sent to that topic may not be received. For more details, including steps for resolution, see Alarm Messages are not Received in Oracle Platform Services Managed Compartments.

• **Unsupported method used to send messages:** Confirm that the method you used to send messages is supported for the subscription protocols used by the topic. Messages sent by unsupported methods are dropped, as indicated by data points in the Failed Messages Count metric chart.

   The value of the metric dimension endpointType corresponds to the subscription protocol. For example, if you attempt to send an SMS message through an unsupported method, then the message is dropped and the counter of this metric chart is increased, with the corresponding data point showing an endpointType value of SMS.

To view dropped messages for your topic
1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Choose the Compartment that contains your topic, and then click the topic's name.
3. In the Resources menu, click Metrics.
   
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Notifications. For more information about the emitted metrics, see Available Metrics: oci_notification on page 3389.
4. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.
5. Review the Failed Messages Count metric chart.
Function not invoked or run

This section provides troubleshooting information for function subscriptions. For an example function subscription, see Scenario A: Automatically Resize VMs on page 3366.

**Note:**
The Notifications service has no information about a function after it's invoked.

**Tip:**
Assess alarms and messages using their unique identifiers. See Prevent Processing of Duplicate Items on page 3356. To view the format used by alarm messages, see Message format and examples on page 2661.

Check these items:

- **Message receipt:** See Message not received on page 3386.
• **Function invocation:** Note times for invocations of your function. Compare to times of the firing alarm or other inciting incident.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If this is the first invocation, response may be delayed.</td>
</tr>
</tbody>
</table>

**To view timing of invocations for your function**

1. Open the detail page for your function by doing one of the following.
   - Find your function on the related subscription page:
     a. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
     b. Choose the **Compartment** that contains your function subscription.
     c. Click **Subscriptions**.
     d. Under **Endpoint**, in the row for your function subscription, click the name of your function.
   - Find your function on a Functions page:
     a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
     b. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. **Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure** on page 2053).
     c. Select the compartment containing the application that contains your function.
        
        The **Applications** page shows all the applications in the compartment you selected.
        
        d. Click the name of the application containing your function.
        
        e. Click the name of your function.

        The function detail page is displayed.

2. Under **Resources**, click **Metrics**.
   
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see **Available Metrics: oci_faas** on page 2107.

3. Adjust the time range by selecting from **Quick Selects** or changing the **Start Time** and **End Time**.

4. Review the **Invocations** chart.

• **Function run:** Note times for runs of your function. Compare to times of the firing alarm or other inciting incident.

**To view timing of runs of your function (logs)**

See **Storing and Viewing Function Logs** on page 2078.

**To view timing of runs of your function (metrics)**

1. Open the detail page for your function by doing one of the following.
   - Find your function on a subscription page:
     a. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
     b. Choose the **Compartment** that contains your function subscription.
     c. Click **Subscriptions**.
     d. Under **Endpoint**, in the row for your function subscription, click the name of your function.
   - Find your function on a Functions page:
     a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**. 
b. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

c. Select the compartment containing the application that contains your function.

   The Applications page shows all the applications in the compartment you selected.

d. Click the name of the application containing your function.

e. Click the name of your function.

   The function detail page is displayed.

2. Under Resources, click Metrics.

   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas on page 2107.

3. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.

4. Review the Duration chart.

Notifications Metrics

You can monitor the health, capacity, and performance of your messages by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_notification (the Notifications service).

Resources: Not applicable. Measures data for messages, which are not resources.

Overview of the Notifications Service Metrics

The Notifications service metrics help you measure the number and size of messages that are in initial requests, are delivered, and are not delivered.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_notification

The metrics listed in the following table are automatically available for messages you publish to topics. You do not need to enable monitoring on any resources to get these metrics.

Each metric includes a subset of the following dimensions:

- AVAILABILITYDOMAIN
  The availability domain in which the associated topic resides.

- ENDPOINTTYPE
  The subscription protocol of the endpoint used for the delivery attempt.

- REGION
  The region in which the associated topic resides.

- RESOURCEID
  The OCID of the resource to which the metric applies.
### TOPICDISPLAYNAME

The friendly name of the associated *topic*.

### Using the Console

**To view default metric charts for a single topic**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Choose the **Compartment** that contains the topic you want to view, and then click the topic's name.
3. In the **Resources** menu, click **Metrics** (if necessary).

   The **Metrics** page displays a default set of charts for the current topic.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view default metric charts for multiple topics**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Metric Namespace**, select **oci_notification**.

   The **Service Metrics** page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

**Tip:**

- Filter metrics by dimension, such as a selected topic, by clicking **Add** above the charts (to the right of **Dimensions**).
For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Using the API**

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 28

Object Storage

This chapter explains how to upload, manage, and access data using Object Storage.

Overview of Object Storage

The Oracle Cloud Infrastructure Object Storage service is an internet-scale, high-performance storage platform that offers reliable and cost-efficient data durability. The Object Storage service can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos.

With Object Storage, you can safely and securely store or retrieve data directly from the internet or from within the cloud platform. Object Storage offers multiple management interfaces that let you easily manage storage at scale. The elasticity of the platform lets you start small and scale seamlessly, without experiencing any degradation in performance or service reliability.

Object Storage is a regional service and is not tied to any specific compute instance. You can access data from anywhere inside or outside the context of the Oracle Cloud Infrastructure, as long you have internet connectivity and can access one of the Object Storage endpoints. Authorization and resource limits are discussed later in this topic.

Oracle Cloud Infrastructure supports multiple storage tiers that offer cost and performance flexibility. Standard is the default storage tier for Object Storage buckets.

Object Storage also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Object Storage public endpoints from private IP addresses in private subnets. For example, you can back up DB systems to an Object Storage bucket over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Object Storage. See Access to Oracle Services: Service Gateway on page 3256 for details.

Object Storage is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

Object Storage Resources

Use the following Object Storage resources to store and manage data. Authorization and resource limits are discussed later in this topic.

**Buckets**

Buckets are logical containers for storing objects. Users or systems create buckets as needed within a region. A bucket is associated with a single compartment that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

**Objects**

Any type of data, regardless of content type, is stored as an object. An object is composed of the object itself and metadata about the object. Each object is stored in a bucket.
Namespace

A namespace serves as the top-level container for all buckets and objects. At account creation time, each tenant is assigned one unique system-generated and immutable namespace name. The namespace spans all compartments within a region. You control bucket names, but those bucket names must be unique within a namespace. While the namespace is region-specific, the namespace name itself is the same in all regions. See Understanding Object Storage Namespaces on page 3395 for more details, including information about older tenancy names, illustrative examples of namespaces, and how to obtain your namespace string.

Compartment

A compartment is the primary building block used to organize your cloud resources. When your tenancy is provisioned, a root compartment is created for you. You can then create compartments under your root compartment to organize your resources. You control access by creating policies that specify what actions groups of users can take on the resources in those compartments. An Object Storage bucket can only exist in one compartment.

Object Storage Features

Object Storage provides the following features:

**STRONG CONSISTENCY**

When a read request is made, Object Storage always serves the most recent copy of the data that was written to the system.

**DURABILITY**

Object Storage is a regional service. Data is stored redundantly across multiple storage servers. Object Storage actively monitors data integrity using checksums and automatically detects and repairs corrupt data. Object Storage actively monitors and ensures data redundancy. If a redundancy loss is detected, Object Storage automatically creates more data copies. For more details about Object Storage durability, see the Object Storage FAQ.

**custom metadata**

You can define your own extensive metadata as key-value pairs for any purpose. For example, you can create descriptive tags for objects, retrieve those tags, and sort through the data. You can assign custom metadata to objects and buckets using the Oracle Cloud Infrastructure CLI or SDK. See Software Development Kits and Command Line Interface on page 4225 for details.

**ENCRYPTION**

Object Storage employs 256-bit Advanced Encryption Standard (AES-256) to encrypt object data on the server. Each object is encrypted with its own data encryption key. Data encryption keys are always encrypted with a master encryption key that is assigned to the bucket. Encryption is enabled by default and cannot be turned off. By default, Oracle manages the master encryption key.

In addition to this default encryption, you can employ these other strategies to encrypt data:

- You can optionally configure a bucket so that it's assigned an Oracle Cloud Infrastructure Vault master encryption key that you control and rotate on your own schedule. See Overview of Vault on page 3952 for details.
- You can optionally encrypt each Object Storage object using your own encryption key. See Using Your Own Keys for Server-Side Encryption on page 3491 for details.

Ways to Access Object Storage

You can access Object Storage using any of the following options, based on your preference and its suitability for the task you want to complete:
• The Console is an easy-to-use, browser-based interface.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

You are prompted to enter your cloud tenant, your user name, and your password.

• The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Using the CLI on page 4207.

• The REST API provides the most functionality, but requires programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs on page 4368. Object Storage is accessible with the following APIs:
  • Object Storage Service
  • Amazon S3 Compatibility API
  • Swift API (for use with Oracle RMAN)
  • Oracle Cloud Infrastructure provides SDKs that interact with Object Storage without you having to create a framework. For general information about using the SDKs, see Software Development Kits and Command Line Interface on page 4225.

Using Object Storage

If you are ready to use Object Storage, you can find more information in the following topics:

• For instructions on how to create a bucket and store an object in the bucket, see "Putting Data into Object Storage" in the Oracle Cloud Infrastructure Getting Started Guide.

• For task documentation related to buckets, see Managing Buckets on page 3398, Using Replication on page 3440, and Using Retention Rules to Preserve Data on page 3458.

• For task documentation related to objects, see Managing Objects on page 3419, Using Object Versioning on page 3446, and Copying Objects on page 3487.

• For task documentation related to lifecycle management, see Using Object Lifecycle Management on page 3466.

• For API reference documentation, see Object Storage Service API.

• For SDK and CLI information, see Software Development Kits and Command Line Interface on page 4225.

• For more information about using Archive Storage, see Overview of Archive Storage on page 484.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API). IAM also manages user credentials for things like API signing keys, auth tokens, and customer secret keys for Amazon S3 Compatibility API. See User Credentials on page 2360 for details.

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create users and groups, create buckets, download objects, and manage Object Storage-related policies and rules. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see the Policy Reference on page 2167. For specific details about writing policies for Object Storage, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.
Blocking Access to Object Storage Resources from Unauthorized IP Addresses

You can enhance the security of your Object Storage policies by restricting access only to requests that originate from an allowed IP address. First, you create a network source to specify the allowed IP addresses, then you add a condition to your policy to restrict access to the IP addresses in the network source. An example of a policy that restricts access to only IP addresses in a network source is:

```
    allow group CorporateUsers to manage object-family in tenancy where
    request.networkSource.name='corpnet'
```

For information on creating network sources and using them in a policy, see Managing Network Sources on page 2427.

Object Storage IP Addresses

The Oracle Cloud Infrastructure Object Storage service uses the CIDR block IP range 134.70.0.0/17 for all regions.

Limits on Object Storage Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

To set tenancy or compartment-specific storage limits, administrators can use Object Storage Quotas on page 256.

Other limits include:

- Number of Object Storage namespaces per root compartment: 1
- Maximum object size: 10 TiB
- Maximum object part size in a multipart upload: 50 GiB
- Maximum number of parts in a multipart upload: 10,000
- Maximum object size allowed by PutObject API: 50 GiB
- Maximum size of object metadata: 2 K

Understanding Object Storage Namespaces

, namespace serves as the top-level container for all buckets and objects. At account creation time, each tenant is assigned one unique system-generated and immutable namespace name. The namespace spans all compartments within a region. You control bucket names, but those bucket names must be unique within a namespace. While the namespace is region-specific, the namespace name itself is the same in all regions.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot customize, change, or request a namespace name change.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For some older tenancies, the namespace name string might be based on your tenancy name instead of being machine generated. If your namespace was created based on your tenancy name, your namespace uses all lowercase letters (regardless of the presence of capital letters in your tenancy name). When using the API, CLI, or SDKs, do not use capital letters in your namespace name string.</td>
</tr>
</tbody>
</table>

If your tenancy is assigned a namespace name of axaxncorw5, that is your namespace name in all regions. You can create a bucket named MyBucket in US West (Phoenix). You cannot create another bucket named MyBucket in US West (Phoenix). You can, however, create a bucket named MyBucket in Germany Central (Frankfurt).

Because the namespace name is unique to a tenant, other customers can create buckets named MyBucket in their own namespaces.

Within a namespace, buckets and objects exist in flat hierarchy, but you can simulate a directory structure to help navigate a large set of objects. See Object Naming Using Prefixes and Hierarchies on page 3420 for details.
The namespace metadata stores the default compartment assignments for the Amazon S3 Compatibility API and the Swift API. For more information, see Viewing and Specifying Designated Compartments.

Using the Console

To view your Object Storage namespace string:

Open the Profile menu and click Tenancy: <your_tenancy_name>.

Your namespace string is listed under Object Storage Settings.

Note:

While the Object Storage namespace string is displayed under Object Storage Settings, you cannot edit the namespace string. The namespace string appears here for information only.

Using the Command Line Interface (CLI)

Run the following command get your Object Storage namespace:

```sh
oci os ns get
```

Your Object Storage namespace is returned:

```json
{
  "data": "MyNamespace"
}
```

Tip:

You can use -ns, --namespace, or --namespace-name for CLI commands that require you to specify the Object Storage namespace string.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the GetNamespace operation to get your Object Storage namespace. If you have the OBJECTSTORAGE_NAMESPACE_READ permission and supply the compartment or tenancy OCID in the optional compartmentId parameter, you can also get the namespace of a different tenancy's Object Storage namespace.

Understanding Storage Tiers

Oracle Cloud Infrastructure offers distinct storage class tiers to address the need for both performant, frequently accessed "hot" storage, less frequently accessed "cool" storage, and rarely accessed "cold" storage. Storage tiers help you maximize access performance where appropriate and minimize storage costs where possible.

You interact with the data stored in any of the storage tiers using the same resources and management interfaces that you use for Object Storage. In addition, each storage tier supports the full range of Object Storage features. Specific storage tier details or interactions that you need to be aware of are covered in the Scope and Constraints section for the feature.
**Standard Tier**

The **Standard** tier is the primary, default storage tier used for Object Storage service data. The Standard storage tier is "hot" storage used for data that you need to access quickly, immediately, and frequently. Data accessibility and performance justifies a higher price to store data in the Standard tier.

You choose a default storage tier (Standard or Archive) when you create a bucket. Once set at bucket creation, you cannot change the default storage tier for a bucket. When you upload objects to a bucket, the default storage tier is selected by default. You can, however, change the storage tier when uploading objects to either the Infrequent Access or Archive tier. Standard buckets can therefore contain a mix of objects residing in all storage tiers.

The following list summarizes some of the use cases for the Standard tier.

- Primary content repository for accessible scalable data, images, logs, and video
- Primary data repository for Hadoop/big data. Provides a scalable storage platform to store large datasets and operate seamlessly on those datasets. The HDFS Connector for Object Storage on page 4347 provides connectivity to various big data analytic engines like Apache Spark and MapReduce. This connectivity enables the analytics engines to work directly with data stored in Object Storage. For more information, see Hadoop Support on page 3505.

**Infrequent Access**

The **Infrequent Access** tier is "cool" storage used for data that you access infrequently, but that must be available immediately when needed. Storage costs are lower than **Standard**.

The use cases for the Infrequent Access tier include the following:

- Backups of on-premises data
- Storage for data replicated or copied from another region

The Infrequent Access tier has a minimum storage retention period and data retrieval fees:

- The minimum storage retention period for the Infrequent Access tier is 31 days. If you delete objects from the Infrequent Access tier before the minimum retention requirements are met, you are charged the prorated cost of storing the data for the full 31 days.
- When you need to access objects stored in this tier, you are charged a per GiB data retrieval fee.

**Archive**

The **Archive** tier is the primary, default storage tier used for Archive Storage service data. The Archive storage tier is "cold" storage used for data seldom or rarely access, but that must be retained and preserved for long periods of time.

You can choose a default storage tier (Standard or Archive) when you create a bucket. When you upload objects to a bucket in an Archive tier, the objects are automatically uploaded to the Archive tier. You cannot upload objects in an Archive bucket to any other storage tier. Archive buckets can only contain objects in the Archive storage tier.

The use cases for the Archive tier include the following:

- Compliance and audit mandates
- Retroactive log data analysis to determine usage pattern or to debug problems
- Historical or rarely accessed content repository data
- Application-generated data requiring archival for future analysis or legal purposes

Objects in the Archive tier must be restored before they are available for access. The cost efficiency of the Archive tier offsets the lead time required to access the data. However, the Archive tier has a minimum storage retention period and some additional storage fees:

- The minimum storage retention period for the Archive tier is 90 days. If you delete objects from the Archive tier before the minimum retention requirements are met, you are charged the prorated cost of storing the data for the full 90 days.
- When you restore objects, you are returning those objects to the Standard tier for access. You are billed for the Standard class tier while the restored objects reside in that tier.
Managing Buckets

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment. The compartment has policies that indicate what actions you can perform on a bucket and all the objects in the bucket.

You cannot nest buckets—a bucket cannot contain other buckets.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you are new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators:

- The policy Let Object Storage admins manage buckets and objects on page 2149 lets the specified group do everything with buckets and the associated objects.
- If you must write more restrictive policies for buckets, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to manage buckets:

- You can't move a bucket from a security zone to a standard compartment because it might be less secure. For details, see Restrict Resource Movement.
- Buckets in a security zone must be private.
- Buckets in a security zone must use customer-managed master encryption keys in the Vault service.

Pre-Authenticated Requests

Pre-authenticated requests provide a way to let you access a bucket or an object without having your own credentials. For example, you can create a request that lets you upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests on page 3482 for details.

Object Versioning

You can enable object versioning to retain previous versions of objects. Object versioning lets you view, retrieve, and recovery previous versions of objects and provides protection against accidental or malicious object overwrite or deletion. For information about this feature, see Using Object Versioning on page 3446.

Object Lifecycle Policies

Using object lifecycle policies applied at the bucket level, you can automatically manage the archiving and deletion of objects according to a pre-defined schedule. For information about this feature, see Using Object Lifecycle Management on page 3466.

Retention Rules

You can apply retention rules at the bucket level to provide immutable object storage options for data written to Object Storage for governance, regulatory compliance, and legal requirements. For information about this feature, see Using Retention Rules to Preserve Data on page 3458.
Replication Policy

Using a replication policy for a bucket, you can automatically replicate the objects in one Object Storage bucket to another bucket in the same region or a different region. For information about this feature, see Using Replication on page 3440.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

Object Storage currently supports adding tags to buckets.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring buckets, see Object Storage Metrics on page 3499.

Usage Reports

A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation. A usage report is generated daily and stored in an Object Storage bucket. For more information, see Cost and Usage Reports Overview on page 278 and Accessing Cost and Usage Reports on page 281.

Creating Automation for Buckets and Objects Using the Events Service

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Buckets emit events for bucket state changes by default. Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Bucket Names

Bucket names are system generated by default, but you can overwrite the default with a name you specify.

System-Generated Bucket Names

When a bucket is created, the system generates a default name for that bucket, for example bucket-20190306-1359. This bucket name identifies the current year, month, and day that the bucket was created. You can use that system-generated name for your new bucket or you can specify a different name.

User-Specified Bucket Names

If you change this default bucket name or the name of any bucket, observe the following:

- Make the name unique within your tenancy's Object Storage namespace.
- Use from 1 to 256 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bucket names and object names are case-sensitive. Object Storage handles accounts-payable and Accounts-Payable as separate buckets.</td>
</tr>
</tbody>
</table>

- Avoid entering confidential information.
**Default Storage Tiers**

When you create a bucket, you decide which default storage tier is appropriate for storing objects:

- Use the **Standard** tier for data to which you need fast, immediate, and frequent access.
- Use the **Archive** tier for data to which you seldom or rarely access, but that must be retained and preserved for long periods of time.

For more information, see Understanding Storage Tiers on page 3396.

**Important:**

You cannot change the storage tier in which a bucket resides.

**Public Buckets**

When you create a bucket, the bucket is considered a private bucket and the access to the bucket and bucket contents requires authentication and authorization. However, Object Storage supports anonymous, unauthenticated access to a bucket that is not in a security zone. You make a bucket public by enabling read access to the bucket.

**Important:**

Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, any user can obtain object metadata, download bucket objects, and optionally list bucket contents.

**Required Permissions**

The following permissions are required to configure a public bucket:

- To enable public access when creating a bucket, use permission `BUCKET_CREATE`.
- To enable public access for an existing bucket, use permission `BUCKET_UPDATE`.

**Options**

When creating a public bucket, you have the following options:

- You can configure the access to allow listing and downloading objects. List and download access is the default.
- You can configure the access to allow downloading objects only. A user would not be able to list bucket contents.

**Scope and Constraints**

Understand the following scope and constraints regarding public access:

- Buckets in a security zone can't be public.
- Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
- Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

You can enable anonymous public access for new or existing buckets using the Console, CLI, or an SDK to access the API.

**Using the Console**

**To get a list of buckets**

Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
To create a bucket

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Select a compartment from the Compartment list on the left side of the page.

A list of existing buckets is displayed.
3. Click Create Bucket.
4. In the Create Bucket dialog box, specify the attributes of the bucket:
   - **Bucket Name:** The system generates a default bucket name that reflects the current year, month, day, and time, for example bucket-20190306-1359. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Default Storage Tier:** Select the default tier in which you want to store your data. When you upload objects, the objects are uploaded to this tier by default. Available default tiers include:
     - **Standard** is the primary, default storage tier used for Object Storage service data. Use the Standard tier for storing data that requires fast and immediate access.
     - **Archive** is the default storage tier used for Archive Storage service data. Use the Archive tier for storing data that does not require immediate access, but requires long retention periods. Access to data in the Archive tier is not immediate. Archived data must be restored before the data is accessible.
   - **Object Events:** Select Emit Object Events if you want to enable the bucket to emit events for object state changes. For more information about events, see Overview of Events on page 1784.
   - **Object Versioning:** Select Enable Object Versioning if you want Object Storage to create an object version each time the content changes or the object is deleted. For more information, see Using Object Versioning on page 3446.
   - **Encryption:** Buckets are encrypted with keys managed by Oracle by default, but you can optionally encrypt the data in this bucket using your own Vault encryption key. To use Vault for your encryption needs, select Encrypt Using Customer-Managed Keys. Then, select the Vault Compartment and Vault that contain the master encryption key you want to use. Also select the Master Encryption Key Compartment and Master Encryption Key. For more information about encryption, see Overview of Vault on page 3952. For details on how to create a vault, see Managing Vaults on page 3957.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click Create Bucket.

The bucket is created immediately and you can start uploading objects. Objects added to archive buckets are immediately archived and must be restored before they are available for download.

To view bucket details

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment that contains your buckets.

A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.

To change the visibility of a bucket

A bucket is either private (the default) or public. See Public Buckets on page 3400 for more information.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can't change the visibility of a bucket from private to public if that bucket is in a security zone.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.

A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name to see the bucket details.
   - **Visibility**: shows the current bucket setting, which is **Private** by default.
3. Click **Edit Visibility**.
4. In the **Edit Visibility** dialog box, edit the visibility settings:
   - **Visibility**
     - **Public**
     - **Private**
   - If you select **Public** to enable public access, decide whether you want to let users list the bucket contents. To set the visibility of bucket object lists, click **Allow users to list objects from this bucket**.
5. Click **Save Changes**.

**To move a bucket to a different compartment**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can't move a bucket from a security zone to a standard compartment. You also need to ensure that the resource users have sufficient access permissions for the compartment to which the resource is being moved.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. In the **Scope** section, select a compartment.
3. Find the bucket in the list, click the Actions icon (three dots), and then click **Move Resource**.
   - Alternatively, you can choose a bucket, and then click **Move Resource** on the bucket details page.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To manage tags for a bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
3. Click the bucket name.
4. You can manage tags in the following ways:
   - To view the tags associated with the bucket, click the **Tags** tab, located to the right of the **Bucket Information** tab.
   - To add one or more tags, click **Add Tags**.
   - To rename a tag, click the pencil icon to the left of a tag name, edit the name, and save.
   - To delete a tag, click the pencil icon to the left of a tag name and click **Remove Tag**.

For more information, see **Resource Tags** on page 211.

**To delete a bucket**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot recover a deleted bucket.</td>
</tr>
</tbody>
</table>

You can permanently delete an *empty* bucket. You cannot delete a bucket that contains any of the following:
- Any objects
- Previous versions of an object
- A multipart upload in progress
- A pre-authenticated request
Tip:

When you delete an object in a version-enabled bucket, a previous version of that object is created. Select Show Deleted Objects to display the object versions that might prevent you from deleting the bucket. For more information, see Using Object Versioning on page 3446.

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.

   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Find the bucket that you want to delete.

3. Click the Actions icon (three dots), and then click Delete.

   Alternatively, you can choose a bucket, click More Actions on the bucket details page, and then click Delete.

4. Confirm deletion when prompted.

To assign a Vault master encryption key to a bucket

Buckets are encrypted with keys managed by Oracle by default. Optionally, you can encrypt the data encryption keys that encrypt the objects in a bucket using your own Vault master encryption key.

Important:

Buckets in a security zone can't use the default encryption key managed by Oracle. You must use your own Vault master encryption key.

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.

   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket that you want to encrypt.

3. Next to Encryption Key, do one of the following:

   • If the bucket is encrypted with a key managed by Oracle, click the Assign link.
   • If the bucket already has a Vault master encryption key assigned, to assign a different key, click the Edit link.

4. In the dialog box, provide or edit the following information:

   • Vault Compartment and Vault that contain the master encryption key you want to use. The current compartment is displayed by default.
   • Master Encryption Key Compartment and Master Encryption Key. The current compartment is displayed by default.

5. When you are finished, click Assign or Edit.

See Overview of Vault on page 3952 for more details.

To remove a Vault master encryption key from a bucket

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.

   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket for which you want to remove a Vault key assignment.

3. Next to Encryption Key, click the Unassign link.

4. In the Confirm dialog box, click OK to remove the key assignment from the bucket.

To re-encrypt a bucket's data encryption keys

If you've rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same, most recent version of the assigned master encryption key, re-encrypt the bucket.
1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket for which you want to re-encrypt all data encryption keys.

3. Click **Re-encrypt**. (If the button is not enabled, that's because the bucket is using a master encryption key managed by Oracle rather than a Vault master encryption. Or, the bucket does not contain any objects.)

4. In the confirmation dialog box, click **Re-encrypt** to generate a work request to re-encrypt all data encryption keys associated with the bucket.

The **Work Requests Details** dialog box that displays tells you about the work request, including the percentage completed and the work request ID. You can copy the work request ID to monitor the request status later.

**To view the approximate bucket size and number of objects in the bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

2. Choose the compartment that contains your buckets.

A list of buckets is displayed.

3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.

- **Approximate Count** is the approximate number of objects in the bucket. Count statistics are reported periodically. A lag can occur between what is displayed and the actual object count.

- **Approximate Size** is the approximate total size of all objects in the bucket. Size statistics are reported periodically. A lag can occur between what is displayed and the actual size of the bucket.

**To enable or disable emitting events for object state changes**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see **Overview of Events** on page 1784.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

2. Choose the compartment that contains your buckets.

A list of buckets is displayed.

3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.

4. Next to **Emit Object Events**, click **Edit**.

5. In the dialog box, select (to enable) or deselect (to disable) **Emit Object Events**.

6. Click **Save Changes**.

**To view or copy the Oracle Cloud Identifier (OCID) for a bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

2. Choose the compartment that contains your buckets.

A list of buckets is displayed.

3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**Note:**

The examples in this section use the full syntax for all parameters, for example `--namespace` and `--compartment-id`. For some parameters, there are shortened versions that you can use instead, like `-ns` and `-c`. See the CLI online help for instances of a shortened parameter associated with a command.
To get a list of buckets

```bash
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id>
```

For example:

```bash
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```json
{
  "data": [
    {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5",
      "freeform-tags": null,
      "name": "MyBucket1",
      "namespace": "MyNamespace",
      "time-created": "2020-05-22T19:22:25.032000+00:00"
    },
    {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
      "freeform-tags": null,
      "name": "MyBucket2",
      "namespace": "MyNamespace",
      "time-created": "2020-06-22T13:04:05.879000+00:00"
    }
  ]
}
```

By default, getting a list of buckets returns up to the first 1,000 buckets in the compartment.

**Note:**

If you do not specify the `--fields tags` option when listing buckets, null is returned as the value for both freeform and defined tags.

For example:

To include resource tag data, use the `--fields tags` option:

```bash
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id> --fields tags
```

For example:

```bash
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID --fields tags
```

```json
{
  "data": [
    {
      "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": {
        "example_tag_namespace_Financials": {

```
To create a Standard tier bucket

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id>
```

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
```

By default, a bucket is created in the standard Object Storage tier. You do not need to explicitly set `--storage-tier`.

A Standard tier bucket is created immediately and you can start uploading objects.
To create an Archive tier bucket

To create an Archive tier bucket, you must explicitly set --storage-tier Archive.

```bash
oci os bucket create --namespace <object_storage_namespace> --name <archivebucket_name> --compartment-id <target_compartment_id> --storage-tier Archive
```

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyArchiveBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyArchiveBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policyetag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Archive",
    "time-created": "2020-06-12T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5"
}
```

An Archive Storage bucket is created and you can start uploading objects. Objects uploaded to Archive Storage buckets are immediately archived and must be restored before they are available for download.

To create a public bucket that allows listing and downloading bucket objects

To create a public bucket that allows listing and downloading bucket objects, you must explicitly set --public-access-type ObjectRead.

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --public-access-type ObjectRead
```

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "01096e0b-659a-4d9d-a806-d57568cf1b22",
    "freeform-tags": {}
  }
```

Oracle Cloud Infrastructure User Guide
To create a public bucket that allows downloading bucket objects only

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --public-access-type ObjectReadWithoutList
```

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyPublicObjectReadBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --public-access-type ObjectReadWithoutList
```

```json
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "ec20c59a-f5ba-4a6d-8a7e-b69bb9bb76ad",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyPublicObjectReadWithoutListBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectReadWithoutList",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-22T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "01096e0b-659a-4d9d-a806-d57568cf1b22"
}
```

To create a bucket with resource tags

You can create standard Object Storage tier or Archive tier buckets with resource tags.

To add resource tags when creating a bucket, set one or both of the `--defined-tags` and `--freeform-tags` options.
Tip:
The `--defined-tags` and `--freeform-tags` options require that the input to be a complex type formatted in valid JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

The following example syntax creates a standard Object Storage tier bucket with a defined tag:

```
ooci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --defined-tags '{<JSON_formatted_defined_tag>}'
```

Examples of defined tag formatting:

```
'{"Operations": {"CostCenter": "42"}}

'{"Logistics": {"Procurement": "Madrid Center"}},"Financials":{"Production": "Unit 5"}}
```

Note:
If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single defined tag is formatted '{"Logistics": \"Procurement\": \"Madrid Center\"}''

For example:

```
ooci os bucket create --namespace MyNamespace --name MyBucketDefined --compartment-id ocid.compartment.oc1..exampleuniqueID --defined-tags '{"Operations": {"CostCenter": "42"}}
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "ea88f444-842c-462d-965e-d3540b3b54f6",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucketDefined",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-23T19:47:51.362000+00:00",
    "versioning": "Disabled"
  },
  "etag": "ea88f444-842c-462d-965e-d3540b3b54f6"
}
```
The following example syntax creates a Standard tier bucket with a free-form tag:

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --freeform-tags <JSON_formated_free-form_tag>
```

Examples of free-form tag formatting:

```json
'{"Chicago_Team": "marketing_videos"}'

'{"Project": "prototype 3","Manager": "Meadows"}'
```

**Note:**
If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single free-form tag is formatted as `{"Chicago_Team": {"marketing_videos"}}`

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyBucketFreeform --compartment-id ocid.compartment.oc1..exampleuniqueID --freeform-tags '{"Chicago_Team": "marketing_videos"}'
```

To view bucket details

```bash
oci os bucket get --name <bucket_name>
```

For example:

```bash
oci os bucket get --name MyBucket
```

```json
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "6f4bda10-fc8b-462e-8563-875639fd7294",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "is-read-only": false,
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucketFreeform",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2020-06-23T20:51:16.260000+00:00"
  },
  "etag": "6f4bda10-fc8b-462e-8563-875639fd7294"
}
```
To add custom key-value metadata pairs to a bucket

```bash
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --metadata <JSON-formatted_key-value_pair>
```

<JSON-formatted_key-value_pair> is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

For example:

```bash
oci os bucket update --namespace MyNamespace --name MyBucket --metadata '{"Department": "Finance"}'
```

```json
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "4b09d7b9-a8bf-42f6-8d67-bb357694f92d",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-22T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "4b09d7b9-a8bf-42f6-8d67-bb357694f92d"
}
```
To make a bucket private or public

```plaintext
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --public-access-type [NoPublicAccess|ObjectReadWithoutList|ObjectRead]
```

- **NoPublicAccess**: Allows only an authenticated caller to access the bucket and bucket contents. NoPublicAccess is the default value.
- **ObjectReadWithoutList**: Allows public access for the GetObject, HeadObject, and ListObjects operations.
- **ObjectRead**: Allows public access for the GetObject and HeadObject operations.

For example:

```plaintext
oci os bucket update --namespace MyNamespace --name MyBucket --public-access-type ObjectRead
```

```
{  
  "data": {  
    "approximate-count": null,  
    "approximate-size": null,  
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",  
    "created-by": "ocid1.user.oc1..exampleuniqueID",  
    "defined-tags": {},  
    "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60",  
    "freeform-tags": {},  
    "id": "ocid1.bucket.oc1..exampleuniqueID",  
    "is-read-only": false,  
    "kms-key-id": null,  
    "metadata": {  
      "department": "Finance"  
    },  
    "name": "MyBucket",  
    "namespace": "MyNamespace",  
    "object-events-enabled": false,  
    "object-lifecycle-policy-etag": null,  
    "public-access-type": "ObjectRead",  
    "replication-enabled": false,  
    "storage-tier": "Standard",  
    "time-created": "2020-06-22T19:04:05.879000+00:00",  
    "versioning": "Disabled"  
  },  
  "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60"
}
```

To move a bucket to a different compartment

```plaintext
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <new_target_compartment_id>
```

*<new_target_compartment_id>* is the compartment ID associated with the compartment to which you are moving the bucket.

For example:

```plaintext
oci os bucket update --namespace MyNamespace --name MyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```
{  
  "data": {  
    "approximate-count": null,  
    "approximate-size": null,  
    "compartment-id": "new_ocid.compartment.oc1..exampleuniqueID",  
    "created-by": "ocid1.user.oc1..exampleuniqueID",  
    "defined-tags": {}  
  }
```
To add resource tags to a bucket

To add defined resource tags to a bucket:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --defined-tags <JSON_formatted_defined_tag>
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --defined-tags '{"Operations": {"CostCenter": "42"}}'
```

```json
{
   "data": {
      "approximate-count": null,
      "approximate-size": null,
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": {
         "operations": {
            "costcenter": "42"
         }
      },
      "etag": "0a26b47d-c43f-4ef8-9c26-02bb8d69fa34",
      "freeform-tags": {},
      "id": "ocid1.bucket.oc1..exampleuniqueID",
      "is-read-only": false,
      "kms-key-id": null,
      "metadata": {
         "department": "Finance"
      },
      "name": "MyBucket",
      "namespace": "MyNamespace",
      "object-events-enabled": false,
      "object-lifecycle-policy-etag": null,
      "public-access-type": "NoPublicAccess",
      "replication-enabled": false,
      "storage-tier": "Standard",
      "time-created": "2020-06-22T19:04:05.879000+00:00",
      "versioning": "Disabled"
   },
   "etag": "0a26b47d-c43f-4ef8-9c26-02bb8d69fa34"
}
```
To add free-form resource tags to a bucket:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --freeform-tags <JSON_formatted_free-form_tag>
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --freeform-tags '{"Chicago_Team": "marketing_videos"}'
```

```
"data": {
  "approximate-count": null,
  "approximate-size": null,
  "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
  "created-by": "ocid1.user.oc1..exampleuniqueID",
  "defined-tags": {
    "operations": {
      "costcenter": "42"
    }
  },
  "etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48",
  "freeform-tags": {
    "Chicago_Team": "marketing_videos"
  },
  "id": "ocid1.bucket.oc1..exampleuniqueID",
  "is-read-only": false,
  "kms-key-id": null,
  "metadata": {
    "department": "Finance"
  },
  "name": "MyBucket",
  "namespace": "MyNamespace",
  "object-events-enabled": false,
  "object-lifecycle-policyetag": null,
  "public-access-type": "NoPublicAccess",
  "replication-enabled": false,
  "storage-tier": "Standard",
  "time-created": "2020-06-22T19:04:05.879000+00:00",
  "versioning": "Disabled"
},
"etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48"
```

**Tip:**

Provide key-value pair input for `--defined-tags` and `--freeform-tags` as valid formatted JSON. For examples of JSON-formatted resource tags, see To create a Standard or Archive tier bucket with resource tags. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

To delete a bucket

**Caution:**

You cannot recover a deleted bucket.

You can permanently delete an *empty* bucket. You cannot delete a bucket that contains any of the following:

- Any objects
- Previous versions of an object
Object Storage

- A multipart upload in progress
- A pre-authenticated request

```bash
oci os bucket delete --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```bash
oci os bucket delete --namespace MyNamespace --name MyDeletedBucket
Are you sure you want to delete this resource? [y/N]:
```

Select y and press Enter. The bucket is deleted with no further prompting.

**To assign a Vault key to a bucket**

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
```

<target_key_id> is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where the data is stored.

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyKeyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --kms-key-id ocid1.key.region1.sea..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID",
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess"
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-29T23:00:35.490000+00:00",
    "versioning": "Disabled"
  },
  "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

See Overview of Vault on page 3952 for more details.

**To update the Vault key assigned to a bucket**

```bash
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id <target_key_id>
```
<target_key_id> is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where the data is stored.

For example:

```bash
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id ocid1.key.region1.sea.exampleuniqueID_updated
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID_updated",
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-29T23:00:35.490000+00:00",
    "versioning": "Disabled"
  },
  "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

To remove the Vault key assigned to a bucket

```bash
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id ""
```

For example:

```bash
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id ""
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "10a50818-e495-45a9-b1ce-cc815f7b39ad",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-29T23:00:35.490000+00:00",
    "versioning": "Disabled"
  }
}
To re-encrypt a bucket's data encryption keys

If you've rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same, most recent version of the assigned master encryption key, re-encrypt the bucket.

`oci os bucket reencrypt --name <bucket_name>`

For example:

`oci os bucket reencrypt --name MyBucket`

To view the approximate bucket size and number of objects in the bucket

`oci os bucket get --name <bucket_name> --fields approximateCount --fields approximateSize`

- `approximateCount` is the approximate number of objects in the bucket. Count statistics are reported periodically. You might see a lag between what is displayed and the actual object count.
- `approximateSize` is the approximate total size of all objects in the bucket. Size statistics are reported periodically. You might see a lag between what is displayed and the actual size of the bucket.

For example:

`oci os bucket get --name MyBucket --fields approximateCount --fields approximateSize`

```json
{  "data": {    "approximate-count": 25,    "approximate-size": 8075918,    "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",    "created-by": "ocid1:user:oc1:phx:1458751937789:exampleuniqueID",    "defined-tags": {},    "etag": "218f201f-28a4-434d-9591-f05b6223c67a",    "freeform-tags": {},    "id": "ocid1.bucket.oc1..exampleuniqueID",    "is-read-only": false,    "kms-key-id": null,    "metadata": {},    "name": "MyBucket",    "namespace": "MyNamespace",    "object-events-enabled": false,    "object-level-audit-mode": "Disabled",    "object-lifecycle-policy-etag": null,    "public-access-type": "NoPublicAccess",    "replication-enabled": false,    "storage-tier": "Standard",    "time-created": "2017-10-19T04:11:32.040000+00:00",    "versioning": "Disabled"  },  "etag": "218f201f-28a4-434d-9591-f05b6223c67a"}
```
To enable or disable emitting events for object state changes

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --object-events-enabled [true|false]
```

For example, to enable emitting events for all objects in the bucket named MyBucket:

```
oci os bucket update --namespace MyNamespace --name MyBucket --object-events-enabled true
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1:user:oc1:phx:1458751937789:exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "39d1db02-27d0-4263-b3ff-5e6450495457",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": true,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-22T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "39d1db02-27d0-4263-b3ff-5e6450495457"
}
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

When accessing the Object Storage API, the bucket name is used with the Object Storage namespace name to form the request URL:

```
n/<object_storage_namespace>/b/<bucket>
```

Use the following API operations to manage buckets:

- CreateBucket
- DeleteBucket
- GetBucket
Managing Objects

In the Oracle Cloud Infrastructure Object Storage service, an object is a file or unstructured data you upload to a bucket within a compartment within an Object Storage namespace. The object can be any type of data, for example, multimedia files, data backups, static web content, or logs. You can store objects that are up to 10 TiB. Objects are processed as a single entity. You can't edit or append data to an object, but you can replace the entire object.

This topic describes how to manage objects within a single bucket. For information on copying an object to another bucket, see Copying Objects.

You might also be interested in exploring an Object Storage feature that retains previous versions of objects. Among other things, object versioning protects objects from accidental or malicious overwrite or deletion. For more information, see Using Object Versioning on page 3446.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators:

- The policy Let Object Storage admins manage buckets and objects on page 2149 lets the specified group do everything with buckets and objects. Objects always reside in the same compartment as the bucket.
- If you need to write a more restrictive policy for objects, the inspect objects lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, read objects lets you download the object itself.
- If you create more restrictive policies that grant individual permissions:
  - OBJECT_VERSION_DELETE is required to delete previous object versions on your behalf using lifecycle policies.
  - OBJECT_UPDATE_TIER is required to change the storage tier of an object.

See Details for Object Storage, Archive Storage, and Data Transfer on page 2324 for more information on Object Storage user permissions.

Pre-Authenticated Requests

Pre-authenticated requests provide a way to let users access a bucket or object without having their own credentials. For example, you can create a request that lets a user upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests on page 3482 for details.
Object Names

Unlike other resources, objects do not have Oracle Cloud Identifiers (OCIDs). Instead, users define an object name when they upload an object.

Use the following guidelines when naming an object:

- Use from 1 to 1024 characters.
- Valid characters are letters (upper or lower case), numbers, and characters other than line feed, carriage return, and NULL.

  **Important:**

  Bucket names and object names are case-sensitive. Object Storage handles q3-field-assets.xlsx and Q3-Field-Assets.XSLX as separate objects.

- Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
- Avoid entering confidential information.
- Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

  **Tip:**

  Object names can include one or more forward slash (/) characters in the name. See **Object Naming Using Prefixes and Hierarchies** for more information on using the forward slash in object names to create hierarchies.

Object Naming Using Prefixes and Hierarchies

Within an Object Storage namespace, buckets and objects exist in a flat structure, but you can simulate a directory structure using a prefix string that includes the forward slash (/) to add hierarchy to an object name. Doing so lets you list one directory at a time, which is helpful when navigating a large set of objects.

For example:

```
marathon/finish_line.jpg
marathon/participants/p_21.jpg
```

If you added prefixes to object names, you can:

- Use the Console to display a hierarchical view of your objects in virtual folders. In the previous example, marathon would be displayed as a folder containing an object named finish_line.jpg and participants would be a subfolder of marathon, containing an object named p_21.jpg. You can bulk upload objects to any level of the hierarchy and perform bulk deletes of all the objects in a bucket or folder.
- Use the CLI or API to perform bulk downloads and bulk deletes of all objects at a specified level of the hierarchy.

Bulk operations at a specified level of the hierarchy do not affect objects in any level above.

When naming objects, you can also use prefix strings without a delimiter. No delimiters would allow search operations in the Console and certain bulk operations in the CL or API to match on the prefix portion of the object name. For example, in the object names below, the string gloves_27_ can serve as a prefix for matching purposes when performing bulk operations:

```
gloves_27_dark_green.jpg
gloves_27_light_blue.jpg
```

When you perform bulk uploads with the Console, CLI, or API, you can prepend a prefix string to the names of the files you are uploading.
For hierarchy and prefix string details for a particular management interface, see the individual tasks in Using the Console on page 3400, Using the Command Line Interface (CLI) on page 3404, and Using the API on page 3439.

Optional Response Headers and Metadata

When you upload objects, you can provide optional response headers and user-defined metadata. Response headers are HTTP headers sent from Object Storage to Object Storage clients when objects are downloaded. User-defined metadata are name-value pairs stored with an object. You can use the Console, REST API, or CLI to provide these optional attributes.

**Important:**

No validation is performed on the response headers or metadata you provide.

You can specify values for the following response headers:

- **Content-Disposition**
  
  Defines presentation only information for the object. Specifying values for this header has no effect on Object Storage behavior. Programs that read the object determine what to do based on the value provided. For example, you could use this header to let users download objects with custom file names in a browser:

  
  ```
  attachment; filename="fname.ext"
  ```

  See https://tools.ietf.org/html/rfc2616#section-19.5.1 for more information.

- **Cache-Control**
  
  Defines the caching behavior for the object. Specifying values for this header has no effect on Object Storage behavior. Programs that read the object determine what to do based on the value provided. For example, you could use this header to identify objects that require caching restrictions:

  ```
  no-cache, no-store
  ```

You specify user-defined metadata in the form of name-value pairs. User-defined metadata names are stored and returned to Object Storage clients with the mandatory prefix of **opc-meta-**.

Object Lifecycle Management

Object Lifecycle Management lets you automatically manage the deletion of uncommitted multipart uploads, the movement of objects to a different storage tier, and the deletion of supported resources on your behalf within a given bucket. These automated actions are based on rules that you define and manage. See Using Object Lifecycle Management on page 3466 for more information about this feature.

Multipart Uploading and Downloading

The Oracle Cloud Infrastructure Object Storage service supports multipart uploading and downloading for objects.

- For information about the API and CLI multipart uploading functionality, see Using Multipart Uploads on page 3477.
- For CLI information on multipart downloading, see downloading an object using multipart download.
- For API documentation related to multipart downloading, see the GetObject API call and its range parameter.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.
For more information about monitoring objects, see Object Storage Metrics on page 3499.

**Creating Automation for Objects Using the Events Service**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

**Using Storage Gateway to Upload and Download Objects**

Storage Gateway is another way you can upload objects to and download objects from Oracle Cloud Infrastructure Object Storage.

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through file systems that you create in Storage Gateway. Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket to upload and download objects.

See Overview of Storage Gateway on page 3790 for details.

**Using the Console**

**To upload objects to a bucket or folder**

The Console uses multipart uploads to upload objects larger than 64 MiB.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your objects are larger than 64 MiB and will be uploaded using multipart uploads, you need OBJECT_CREATE and OBJECT_OVERWRITE permissions.</td>
</tr>
</tbody>
</table>

See Using Multipart Uploads on page 3477 and Details for Object Storage, Archive Storage, and Data Transfer on page 2324 for details.

1. From the Object Storage Buckets screen, click the bucket name to view its details.
2. Click Objects under Resources.
3. To upload objects to the bucket, click Upload. To upload objects to a folder in the bucket, click the Actions icon (three dots) to the right of the folder that you want to upload objects to, then click Upload.
4. Optionally, specify an Object Name Prefix. If provided, this prefix is prepended to each one of the files you upload. You can specify the following prefix strings:
   - Prefix strings with a forward slash (/) delimiter to simulate hierarchy and create folders or subfolders
   - Prefix strings without a delimiter for matching purposes to perform allowed bulk operations

   See Object Naming Using Prefixes and Hierarchies on page 3420 for more details.
5. If the Storage Tier field displays Standard, you can optionally change the tier to upload objects to:
   - Infrequent Access
   - Archive
6. Select the object or objects that you want to upload in one of two ways:
   • Drag and drop one or more files from your computer.
   • Click the select files link to display a file selection dialog box.

   The files you select to upload are displayed in a list. If you decide that you do not want to upload a particular file, click the X to the right of the file name.

   If the files you select to upload are already stored in the bucket or folder with the same name, the Console displays messages warning you of an overwrite.

7. To specify values for optional response headers and metadata to be displayed in Object Details, click Show Optional Response Headers and Metadata.
   a. Select the attribute Type that you are adding.
   b. To add a Response Header, select the Name and enter a Value.
   c. To add Metadata, enter the Name and Value.
   d. To add attributes, click + Add More Headers or Metadata.

8. Click Upload.

   The selected objects are uploaded and displayed in the list of objects in the bucket or folder.

**To download an object from a bucket or folder**

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment that contains the bucket that contains your object.
   
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to download.
6. For the object you want to download, click the Actions icon (three dots), and then click Download.

**To create a folder or subfolder**

If the Virtual Folders view is enabled, you can create a folder in a bucket or you can create a subfolder in an existing folder or subfolder.

1. From the Object Storage Details screen, click the bucket name to view its details.
2. Click Objects under Resources.
3. To create a folder in a bucket, click More Actions above the Objects table, then click Create New Folder. To create a subfolder in a folder or subfolder, click the Actions icon (three dots) to the right of the folder that you want to create a folder or subfolder, then click Create New Folder.
4. Enter a Name for the folder or subfolder. Avoid entering confidential information.
5. Click Create.
   
   The folder or subfolder is created and displayed in the Objects table.

**To view object details**

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment that contains the bucket that contains your object.
   
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want details.
6. Choose the object for which you want details.
7. Click the Actions icon (three dots), and then click **View Object Details**. Object details include:
   - Basic Information
   - Response Headers
   - Metadata
8. Optionally, click **Download** to download the selected object.

**To rename an object**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to rename.
6. For the object you want to rename, click the Actions icon (three dots), and then click **Rename**.
7. In the **Rename Object** dialog box, provide the new name for the object and an optional delimited directory structure prefix. For example, `p_94.jpg` or `/marathon/participants/p_94.jpg`.

   Avoid entering confidential information.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buckets cannot store two objects that use identical names (case-sensitive). If you choose to rename an object using the name of another object in the same bucket, the object that originally used the name is overwritten.</td>
</tr>
</tbody>
</table>

8. Click **Save Changes**.

**To determine which storage tier an object resides**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want details.
6. The **Storage Tier** column identifies the storage tier in which each object resides.

**To update the storage tier of an object**

You can only update the storage tier for objects that reside in the **Standard** and **Infrequent Access** tiers. You cannot update the storage tier for objects that reside in the **Archive** tier.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You also need to understand the ramifications of updating the storage tier for an object. Objects in the Archive and Infrequent Access tiers have a minimum storage retention period and data retrieval fees. For more information, see <strong>Understanding Storage Tiers</strong> on page 3396.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_UPDATE_TIER permissions to update the storage tier of an object.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want to update the storage tier.
6. Choose the object for which you want to update the storage tier.
7. Click the Actions icon (three dots), and then click **Update Storage Tier**.
8. In the **Update Storage Tier** dialog, select from the available storage tiers.
9. Click **Save Changes**.

**To restore objects from Archive Storage**

Depending on the size of the object, it can take at most an hour to restore an object from Archive Storage. You cannot download an item until the item is fully restored.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_RESTORE permissions to restore Archive Storage objects.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders (if enabled) and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to restore.
6. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.
7. Optionally, specify the **Time Available for Download in Hours**.
   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object **Details** or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.
   After the allotted download time expires, the object returns to Archive Storage.
8. Click **Restore Objects**.
   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option**.

**To check the status of an Archive Storage object restoration**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want to check the restoration status.
6. Check the **Status** field in the **Object** table.

   **Status** displays one of the following:
   
   • Archived
   • Restoring
   • Restored

**To re-encrypt an object**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_READ and OBJECT_OVERWRITE permissions to re-encrypt an object.</td>
</tr>
</tbody>
</table>

To encrypt and decrypt an object's data encryption keys with a different master encryption key, you can re-encrypt the object. When re-encrypting an object, you can choose either a different key from the one assigned to the bucket or the most recent version of the key assigned to the bucket. Until you explicitly re-encrypt an object, the key version associated with the bucket (when the object was inserted into the bucket) continues to decrypt all the object's data encryption keys.

You can re-encrypt an object's data encryption keys with a key managed by Oracle, a key that you created and control through a vault that you manage, or a customer-provided encryption key (SSE-C).

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you use server-side encryption with customer-provided keys (SSE-C), you must use the CLI to provide the SSE-C key during the encryption or re-encryption process. Using the CLI, you can re-encrypt an object with a different SSE-C key, a key managed by Oracle, or a key that you manage through the Vault service. In the Console, you can only re-encrypt an object to use the latest version of the Oracle-managed key assigned to the bucket or the latest version of a Vault key. It does not matter whether the chosen key version is the one assigned to the bucket.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket that has the object for which you want to re-encrypt data encryption keys.

3. Under **Objects**, find the object that you want to re-encrypt. Click the Actions icon (three dots), and then click **Re-encrypt**.

4. Do one of the following, depending on whether the key assigned to the bucket is an Oracle-managed key or a key in a vault that you manage:
   
   • For buckets encrypted with an Oracle-managed key, you can re-encrypt the object with the latest version of that key by clicking **Use the key assigned to the bucket**. Or, you can re-encrypt the object with a key in a vault by clicking **Use a customer-managed key** and then choosing a key from a compartment and vault that you have access to.
   
   • For buckets encrypted with a customer-managed key, you can re-encrypt the object with the latest version of that key by clicking **Use the key assigned to the bucket**. Or, you can re-encrypt the object with a different Vault key by clicking **Use a different customer-managed key** and then choosing another key from a compartment and vault that you have access to.

5. When you are ready, click **Re-encrypt** to re-encrypt all data encryption keys associated with the object.

If you receive an error, verify that you have the correct permissions. If you have access to the object, confirm that the object exists and has not recently been deleted. If you have permissions and the object exists, also confirm whether the object is encrypted with an SSE-C key. To re-encrypt an object that you encrypted with an SSE-C key, you need to use the CLI to provide the SSE-C key to the Object Storage service for use during decryption and subsequent re-encryption, as appropriate. For more information, see the **To re-encrypt an object** on page 3436 CLI topic.
To delete objects from a bucket or a folder

You can permanently delete an object from a bucket or folder. You cannot, however, recover a deleted object unless you have object versioning enabled. See Using Object Versioning on page 3446 for details.

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment that contains the bucket that contains the object or objects you want to delete. A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources. A list of folders and objects in the bucket are displayed.
5. Expand the folders and subfolders as needed to locate the object or objects that you want to delete.
6. To delete a single object, click the Actions icon (three dots) to the right of the object you want to delete, and then click Delete. To delete multiple objects, select the check boxes to the left of each object you want to delete, and then click Delete.
7. Confirm when prompted.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Note:
The examples in this section use the full syntax for parameters, for example --namespace and --bucket-name. Sometimes, there are shortened parameter terms that you can use instead of the full ones, for example -ns for --namespace and -bn for --bucket-name. The CLI online --help for a particular command displays the shortened parameters that you can use.

To list the objects in a bucket

oci os object list --namespace <object_storage_namespace> --bucket-name <bucket_name>

By default, a minimal number of fields are returned for each object. For example:

oci os object list --namespace MyNamespace --bucket-name MyBucket

```json
{
  "data": [
    {
      "etag": "7588e71f-433f-4518-ba2d-90082208bd5d",
      "md5": "As+3syaEbVhPnm8fM+DSAw==",
      "name": "eventslogreference.htm",
      "size": 13515,
      "storage-tier": "InfrequentAccess",
      "time-created": "2021-01-11T15:47:44.427000+00:00",
      "time-modified": "2021-01-11T15:44.441000+00:00"
    },
    {
      "etag": "833c7099-f74e-4ce5-a7c8-ffa29a12d88",
      "md5": "J19Yxzog5HsbPSANkTVyG==",
      "name": "flowlogreference.htm",
      "size": 16601,
      "storage-tier": "Archive",
      "time-created": "2021-01-11T15:44.617000+00:00",
      "time-modified": "2021-01-11T15:44.638000+00:00"
    }
  ]
}``
To get object details

```bash
oci os object head --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```

For example:

```bash
oci os object head --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
```

If the object resides in an Archive tier bucket, the output also includes `archival-state`.

To upload an object to a bucket

```bash
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> --storage-tier <object_storage_tier> --name <object_name> --no-multipart
```

`<file_location>` is the source directory path of the object being uploaded, such as `C:\workspace\Uploads\MyFile.txt` or `/home/user/Documents/Uploads/MyFile.txt`.

If you are uploading to a Standard tier bucket, you can optionally specify the `<object_storage_tier>` to upload the object to:

- InfrequentAccess
- Archive

If you do not specify --storage-tier option, the object is uploaded to the default storage tier of the bucket.
Object Storage

<object_name> is the name of the uploaded object excluding the path. This parameter is required if the object is being read from STDIN. If you want to use the filename as the uploaded object’s name (if not being read from STDIN), omit the --name option. The resulting object name does not include the path information (for example, C:\workspace\Uploads\, just the actual file name by itself (MyFile.txt).

An object can be uploaded as a single part or as multiple parts. Use the --no-multipart option to upload as a single part. For detailed information on multipart uploads, see Using Multipart Uploads on page 3477.

For example, to upload an object to the default storage tier of the bucket:

```bash
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\Uploads\MyFile.txt --name MyFile.txt --no-multipart
{
"etag": "cadb9f8a-3292-45e6-a1e8-f075699fb619",
"last-modified": "Fri, 11 Dec 2020 14:04:19 GMT",
"opc-content-md5": "9P610SaYe4fXXaeK8siuDw=="
}
```

For example, to upload an object using the original filename, omit the --name option:

```bash
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\Uploads\MyFile.txt --no-multipart
{
"etag": "cadb9f8a-3292-45e6-a1e8-f075699fb619",
"last-modified": "Fri, 11 Dec 2020 14:04:19 GMT",
"opc-content-md5": "9P610SaYe4fXXaeK8siuDw=="
}
```

For example, to upload an object to the Infrequent Access tier:

```bash
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\Uploads\MyDocument.txt --storage-tier InfrequentAccess --no-multipart
{
"etag": "6b292cla-b01b-4f36-97c8-4567fb43d071",
"last-modified": "Sat, 12 Dec 2020 12:58:01 GMT",
"opc-content-md5": "9P610SaYe4fXXaeK8siuDw=="
}
```

For example, to upload an object to the Archive tier:

```bash
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\Uploads\MyDocument.txt --storage-tier Archive --no-multipart
{
"etag": "6b292cla-b01b-4f36-97c8-4567fb43d071",
"last-modified": "Sat, 12 Dec 2020 12:58:01 GMT",
"opc-content-md5": "9P610SaYe4fXXaeK8siuDw=="
}
```

To add optional response headers, use one or more of the following options:

- --cache-control
- --content-disposition
- --content-encoding
- --content-language
- --content-disposition
- --content-type

For more information about attributes that you can add when you upload an object, see Optional Response Headers and Metadata on page 3421. For more details about these headers, see the Command Line Reference.
For example:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\MyFile --cache-control no-cache --no-multipart
```

To add custom metadata key-value pairs, use the `--metadata` option:

```
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> --name <object_name> --metadata <json_formatted_key-value_pairs> --no-multipart
```

`<JSON-formatted_key-value_pair>` is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.

For example:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\MyFile.txt --metadata '{"Department": "Finance"}' --no-multipart
```

To bulk upload objects to a bucket

```
oci os object bulk-upload --namespace <object_storage_namespace> --bucket-name <bucket_name> --src-dir <source_directory_location>
```

`<source_directory_location>` is the upload directory path, such as `C:\workspace\Upload\` or `/home/user/Documents/Upload`. If your source directory has subdirectories, the subdirectory names are prepended to the names of the files stored in those subdirectories, delimited with a forward slash (/) character. For example, if a file named `maple.jpg` is stored in the subdirectory `trees`, when the file is uploaded, Object Storage assigns the name `trees/maple.jpg` to the resulting object.

If you are uploading to a Standard tier bucket, you can optionally specify the `<object_storage_tier>` to upload the object to:

- InfrequentAccess
- Archive

If you do not specify `--storage-tier` option, the object is uploaded to the default storage tier of the bucket.

For example, to upload objects to the default storage tier of the bucket:

```
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files
```

Uploaded logFile.log [########################################] 100%
Uploaded MyFile.txt [########################################] 100%

```
For example, to upload objects to the Infrequent Access storage tier:

```bash
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --storage-tier InfrequentAccess
```

Uploaded logFile.log [########################################] 100%
Uploaded MyFile.txt [########################################] 100%

```
{
  "skipped-objects": [],
  "upload-failures": {},
  "uploaded-objects": {
    "MyFile.txt": {
      "etag": "e25f95e6-a2bd-435c-83d6-785f838134d5",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "vqglL/ToD0FxnuqE83wBycw=="
    },
    "logFile.log": {
      "etag": "bbcf33dd-a177-4406-bed1-a4f7125da800",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "K8vB8NVAS1vtL2BE5ksUjw=="
    }
  }
}
```

For example, to upload objects to the Archive tier:

```bash
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --storage-tier Archive
```

Uploaded logFile.log [########################################] 100%
Uploaded MyFile.txt [########################################] 100%

```
{
  "skipped-objects": [],
  "upload-failures": {},
  "uploaded-objects": {
    "MyFile.txt": {
      "etag": "e25f95e6-a2bd-435c-83d6-785f838134d5",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "vqglL/ToD0FxnuqE83wBycw=="
    },
    "logFile.log": {
      "etag": "bbcf33dd-a177-4406-bed1-a4f7125da800",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "K8vB8NVAS1vtL2BE5ksUjw=="
    }
  }
}
```

To append a prefix string to the object names created by your uploads, use the `--object-prefix` option. For example:

```bash
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --object-prefix /bicycling/gloves/
```

Uploaded /bicycling/gloves/gloves_27_A.jpg [########################################] 100%
Uploaded `/bicycling/gloves/gloves_31_A.jpg`
[########################################] 100%
{
    "skipped-objects": [],
    "upload-failures": {},
    "uploaded-objects": {
        "/bicycling/gloves/gloves_27_A.jpg": {
            "etag": "7ba793ce-a341-4c56-9baf-61ca2c56ad50",
            "last-modified": "Sat, 12 Dec 2020 18:35:09 GMT",
            "opc-content-md5": "1B2M2Y8AsgTpgAmY7PhCfg="
        },
        "/bicycling/gloves/gloves_31_A.jpg": {
            "etag": "6efa58a6-a723-4696-a31f-3c5099adbec4",
            "last-modified": "Sat, 12 Dec 2020 18:35:09 GMT",
            "opc-content-md5": "6GxlLP9fa71HvnpLNJ+DQ=="
        }
    }
}

To add custom metadata key-value pairs, use the `--metadata <JSON_formatted_key-value_pairs>` option.

*<JSON-formatted_key-value_pairs>* is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

**To download an object from a bucket**

```bash
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location>
```

*<file_location>* is the destination path for the file being downloaded, such as `C:\workspace\Downloads\MyFile.txt` or `/home/user/Documents/Downloads/MyFile.txt`.

The `--name <object_name>` parameter is required.

For example:

```bash
oci os object get --namespace MyNamespace --bucket-name MyBucket --file c:\workspace\Downloads\MyFile.txt --name MyFile.txt
```

No information is returned when you run the command. The file is downloaded to the specified destination.

**To download an object using multipart download**

Multipart object downloading is available using the byte-range request standard defined in [RFC 7233, section 2.1](https://tools.ietf.org/html/rfc7233).

```bash
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location> --range bytes=<byte_range>
```

For example:

```bash
oci os object get --namespace MyNamespace --bucket-name MyBucket --name MyObject.mp4 --file c:\workspace\Downloads\MyObject.mp4 --range bytes=0-499
```

**To bulk download all objects within a bucket**

```bash
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location>
```
<download_directory_location> is the destination path for the objects being downloaded, such as C:\workspace \Downloads\ or /home/user/Documents/Downloads/. If the directory does not exist, Object Storage creates the directory when the command is run.

For example:

```
oci os object bulk-download --namespace MyNamespace --bucket-name MyBucket --download-dir c:\workspace\Downloads
```

Downloaded MyFile.txt [############################] 100%
Downloaded logFile.log [############################] 100%

```
{
  "download-failures": {},
  "skipped-objects": []
}
```

For a complete list of object bulk download options, see the Command Line Reference.

**To bulk download objects by object name prefix string**

If you have named your objects with prefix strings, you can bulk download objects in a bucket that match a specified prefix string.

```
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <prefix_string>
```

<download_directory_location> is the destination path for the objects being downloaded, such as C:\workspace \Downloads\ or /home/user/Documents/Downloads/. If the directory does not exist, Object Storage creates the directory when the command is run.

For example:

```
oci os object bulk-download --namespace MyNamespace --bucket-name MyBucket --download-dir c:\workspace\Downloads --prefix gloves_27
```

In the example above, an object named gloves_27_A.jpg is downloaded, while an object named gloves_31_A.jpg is not downloaded.

If you named your objects so that they exist in Object Storage in a hierarchy, you can download objects at a specified level and below. Specify the prefix that matches the level of your choosing:

```
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <level_1/level_2/>
```

The preceding command downloads the following objects:

- <level_1/level_2/object_name>
- <level_1/level_2/level_3/object_name>
- <level_1/level_2/level_3/level_4/object_name>

To download only those objects at a given hierarchy level (and not objects in levels above or below), see To bulk download objects at a specified hierarchy level.
To bulk download objects at a specified hierarchy level

If you named your objects so that they exist in Object Storage in a hierarchy, you can bulk download all objects at a specified hierarchy level.

```
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <level_1/level_2/> --delimiter /
```

`<download_directory_location>` is the destination path for the objects being downloaded, such as `C:\workspace\Downloads\` or `/home/user/Documents/Downloads/`. If the directory does not exist, Object Storage creates the directory when the command is run.

**Note:**
Currently, only the forward slash (`/`) is the supported delimiter for the `--delimiter` option.

The preceding command downloads objects only at `<level_2>` of the hierarchy. For example, the following object is downloaded:

`<level_1/level_2/object_name>`

The preceding command does not download objects in levels above or below `<level_2>`. For example, the preceding command does not download the following objects:

- `<level_1/object_name>`
- `<level_1/level_2/level_3/object_name>`
- `<level_1/level_2/level_3/level_4/object_name>`

To download objects at a given hierarchy level along with all objects in the hierarchy sublevels, see To bulk download objects by object name prefix string.

To rename an object

```
oci os object rename --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_original_name> --new-name <object_new_name>
```

For example:

```
oci os object rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt

{
  "etag": "3504606b-8412-4b5d-924a-aeeacfd1df1e"
}
```

To make the rename operation dependent on the object having a specific entity tag, use the `--src-obj-if-match-e-tag` option.

For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --src-obj-if-match-e-tag 6672BECB67CCFFBCE0530292F20ZBACE
```

For rename operations where you intend to overwrite one object in a bucket with another, you can make the renaming dependent on having a specific entity tag. To do so, use the `--new-obj-if-match-e-tag` option.
For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --new-obj-if-match-e-tag 6672BECB67CCFDBCE0530292F20ZBACE
```

When renaming an object, you can prevent the system from overwriting another object in the same bucket by using the `--new-obj-if-none-match-e-tag *` option. This option prevents the renaming operation from completing if an object exists with the `--new-name` value specified and the same entity tag of the source object.

For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --new-obj-if-none-match-e-tag *
```

To determine which storage tier an object resides

```
oci os object head --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```

For example:

```
oci os object head --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
{
  "accept-ranges": "bytes",
  "access-control-allow-credentials": "true",
  "access-control-allow-methods": "POST,PUT,GET,HEAD,DELETE,OPTIONS",
  "access-control-allow-origin": "*",

}
```

If the object resides in an Archive tier bucket, the output also includes `archival-state`.

You can also determine which storage tier an object resides by listing the objects or object versions for a bucket. See To list the objects in a bucket.

To update the storage tier of an object

```
oci os object update-storage-tier --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --storage-tier <object_storage_tier>
```
For example:

```
oci os object update-storage-tier --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --storage-tier Archive
```

**To restore an Archive Storage tier object**

**Tip:**
You need OBJECT_RESTORE permissions to restore Archive Storage objects.

```
oci os object restore --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]
```

By default, you have 24 hours to download an object after restoration. However, you can optionally specify --hours with an integer value of download time of from 1 to 240 hours.

**To check the status of an Archive Storage object restoration**

```
oci os object restore-status --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name>
```

**To re-encrypt an object**

**Tip:**
You need OBJECT_READ and OBJECT_OVERWRITE permissions to re-encrypt an object.

You can re-encrypt the data encryption keys that encrypt an object. You can do so by re-encrypting the object's data encryption keys with the latest version of the master encryption key assigned to the bucket, whether it's an Oracle managed key or a key in a vault that you manage. You can also re-encrypt the object's data encryption keys with a different key in a vault or a different SSE-C key. If you use SSE-C keys, you must provide the SSE-C key during the object decryption and subsequent re-encryption process, as appropriate.

You can re-encrypt an object's data encryption keys with the latest key version of the key assigned to the bucket.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```

For example:

```
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
```

The object's data encryption keys are re-encrypted with no further information returned.

If the object's data encryption keys are currently encrypted with an SSE-C key, you must also provide the name of the file that contains the base64-encoded string of the AES-256 source encryption key to first decrypt the object.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key>
```

For example:

```
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey
```
You can re-encrypt an object's data encryption keys with a specific Vault key.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --kms-key-id <key_OCID>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoyp4m5cvblugizcoeu2nfc6b3zfaux2lmqz245gezevsq
```

Again, if the key is currently encrypted with an SSE-C key, you must also provide the name of the file that contains the base64-encoded string of the AES-256 source encryption key to first decrypt the object.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key> --kms-key-id <key_OCID>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoyp4m5cvblugizcoeu2nfc6b3zfaux2lmqz245gezevsq
```

You can re-encrypt an object's data encryption keys with an SSE-C key.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --encryption-key-file MySSE-CKey
```

If the object is currently encrypted with an SSE-C key, and you want to encrypt the object's data encryption keys with a different SSE-C key, provide the file name of each key.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key_currently_assigned> --encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key_desired>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey --encryption-key-file MyNewSSE-CKey
```

**To delete an object**

If object versioning is disabled or suspended, you can permanently delete an object.

```bash
oci os object delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```
For example:

```
oci os object delete --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt

Are you sure you want to delete this resource? [y/N]: y
```

The object is deleted with no further information returned.

**To bulk delete all objects within a bucket**

```
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```
oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket

WARNING: This command will delete 2 objects. Are you sure you wish to continue? [y/N]:

Deleted MyRenamedFile.txt [####################################] 100%
Deleted logFile.log [####################################] 100%

{
  "delete-failures": {},
  "deleted-objects": [
    "MyRenamedFile.txt",
    "logFile.log"
  ]
}
```

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

For example:

```
oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket --dry-run
{
  "delete-failures": {},
  "deleted-objects": [
    "MyFile.txt",
    "logFile.log"
  ]
}
```

**To bulk delete objects by object name prefix string**

If you named your objects with prefix strings, you can bulk delete objects in a given bucket by providing a prefix to match.

```
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <prefix_string>
```

For example:

```
oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket --prefix gloves_A
```

The preceding command deletes the objects `gloves_27_A.jpg` and `gloves_31_A.jpg`, but does not delete the object `shoes_1.jpg`. 
If you named your objects so that they exist in a hierarchy, specify a prefix to match to bulk delete objects at a given level and below.

```bash
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <level_1/level_2/>
```

The preceding command deletes the following files:

- `<level_1/level_2/object_name>`
- `<level_1/level_2/level_3/object_name>`
- `<level_1/level_2/level_3/level_4/object_name>`

To delete only those objects at a given hierarchy level (and not objects in levels above or below), see **To bulk delete objects at a specified hierarchy level**.

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

**To bulk delete objects at a specified hierarchy level**

If you named your objects so that they exist in a hierarchy, you can bulk delete only those objects at a given hierarchy level (and not objects in levels above or below).

```bash
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <level_1/level_2/> --delimiter /
```

**Note:**
Currently, only the forward slash (/) is the supported delimiter for the `--delimiter` option.

The preceding bulk delete command deletes the following object:

`<level_1/level_2/>object_name`

The preceding command does not bulk delete objects in levels above or below `<level_2>`. For example, the command would not delete the following objects:

- `<level_2/object_name>`
- `<level_1/level_2/level_3/object_name>`
- `<level_1/level_2/level_3/level_4/object_name>`

To delete objects at a given hierarchy level along with all objects in the hierarchy sublevels, see **To bulk delete objects by object name prefix string**.

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Object Storage prepends the Object Storage namespace string and bucket name to the object name when constructing a URL for use with the API:

```
/n/<object_storage_namespace>/b/<bucket>/o/<object_name>
```

The object name is everything after the `/o/`, which could include hierarchy levels and prefix strings.

Use the following API operations to manage objects:

- **DeleteObject**
Object Storage

- GetObject
- HeadObject
- ListObjects
- PutObject (see Special Instructions for Object Storage PUT for signing request requirements)
- RenameObject
- ReencryptObject
- RestoreObjects

Using Replication

Replication provides protection from regional outages, aids in disaster recovery efforts, and addresses data redundancy compliance requirements. Maintaining multiple copies of data in regional locations closer to user access can also reduce latency.

This topic describes Object Storage replication and provides details on how to replicate the objects in one bucket to another bucket in the same region or a different region.

About Object Storage Replication

Enabling Object Storage replication is as simple as creating a replication policy on the source bucket that identifies the region and the bucket to replicate to. After the replication policy is created, the destination bucket is read-only and updated only by replication from the source bucket. Objects uploaded to a source bucket after policy creation are asynchronously replicated to the destination bucket. Objects deleted from the source bucket after policy creation are automatically deleted from the destination bucket. Objects uploaded to a source bucket before policy creation are not replicated.

Replication overwrites any object in the destination bucket that has the same name as an object in the source bucket. A replicated object has the same name, metadata, ETag, and MD5 value as the object in the source bucket. The creation timestamp, modified timestamp, and archival state can be different, so these attributes are not replicated from the source.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Caution:

Replication does not work if you do not authorize the Object Storage service to replicate objects on your behalf. See Service Permissions on page 3441 for more information.

User Permissions

You must have the required access to both the source and destination buckets when configuring replication. You must also have permissions to manage objects in the source and destination buckets.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, here is a simple user access policy that lets a StorageAdmins group do anything with the Object Storage service resources in the tenancy:

  Allow group StorageAdmins to manage object-family in tenancy
• Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage buckets and objects in a compartment called ObjectStore in the tenancy:

| Allow group StorageAdmins to manage buckets in compartment ObjectStore |
| Allow group StorageAdmins to manage objects in compartment ObjectStore |

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

**Service Permissions**

Because Object Storage is a regional service, you must authorize the Object Storage service for each region carrying out replication on your behalf. For example, you might authorize the Object Storage service in region US East (Ashburn) to manage objects on your behalf. After you authorize the Object Storage service, you can replicate the objects in a bucket in US East (Ashburn) to a bucket in another region.

To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 180.

For administrators:

To enable replication, you must authorize the service to manage objects on your behalf:

• For example, here is a service access policy that lets the Object Storage service do anything with the resources in the tenancy in the US West (Phoenix) region:

| Allow service objectstorage-us-phoenix-1 to manage object-family in tenancy |

• Alternatively, you can create policies that reduce the scope of access. For example, you can create a policy that lets the Object Storage service do anything with the resources in a compartment called ObjectStore in the US West (Phoenix) region:

| Allow service objectstorage-us-phoenix-1 to manage object-family in compartment ObjectStore |

• You can also create more restrictive policies that grant the individual permissions required for replication. For example:

| Allow service objectstorage-us-phoenix-1 to manage object-family in compartment ObjectStore where any {request.permission='BUCKET_READ', request.permission='BUCKET_UPDATE', request.permission='OBJECT_READ', request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE', request.permission='OBJECT_OVERWRITE', request.permission='OBJECT_RESTORE', request.permission='OBJECT_DELETE'} |

**Scope and Constraints**

• Replication policy creation does not automatically create a destination bucket. Create the destination bucket before creating the replication policy on the source bucket.

• A source or destination bucket can be in the Standard (Object Storage) or Archive Storage tier.

• Maximum of one replication policy per bucket.

• Maximum of one destination for each replication source bucket.

• A destination bucket cannot also be a replication source. Chained replication is not supported.

• After the replication policy is created, the destination bucket is read-only and updated only by replication from the source bucket. Objects uploaded to the source bucket are automatically replicated to the destination bucket. Objects deleted from the source bucket are automatically deleted from the destination bucket.
Interaction Between Replication and Other Object Storage Features

This section describes some key things you need to know about the interaction between replication and other Object Storage features.

Lifecycle Management

You can combine replication with Lifecycle Management policies that manage the archiving and deletion of objects. Lifecycle policies must, however, honor the read-only properties of the replication destination bucket. A lifecycle policy that deletes objects from the replication destination bucket does not work. Carefully review and test any combination replication and lifecycle policies that you implement.

Here are examples of combination policies that might benefit you:

- You can create a lifecycle policy on the source that deletes objects with certain file extensions after a specified number of days. The result of that deletion would also be reflected in the replication destination.
- You can create a lifecycle policy on the destination that archives objects after a specified number of days. If you do not need immediate access to those objects, you could benefit from reduced storage costs.

Server-Side Encryption Using Your Own Keys

Replication cannot replicate objects that have been encrypted with an SSE-C key. For more information, see Using Your Own Keys for Server-Side Encryption on page 3491.

Stopping Replication

Stopping replication can be initiated from either the replication source or the destination.

- To stop replication from the source, delete the replication policy. Deleting a replication policy is permanent. You cannot recover a deleted policy. If you want to replicate to that target destination again, create a new policy.
- To stop replication from the destination, make the destination bucket writable again. When you make the bucket writable, the destination bucket no longer accepts replication requests from the source. Replication status on the source changes from active to a client error state. If you want this destination to again be the target replication destination, delete the policy on the source bucket and create a new policy.

Troubleshooting Replication

This topic provides troubleshooting solutions for issues you might encounter using replication.

Unable to create a replication policy on the source bucket

If creating a replication policy fails, the most likely cause is missing or incomplete IAM permissions. Policy creation requires:

- User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
- Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 3440.

Policy is in error on the source bucket

If the policy status changes from active to error, check these items:

- You intentionally or unintentionally stopped replication on the destination bucket. To once again replicate to this target bucket, delete the existing policy on the source bucket and create a new policy.
- Ensure that your user permissions are still in place.
- Ensure that the policies that authorize Object Storage access to the source and destination buckets and their objects are still in place.
• You might have exceeded your storage limits on the destination bucket. If you are a Free Trial or Always Free customer, your storage is limited. Upgrade to paid account or delete your replication policy.

Unable to stop replication on the destination bucket and make the bucket writable

If stopping a replication policy fails, the most likely cause is missing or incomplete IAM permissions. Policy creation requires:

• User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
• Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 3440.

Using the Console

To create a replication policy

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. Choose the compartment that contains the bucket you want to replicate from.
4. Click the bucket name.
5. Click Replication Policy under Resources to access the replication policy list.
6. Click Create Policy.
7. In the Create Policy dialog, enter the following:
   • Name: Required. The system generates a default policy name that reflects the current year, month, day, and time, for example replication-policy-20200129-2230. If you change this default to a different policy name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   • Destination Region: Required. The Oracle Cloud Infrastructure region containing the destination bucket that you want to replicate to. Your tenancy must be subscribed to a region for you to replicate to that region.
   • Destination Bucket: The name of the destination bucket for replication. Specify an existing target bucket. Replication cannot automatically create the bucket.
8. Click Create.

After the policy is created, Replication: Source is added to Bucket Information. Objects uploaded to the source bucket after policy creation are asynchronously replicated to the destination bucket.

To view the source replication policy details

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the source replication bucket.
4. Click the source replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

To view the destination replication policy details

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the destination replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

To stop replication on the destination bucket and make the bucket writable

If you stop replication, the policy is removed from this destination bucket and cannot be recovered. The bucket reverts to a standard read/write bucket and is no longer a replication target.

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct replication destination region is selected from the regions menu (shown at the top of the
Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the destination replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.
6. Click Stop Replication.

To delete the replication policy on the source bucket
1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the replication destination bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags
and options available for CLI commands, see the Command Line Reference.

To create a replication policy

```
oci os replication create-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --destination-region <destination_region_identifier> --destination-bucket <destination_bucket_name>
```

For example:

```
oci os replication create-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --destination-region us-ashburn-1 --destination-bucket MyDestinationBucket --name MyReplicationPolicy
```

```
{
    "data": {
        "destination-bucket": "MyDestinationBucket",
        "destination-region": "us-ashburn-1",
        "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",
        "name": "MyReplicationPolicy",
        "status": "ACTIVE",
        "status-message": "The policy is active.",
        "time-created": "2020-02-06T16:44:10+00:00",
        "time-last-sync": "2020-02-06T16:44:20+00:00"
    }
}
```

Objects uploaded to the source bucket after policy creation are asynchronously replicated to the destination bucket.

To view the replication policy details

```
oci os replication get-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --replication-id <replication_policy_identifier>
```

For example:

```bash
oci os replication get-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --replication-id bacb8334-b191-4026-aa65-5e4f5165ae3e
```

```
{
  "data": {
    "destination-bucket": "MyDestinationBucket",
    "destination-region": "us-ashburn-1",
    "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",
    "name": "MyReplicationPolicy",
    "status": "ACTIVE",
    "status-message": "The policy is active.",
    "time-created": "2020-02-06T16:44:10+00:00",
    "time-last-sync": "2020-02-06T16:49:40+00:00"
  }
}
```

**To list replication policies**

**Note:**

There is currently a maximum of one replication policy per bucket.

```bash
oci os replication list-replication-policies --namespace <object_storage_namespace> --bucket-name <destination_bucket_name>
```

For example:

```bash
oci os replication list-replication-policies --namespace MyNamespace --bucket-name MySourceBucket
```

```
{
  "data": [
    {
      "destination-bucket": "MyDestinationBucket",
      "destination-region": "us-ashburn-1",
      "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",
      "name": "MyReplicationPolicy",
      "status": "ACTIVE",
      "status-message": "The policy is active.",
      "time-created": "2020-02-06T16:44:10+00:00",
      "time-last-sync": "2020-02-06T16:49:40+00:00"
    }
  ]
}
```

**To list the replication source for a destination bucket**

```bash
oci os replication list-replication-sources --namespace <object_storage_namespace> --bucket-name <destination_bucket_name> --region <destination_region_identifier>
```

For example:

```bash
oci os replication list-replication-sources --namespace MyNamespace --bucket-name MyDestinationBucket --region us-ashburn-1
```

```
{
  "data": [
```
To stop replication on the destination bucket and make the bucket writable

```bash
oci os replication make-bucket-writable --namespace <object_storage_namespace> --bucket-name <destination_bucket_name> --region <destination_region_identifier>
```

For example:

```bash
oci os replication make-bucket-writable --namespace MyNamespace --bucket-name MyDestinationBucket --region us-ashburn-1
```

If the command is successful, you are returned to the prompt.

To delete the replication policy on the source bucket

```bash
oci os replication delete-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --replication-id <replication_policy_identifier>
```

For example:

```bash
oci os replication delete-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --replication-id bacb8334-b191-4026-aa65-5e4f5165ae3e
```

Are you sure you want to delete this resource? [y/N]: y

If the command is successful, you are returned to the prompt.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to use and manage replication:

- CreateReplicationPolicy
- GetReplicationPolicy
- ListReplicationPolicies
- ListReplicationSources
- MakeBucketWritable (Stops replication)

Using Object Versioning

Object versioning provides data protection against accidental or malicious object update, overwrite, or deletion.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard Oracle Cloud Infrastructure pricing applies to each bucket that is enabled for versioning. You are charged for all latest object versions and...</td>
</tr>
</tbody>
</table>
This topic describes Object Storage versioning and provides details on how to create and manage object versions.

**About Object Versioning**

Object versioning is enabled at the bucket level. Versioning directs Object Storage to automatically create an object version each time a new object is uploaded, an existing object is overwritten, or when an object is deleted. You can enable object versioning at bucket creation time or later.

A bucket that is versioning-enabled can have many versions of an object. There is always one latest version of the object and zero or more previous versions.

**Understanding Object Versioning Status**

Each Object Storage bucket has object versioning status of disabled, enabled, or suspended. By default, object versioning is disabled on a bucket. It's important to understand the behavior associated with each object versioning status.

**Disabled**

If object versioning is disabled on a bucket:

- Object versioning has never been enabled on the bucket.
- When you upload an object with the same name as an existing object, the object is overwritten and the overwritten object is not retained or recoverable.
- When you delete an object, the deletion is permanent and objects are not recoverable.

**Enabled**

If object versioning is enabled on a bucket:

- When you upload an object with the same name as an existing object, the existing object becomes a previous version and the newly uploaded object becomes the latest version.
- Each uploaded object is assigned a unique version identifier. The identifier lets you direct Object Storage actions to a specific version.
- When you delete an object, Object Storage retains a version of the deleted object. For more information about object deletion, see Understanding Object Version Deletion on page 3447.
- You cannot disable object versioning. You can, however, suspend versioning.

**Suspended**

If object versioning is suspended on a bucket:

- Upload and delete behavior is the same as a bucket that has versioning disabled.
- Object versions created before versioning suspension are retained, unless you take explicit action to delete them.
- You can re-enable object versioning at any time.

**Understanding Object Version Deletion**

No object is physically deleted from a bucket that has versioning enabled until you take explicit action to do so. When you delete an object without targeting a specific version, the latest object version becomes a previous object version and a special delete marker is created that marks the deletion point. A delete marker contains only minimal metadata. If you delete a folder, a delete marker is created for each object in the folder. You can simply delete the delete marker to make that deleted version become the latest object version.
When you upload an object with the same name as the delete marker, the uploaded object becomes the latest version of the object. The delete marker remains. There can be multiple delete markers for an object and you can recover any of the previous object versions.

Object version deletion is different. When you delete an object version, the version is permanently deleted. **Permanent deletion also happens if you explicitly delete the latest version by version ID.** All delete operations that target a specific object version ID permanently deletes the data.

**Required IAM Policies**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, to let the IAM group StorageAdmins do everything in the tenancy:

  ```
  Allow group StorageAdmins to manage object-family in tenancy
  ```

- Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage only buckets and objects in a compartment called ObjectStore in the tenancy:

  ```
  Allow group StorageAdmins to manage buckets in compartment ObjectStore
  Allow group StorageAdmins to manage objects in compartment ObjectStore
  ```

- If you create more restrictive policies that grant individual permissions, BUCKET_UPDATE is required to enable versioning. Uploading objects, overwriting existing objects, or deleting objects require the regular permissions necessary for those operations. OBJECT_VERSION_DELETE is required to delete object versions. For example, to allow a group called StorageSupport to manage Object Storage resources, but prevent that group from permanently removing object versions:

  ```
  Allow group StorageSupport to manage object-family in tenancy where request.operation != 'DeleteObjectVersion'
  ```

For more information about other alternatives for writing policies, see [Details for Object Storage, Archive Storage, and Data Transfer](#) on page 2324.

**Scope and Constraints**

- Versioning can be enabled on a bucket in the Standard (Object Storage) or Archive Storage tier.
- Restoring an archived object is an in-place operation and does not create an object version.
- You can rename the latest version of an object, but you cannot rename a previous object version. Renaming an object creates a new object.

**Interaction Between Versioning and Other Object Storage Features**

This section describes some key things you need to know about the interaction between object versioning and other Object Storage features.

**Bucket Re-Encryption**

Bucket re-encryption (using either Oracle or your own master encryption key) also re-encrypts any existing object versions.
Lifecycle Management

Lifecycle policies can archive the latest version or previous versions of an object. When Lifecycle policies delete the latest version of an object, that object becomes a previous version and a delete marker is created. When Lifecycle policies delete a previous version of an object, that deletion is permanent.

Copying Objects

If you copy the latest version of an object to a different bucket, only the object is copied. None of the object's previous versions are copied. You can copy a previous version of an object to another bucket, but that action creates either the latest version of a new object or a new object version in the destination bucket.

Replication

- Replication cannot replicate previous object versions.
- You cannot enable versioning on a replication destination bucket. A destination bucket is read-only.

Retention Rules

- You cannot add retention rules to a bucket that has versioning enabled.
- You cannot enable versioning on a bucket with active retention rules.
- You can add retention rules to bucket that has versioning suspended. However, you cannot resume versioning with active retention rules.

Troubleshooting Versioning

This topic provides troubleshooting solutions for issues you might encounter using versioning.

Unable to enable versioning

If enabling versioning fails, the most likely cause is missing or incomplete IAM permissions. Enabling versioning requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, BUCKET_UPDATE permissions.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 3448.

Unable to delete a bucket

If deleting a bucket fails, the most likely cause is that the bucket is not empty.

Caution:

You cannot recover a deleted bucket.

You can permanently delete an empty bucket. You cannot delete a bucket that contains any of the following:

- Any objects
- Previous versions of an object
- A multipart upload in progress
- A pre-authenticated request

Tip:

When you delete an object in a version-enabled bucket, a previous version of that object is created. Select Show Deleted Objects to display the object versions that might prevent you from deleting the bucket.
Unable to delete a previous object version

If deleting a previous object version fails, the most likely cause is missing or incomplete IAM permissions. Object version deletion requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, OBJECT_VERSION_DELETE permissions.

Using the Console

To enable versioning during bucket creation

1. Follow the steps for creating a bucket.
2. Select Enable Object Versioning to direct Object Storage to create an object version each time the content changes or the object is deleted.

To enable object versioning after bucket creation

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that you want to enable object versioning.
4. Click the bucket name.
5. In Bucket Information, locate Object Versioning.

   Object Versioning indicates the current versioning status. Versioning is disabled by default. If you did not enable object versioning during bucket creation, Object Versioning is Disabled.
6. Click Edit.
7. Click Enable Versioning.

To suspend object versioning

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that you want to suspend object versioning.
4. Click the bucket name.
5. In Bucket Information, locate Object Versioning.

   Object Versioning indicates the current versioning status. Versioning is Enabled.
6. Click Edit.
7. Click Suspend Versioning.

To re-enable object versioning from suspension

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that you want to re-enable object versioning.
4. Click the bucket name.
5. In Bucket Information, locate Object Versioning.

   Object Versioning indicates the current versioning status. Versioning is Suspended.
6. Click Edit.
7. Click Enable Versioning.

To view the latest version of an object

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that you want to see the list of object versions.

4. Click the bucket name.

5. Click **Objects** under **Resources**.

6. Expand any folders and subfolders as needed to find the object for which you want to display previous versions.

   The latest version of each object is displayed.

**To view the previous versions of an object**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).

3. In the **List Scope** section, select the compartment that contains the bucket that you want to see the list of object versions.

4. Click the bucket name.

5. Click **Objects** under **Resources**.

6. Expand any folders and subfolders as needed to find the object for which you want to display previous versions.

   The latest version of each object is displayed.

7. Locate the object for which you want to display previous versions.

8. Click the file expander, located to the left of the the Actions icon (three dots).

   The list of all previous versions of the object is displayed.

**To view the details of an object version**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).

3. In the **List Scope** section, select the compartment that contains the bucket that has the object version that you want to delete.

4. Click the bucket name.

5. Click **Objects** under **Resources**.

   A list of folders and the latest versions of objects in the bucket are displayed.

6. Expand any folders and subfolders as needed to locate the object for which you want to view details.
7. To display the details for the latest version of an object, click the Actions icon (three dots) to the right of the object, and then click **View Object Details**.

8. To display the details for a previous version of an object, click the file expander, located to the left of the the Actions icon (three dots).

The list of all previous versions of the object is displayed.

9. Click the Actions icon (three dots) to the right of the object version, and then click **View Object Details**.

**To delete an object**

When versioning is enabled, deleting an object without targeting a specific version creates a delete marker and a previous version of the object that can be recovered.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that has the object that you want to delete.
4. Click the bucket name.
5. Click **Objects** under **Resources**.

A list of folders and objects in the bucket are displayed.

6. Expand any folders and subfolders as needed to locate the object that you want to delete.
7. Click the Actions icon (three dots) to the right of the object, and then click **Delete**.
8. Confirm the deletion when prompted.

**To delete the previous version of an object**

When versioning is enabled, deleting an object without targeting a specific version creates a delete marker and previous version of the object that can be recovered. However, **deleting a previous version of an object is a permanent deletion.**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that has the object version that you want to delete.
4. Click the bucket name.
5. Click **Objects** under **Resources**.

   A list of folders and objects in the bucket are displayed.

6. Expand any folders and subfolders as needed to locate the object for which you want to delete a previous version.

7. Click the file expander, located to the left of the the Actions icon (three dots).

   ![Objects](image)

   The list of all previous versions of the object is displayed.

8. Locate the previous version of the object that you want to delete.

9. Click the Actions icon (three dots) to the right of the object version, and then click **Delete**.

10. Confirm the deletion when prompted.

**To recover a deleted object version**

   Recovering a deleted object version is as simple as deleting the delete marker that was created when you deleted the latest version of an object. The previous version of the object listed just below the delete marker is recovered and becomes the latest version of the object.

   1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
   3. In the **List Scope** section, select the compartment that contains the bucket that has the object version that you want to recover.
   4. Click the bucket name.
   5. Click **Objects** under **Resources**.

      A list of folders and objects in the bucket are displayed.

   6. Select **Show Deleted Objects**.
   7. Expand any folders and subfolders as needed to locate the object that you want to recover.
   8. Click the file expander, located to the located to the left of the the Actions icon (three dots) of the deleted object to display the versions that you can recover.
   9. Click the Actions icon (three dots) to the right of the delete marker of the object, and then click **Delete**.
   10. Confirm deletion when prompted.

**Using the Command Line Interface (CLI)**

   For information about using the CLI, see [Command Line Interface (CLI)](CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the [Command Line Reference](Reference).
To determine the object versioning status for a bucket

```
oci os bucket get --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```
oci os bucket get --namespace MyNamespace --name MyBucket
{
   "approximate-count": null,
   "approximate-size": null,
   "compartment-id": "ocid1.compartment.oc1..aaaaaaaamnk2ilreg5fkgu7rarfbbhdv3a5j4e1xxgk14uprbqk6aefv5sq",
   "created-by": "ocid1.user.oc1..aaaaaaaah46lg3ueuftovn3urjgst1g4laxnre3djelu5jxy5uaqhgy7acgq",
   "defined-tags": {
      "Financials": {
         "key1": "nondefault"
      }
   },
   "etag": "79833b3f-89bd-41ac-bf86-0fbe331f3071",
   "freeform-tags": {},
   "id": "ocid1.bucket.oc1.phx.aaaaaaaa4feuzkcdagy77lxujdneuvoiza7rh2unbpzmywytinbxymy5zku6q",
   "is-read-only": false,
   "kms-key-id": null,
   "metadata": {},
   "name": "MyBucket",
   "namespace": "MyNamespace",
   "object-events-enabled": false,
   "object-level-audit-mode": "Disabled",
   "object-lifecycle-policy-etag": null,
   "public-access-type": "NoPublicAccess",
   "replication-enabled": false,
   "storage-tier": "Standard",
   "time-created": "2020-04-14T14:25:32.465000+00:00",
   "versioning": "Disabled"
},
"etag": "79833b3f-89bd-41ac-bf86-0fbe331f3071"
}
```

To enable versioning during bucket creation

To enable versioning in a Standard tier bucket, you do not need to explicitly set `--storage-tier` because a bucket is created in the standard Object Storage tier by default:

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --versioning enabled
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --versioning enabled
{
   "data": {
      "approximate-count": null,
      "approximate-size": null,
      "compartment-id": "ocid1.compartment.oc1..aaaaaaaamnk2ilreg5fkgu7rarfbbhdv3a5j4e1xxgk14uprbqk6aefv5sq",
```
To enable versioning in an Archive tier bucket, you must explicitly set --storage-tier Archive:

```
oci os bucket create --namespace <object_storage_namespace> --name <archivebucket_name> --compartment-id <target_compartment_id> --storage-tier Archive
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyArchiveBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --storage-tier Archive --versioning enabled
```

```json

"created-by":
"ocid1.user.oc1..aaaaaaaah46lg3ueuftovn3urjgst1g41axnre3djelu5jxy5uaqgy7acgq",
"defined-tags": {
  "Financials": {
    "key1": "nondefault"
  }
},
"etag": "a91fd091-e112-483e-8e23-2b5d11e3dc2d",
"freeform-tags": {},
"id":
"ocid1.bucket.oc1.phx.aaaaaaaqagwnd5foe23xhpqk6ts754igpww5t7qrapbmr5tjiugvjoicq",
"is-read-only": false,
"kms-key-id": null,
"metadata": {},
"name": "MyStandardBucket",
"namespace": "MyNamespace",
"object-events-enabled": false,
"object-level-audit-mode": "Disabled",
"object-lifecycle-policy-etag": null,
"public-access-type": "NoPublicAccess",
"replication-enabled": false,
"storage-tier": "Standard",
"time-created": "2020-04-14T14:08:421000+00:00",
"versioning": "Enabled"
},
"etag": "a91fd091-e112-483e-8e23-2b5d11e3dc2d"
}
```
To enable object versioning after bucket creation

oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --versioning Enabled

For example:

oci os bucket update --namespace MyNamespace --name MyBucket --versioning Enabled

To list object versions

oci os object list-object-versions --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example:
oci os object list-object-versions --namespace MyNamespace --bucket-name MyStandardBucket
{
  "data": {
    "items": [
      {
      "etag": null,
      "is-delete-marker": false,
      "md5": null,
      "name": "MyTextDocument.txt",
      "size": null,
      "time-created": null,
      "time-modified": "2020-04-14T22:18:08.777000+00:00",
      "version-id": "2d528a44-5b15-40dc-b303-20993d1ade66"
      },
      {
      "etag": null,
      "is-delete-marker": false,
      "md5": null,
      "name": "MyTextDocument.txt",
      "size": null,
      "time-created": null,
      "time-modified": "2020-04-14T22:17:10.371000+00:00",
      "version-id": "a175ddc0-cc86-425f-bc2e-9b9bcb9b9f92"
      },
      {
      "etag": null,
      "is-delete-marker": false,
      "md5": null,
      "name": "MyTextDocument.txt",
      "size": null,
      "time-created": null,
      "time-modified": "2020-04-14T22:14:47.675000+00:00",
      "version-id": "8d8f06ef-e0c2-4435-bea6-f7c3ec80a444"
      }
    ],
    "prefixes": null
  }
}

To get the contents of an object version

oci os object get --name <object_name> --file path/to/file/name --version-id <version_identifier> --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example, to retrieve the contents of an object version into a file called TextDocument.txt:

To delete an object version

oci os object delete --name <object_name> --version-id <version_identifier> --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example:

oci os object delete --name MyTextDocument.txt delete --version-id 8d8f06ef-e0c2-4435-bea6-f7c3ec80a444 --namespace MyNamespace --bucket-name MyStandardBucket
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to enable object versioning:

- **CreateBucket** (enable versioning during bucket creation)
- **UpdateBucket** (enable versioning after bucket creation)

Use the following API operation to list object versions:

- **ListObjectVersions**

To perform version-specific operations, use the following APIs with a version identifier query parameter:

- **CopyObject**
- **DeleteObject**
- **GetObject**
- **HeadObject**
- **RestoreObjects**

Object-related APIs that do not take a version identifier query parameter operate only on an object, not object versions.

Using Retention Rules to Preserve Data

Retention rules provide immutable, WORM-compliant storage options for data written to Object Storage and Archive Storage for data governance, regulatory compliance, and legal hold requirements. Retention rules can also protect your data from accidental or malicious update, overwrite, or deletion. Retention rules can be locked to prevent rule modification and data deletion or modification even by administrators.

This topic describes Object Storage rule-based retention and provides details on how to create and manage these rules.

About Object Storage Data Retention

Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. Object Storage provides a flexible approach to data retention that supports the following use cases.

**REGULATORY COMPLIANCE**

Your industry might require you to retain a certain class of data for a defined length of time. Your data retention regulations might also require that you lock the retention settings. If you lock the settings, the only change you can make is to increase the retention duration.

For Object Storage regulatory compliance, you create a time-bound retention rule and specify a duration. Object modification and deletion are prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp. Lock the rule as required.

**DATA GOVERNANCE**

You might need to protect certain data sets as a part of internal business process requirements. While retaining the data for a defined length of time is necessary, that time period could change.

For Object Storage data governance, you create a time-bound retention rule and specify a duration. Object modification and deletion are prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp. To be able to delete the rule and allow changes to the duration as required, do not lock the rule.
LEGAL HOLD

You might need to preserve certain business data in response to potential or on-going lawsuits. A legal hold does not have a defined retention period and remains in effect until removed.

For Object Storage legal holds, you create an indefinite retention rule. Object modification and deletion are prevented until you delete the rule. You cannot lock an indefinite retention rule because the rule has no duration.

It's important to understand retention duration for time-bound rules. Even though you are creating retention rules for a bucket, the duration of a rule is applied to each object in the bucket individually, and is based on the object's Last Modified timestamp. Let's say you have two objects in the bucket, ObjectX and ObjectY. ObjectX was last modified 14 months ago and ObjectY was last modified 3 months ago. You create a retention rule with a duration of 1 year. This rule prevents the modification or deletion of ObjectY for the next 9 months. The rule allows the modification or deletion of ObjectX because the retention rule duration (1 year) is less that the object's Last Modified timestamp (14 months). If ObjectX is overwritten some time in the coming year, modification and deletion would be prevented for the rule duration time remaining.

Locking a retention rule is an irreversible operation. Not even a tenancy administrator can delete a locked rule. There is a mandatory 14-day delay before a rule is locked. This delay lets you thoroughly test, modify, or delete the rule or the rule lock before the rule is permanently locked. A rule is active at the time of creation. The lock only controls whether the rule itself can be modified. After a rule is locked, only increases in the duration are allowed. Object modification is prevented and the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators:

- You can create a rule that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, to let the IAM group StorageAdmins do everything in the tenancy:

  Allow group StorageAdmins to manage object-family in tenancy

- Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage only buckets and objects in a compartment called ObjectStore in the tenancy:

  Allow group StorageAdmins to manage buckets in compartment ObjectStore
  Allow group StorageAdmins to manage objects in compartment ObjectStore

- If you create more restrictive policies that grant individual permissions, BUCKET_UPDATE and RETENTION_RULE_MANAGE is required to create, edit, and delete retention rules. BUCKET_UPDATE, RETENTION_RULE_MANAGE, and RETENTION_RULE_LOCK is required to lock retention rules.

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

Scope and Constraints

- Retention rules can be applied to a bucket in the Standard (Object Storage) or Archive Storage tier.
- The actions that you can perform on a bucket with active retention rules are limited. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration
specified (time-bound rules). The duration for time-bound rules is applied to each object individually, and is based on the object's Last Modified timestamp.

- You can create multiple retention rules for a bucket. Indefinite retention rule is applied before any time-bound rule is considered.
- When a retention rule is locked, the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

**Interaction Between Retention and Other Object Storage Features**

Carefully review the policies and rules that you have in place for the other Object Storage features that you are using. Some of these policies and rules may no longer make sense with retention rules. This section describes some key things you need to know about the interaction between retention rules and other Object Storage features.

**Bucket Re-Encryption**

Retention rules do not block bucket re-encryption using either Oracle or your own Vault master encryption keys.

**Multipart Uploads**

Uncommitted (unfinished or failed) multipart uploads are not protected by retention rules and can be deleted at any time.

**Lifecycle Management**

- Lifecycle policies can archive objects with retention rules.
- Lifecycle Management cannot remove objects protected by active retention rules.

**Replication**

- You can create retention rules on a replication source bucket.
- You cannot create retention rules on a replication destination bucket.
- You cannot enable replication on a destination bucket that has retention rules.

**Versioning**

- You cannot add retention rules to a bucket that has versioning enabled.
- You cannot enable versioning on a bucket with active retention rules.
- You can add retention rules to bucket that has versioning suspended. However, you cannot resume versioning with active retention rules.

**Troubleshooting Retention Rules**

This topic provides troubleshooting solutions for issues you might encounter using retention rules.

**Unable to create a retention rule**

If creating a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule creation requires:

- User permissions that let you access the bucket and manage the objects in those buckets.
- Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

Review the existing policies that grant user permissions. For more information, see [Required IAM Policies](#) on page 3459.

**Unable to lock a retention rule**

If locking a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Minimally, BUCKET_UPDATE, RETENTION_RULE_MANAGE, and RETENTION_RULE_LOCK permissions are required to lock retention rules.
Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 3459.

**Unable to delete a retention rule**

You cannot delete a time-bound retention rule that is locked. When a retention rule is locked, the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

If deleting an indefinite retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule deletion requires:
- User permissions that let you access the bucket and manage the objects in those buckets.
- Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

**Using the Console**

To create a retention rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. Choose the compartment that contains the bucket where you want to create a retention rule.
4. Click the bucket name.
5. Click **Retention Rules** under **Resources** to access the retention rule list.
6. Click **Create Rule**.
7. In the Create Retention Rule dialog, enter the required rule **Name**. The system generates a default rule name that reflects the current year, month, day, and time, for example retention-rule-20200229-1002. If you change this default to a different rule name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
8. Choose the retention rule type that you want to create:
   - **Time-Bound** rules have a user-defined duration. Object modification is prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp.
   - **Indefinite** rules have no duration or expiration. Object modification is prevented until an indefinite rule is deleted.
9. If you are creating a time **Time-Bound** rule, enter the retention rule duration attributes:
   - **Retention Time Amount**
   - **Retention Time Unit**
10. Optionally, select **Enable Retention Rule Lock** if you want to lock the rule.
11. Click **Create**.

The rule is displayed in the **Retention Rules** list.

To lock a time-bound retention rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click **Retention Rule** under **Resources** to access the rule list.
   - If you are creating a retention rule, click **Create Retention Rule**. Specify the duration amount and unit, then select **Enable Retention Rule Lock**. Click **Create**.
   - If you are editing a retention rule, click the Actions icon (three dots) to the right of the rule name, and then click **Edit**. Select **Enable Retention Rule Lock**. Click **Save Changes**.

To view retention rule details

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click **Retention Rule** under **Resources** to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click **View Details**.

### To edit a retention rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click **Retention Rule** under **Resources** to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click **Edit**.
   - If you are editing an indefinite retention rule, you can only edit the name of the rule.
   - If you are editing a time-bound retention rule, you can edit multiple attributes. You can edit the name, the duration time amount and time unit, and optionally select whether to lock the rule.
   - If you are removing a retention rule lock during the delay period, deselect **Enable Retention Rule Lock**. For more information about retention rule locking, see [About Object Storage Data Retention](#) on page 3458.
7. If you are enabling a retention rule lock, confirm the rule lock details by selecting **Update the Retention Rule with a Scheduled Lock Time of <date and time>**.
8. Click **Save Changes**.

### To delete a retention rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket.
4. Click the bucket name.
5. Click **Retention Rule** under **Resources** to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click **Delete**.
7. Confirm deletion when prompted.

### Using the Command Line Interface (CLI)

For information about using the CLI, see [Command Line Interface (CLI)](#) on page 4192. For a complete list of flags and options available for CLI commands, see the [Command Line Reference](#).

#### To create an indefinite retention rule

```
oci os retention-rule create --namespace <object_storage_namespace> --bucket-name <bucket_name> --display-name <display_name>
```

For example:

```
oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket --display-name LegalHold
{
  "data": {
    "display-name": "LegalHold",
    "duration": null,
    "etag": "7f51ef6c-3fca-48f7-9060-c129911c1a50",
    "id": "5772c87f-6723-4ecc-b44c-bef86643be92",
    "time-created": "2020-03-25T14:53:20.792000+00:00",
    "time-modified": "2020-03-25T14:53:20.792000+00:00",
    "time-rule-locked": null
  },
  "etag": "7f51ef6c-3fca-48f7-9060-c129911c1a50"
}
```
To create a time-bound, unlocked retention rule

```
oci os retention-rule create --namespace <object_storage_namespace> --bucket-name <bucket_name> --display-name <display_name> --time-amount <time_integer> --time-unit <days|years>
```

For example:

```
oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket --display-name DataGovernance --time-amount 5 --time-unit days
```

```
{  
  "data": {  
    "display-name": "DataGovernance",
    "duration": {  
      "time-amount": 5,
      "time-unit": "DAYS"
    },
    "etag": "efb9178f-4213-49f7-878d-7bbe57decc0b",
    "id": "89f4ca0c-4ad9-4fa5-8005-95e7741c531c",
    "time-created": "2020-03-25T15:08:01.601000+00:00",
    "time-modified": "2020-03-25T15:08:01.601000+00:00",
    "time-rule-locked": null
  },
  "etag": "efb9178f-4213-49f7-878d-7bbe57decc0b"
}
```

To create a time-bound, locked retention rule

See the Command Line Interface (CLI) on page 4192 or the Command Line Reference for supported date and time formats for --time-rule-locked.

```
oci os retention-rule create --namespace <object_storage_namespace> --bucket-name <bucket_name> --display-name <display_name> --time-amount <time_integer> --time-unit <days|years> --time-rule-locked <date and time>
```

For example:

```
oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket --display-name RegulatoryCompliance --time-amount 5 --time-unit years --time-rule-locked "2020-04-28 00:00"
```

```
{  
  "data": {  
    "display-name": "RegulatoryCompliance",
    "duration": {  
      "time-amount": 5,
      "time-unit": "YEARS"
    },
    "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f",
    "id": "b1a6c84c-57c4-416c-b006-f864b0904e9e",
    "time-created": "2020-03-25T15:11:44.423000+00:00",
    "time-modified": "2020-03-25T15:11:44.423000+00:00",
    "time-rule-locked": "2020-04-28T00:00:00+00:00"
  },
  "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f"
}
```

To list retention rules
oci os retention-rule list --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example:

oci os retention-rule list --namespace MyNamespace --bucket-name MyBucket
{
    "data": {
        "items": [
            {
                "display-name": "RegulatoryCompliance",
                "duration": {
                    "time-amount": 5,
                    "time-unit": "YEARS"
                },
                "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f",
                "id": "b1a6c84c-57c4-416c-b006-f864b0904c9e",
                "time-created": "2020-03-25T15:11:44.423000+00:00",
                "time-modified": "2020-03-25T15:11:44.423000+00:00",
                "time-rule-locked": "2020-04-28T00:00:00+00:00"
            },
            {
                "display-name": "DataGovernance",
                "duration": {
                    "time-amount": 5,
                    "time-unit": "DAYS"
                },
                "etag": "efb9178f-4213-49f7-878d-7bbee57dec0b",
                "id": "89f4ca0c-4ad9-4fa5-8005-95e7741c531c",
                "time-created": "2020-03-25T15:08:01.601000+00:00",
                "time-modified": "2020-03-25T15:08:01.601000+00:00",
                "time-rule-locked": null
            },
            {
                "display-name": "LegalHold",
                "duration": null,
                "etag": "7f51ef6c-3fca-48f7-9060-c129911c1a50",
                "id": "5772c87f-6723-4ecc-b44c-bef86643be92",
                "time-created": "2020-03-25T14:53:20.792000+00:00",
                "time-modified": "2020-03-25T14:53:20.792000+00:00",
                "time-rule-locked": null
            }
        ]
    }
}

To view retention rule details

oci os retention-rule get --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id <retention_rule_identifier>

For example:

oci os retention-rule get --namespace MyNamespace --bucket-name MyBucket --retention-rule-id b1a6c84c-57c4-416c-b006-f864b0904c9e
{
    "data": {
        "display-name": "RegulatoryCompliance",
        "duration": {
            "time-amount": 5,
            "time-unit": "YEARS"
        }
    }
}
To update a time-bound retention rule after creation

```shell
oci os retention-rule update --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id --display-name <display_name> --time-amount <time_integer> --time-unit <days|years> --time-rule-locked <date and time>
```

For example, to increase the duration of and change the date a retention rule is locked:

```shell
oci os retention-rule update --namespace MyNamespace --bucket-name MyBucket --retention-rule-id bla6c84c-57c4-416c-b006-f864b0904c9e --time-amount 6 --time-unit years --time-rule-locked "2020-03-25T15:11:44.423000+00:00"
```

```json
{
  "data": {
    "display-name": "RegulatoryCompliance",
    "duration": {
      "time-amount": 6,
      "time-unit": "YEARS"
    },
    "etag": "700ada5c-6a2a-4c6c-acb6-4ebb173e0f8f",
    "id": "bla6c84c-57c4-416c-b006-f864b0904c9e",
    "time-created": "2020-03-25T15:11:44.423000+00:00",
    "time-modified": "2020-03-25T15:11:44.423000+00:00",
    "time-rule-locked": "2020-04-28T00:00:00+00:00"
  },
  "etag": "700ada5c-6a2a-4c6c-acb6-4ebb173e0f8f"
}
```

To remove a retention rule lock during the delay period

```shell
oci os retention-rule update --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id --display-name <display_name> --time-rule-locked ""
```

```shell
oci os retention-rule update --namespace MyNamespace --bucket-name MyBucket --retention-rule-id bla6c84c-57c4-416c-b006-f864b0904c9e --time-rule-locked ""
```

```json
{
  "data": {
    "display-name": "RegulatoryCompliance",
    "duration": {
      "time-amount": 6,
      "time-unit": "YEARS"
    },
    "etag": "5b4fa526-faec-47d4-9162-4acdf1813ee0",
    "id": "bla6c84c-57c4-416c-b006-f864b0904c9e",
    "time-created": "2020-03-25T15:11:44.423000+00:00",
    "time-modified": "2020-03-25T15:11:44.423000+00:00",
    "time-rule-locked": null
  },
  "etag": "5b4fa526-faec-47d4-9162-4acdf1813ee0"
}
```
To delete a retention rule

```bash
oci os retention-rule delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id <retention_rule_identifier>
```

For example:

```bash
oci os retention-rule delete --namespace MyNamespace --bucket-name MyBucket --retention-rule-id 4ed833b1-fb27-4a40-a8ab-14e09636a724
```

Are you sure you want to delete this resource? [y/N]: y

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to use and manage retention rules:

- CreateRetentionRule
- GetRetentionRule
- ListRetentionRules
- UpdateRetentionRule
- DeleteRetentionRule

Using Object Lifecycle Management

By using Object Lifecycle Management to manage your Object Storage and Archive Storage data, you can reduce your storage costs and the amount of time you spend manually managing data.

Object Lifecycle Management works by taking automated action based on rules that you define. These rules instruct Object Storage to delete uncommitted multipart uploads, move objects to a different storage tier, and delete supported resources on your behalf within a given bucket. A bucket's lifecycle rules are collectively known as an object lifecycle policy. The resources that Object Lifecycle Management supports include objects, object versions, and uncommitted or failed multipart uploads.

For example, you can define rules that automatically do things like the following:

- Move Standard tier objects with a `.doc` extension to either the Infrequent Access or Archive tier 60 days after creation.
- Move Standard tier objects to the Archive tier 30 days after creation, and then automatically delete those archived objects after 180 days.
- Move Standard tier objects to the Infrequent Access tier 90 days after creation.
- Delete any previous object versions 120 days after the object version transitions from the latest version to a previous version.
- Delete uncommitted or failed multipart uploads after 5 days.

Each Object Storage or Archive Storage bucket can have a single lifecycle policy consisting of up to 1,000 rules. Object-related rules can have object name prefix and pattern matching conditions. Uncommitted multipart upload rules do not support prefix and pattern matching conditions.

You can create, edit, delete, enable, and disable individual rules in the Console as needed. To update a lifecycle policy using the CLI or API, overwrite an existing policy with a new policy. Ensure that the new policy is inclusive of all the policy rules that you want to apply to the bucket.
Object Storage

Required IAM Policies

Important:
You cannot use Object Lifecycle Management until you authorize the Object Storage service to archive and delete objects on your behalf. See Service Permissions on page 3467 for more information.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

User Permissions

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators:

• The policy Let Object Storage admins manage buckets and objects on page 2149 lets the specified group do everything with buckets and objects, including adding and managing lifecycle policies.
• If you create more restrictive policies that grant individual permissions:
  • OBJECT_VERSION_DELETE is required to delete previous object versions on your behalf using lifecycle policies.
  • OBJECT_UPDATE_TIER is required to change the storage tier of an object.

See Details for Object Storage, Archive Storage, and Data Transfer on page 2324 for more information on Object Storage user permissions.

Service Permissions

To execute object lifecycle policies, you must authorize the service to archive and delete objects on your behalf. To do so, create the following policy in the root compartment of your tenancy:

Allow service objectstorage-<region_identifier> to manage object-family in compartment <compartment_name>

Because Object Storage is a regional service, you must authorize the Object Storage service in each region you use lifecycle policies. Object Storage ensures that your data is not read from any unauthorized region.

If you don't have permissions to write policies for the root compartment of your tenancy, contact your Oracle Cloud Infrastructure administrator. To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 180.

Instead of using the policy verb manage, you can grant individual permissions to the service. For example:

Allow service objectstorage-<region_identifier> to manage object-family in compartment <compartment_name>
where any {request.permission='BUCKET_INSPECT',
request.permission='BUCKET_READ',
request.permission='OBJECT_INSPECT',
request.permission='OBJECT_CREATE',
request.permission='OBJECT_DELETE',
request.permission='OBJECT_VERSION_DELETE'}

Options

When creating object lifecycle policy rules, you have the following options:

• When a lifecycle rule is created, the system generates a default name for that rule, for example lifecycle-rule-20190321-1559. This rule name identifies the current year, month, day, and time that the rule was created. You can use that system-generated name for your new rule or you can specify a different name for it.
• You can create lifecycle rules that do the following:
  • Move or delete all objects in the bucket.
  • Move or delete objects in the bucket that match the object name filters you specify. You can select objects using both object name prefixes and pattern matching. See Using Object Name Filters on page 3468 for details.
  • Delete uncommitted or failed multipart uploads. For more information, see Using Multipart Uploads on page 3477.

If object versioning is enabled or suspended on a bucket, you can also create lifecycle rules that do the following:
  • Move or delete the previous versions of all objects in the bucket.
  • Move or delete the previous versions of objects in the bucket that match the name filters you specify. You can select objects using both object name prefixes and pattern matching. See Using Object Name Filters on page 3468 for details.

• You specify the number of days until the specified action is taken.
• You decide whether a new rule is enabled or disabled upon creation.

Using Object Name Filters

Use object name filters to specify a subset of objects, object versions, or previous object versions that a lifecycle rule applies to. Create a separate object name filter rule for each rule target (objects, object versions, or previous object versions).

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not specify object name filters if you want a rule to apply to the all objects, all object versions, or all previous object versions target.</td>
</tr>
</tbody>
</table>

You can add object name filters in any order. Object Lifecycle Management evaluates the precedence of the rules as follows:
1. Pattern exclusions
2. Pattern inclusions
3. Prefix inclusions

Using Prefix Matching to Filter Objects

When naming objects, you can use prefix strings without a delimiter so that certain bulk operations can be performed by matching on the prefix portion of the object name. For example, in the object names below, the string `gloves_27_` serves as a prefix for matching purposes when performing lifecycle management archive or deletions:

- `gloves_27_dark_green.jpg`
- `gloves_27_light_blue.jpg`
- `gloves_27_deep_purple.jpg`
- `gloves_27_bright_orange.jpg`

See Object Naming Using Prefixes and Hierarchies on page 3420 for complete details.

Using Pattern Matching to Filter Objects

Object Storage supports the following pattern matching characters to either include or exclude objects:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
<th>Pattern Examples</th>
<th>Matches</th>
<th>Doesn’t Match</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Matches 0 or more characters</td>
<td>*.tmp</td>
<td>foo.tmp&lt;br&gt;foo/bar/baz.tmp</td>
<td>tmp&lt;br&gt;Atmp</td>
</tr>
<tr>
<td></td>
<td></td>
<td>*.xls</td>
<td>.xls&lt;br&gt;/home/user/file.xlsx</td>
<td>xls&lt;br&gt;.xl</td>
</tr>
<tr>
<td>Character</td>
<td>Description</td>
<td>Pattern Examples</td>
<td>Matches</td>
<td>Doesn't Match</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>-----------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td></td>
<td>/archive/*</td>
<td>/archive/sub/dir/</td>
<td>/archive/1/2/3/4/ /archive/1/2/3/4/ /f0o.txt</td>
<td>/src/archive/a /archive/b</td>
</tr>
<tr>
<td>?</td>
<td>Matches any one character</td>
<td>X?Z</td>
<td>XyZ</td>
<td>XZ</td>
</tr>
<tr>
<td></td>
<td>X_Z</td>
<td>XYYZ</td>
<td></td>
<td></td>
</tr>
<tr>
<td>\</td>
<td>Escapes the next character</td>
<td>\dir\sub/*</td>
<td>\dir\sub\ABC</td>
<td>dir\sub\abc</td>
</tr>
<tr>
<td></td>
<td>\dir\sub\</td>
<td></td>
<td>\dir\sub\</td>
<td>dirstub</td>
</tr>
<tr>
<td>[...]</td>
<td>Matches a group of characters, which can be:</td>
<td>[-ab3]</td>
<td>-</td>
<td>-a</td>
</tr>
<tr>
<td></td>
<td>A set of characters, for example:</td>
<td>a</td>
<td>-ab</td>
<td></td>
</tr>
<tr>
<td></td>
<td>[Zaf9@ ].</td>
<td>b</td>
<td>3b</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Matches any character in the brackets.</td>
<td>backup.tar.gz.[0-9]</td>
<td>backup.tar.gz.0</td>
<td>backup.tar.gz10</td>
</tr>
<tr>
<td></td>
<td>A range of characters, for example: [a-f].</td>
<td>backup.tar.gz.5</td>
<td>backup.tar.gz.9</td>
<td>backup.tar.gz</td>
</tr>
<tr>
<td></td>
<td>Matches any character in the range:</td>
<td>page-[0-9]*</td>
<td>page-0</td>
<td>page-</td>
</tr>
<tr>
<td></td>
<td>[a-f] is equivalent to [abcdef].</td>
<td>page-2</td>
<td>page-A1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For character ranges only the CHARACTER-CHARACTER-CHARACTER pattern is supported:</td>
<td>page-22</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>[ab-yz] is not valid.</td>
<td>page-2X</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>[a-mn-z] is not valid.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Character ranges cannot start with ^ or colon (:).</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>To include a hyphen (-) in the range, make it the first or last character.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>[a-z]</td>
<td>[a-z]</td>
<td>a</td>
<td>z</td>
<td>[a-z]</td>
</tr>
</tbody>
</table>
Patterns are limited to 1024 characters. The following are examples of invalid patterns:

- \n
- [^a-z]

- [z-a]

- [:isalpha:]

**Scope and Constraints**

Understand the following scope and constraints regarding object lifecycle policy rules:

- When you create a lifecycle policy rule, that rule applies to all objects, all object versions, or all previous object versions that exist in the bucket unless you add object name filters for that target.

- **Prefix** and **pattern matching** filtering applies only to rules for objects, object versions, or previous object versions. Object filtering does not apply to uncommitted multipart uploads.

- A rule that deletes an object always takes priority over a rule that would move that same object to another storage tier.

- When you create a rule that moves or deletes previous object versions, you specify the number of days until the move or deletion occurs. The "number of days" countdown is based on when the object version transitioned from being the latest object version to being a previous object version. This time can be determined by looking at the "last modified" time of the preceding most recent version of the object. The following screenshot illustrates the time used to start the countdown for archival or deletion in the.

- Be aware of minimum retention periods when you create rules that move or delete the latest version or previous versions of objects.
  
  - The Archive tier has a minimum retention requirement of 90 days. Objects moved or deleted from the Archive tier that have not met the 90-day retention minimum are billed for 90 days of storage.
  
  - Infrequent Access tier has a minimum retention requirement of 31 days. Objects moved or deleted from the Infrequent Access tier that have not met the 31-day retention minimum are billed for 31 days of storage.

- You can create up to 1,000 lifecycle rules per bucket.

**Working with Object Lifecycle Management Policies**

You can create, delete, edit, or disable lifecycle policy rules using the Console, the Command Line Interface (CLI), an SDK, or the API.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Objects deleted on your behalf by lifecycle policies cannot be recovered. Be sure when creating and editing your lifecycle policies that you are not unintentionally deleting data you want to retain. Oracle recommends that you test your lifecycle policy on development data before using the policy in production.</td>
</tr>
</tbody>
</table>
Using the Console
To create a lifecycle policy rule

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment containing the bucket for which you want to create a lifecycle rule.
3. Click the bucket name.
4. Click Lifecycle Policy Rules under Resources to access the lifecycle policy rule list.
5. Click Create Rule.
6. Provide the following information:

   • **Name:** Required. The system generates a default rule name that reflects the current year, month, day, and time, for example lifecycle-rule-20190321-1559. If you change this default to any other rule name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   
   • **Target:** Required. Select the target to which the lifecycle rule applies.
     • If object versioning is **Disabled**, select the rule target **Objects** or **Uncommitted Multipart Uploads**.
     • If object versioning is **Enabled** or **Suspended** select the rule target **Latest Version of Objects**, **Previous Versions of Objects**, or **Uncommitted Multipart Uploads**.

   • **Lifecycle Action:**
     • If the rule target is **Objects**, **Latest Version of Objects**, or **Previous Versions of Objects**, select **Move to Archive**, **Move to Infrequent Access**, or **Delete**.
     • If the rule target is **Uncommitted Multipart Uploads**, **Delete** is the only option and is selected by default.
   
   • **Number of Days:** The number of days until the specified action is taken.

Note:  
If the rule archives or deletes a previous object version, the "number of days" countdown is based on when the object version transitioned from being the latest object version to being a previous object version. This time can be determined by looking at the "last modified" time of the preceding most recent version of the object. The following screenshot illustrates the time used to start the countdown for archival or deletion in the.

7. If the rule target is **Objects**, **Latest Version of Objects**, or **Previous Versions of Objects**, you can optionally add one or more **Object Name Filters** to specify which objects the lifecycle rule applies to. You can choose objects or
object versions using prefixes and pattern matching. If no object name filters are specified, the rule applies to all objects in the bucket.

To create an object name filter:

a. Click Add Filter.
b. Select the Filter Type.
c. Enter the Filter Value.
d. Click Add Another Filter to add as many filters as you need for this rule.

8. Select whether the rule is enabled or disabled upon creation using the State selector.
9. Click Create.

To edit a lifecycle policy rule

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment containing the bucket for which you want to edit a lifecycle rule.
3. Click the bucket name.
4. Click Lifecycle Policy Rules under Resources to access the rule list.
5. Click the Actions icon (three dots) to the right of the rule that you want to edit, and then click Edit.
6. In the Edit Lifecycle Rule dialog box, edit the following as needed for each rule you want to change.
   • Name: A user-friendly name for the rule. Avoid entering confidential information.
   • Lifecycle Action:
     • If the rule target is Objects, Latest Version of Objects, or Previous Versions of Objects, select Move to Archive, Move to Infrequent Access, or Delete.
     • If the rule target is Uncommitted Multipart Uploads, Delete is the only option and is selected by default.
     • Number of Days: The number of days until the specified action is taken.
     • If the rule pertains to objects or object versions, you can edit, delete, or add prefix or pattern Object Name Filters.
   • Enable or disable the rule using the State selector.
7. Click Save Changes.

To enable, disable, or delete a lifecycle policy rule

You can enable, disable, or delete a rule using the Console. The system stops the execution of disabled or deleted rules immediately.

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment containing the bucket for which you want to enable, disable, or delete a lifecycle rule.
3. Click the bucket name.
4. Click Lifecycle Policy Rules under Resources to access the rule list.
5. Click the Actions icon (three dots) to the right of the rule that you want to manage, and then click one of the following:
   • Enable (only displays if the rule is disabled)
   • Disable (only displays if the rule is enabled)
   • Delete

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.
To create or replace a lifecycle policy for a bucket

**Note:**

To edit an existing lifecycle policy using the CLI, you need to replace the policy with a new complete version that includes all changed rules.

```bash
oci os object-lifecycle-policy put --namespace <object_storage_namespace> --bucket-name <bucket_name> --items <json_formatted_lifecycle_policy>
```

**Tip:**

The `--items` option requires that you provide key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

The `--items` key-value pair input must specify the following:

```json
[
  {
    "action": "string",
    "isEnabled": true,
    "name": "string",
    "objectNameFilter": {
      "exclusionPatterns": [
        "string",
        "string"
      ],
      "inclusionPatterns": [
        "string",
        "string"
      ],
      "inclusionPrefixes": [
        "string",
        "string"
      ]
    },
    "target": "string",
    "timeAmount": 0,
    "timeUnit": "string"
  }
]
```

Specify one of the following values for `action`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHIVE</td>
<td>Specify this action to move objects, object versions, or previous object versions to the Archive tier.</td>
</tr>
<tr>
<td>INFREQUENT_ACCESS</td>
<td>Specify this action to move objects, object versions, or object versions to the Infrequent Access tier.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Specify this action to delete objects, object versions, or object versions.</td>
</tr>
<tr>
<td>ABORT</td>
<td>Use this action to delete failed or incomplete multipart uploads.</td>
</tr>
</tbody>
</table>

Specify one of the following values for `target`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objects</td>
<td>Use this action to move objects, object versions, or previous object versions to the Archive tier.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>object-versions</td>
<td>Use this action to move objects, object versions, or previous object versions to the Infrequent Access tier.</td>
</tr>
<tr>
<td>multipart-uploads</td>
<td>Use this action to delete objects, object versions, or previous object versions.</td>
</tr>
</tbody>
</table>

Specify `timeUnit` in days.

The following example creates or replaces a lifecycle policy that includes a rule for moving previous object versions with names that include the pattern `*.doc` from the Standard tier to the Archive tier after 60 days. The policy also includes a rule that deletes previous object versions after 180 days.

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --items '[
  {
    "action": "ARCHIVE",
    "is-enabled": true,
    "name": "Move-to-Archive-Rule",
    "object-name-filter": {
      "exclusion-patterns": null,
      "inclusion-patterns": [
        "*.doc"
      ],
      "inclusion-prefixes": null
    },
    "target": "previous-object-versions",
    "time-amount": 60,
    "time-unit": "DAYS"
  },
  {
    "action": "DELETE",
    "is-enabled": true,
    "name": "Delete-Rule",
    "object-name-filter": {
      "exclusion-patterns": null,
      "inclusion-patterns": [
        "*.doc"
      ],
      "inclusion-prefixes": null
    },
    "target": "previous-object-versions",
    "time-amount": 180,
    "time-unit": "DAYS"
  }
]
```

The following example creates or replaces a lifecycle policy that includes a rule for moving all objects from the Standard tier to the Infrequent Access tier after 45 days. The policy also includes a rule that moves all objects to the Archive tier after 90 days.

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --items '[
  {
    "action": "INFREQUENT_ACCESS",
    "is-enabled": true,
    "name": "Move-to-Infrequent-Access-Rule",
    "object-name-filter": null,
    "target": "objects",
    "time-amount": 45,
    "time-unit": "DAYS"
  },
  {
    "action": "ARCHIVE",
    "is-enabled": true,
    "name": "Move-to-Archive-Rule",
    "object-name-filter": null,
    "target": "objects",
    "time-amount": 90,
    "time-unit": "DAYS"
  }
]
```
The following example creates or replaces a lifecycle policy rule that deletes previous object versions from the Archive tier after 240 days:

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyArchiveTierBucket --items
'[  
  {  
      "action": "DELETE",  
      "is-enabled": true,  
      "name": "Delete-from-Archive-Rule",  
      "object-name-filter": null,  
      "target": "previous-object-versions",  
      "time-amount": 240,  
      "time-unit": "DAYS"
  }
]
```

The following example creates or replaces a lifecycle policy rule that deletes all uncommitted or failed multipart uploads after 5 days:

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyBucket --items
'[  
  {  
      "action": "ABORT",  
      "is-enabled": true,  
      "name": "Delete-Failed-Multipart-Uploads-Rule",  
      "object-name-filter": null,  
      "target": "multipart-uploads",  
      "time-amount": 5,  
      "time-unit": "DAYS"
  }
]
```

Instead of using the `--items` option, you can pass the JSON key-value pairs in a file. For example:

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --file /path/to/file/filename
```

On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

For example:

```bash
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --items "[{"action"":"ARCHIVE","is-enabled":true,"name":"move-to-Archive-rule","target":"previous-object-versions","timeAmount":180,"timeUnit":"DAYS"}]"
```
To delete a bucket's lifecycle policy

Delete all of the lifecycle policy rules that you have defined for the specified bucket.

```
oci os object-lifecycle-policy delete --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```
oci os object-lifecycle-policy delete --namespace MyNamespace --bucket-name MyStandardTierBucket
```

When prompted, confirm the deletion.

To get a bucket's lifecycle policy

Get all of the lifecycle policy rules that you have defined for the specified bucket.

```
oci os object-lifecycle-policy get --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```
oci os object-lifecycle-policy get --namespace MyNamespace --bucket-name MyStandardTierBucket
{
  "data": {
    "items": [
      {
        "action": "ABORT",
        "is-enabled": true,
        "name": "Delete-Failed-Multipart-Uploads-Rule",
        "object-name-filter": null,
        "target": "multipart-uploads",
        "time-amount": 5,
        "time-unit": "DAYS"
      },
      {
        "action": "DELETE",
        "is-enabled": true,
        "name": "Delete-from-Archive-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "target": "objects",
        "time-amount": 240,
        "time-unit": "DAYS"
      },
      {
        "action": "INFREQUENT_ACCESS",
        "is-enabled": true,
        "name": "Move-to-Infrequent-Access-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "target": "objects",
        "time-amount": 45,
        "time-unit": "DAYS"
      }
    ]
  }
}``

For example, to get the lifecycle policy that archives objects after 30 days:

```bash
oci os object-lifecycle-policy get --namespace MyNamespace --bucket-name MyBucketWithoutVersioning
```

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage object lifecycle policies:

- PutObjectLifecyclePolicy
- GetObjectLifecyclePolicy
- DeleteObjectLifecyclePolicy

Using Multipart Uploads

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. You can perform multipart uploads using the API, the Software Development Kits and Command Line Interface on page 4225, or the Command Line Interface (CLI) on page 4192. The Console uses multipart uploads to upload objects larger than 64 MiB.
With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads performed through the API can also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload.

Multipart uploads can accommodate objects that are too large for a single upload operation. Oracle recommends that you perform a multipart upload to upload objects larger than 100 MiB. The maximum size for an uploaded object is 10 TiB. Object parts must be no larger than 50 GiB. For large uploads performed through the API, you have the flexibility of pausing between the uploads of individual parts, and resuming the upload when your schedule and resources allow.

You can use object lifecycle policy rules to automatically delete any uncommitted or failed multipart uploads after a specified number of days. See Using Object Lifecycle Management on page 3466 for details.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you are new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  ```
  Allow group <IAM_group_name> to manage object-family in tenancy
  ```

- Alternatively, you can create policies that reduce the scope of access. For example, to let the specified group manage only buckets and objects in a particular compartment in the tenancy:

  ```
  Allow group <IAM_group_name> to manage buckets in compartment <compartment_name>
  ```

  **Important:**
  
  If you write more restrictive policies, ensure that you include the permissions required for multipart uploads. The user needs a policy that grants both OBJECT_CREATE and OBJECT_OVERWRITE permissions.

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For more information about monitoring multipart uploads, see Object Storage Metrics on page 3499.

**Using the Multipart Upload API**

A multipart upload performed using the API consists of the following steps:

1. Initiating an upload
2. Uploading object parts
3. Committing the upload

Before you use the multipart upload API, you are responsible for creating the parts to upload. Object Storage provides API operations for the remaining steps. The service also provides API operations for listing in-progress multipart
uploads, listing the object parts in an in-progress multipart upload, and aborting in-progress multipart uploads
initiated through the API. Here we provide a high-level overview of the API steps, but you can refer to the API
Reference for specifics about supported API calls.

Creating Object Parts
With multipart upload, you split the object you want to upload into individual parts. Individual parts can be as large as
50 GiB. Decide what part number you want to use for each part. Part numbers can range from 1 to 10,000. You do not
need to assign contiguous numbers, but Object Storage constructs the object by ordering part numbers in ascending
order.

Initiating an Upload
After you finish creating object parts, initiate a multipart upload by making a CreateMultipartUpload REST API call.
Provide the object name and any object metadata. Object Storage responds with a unique upload ID that you must
include in any requests related to this multipart upload. Object Storage also marks the upload as active. The upload
remains active until you explicitly commit it or abort it.

Uploading Object Parts
Make an UploadPart request for each object part upload. In the request parameters, provide the Object Storage
namespace, bucket name, upload ID, and part number. In the request body, include the object part. Object parts can
be uploaded in parallel and in any order. When you commit the upload, Object Storage uses the part numbers to
sequence object parts. Part numbers do not have to be contiguous. If multiple object parts are uploaded using the same
upload ID and part number, the CommitMultipartUpload API commits the last part uploaded.

Object Storage returns an ETag (entity tag) value for each part uploaded. You need both the part number and
corresponding ETag value for each part when you commit the upload.

If you have network issues, you can restart a failed upload for an individual part. You do not need to restart the entire
upload. If for some reason, you cannot perform an upload all at once, multipart upload lets you continue uploading
parts at your own pace. While a multipart upload is still active, you can keep adding parts as long as the total number
is less than 10,000.

You can check on an active multipart upload by listing all parts that have been uploaded. (You cannot list information
for an individual object part in an active multipart upload.) The ListMultipartUploadParts operation requires the
Object Storage namespace, bucket name, and upload ID. Object Storage responds with information about the parts
associated with the specified upload ID. Parts information includes the part number, ETag value, MD5 checksum, and
part size (in bytes).

Similarly, if you have multiple multipart uploads occurring simultaneously, you can see what uploads are in-progress.
Make an ListMultipartUploads API call to list active multipart uploads in the specified Object Storage namespace and
bucket.

Charges for parts storage begin accruing when you upload data.

Committing the Upload
When you have uploaded all object parts, commit the upload. Use the CommitMultipartUpload request parameters
to specify the Object Storage namespace, bucket name, and upload ID. Include the part number and corresponding
ETag value for each part in the body of the request. When you commit the upload, Object Storage constructs the
object from its constituent parts. The object is stored in the specified bucket and Object Storage namespace. You can
treat it like you would any other object. Garbage collection releases storage space occupied by any part numbers you
uploaded, but did not include in the CommitMultipartUpload request.

You cannot list or retrieve parts from a completed upload. You cannot append or remove parts from the completed
upload either. If you want, you can replace the object by initiating a new upload.

If you decide to abort a multipart upload instead of committing it, wait for in-progress part uploads to complete and
then use the AbortMultipartUpload operation. If you abort an upload while part uploads are still in progress anyway,
Object Storage cleans up both completed and in-progress parts. Upload IDs from aborted multipart uploads cannot be reused.

**API Documentation**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage multipart uploads:

- AbortMultipartUpload
- CommitMultipartUpload
- CreateMultipartUpload
- ListMultipartUploadParts
- ListMultipartUploads
- UploadPart (see Special Instructions for Object Storage PUT for signing request requirements)

**Using the CLI**

When you perform a multipart upload using the CLI, you do not need to split the object into parts as you are required to do by the API. Instead, you specify the part size of your choice, and Object Storage splits the object into parts and performs the upload of all parts automatically. You can choose to set the maximum number of parts that can be uploaded in parallel. By default, the CLI limits the number of parts that can be uploaded in parallel to three. When using the CLI, you do not have to perform a commit when the upload is complete.

You can also use the CLI to list in-progress multipart uploads, and to abort multipart uploads initiated through the API.

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To perform a multipart upload using the CLI**

To upload an object, run `oci os object put` with the `--part-size` flag. The `--part-size` value represents the size of each part in mebibytes (MiBs). Object Storage waives the minimum part size restriction for the last uploaded part. The `--part-size` value must be an integer.

Optionally, you can use the `--parallel-upload-count` flag to set the maximum number of parallel uploads allowed.

```
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> --name <object_name> --part-size <upload_part_size_in_MB> --parallel-upload-count <maximum_number_parallel_uploads>
```

For example:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file ~/path/to/file --name MyObject --parallel-upload-count 10 --part-size 500
```

Upload ID: 277fff55-e1b5-e81d-5f81-c374a8f33998

Split file into 12 parts for upload.

Uploading object ################################################################ 100%

```
{ "etag": "861c8341-74d8-4142-8da4-28e1ce7783ba", "last-modified": "Wed, 25 Sep 2019 19:59:15 GMT", "opc-multipart-md5": "9Qnleyou2yMiyOO9Bc7o1A==--12" }
```

For more information on the `oci os object put` command, see To upload an object to a bucket.
To list the parts of an unfinished or failed multipart upload

```
oci os multipart list --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```
oci os multipart list --namespace MyNamespace --bucket-name MyBucket

"data": [
  {
    "bucket": "MyBucket",
    "namespace": "MyNamespace",
    "object": "MyObject",
    "time-created": "2019-07-25T21:55:21.973000+00:00",
    "upload-id": "0b7abd48-9ff2-9d5f-2034-63a02fdd7afa"
  },
  {
    "bucket": "MyBucket",
    "namespace": "MyNamespace",
    "object": "MyObject",
    "time-created": "2019-07-25T21:53:09.246000+00:00",
    "upload-id": "1293ac9d-83f8-e055-a5a7-d1e13277b5c0"
  },
  {
    "bucket": "MyBucket",
    "namespace": "MyNamespace",
    "object": "MyObject",
    "time-created": "2019-07-25T21:46:34.981000+00:00",
    "upload-id": "33e7a875-9e94-c3bc-6577-2ee5d8226b53"
  }
...]
```

**Tip:**

See the Command Line Reference for command options to control the pagination of the list output.

To delete a part of an uncommitted or failed multipart upload

```
oci os multipart abort --namespace <object_storage_namespace> --bucket-name <bucket_name> --object-name <object_name> --upload-id <upload_ID>
```

For example:

```
oci os multipart abort --namespace MyNamespace --bucket-name MyBucket --object-name MyObject --upload-id 0b7abd48-9ff2-9d5f-2034-63a02fdd7afa
WARNING: Are you sure you want to permanently remove this incomplete upload? [y/N]: y
```

**Tip:**

The CLI interface asks you to confirm the deletion request. To delete without the confirmation prompt, use the --force flag.

You can also create a lifecycle policy that automatically deletes uncommitted or failed multipart uploads. See Using Object Lifecycle Management on page 3466 for details.

To delete all parts of an uncommitted or failed multipart upload

```
#!/bin/bash
BUCKET=$1
```
oci os multipart list --bucket-name $BUCKET | \
  jq -c '.data | map({"o": .object, "i": "upload-id"}) | .[]' | \ 
while read JSON; do
  OBJECTNAME=$(echo $JSON | jq '.o' | sed -e 's/"//g;')
  UPLOADID=$(echo $JSON | jq '.i' | sed -e 's/"//g;')
  echo Removing Object name $OBJECTNAME, ID $UPLOADID
  oci os multipart abort --bucket-name $BUCKET \
    --object-name $OBJECTNAME \
    --upload-id $UPLOADID \
    --force
done

You can also create a lifecycle policy that automatically deletes uncommitted or failed multipart uploads. See Using Object Lifecycle Management on page 3466 for details.

Using Pre-Authenticated Requests

Pre-authenticated requests provide a way to let users access a bucket or an object without having their own credentials, as long as the request creator has permissions to access those objects. For example, you can create a request that lets an operations support user upload backups to a bucket without owning API keys. Or, you can create a request that lets a business partner update shared data in a bucket without owning API keys.

When you create a pre-authenticated request, a unique URL is generated. Anyone you provide this URL to can access the Object Storage resources identified in the pre-authenticated request, using standard HTTP tools like curl and wget.

**Important:**

Assess the business requirement for and the security ramifications of pre-authenticated access to a bucket or objects.

A pre-authenticated request URL gives anyone who has the URL access to the targets identified in the request. Carefully manage the distribution of the URL.

**Required Permissions**

**To Create a Pre-Authenticated Request**

To create or manage pre-authenticated requests, you need `PAR_MANAGE` permission to the target bucket or object.

While you only need `PAR_MANAGE` permission to create a pre-authenticated request, you must also have the appropriate permissions for the access type that you are granting. For example:

- If you are creating a pre-authenticated request for uploading objects to a bucket, you need `OBJECT_CREATE` and `OBJECT_OVERWRITE` permissions in addition to `PAR_MANAGE`.
- If you are creating a pre-authenticated request for read/write access to objects in a bucket, you need `OBJECT_READ`, `OBJECT_CREATE`, and `OBJECT_OVERWRITE` permissions in addition to `PAR_MANAGE` to grant user read/write access to objects.

**Important:**

If the creator of a pre-authenticated request is deleted or loses the required permissions after they created the request, the request will no longer work.

**To Use a Pre-Authenticated Request**

Permissions of the pre-authenticated request creator are checked each time you use a pre-authenticated request. The pre-authenticated request no longer works when any of the following occurs:

- Permissions of the pre-authenticated request creator have changed.
- User who created the pre-authenticated request is deleted.
• Federated user who created the pre-authenticated request has lost the user capabilities that they had when they created the request.
• Pre-authenticated request has expired.

Options
When creating a pre-authenticated request, you have the following options:
• You can specify the name of a bucket that a pre-authenticated request user has write access to and can upload one or more objects to.
• You can specify the name of an object that a pre-authenticated request user can read from, write to, or read from and write to.

Scope and Constraints
Understand the following scope and constraints regarding pre-authenticated requests:
• Users can't list bucket contents.
• You can create an unlimited number of pre-authenticated requests.
• There is no time limit to the expiration date that you can set.
• You can't edit a pre-authenticated request. If you want to change user access options in response to changing requirements, you must create a new pre-authenticated request.
• The target and actions for a pre-authenticated request are based on the creator's permissions. The request is not, however, bound to the creator's account login credentials. If the creator's login credentials change, a pre-authenticated request is not affected.
• You cannot delete a bucket that has a pre-authenticated request associated with that bucket or with an object in that bucket.

Working with Pre-Authenticated Requests
You can create, delete, or list pre-authenticated requests using the Console, using the CLI, or by using an SDK to access the API.

Important:
The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

After creating a pre-authenticated request, you can use a tool like curl to read and write data using the pre-authenticated request.

To put an object

$ curl -X PUT --data-binary '@<local-filename>' <unique-PAR-URL>

For example:

$ curl -X PUT --data-binary '@using-dita-guide.pdf'
https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvgQHbUaw6ADzHkDlnaqMuXWeF_lhTxCiS9ngCw/n/docs/b/par-bucket/o/using-dita-guide.pdf

To get an object

$ curl -X GET <unique-PAR-URL>
For example:

```bash
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvqQHbUaw6ADzHkD1naqMuXWef_lhTxCiS9ngCw/n/namespace/b/par-bucket/o/using-dita-guide.pdf
```

### Using the Console

**To create a pre-authenticated request for a bucket**

See [Service Limits](#) on page 215 for a list of applicable limits and instructions for requesting a limit increase.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Pre-Authenticated Requests** under **Resources** to display the list of pre-authenticated requests.
5. Click **Create Pre-Authenticated Request**.
6. Provide the following information:
   - **Name**: The system automatically generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example `par-bucket-20191101-1327`.
     If you change this default or any other pre-authenticated request name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Pre-Authenticated Request Target**: Select **Bucket**.
   - **Expiration**: Accept the one week, system-generated expiration date or use the date and time editor to use a different expiration date and time.
7. Click **Create Pre-Authenticated Request**.

   After a request is created, the **Pre-Authenticated Request Details** dialog box displays the URL used to access the bucket.

8. Click **Copy** to copy the URL for future reference.

```
Note:
The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.
```

9. Click **Close**.

**To create a pre-authenticated request for an object**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Objects** under **Resources** to display the list of objects.
5. For the object you want to create a pre-authenticated request, click the Actions icon (three dots), and then click **Create Pre-Authenticated Request**.
6. Provide the following information:
   • **Name**: The system generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example `par-object-object-name-20191101-1429`. If you change this default or any other pre-authenticated request name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   • **Pre-Authenticated Request Target**: Select **Object**.
   • **Object Name**: The name of the object that you want authenticated by this rule.
   • **Access Type**: Select one of the following.
     - Permit read on the object
     - Permit writes to the object
     - Permit reads on and writes to the object
   • **Expiration**: Accept the one week, system-generated expiration date or use the date and time editor to a different expiration date and time.

7. Click **Create Pre-Authenticated Request**. After a request is created, the **Pre-Authenticated Request Details** dialog displays the URL used to access the object.

8. Click **Copy** to copy the URL for future reference.

   **Note:**
   The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

9. Click **Close**.

**To copy a pre-authenticated request ID**

To copy the ID for a pre-authenticated request to the clipboard, do the following:

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Pre-Authenticated Requests** under **Resources** to display the list of pre-authenticated requests.
5. For the pre-authenticated request ID that you want to copy, click the Actions icon (three dots), and then click **Copy Pre-Authenticated Request ID**.

   The ID for the selected pre-authentication request is copied to the clipboard.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**To create a pre-authenticated request for a bucket**

```bash
oci os preauth-request create --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <preauthenticated_request_name> --access-type AnyObjectWrite --time-expires <timestamp>
```

Note the following:

- To create a pre-authenticated request for a bucket, use the `AnyObjectWrite` enum value with the `--access-type` flag. Pre-authenticated requests for buckets permit writes to the bucket by default.
- The `<timestamp>` is required and must be an RFC 3339 timestamp. For example:

  2017-09-01T00:09:51.000+02:00.
Note:
The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

To create a pre-authenticated request for an object

**oci os preauth-request create --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <preauthenticated_request_name> --access-type <enum_value> --time-expires <timestamp> -on <object_name_or_null>**

The `<enum_value>` for `--access-type` is one of the following:

- ObjectRead (permits read on the object)
- ObjectWrite (permits writes to the object)
- ObjectReadWrite (permits reads on and writes to the object)

The `<timestamp>` is required and must be an RFC 3339 timestamp. For example: 2017-09-01T00:09:51.000+02:00.

Avoid entering confidential information in the pre-authenticated request name.

Note:
The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

To list a pre-authenticated request

**oci os preauth-request list --namespace <object_storage_namespace> --bucket-name <bucket_name>**

To get a pre-authenticated request

**oci os preauth-request get --namespace <object_storage_namespace> --bucket-name <bucket_name> --par-id <preauthenticated_request_id>**

To delete a pre-authenticated request

**oci os preauth-request delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --par-id <preauthenticated_request_id>**

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to work with pre-authenticated requests:

- CreatePreauthenticatedRequest
- DeletePreauthenticatedRequest
- GetPreauthenticatedRequest
- ListPreauthenticatedRequests
Copying Objects

This topic describes how to copy objects in Object Storage. You can copy objects to other buckets in the same region and to buckets in other regions.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object copy does not work if you do not authorize the Object Storage service to copy objects on your behalf. See Service Permissions on page 3487 for more information.</td>
</tr>
</tbody>
</table>

User Permissions

You must have the required access to both the source and destination buckets when performing an object copy. You must also have permissions to manage objects in the source and destination buckets.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  Allow group <IAM_group_name> to manage object-family in tenancy

- Alternatively, you can create policies that reduce the scope of access. For example, to let the specified group manage only buckets and objects in a particular compartment in the tenancy:

  Allow group <IAM_group_name> to manage buckets in compartment <compartment_name>

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

Service Permissions

Because Object Storage is a regional service, you must authorize the Object Storage service for each region carrying out copy operations on your behalf. For example, you might authorize the Object Storage service in region US East (Ashburn) to manage objects on your behalf. After you authorize the Object Storage service, you can copy an object stored in a US East (Ashburn) bucket to a bucket in another region.

To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 180.

For administrators:

To enable object copy, you must authorize the service to manage objects on your behalf:

- You can create a policy that authorizes the service in the specified region to manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  Allow service objectstorage-<region_identifier> to manage object-family in tenancy
Instead of using the policy verb `manage`, you can create a policy that reduces the scope of access by instead using one of the following statements:

```bash
Allow service objectstorage-<region_identifier> to manage object-family in tenancy where any {request.permission='OBJECT_READ',
  request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE',
  request.permission='OBJECT_OVERWRITE',
  request.permission='OBJECT_DELETE'}

Allow service objectstorage-<region_identifier> to manage object-family in compartment <compartment_name>
  where any {request.permission='OBJECT_READ',
  request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE',
  request.permission='OBJECT_OVERWRITE',
  request.permission='OBJECT_DELETE'}
```

**Copy Object Work Requests**

The Object Storage service handles copy requests asynchronously. The service creates a queue for copy requests, and then processes the requests when system resources become available. To provide visibility for in-progress copy operations, Object Storage creates a work request. You can track the progress of the copy operation by monitoring the status of the work request.

The work request statuses are:

- **ACCEPTED**
  The copy request is in the work request queue to be processed.

- **IN PROGRESS**
  The object copy is in progress.

- **SUCCEEDED**
  The copy operation has successfully completed.

- **CANCELLING**
  The copy request is in the process of being canceled.

- **CANCELED**
  The copy request has been canceled.

- **FAILED**
  The copy operation has failed. Work requests that do not complete because of overwrite rules or insufficient user authorizations are assigned the failed status.

  You can determine the reason a copy failed in the following ways:

  - To use the CLI, see To obtain the details of a failed copy work request on page 3491.
  - To use the API, see ListWorkRequestErrors.

**Copy Object Overwrite Rules**

Use overwrite rules to control the copying of objects based on their entity tag (ETag) values.

- **Overwrite destination object**: Use this option when you do not want to limit a copy operation by an ETag value. This option is the default. This option can be used for any copy operation, regardless of whether it involves overwriting an existing object.

- **Do not overwrite any destination object**: Use this option to prevent the overwriting an existing copy of an object in the destination location, regardless of the destination object's ETag value.
• **Overwrite destination object only if it matches the specified ETag**: Use this option to prevent the accidental overwriting of an object in the destination location that does not have the specified ETag. When you use this option, the copy operation only succeeds if the ETag you supply when initiating the copy request matches the ETag of the destination object.

• **Copy object only if the source matches the specified ETag**: Use this option if you want the copy operation successful only if the ETag you supply when initiating the copy request matches the ETag of the source object. For objects that are intentionally updated and overwritten as part of data management activity, this option ensures that only the specified version of the object (as indicated by the ETag) is allowed to be copied. If the object's ETag value changes after the copy work request is created, but before the copy operation is run, the copy operation will not complete.

Caution: If you overwrite an object, the operation cannot be undone.

### Scope and Constraints

- Objects cannot be copied directly from Archive Storage. To copy objects that are currently in Archive Storage, you must first restore the object to the Standard Object Storage tier. Objects can be copied directly to Archive tier buckets from the Standard or Infrequent Access tiers. When you copy objects into an Archive Storage bucket, the copy of the object is immediately archived.
- Specify an existing target bucket for the copy request. The copy operation does not automatically create buckets.
- When an object is copied, the destination object receives a new ETag value.
- If you rename, overwrite, or delete a source object during a copy operation, the copy operation fails and the destination object is not created or overwritten.
- Bulk copying is not supported. Identify a single object in the copy request.

### Using the Console

The Console consumes the REST API and is subject to the same considerations as any Oracle Cloud Infrastructure client.

**To make a copy of an object**

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment that contains the bucket that contains your object.
3. Select the bucket containing the object that you want to copy.
4. Click Objects under Resources to display a list of objects in the bucket.
5. For the object you want to copy (the source object), click the Actions icon (three dots), and then click Copy.
6. In the Copy Object dialog, enter the following:
   - **Destination Namespace**: The Object Storage Namespace of the destination bucket for your copied object. The namespace string of your tenancy is supplied as the default value.
   - **Destination Region**: The Oracle Cloud Infrastructure region containing the destination bucket for your copied object. Your tenancy must be subscribed to a region for you to copy an object to a bucket in that region.
   - **Destination Bucket**: The name of the destination bucket for your copied object. Specify an existing target bucket. The copy operation does not automatically create buckets.
   - **Destination Object Name**: Optionally, you can specify a different destination object name. By default, the Destination Object Name is the same name as the object you are copying.
   - **Destination Storage Tier**: If you are uploading to a Standard tier bucket, you can optionally specify the storage tier to upload the object to:
     - Infrequent Access
     - Archive
   - **Overwrite Rule**: Select the overwrite rule appropriate for your copy request. See Copy Object Overwrite Rules for information on the overwrite rule options.
7. Click **Copy Object**.
   
   A dialog confirms that your copy request was submitted successfully.

**To monitor the status of an object copy work request**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment containing your bucket.
3. Click the bucket name of the bucket containing the object being copied.
4. Click **Work Requests** under **Resources**.
   
   A list of work requests is displayed. The **status** of the request and details including object name, request ID, and the destination bucket's name, region, and **namespace** is also displayed.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To make a copy of an object**

```
oci os object copy --namespace-name <object_storage_namespace> --bucket-name <source_bucket_name> --source-object-name <source_object> --destination-namespace <destination_namespace_string> --destination-region <destination_region> --destination-bucket <destination_bucket_name> --destination-object-name <destination_object_name>
```

For example:

```
oci os object copy --namespace-name ansh8lvrlzpy --bucket-name photos --source-object-name hummingbird.jpg --destination-namespace ansh8lvrlzpy --destination-region uk-london-1 --destination-bucket UK_photos --destination-object-name hummingbird.jpg
```

If you are uploading to a Standard tier bucket, you can optionally specify the storage tier to upload the object to:

- **Infrequent Access**
- **Archive**

```
oci os object copy --namespace-name <object_storage_namespace> --bucket-name <source_bucket_name> --source-object-name <source_object> --destination-namespace <destination_namespace_string> --destination-object-storage-tier <destination_object_storage_tier> --destination-region <destination_region> --destination-bucket <destination_bucket_name> --destination-object-name <destination_object_name>
```

For example:

```
oci os object copy --namespace-name ansh8lvrlzpy --bucket-name photos --source-object-name hummingbird.jpg --destination-namespace ansh8lvrlzpy --destination-object-storage-tier Archive --destination-region uk-london-1 --destination-bucket UK_photos --destination-object-name hummingbird.jpg
```

**To get the status of an object copy work request**

```
oci os work-request get --work-request-id <request_id>
```

If you do not have the work request ID, you can get a list of work requests, including the request IDs, for a specified compartment, see To get a list of work requests for a compartment on page 3491.
To obtain the details of a failed copy work request

```
oci os work-request-errors list --work-request-id <request_id>
```

If you do not have the work request ID, you can get a list of work requests, including the request IDs, for a specified compartment, see To get a list of work requests for a compartment on page 3491.

To get a list of work requests for a compartment

```
oci os work-request list --compartment-id <compartment_id>
```

To cancel a copy object work request

```
oci os work-request cancel --work-request-id <request_id>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to view and manage work requests for copy object operations:

- CopyObject
- ListWorkRequests
- GetWorkRequest
- CancelWorkRequest
- ListWorkRequestErrors

Using Your Own Keys for Server-Side Encryption

The Oracle Cloud Infrastructure Object Storage service encrypts and decrypts all objects using 256-bit AES encryption. By default, Object Storage service manages the master encryption key used to encrypt each object's encryption keys.

You can alternatively employ one of these encryption strategies:

- You can assign a key that you created and control through the Oracle Cloud Infrastructure Vault service. See Overview of Vault on page 3952 for details.
- You can encrypt objects using your own encryption key. The key you supply is known as a customer-provided encryption key.

This topic provides the details for implementing and using server-side encryption with customer-provided keys (SSE-C).

About SSE-C

Using optional API headers, you can provide your own 256-bit AES encryption key that is used to encrypt and decrypt objects uploaded to and downloaded from Object Storage:

- When you upload an object, you supply the encryption key. Object Storage encrypts the object using that key and immediately deletes the key.
- When you want to download an object, you supply the same key that was used to encrypt the object and Object Storage decrypts and returns the object to you.

You manage the encryption keys and Object Storage manages the encryption and decryption.

**Important:**

Object Storage does not store your encryption keys. You are responsible for tracking the key that is associated with each object and rotating the key as necessary. If you lose your encryption key, you cannot retrieve your object.
Scope and Constraints

Understand the following scope and constraints regarding SSE-C:

- An SSE-C key cannot be associated with a bucket and can only be used to encrypt individual objects.
- You can encrypt objects using your own encryption key using pre-authenticated requests. To retrieve an SSE-C encrypted object using a pre-authenticated request, you need to specify your encryption key.
- To delete or rename an SSE-C encrypted object, you do not need to specify your encryption key.
- You can only specify either a kmsKeyId or an sseCustomerKey in the ReencryptObject request payload, not both. If the request payload is empty, the object is encrypted using the encryption key assigned to the bucket. The bucket encryption mechanism can either be a master encryption key managed by Oracle or the Vault service.
- You can only use the Object Storage APIs and the CLI to provide SSE-C keys. You can't use the Console to upload or retrieve objects using a customer-provided key.
- The Amazon S3 Compatibility API also supports SSE-C.

Using SSE-C

If you want to use your own keys for server-side encryption, specify the following three request headers with the encryption key information:

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>opc-sse-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm.</td>
<td>CopyObject, GetObject, HeadObject, PutObject, CreateMultipartUpload, UploadPart</td>
</tr>
<tr>
<td>opc-sse-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to encrypt or decrypt the data.</td>
<td></td>
</tr>
<tr>
<td>opc-sse-customer-key-sha256</td>
<td>Specifies the base64-encoded SHA256 hash of the encryption key.</td>
<td></td>
</tr>
</tbody>
</table>

For CopyObject:

If the source object is encrypted with an SSE-C key, you must also specify the following three headers so that Object Storage can decrypt the object.

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>opc-source-sse-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm to use to decrypt the source object.</td>
<td>CopyObject</td>
</tr>
<tr>
<td>opc-source-sse-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to decrypt the source object.</td>
<td></td>
</tr>
<tr>
<td>opc-source-sse-customer-key-sha256</td>
<td>Specifies the base64-encoded SHA256 hash of the encryption key used to decrypt the source object.</td>
<td></td>
</tr>
</tbody>
</table>

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.
If you are new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more information about Object Storage-specific policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

**Using the CLI**

You can also use your own encryption keys to encrypt objects using the CLI.

You can supply the optional parameter `--encryption-key-file <filename>` for the following commands:

- `oci os object put`
- `oci os object get`
- `oci os object head`
- `oci os object resume-put`
- `oci os object bulk-upload`
- `oci os object bulk-download`
- `oci os object copy`
- `oci os object reencrypt`

`<filename>` points to a file containing the base64-encoded string of the AES-256 encryption key. No other parameters are required. Object Storage decodes the key to compute the SHA256 hash of the encryption key.

If the source object is encrypted with an SSE-C key, you must also specify the optional parameter `--source-encryption-key-file <filename>` for the following commands:

- `oci os object copy`
- `oci os object reencrypt`

`<filename>` points to a file containing the base64-encoded string of the AES-256 source encryption key. No other parameters are required. Object Storage decodes the key to compute the SHA256 hash of the source encryption key.

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Amazon S3 Compatibility API**

Using the Amazon S3 Compatibility API, customers can continue to use their existing Amazon S3 tools (for example, SDK clients) and partners can make minimal changes to their applications to work with Object Storage. The Amazon S3 Compatibility API and Object Storage datasets are congruent. If data is written to the Object Storage using the Amazon S3 Compatibility API, the data can be read back using the native Object Storage API and conversely.

**Differences between the Object Storage API and the Amazon S3 Compatibility API**

The Object Storage Service provided by Oracle Cloud Infrastructure and Amazon S3 use similar concepts and terminology. In both cases, data is stored as objects in buckets. The differences are in the implementation of features and tools for working with objects.

The following highlights the differences between the two storage technologies:

- **Compartments**
  
  Amazon S3 doesn't use compartments. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.

- **Global bucket namespace**
  
  Object Storage doesn't use a global bucket namespace. Each tenant is associated with one default namespace that spans all compartments within a region. The namespace serves as a container for all of your buckets and objects. You control bucket names within your namespace, however, bucket names must be unique within each region. You can have a bucket named `MyBucket` in US West (Phoenix) and a bucket named `MyBucket` in Germany Central (Frankfurt).
• **Encryption**
  The Oracle Cloud Infrastructure Object Storage service encrypts all data at rest by default. Encryption can't be turned on or off using the API.

• **Object Level Access Control Lists (ACLs)**
  Oracle Cloud Infrastructure does not use ACLs for objects. Instead, IAM policies are used to manage access to compartments, buckets, and objects.

For more information, see [Overview of the Object Storage service](#).

**Amazon S3 Compatibility API Prerequisites**

To enable application access from Amazon S3 to Object Storage, you need to set up access to Oracle Cloud Infrastructure and modify your application.

**Setting up access to Oracle Cloud Infrastructure**

• [Sign Up for Oracle Cloud Infrastructure](#) and obtain a unique namespace.

• Create a [Customer Secret key](#). A Customer Secret key consists of an Access Key/Secret key pair.

**Modifying your application**

• Configure a new endpoint for the application that includes the namespace and the region identifier. For example: mynamespace.compat.objectstorage.us-phoenix-1.oraclecloud.com.

• Set the target region as one of the Oracle Cloud Infrastructure regions.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your application does not support setting the region identifier to the correct Oracle Cloud Infrastructure identifier, you must either set the region to us-east-1 or leave it blank. Using this configuration, you can only use the Amazon S3 Compatibility API in your Oracle Cloud Infrastructure home region. If you can manually set the region, you can use the application against any Oracle Cloud Infrastructure region.</td>
</tr>
</tbody>
</table>

• Configure the application to use the Customer Secret key. The Customer Secret Key consists of an Access Key and Secret Key. Both of these keys must be supplied to the application.

• The application must use path-based access. Virtual host-style access (accessing a bucket as bucketname.namespace.compat.objectstorage.region.oraclecloud.com) is not supported.

You can now use the Amazon S3 Compatibility API to access Object Storage in Oracle Cloud Infrastructure.

**Amazon S3 Compatibility API Support**

Amazon S3 Compatibility API support is provided at the bucket level and object level.

**Bucket APIs**

The following bucket APIs are supported:

• [DeleteBucket](#)

• [GetLocation](#)

• [HeadBucket](#)

• [GetService](#) (list all my buckets)

• [ListObjects](#)

• [PutBucket](#)

**Object APIs**

The following object APIs are supported:

• [BulkDelete](#)
Object Storage

- **DeleteObject**
- **GetObject**
- **HeadObject**
- **PutObject**
- **RestoreObjects**

**Multipart Upload APIs**

The following multipart upload APIs are supported:

- **AbortMultipartUpload**
- **CompleteMultipartUpload**
- **InitiateMultipartUpload**
- **ListParts**
- **ListUploads**
- **UploadPart**

**Tagging APIs**

The following tagging APIs are supported:

- **DeleteBucketTagging**
- **GetBucketTagging**
- **PutBucketTagging**

**SSE-C Support**

Using optional API headers, you can provide your own 256-bit AES encryption key that is used to encrypt and decrypt objects uploaded to and downloaded from Object Storage.

If you want to use your own keys for server-side encryption, specify the following three request headers with the encryption key information:

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-server-side-encryption-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm.</td>
<td>GetObject, HeadObject</td>
</tr>
<tr>
<td>x-amz-server-side-encryption-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to encrypt or decrypt the data.</td>
<td>PutObject, InitiateMultipartUpload, UploadPart</td>
</tr>
<tr>
<td>x-amz-server-side-encryption-customer-key-md5</td>
<td>Specifies the base64-encoded 128-bit MD5 digest of the encryption key. This value is used to check the integrity of the encryption key.</td>
<td></td>
</tr>
</tbody>
</table>

Object Storage has distinct APIs for copying objects and copying parts. Amazon S3 uses the presence of the following headers in **PutObject** and **UploadPart** to determine copy operations. To copy a source object that is encrypted with an SSE-C key, you must specify these three headers so that Object Storage can decrypt the object.

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm to use to decrypt the source object.</td>
<td>PutObject, UploadPart</td>
</tr>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to decrypt the source object.</td>
<td></td>
</tr>
<tr>
<td>Headers</td>
<td>Description</td>
<td>APIs Supported</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-key-md5</td>
<td>Specifies the base64-encoded 128-bit MD5 digest of the encryption key used to decrypt the source object.</td>
<td></td>
</tr>
</tbody>
</table>

**Supported Amazon S3 Clients**

Here are some examples of configuring various client applications to talk to Object Storage's Amazon S3-compatible endpoints. Use an existing or create a special signing key to authenticate with Amazon S3, which is an Access Key/Secret Key pair. See Managing User Credentials on page 2456 for details.

**AWS SDK for Java**

The following is an example of configuring AWS SDK for Java.

```java
// Get S3 credentials from the console and put them here
AWSCredentialsProvider credentials = new AWSStaticCredentialsProvider(new
BasicAWSCredentials("gQ4+YC530sBa8qZI6WcbUbtH8oar0exampleuniqueID", "7fa22331be62bf4605dc9a42aaeexampleuniqueID"));

// Your namespace
String namespace = "namespace";

// The region to connect to
String region = "us-ashburn-1";

// Create an S3 client pointing at the region
String endpoint = String.format("%s.compat.objectstorage.%s.oraclecloud.com",namespace,region);
AwsClientBuilder.EndpointConfiguration endpointConfiguration = new
AwsClientBuilder.EndpointConfiguration(endpoint, region);
AmazonS3 client = AmazonS3Client.builder()
  .standard()
  .withCredentials(credentials)
  .withEndpointConfiguration(endpointConfiguration)
  .disableChunkedEncoding()
  .enablePathStyleAccess()
  .build();
```

**AWS SDK for Javascript**

The following is an example of configuring AWS SDK for Javascript.

```javascript
s3 = new AWS.S3({
  region: 'us-ashburn-1',
  endpoint: 'https://' + mynamespace + '.compat.objectstorage.us-ashburn-1.oraclecloud.com',
  accessKeyId: 'gQ4+YC530sBa8qZI6WcbUbtH8oar0exampleuniqueID',
  secretAccessKey: '7fa22331be62bf4605dc9a42aaeexampleuniqueID',
  s3ForcePathStyle: true,
  signatureVersion: 'v4',
});
```
**AWS SDK for Python (Boto 3)**

The following is an example of configuring AWS SDK for Python (Boto 3).

```python
import boto3
s3 = boto3.resource('s3',
   aws_access_key_id="gQ4+YC530sBa8qZ167WcbUbtH8oar0exampleuniqueID",
   aws_secret_access_key="7fa22331ebe62bf4605dc9a42aaexampleuniqueID",
   region_name="us-phoenix-1", # Region name here that matches the endpoint
   endpoint_url="https://mynamespace.compat.objectstorage.us-
   phoenix-1.oraclecloud.com" # Include your namespace in the URL
)

# Print out the bucket names
for bucket in s3.buckets.all():
    print bucket.name
```

**Designating Compartments for the Amazon S3 Compatibility and Swift APIs**

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment and data is stored as objects in buckets.

In addition to the native Object Storage APIs, Object Storage provides API support for both Amazon S3 Compatibility API and Swift API. However these APIs do not understand the Oracle Cloud Infrastructure concept of a compartment. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.

When you designate a different compartment to use for the Amazon S3 Compatibility API or Swift API, any new buckets you create using the Amazon S3 Compatibility API or the Swift API are created in this newly designated compartment. Buckets previously created in a different compartment are not automatically moved to the newly designated compartment. See Managing Buckets on page 3398 if you want to move previously created buckets to this newly designated compartment.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Compartments have policies that indicate what actions a user can perform on a bucket and all the objects in the bucket.

For administrators:

- To change the default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with NAMESPACE_UPDATE permissions.
- To see the current default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with NAMESPACE_READ permissions.
- To move a bucket to a different compartment, a user must belong to a group with BUCKET_UPDATE and BUCKET_CREATE permissions in the source compartment, and BUCKET_CREATE permissions in the target compartment.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for buckets and objects, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.
**Viewing and Specifying Designated Compartments**

You can view the current default compartment designations for Amazon S3 Compatibility API and Swift API data. If your permissions allow, you can also change the Amazon S3 Compatibility API and Swift API compartment designations.

Designated compartment names:
- Must be unique across all the compartments in your tenancy.
- Can be from 1 to 100 characters in length.
- Must not contain confidential information.
- Valid are letters (upper or lower case), numbers, hyphens, and underscore.

**Using the Console**

**To view your Amazon S3 Compatibility API and Swift API compartment designations**

Open the Profile menu and click Tenancy: `<your_tenancy_name>`.

Your default compartment designations for the APIs are listed under Object Storage Settings.

**To edit your tenancy's Amazon S3 Compatibility API and Swift API compartment designations**

1. Open the Profile menu and click Tenancy: `<your_tenancy_name>`.
2. Click Edit Object Storage Settings.
3. In the Edit Object Storage Settings dialog:
   - Select the compartment that you want for the Amazon S3 Compatibility API Designated Compartment.
   - Select the compartment that you want for the Swift API Designated Compartment.
4. Click Save.

   The new Object Storage Settings are displayed.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To get your tenancy's Amazon S3 Compatibility API and Swift API compartment designations**

Use this CLI command to display metadata associated with the Amazon S3 and Swift compartments for the specified namespace in your tenancy.

```
oci os ns get-metadata --namespace <object_storage_namespace>
```

For example:

```
oci os ns get-metadata --namespace MyNamespace
{
   "data": {
      "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "namespace": "MyNamespace"
   }
}
```

**To update your tenancy's Amazon S3 Compatibility API compartment designation**

Use this CLI command to specify the default Amazon S3 compartment for the specified namespace in your tenancy.

```
oci os ns update-metadata --namespace <object_storage_namespace> --default-s3-compartment-id <your_oci_compartment_id>
```
<your_oci_compartment_id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```bash
oci os ns update-metadata --namespace MyNamespace --default-s3-compartment-id ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "default-swift-compartment-id": null,
    "namespace": null
  }
}
```

To update your tenancy's Swift API compartment designations

Use this CLI command to specify the default Swift compartment for the specified namespace in your tenancy.

```bash
oci os ns update-metadata --namespace <object_storage_namespace> --default-swift-compartment-id <your_oci_compartment_id>
```

<your_oci_compartment_id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```bash
oci os ns update-metadata --namespace MyNamespace --default-swift-compartment-id ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "default-s3-compartment-id": null,
    "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "namespace": null
  }
}
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operation to get your default Amazon S3 Compatibility API and Swift API compartment designations, and change those compartment designations:

- GetNamespaceMetadata
- UpdateNamespaceMetadata

Object Storage Metrics

You can monitor the health, capacity, and performance of your buckets and objects by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_objectstorage (the Object Storage service).

Resources include buckets and objects.

Overview of the Object Storage Service Metrics

Object Storage can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos. The Object Storage service metrics help you measure the amount of storage you're using. You can also use these metrics to monitor the performance of requests in terms of latency and utilization as measured by counts of requests made per bucket.
**Required IAM Policy**

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_objectstorage**

The metrics listed in the following tables are automatically available for any buckets you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have an object stored in a bucket to get any metrics. Buckets with no objects emit no metric data.

Each metric includes the following dimensions:

**RESOURCEID**

The OCID of the bucket to which the metric applies.

**RESOURCEDISPLAYNAME**

The name of the bucket.

**TIER**

The storage tier (standard or archive) where the object resides.

**Default Metrics**

The following default metric charts are available for each Object Storage bucket from the bucket details page. See To view default metric charts for a bucket.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjectCount</td>
<td>Number of Objects</td>
<td>count</td>
<td>The count of objects in the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
<td>resourceID resourceDisplayName tier</td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description/ Emit Frequency</td>
<td>Dimensions</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------</td>
<td>--------</td>
<td>--------------------------------------------------------------------------------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>StoredBytes</td>
<td>Bucket Size</td>
<td>bytes</td>
<td>The size of the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
<td></td>
</tr>
</tbody>
</table>

**Custom Query Metrics**

The following custom query metric charts are available using Metrics Explorer. See To view custom query metric charts using Metrics Explorer on page 3503.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllRequests</td>
<td>All Requests Count</td>
<td>count</td>
<td>The total number of all HTTP requests made in a bucket. Emit frequency: every 100 ms</td>
<td>resourceID</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>resourceDisplayName</td>
</tr>
<tr>
<td>ClientErrors</td>
<td>Client-Side Error Count</td>
<td>count</td>
<td>The total number of 4xx errors for requests made in a bucket. Emit frequency: every 100 ms</td>
<td></td>
</tr>
</tbody>
</table>
| EnabledOLM     | Enabled Object Lifecycle Management | count | Indicates whether a bucket has any executable Object Lifecycle Management policies configured. EnabledOLM emits:  
• 1 if policies are configured  
• 0 if no policies are configured  
Emit frequency: every 3 hours |                                  |
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FirstByteLatency</td>
<td>First Byte Latency Time</td>
<td>time (ms)</td>
<td>The per-request time measured from the time Object Storage receives the complete request to when Object Storage returns the first byte of the response. Emit frequency: every 100 ms</td>
<td></td>
</tr>
<tr>
<td>PostRequests</td>
<td>PostObject Request Count</td>
<td>count</td>
<td>The total number of HTTP Post requests made in a bucket. Emit frequency: every 100 ms</td>
<td></td>
</tr>
<tr>
<td>PutRequests</td>
<td>PutObject Request Count</td>
<td>count</td>
<td>The total number of PutObject requests made in a bucket. Emit frequency: every 100 ms</td>
<td></td>
</tr>
<tr>
<td>TotalRequestLatency</td>
<td>Overall Latency Time</td>
<td>time (ms)</td>
<td>The per-request time from the first byte received by Object Storage to the last byte sent from Object Storage. Emit frequency: every 100 ms</td>
<td></td>
</tr>
<tr>
<td>UncommittedParts</td>
<td>Incomplete MultiPart Upload Size</td>
<td>bytes</td>
<td>The size of any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
<td>resourceID, resourceDisplayName, tier</td>
</tr>
</tbody>
</table>
Using the Console
To view default metric charts for a bucket
1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the Compartment that contains the bucket you want to view, and then click the bucket's name.
3. In the Resources menu, click Metrics.

The Metrics page displays a default set of charts for the current bucket.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts by dimension
1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Metric Namespace, select oci_objectstorage.
3. For Dimensions, click Add.
4. For Dimension Name, select a dimension and then select a Dimension Value.

Add more dimensions as needed.
5. Click Done.

The Service Metrics page displays a default set of charts for the selected metric namespace and dimension. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view custom query metric charts using Metrics Explorer
1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.

The Metrics Explorer page displays an empty chart with fields to build a query.
2. Select a compartment.
3. From Metric Namespace, select oci_objectstorage.
4. From Metric Name, select a metric.
5. (Optional) Refine your query.
   For instructions, see To create a query on page 2702.
6. Click Update Chart.

The chart shows the results of your new query. You can optionally add more queries by clicking Add Query below the chart.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:
- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Accessing Object Storage Resources Across Tenancies

This topic describes how to write policies that let your tenancy access Object Storage resources in other tenancies.
If you're new to policies, see Getting Started with Policies on page 2135 and Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

Cross-Tenancy Policies

Your organization might also want to share resources with another organization that has its own tenancy. It could be another business unit in your company, a customer of your company, a company that provides services to your company, and so on. In cases like these, you need cross-tenancy policies in addition to the required user and service policies described previously.

To access and share resources, the administrators of both tenancies need to create special policy statements that explicitly state the resources that can be accessed and shared. These special statements use the words Define, Endorse, and Admit.

Endorse, Admit, and Define Statements

Here's an overview of the special verbs used in cross-tenancy statements:

- **Endorse**: States the general set of abilities that a group in your own tenancy can perform in other tenancies. The Endorse statement always belongs in the tenancy with the group of users crossing the boundaries into the other tenancy to work with that tenancy's resources. In the examples, we refer to this tenancy as the source.

- **Admit**: States the kind of ability in your own tenancy that you want to grant a group from the other tenancy. The Admit statement belongs in the tenancy who is granting "admittance" to the tenancy. The Admit statement identifies the group of users that requires resource access from the source tenancy and identified with a corresponding Endorse statement. In the examples, we refer to this tenancy as the destination.

- **Define**: Assigns an alias to a tenancy OCID for Endorse and Admit policy statements. A Define statement is also required in the destination tenancy to assign an alias to the source IAM group OCID for Admit statements. Define statements must be included in the same policy entity as the endorse or the admit statement.

The Endorse and Admit statements work together, but they reside in separate policies, one in each tenancy. Without a corresponding statement that specifies access, a particular Endorse or Admit statement grants no access. Agreement is required from both tenancies.

Source tenancy policy statements

The source administrator creates policy statements that endorse a source IAM group allowed to manage resources in the destination tenancy.

Here is an example of a broad policy statement that endorses the IAM group StorageAdmins group to do anything with all Object Storage resources in any tenancy:

```plaintext
Endorse group StorageAdmins to manage object-family in any-tenancy
```

To write a policy that reduces the scope of tenancy access, the destination administrator must provide the destination tenancy OCID. Here is an example of policy statements that endorse the IAM group StorageAdmins group to manage Object Storage resources in the DestinationTenancy only:

```plaintext
Define tenancy DestinationTenancy as ocid1.tenancy.oc1..<unique_ID>
Endorse group StorageAdmins to manage object-family in tenancy DestinationTenancy
```

Destination tenancy policy statements

The destination administrator creates policy statements that:

- Defines the source tenancy and IAM group that is allowed to access resources in your tenancy. The source administrator must provide this information.

- Admits those defined sources to access Object Storage resources that you want to allow access to in your tenancy.
Here is an example of policy statements that endorse the IAM group StorageAdmins in the source tenancy to do anything with all Object Storage resources in your tenancy:

```
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StorageAdmins as ocid1.group.oc1..<unique_ID>
Admit group StorageAdmins of tenancy SourceTenancy to manage object-family in tenancy
```

Here is an example of policy statements that endorse the IAM group StorageAdmins in the source tenancy to manage Object Storage resources only the SharedBuckets compartment:

```
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StorageAdmins as ocid1.group.oc1..<unique_ID>
Admit group StorageAdmins of tenancy SourceTenancy to manage object-family in compartment SharedBuckets
```

**Hadoop Support**

Using the HDFS connector, you can run Hadoop or Spark jobs against data in the Oracle Cloud Infrastructure Object Storage service. The connector has the following features:

- Supports read and write data stored in Object Storage
- Is compatible with existing buckets of data
- Is compatible with Hadoop 2.7.2

For information about downloading, configuring, and using the HDFS connector, see [HDFS Connector for Object Storage](#) on page 4347.
Chapter 29

Registry

This chapter explains how to store, share, and manage development artifacts like Docker images in an Oracle-managed registry.

Overview of Registry

Oracle Cloud Infrastructure Registry is an Oracle-managed registry that enables you to simplify your development to production workflow. Oracle Cloud Infrastructure Registry makes it easy for you as a developer to store, share, and manage development artifacts like Docker images. And the highly available and scalable architecture of Oracle Cloud Infrastructure ensures you can reliably deploy your applications. So you don't have to worry about operational issues, or scaling the underlying infrastructure.

You can use Oracle Cloud Infrastructure Registry as a private Docker registry for internal use, pushing and pulling Docker images to and from the Registry using the Docker V2 API and the standard Docker command line interface (CLI). You can also use Oracle Cloud Infrastructure Registry as a public Docker registry, enabling any user with internet access and knowledge of the appropriate URL to pull images from public repositories in Oracle Cloud Infrastructure Registry.

Oracle Cloud Infrastructure Registry supports private access from other Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) in the same region through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as worker nodes in clusters managed by Container Engine for Kubernetes) access Oracle Cloud Infrastructure services such as Oracle Cloud Infrastructure Registry without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway on page 3256.

Oracle Cloud Infrastructure Registry is integrated with IAM, which provides easy authentication with native Oracle Cloud Infrastructure identity.

For an introductory tutorial, see Pushing an Image to Oracle Cloud Infrastructure Registry.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

Note that Oracle Cloud Infrastructure Registry fully implements a Docker protocol that enables you to use the Docker Registry HTTP API (as well as the Oracle Cloud Infrastructure API) to manage images. See Preparing for Registry...
on page 3507 for the list of regional endpoints, and see the Docker documentation for information about using the Docker Registry HTTP API.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Registry Capabilities and Limits**

In each region that is enabled for your tenancy, you can create up to 500 repositories in Oracle Cloud Infrastructure Registry consuming a maximum of 500 GB in total (if you need more storage, Contact Us). Each repository can hold up to 100,000 images. See Service Limits on page 215.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Oracle Cloud Infrastructure Registry, see:

- Policies to Control Repository Access on page 3527
- Details for Registry on page 2335

**Preparing for Registry**

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry:

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Registry is available (see Availability by Region on page 3508).
- You must have access to the Docker CLI (for example, to push and pull images on a local machine, you'll need to have installed Docker on the local machine).
- You must either belong to a group to which a policy grants the appropriate permissions, or belong to the tenancy's Administrators group. See Policies to Control Repository Access on page 3527.
- You must have an Oracle Cloud Infrastructure auth token. If you don't have an auth token already, see Getting an Auth Token on page 3527.
Registry

Availability by Region

Registry is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 180. Refer to that topic to see region identifiers, region keys, and availability domain names.

Note that Oracle Cloud Infrastructure Registry fully implements a Docker protocol that enables you to use the Docker Registry HTTP API (as well as the Oracle Cloud Infrastructure API) to manage images at the regional endpoints below. See the Docker documentation for information about using the Docker Registry HTTP API.

<table>
<thead>
<tr>

Registry Concepts

This topic describes key concepts you need to understand when using Oracle Cloud Infrastructure Registry.

Images

You can store, share, and manage Docker images in Oracle Cloud Infrastructure Registry. A Docker image is a read-only template with instructions for creating a Docker container. A Docker image holds the application that you want Docker to run as a container, along with any dependencies. To create a Docker image, you first create a Dockerfile to describe that application. You then build the Docker image from the Dockerfile. Having created a Docker image, you store it in a Docker registry such as Oracle Cloud Infrastructure Registry.

Typically, you’ll group together different versions of the same Docker image into a named repository in the registry (for example, into a repository named 'project01/acme-web-app'), and give each image version a different tag (for example, '4.6.3'). So each image in the registry is uniquely identified by the combination of its repository name and its tag (for example, 'project01/acme-web-app:4.6.3', 'project01/acme-web-app:4.6.4', and so on).

Repositories

A repository is a meaningfully named collection of related images grouped together for convenience in Oracle Cloud Infrastructure Registry. Typically, you’ll group together different versions of the same source image into the same repository (for example, into a repository named project01/acme-web-app), and give each image version a different tag (for example, 4.6.3). So each image in the registry is uniquely identified by the combination of its repository name and its tag (for example, project01/acme-web-app:4.6.3, project01/acme-web-app:4.6.4, and so on).

Repositories can be private or public. Any user with internet access and knowledge of the appropriate URL can pull images from a public repository in Oracle Cloud Infrastructure Registry.
A repository exists within a particular tenancy, region, and compartment. When referring to the tenancy that owns a repository, you specify the tenancy's namespace. The tenancy namespace is an auto-generated random string of alphanumeric characters. For example, the namespace of the `acme-dev` tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). To find out the tenancy namespace of the current tenancy, open the Profile menu and click Tenancy:

You must belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission to:

- create a new public repository
- change an existing repository into a public repository
- change an existing public repository into a private repository

If you make a repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository. You can use identity policies to allow other users to perform other operations on repositories (both public and private) that you create.

Usually, before pushing any images, you'll create an empty repository in a compartment and give the repository a name (for example, `project01/acme-web-app`). If you belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission, you can also specify whether the repository is to be private or public (see Policies to Control Repository Access on page 3527). Having created the repository, images you subsequently push to Oracle Cloud Infrastructure Registry that include the repository name are pushed to that repository.

For example, for convenience you might want to group together multiple versions of an image in the `acme-dev` tenancy in the Ashburn region into the repository called `project01/acme-web-app`. First, you create the `project01/acme-web-app` repository. Then, you include the name of the repository when you push the image, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. For example, `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:4.6.3`.

Note that creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the root compartment, creating an empty repository in advance is not strictly necessary. For more information, see Notes about Repository Creation on page 3513.

### Terminology Summary

When working with repositories in Oracle Cloud Infrastructure Registry, you'll find it helpful to have a clear understanding of the following terms and how they relate to each other.

**Repository path**

A repository path (sometimes referred to as `<repo-path>` in this documentation) is the fully-qualified path to a repository in Oracle Cloud Infrastructure Registry. It has the following structure:

```
<region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

For example:

- `iad.ocir.io/ansh81vru1zp/project01/acme-web-app`
- `us-phoenix-1.ocir.io/cbujsx0t3wa3r/my-hello-app`

**Region key**

A region key (sometimes referred to as `<region-key>` in this documentation) identifies the Oracle Cloud Infrastructure Registry region you are using.

For example:

- `iad.ocir.io`
Registry

- us-phoenix-1.ocir.io

For the list of region keys, see Availability by Region on page 3508.

tenancy namespace

A tenancy namespace (sometimes referred to as `<tenancy-namespace>` in this documentation) is an auto-generated, random, and immutable string of alphanumeric characters. For example, the namespace of the acme-dev tenancy might be ansh81vru1zp.

Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lowercase letters (for example, acme-dev). To find out the tenancy namespace of the current tenancy, open the Profile menu (<tenancy-namespace>) and click Tenancy: The tenancy namespace is shown in the Object Storage Namespace field.

repository name

A repository name (sometimes referred to as `<repo-name>` in this documentation) is the name of a repository in Oracle Cloud Infrastructure Registry, to and from which you can push and pull images. Repository names can include one or more slash characters, and are unique across all compartments in the entire tenancy.

For example:

- project01/acme-web-app
- project01/my-test-app
- my-hello-app
- project01/acme-web-app/component1
- project01/acme-web-app/component2
- project01/acme-web-app/component1/subcomponent1

Note that although a repository name can include slash characters, the slash does not represent a hierarchical directory structure. It is simply one character in a string of characters. As a convenience, you might choose to start the names of several different repositories with the same string, perhaps ending in a slash (such as project01/). Such a string is sometimes called a 'repository name prefix'. But a repository named project01/acme-web-app need not have any relationship with a repository named project01/my-test-app. Using the same repository name prefix for some repositories simply makes it easier to organize and control access to them in Oracle Cloud Infrastructure Registry, which can contain many other repositories.

registry identifier

A registry identifier is an Oracle Cloud Infrastructure Registry region key and a tenancy namespace. It has the following structure:

```text
<region-key>.ocir.io/<tenancy-namespace>
```

For example:

- iad.ocir.io/ansh81vru1zp
- us-phoenix-1.ocir.io/cbujsx0t3wa3r

image path

An image path is the fully-qualified path to a particular image in a registry. It extends the repository path by adding the tag associated with the image. It has the structure:

```text
<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>
```

For example:

- iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
• us-phoenix-1.ocir.io/cbuwx0t3wa3r/my-hello-app:latest

tag

A tag or image tag (sometimes referred to as \texttt{<tag>} in this documentation) is a string used to refer to a particular image in a known repository. For example:

• 4.6.3
• 4.6.4
• version2.0.test

image name

The term 'image name' is sometimes used as a short-hand way to refer to a particular image in a particular repository. In this context, an image name has the structure:

\texttt{<repo-name>:<tag>}

For example:

• project01/acme-web-app:4.6.3
• project01/acme-web-app:4.6.4
• my-hello-app:latest

Creating a Repository

Using Oracle Cloud Infrastructure Registry, you can create an empty repository in a compartment and give it a name that's unique across all compartments in the entire tenancy.

Having created the new repository, you can push an image to the repository using the Docker CLI (see Pushing Images Using the Docker CLI on page 3513). Any images you subsequently push to the registry that include the same repository name are grouped into that repository.

Note that creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the root compartment, creating an empty repository in advance is not strictly necessary. For more information, see Notes about Repository Creation on page 3513.

Using the Console

To create a repository in Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the region in which to create the repository.
3. Choose a Compartment you have permission to work in.
4. Click Create Repository.
5. In the Create Repository dialog box, specify details for the new repository:

   • **Compartment**: The compartment in which to create the new repository. The default compartment is the one you selected previously, but you can select any compartment that you have permission to work in.

   • **Repository Name**: A name of your choice for the new repository. The name you enter must be unique across all compartments in the entire tenancy. Avoid entering confidential information.

   • **Public**: Whether the new repository will be a public repository or a private repository. You can only make the new repository public if you belong to the tenancy’s Administrators group or have been granted the REPOSITORY_MANAGE permission. If you make the new repository public, any user with internet access and knowledge of the appropriate URL will be able to pull images from the repository. If you make the repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository.
6. Click **Create Repository**.

7. (Optional) If you want to automatically create new private repositories in the tenancy’s root compartment when docker push commands don't include the name of an existing repository:

   a. Click **Settings**, and then select **General**.

   b. Select **Create repositories on first push in root compartment** to automatically create a new private repository in the tenancy's root compartment if the repository referenced in a docker push command doesn't already exist.

For more information about creating a new repository if the repository referenced in a docker push command doesn't already exist, see **Notes about Repository Creation** on page 3513.

### Using the CLI

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

#### To create a repository

```
oci artifacts container repository create --display-name <repo-name> --compartment-id <compartment_ocid>
```

For example:

```
oci artifacts container repository create --display-name project01/acme-web-app --compartment-id ocid1.compartment.oc1..aaaaaaaarvdfa72n...
```

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **CreateContainerRepository** operation to create a repository.

### Notes about Repository Creation

Creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the tenancy's root compartment, creating an empty repository in advance is not strictly necessary.

When you push an image, you normally use a command in the format `docker push <region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. However, if you select the **Create repositories on first push in root compartment** option and push an image with a command that includes the name of a repository that doesn't already exist, a new private repository is created automatically in the root compartment.

For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/project02/acme-web-app:7.5.2` and the `project02/acme-web-app` repository doesn't exist, a private repository called `project02/acme-web-app` is created automatically in the root compartment.

Note that you must belong to the tenancy's Administrators group or have been granted the **REPOSITORY_MANAGE** permission on the tenancy to create the new private repository in the tenancy's root compartment. See **Policies to Control Repository Access** on page 3527.

### Pushing Images Using the Docker CLI

You use the Docker CLI to push images to Oracle Cloud Infrastructure Registry.

To push an image, you first use the `docker tag` command to create a copy of the local source image as a new image (the new image is actually just a reference to the existing source image). As a name for the new image, you
Registry

specify the fully qualified path to the target location in Oracle Cloud Infrastructure Registry where you want to push the image, including the name of a repository.

For example, assume you have a local image named acme-web-app:latest (the image name comprising the repository name of acme-web-app, and the image tag of latest). Let's say you want to push this image to Oracle Cloud Infrastructure Registry into a repository called project01/acme-web-app with an image tag of version2.0.test, in the Ashburn region of the acme-dev tenancy. When you use the `docker tag` command, you'd name the new image with the fully qualified path to its destination, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. So in this case, you'd name the new image `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`. Subsequently, when you use the `docker push` command, the image's name ensures it is pushed to the correct destination.

Your permissions control the images you can push to Oracle Cloud Infrastructure Registry (see Policies to Control Repository Access on page 3527). You can push images to repositories you've created (see Creating a Repository on page 3512). You can also push images to repositories that the groups to which you belong have been granted access by appropriate identity policies. If you belong to the Administrators group, you can push images to any repository in the tenancy.

Note that the instructions in this topic assume that the repository to which you want to push images already exists. That will usually be the case, but need not always be so (see Notes about Repository Creation on page 3513).

To push images to Oracle Cloud Infrastructure Registry using the Docker CLI:

1. If you already have an auth token, go to the next step. Otherwise:
   a. In the top-right corner of the Console, open the Profile menu (.userdetails) and then click User Settings to view the details.
   b. On the Auth Tokens page, click Generate Token.
   c. Enter a friendly description for the auth token. Avoid entering confidential information.
   d. Click Generate Token. The new auth token is displayed.
   e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won’t see the auth token again in the Console.
   f. Close the Generate Token dialog.
2. In a terminal window on the client machine running Docker, log in to Oracle Cloud Infrastructure Registry by entering `docker login <region-key>.ocir.io`, where `<region-key>` corresponds to the key for the Oracle Cloud Infrastructure Registry region you’re using. For example, `docker login iad.ocir.io`. See Availability by Region on page 3508.
3. When prompted for a username, enter your username in the format `<tenancy-namespace>/jdoe@acme.com`. For example, `ansh81vru1zp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.
4. When prompted for a password, enter the auth token you copied earlier.
5. Locate the image on the client machine that you want to push:
   a. In a terminal window on your client machine, enter `docker images` to list the available images.

For example:

```
$ docker images
REPOSITORY       TAG          IMAGE ID       CREATED          SIZE
acme-web-app      latest       8e0506e14874  2 hours ago     162.6 MB
acme-web-app      version1.0   7d9495d03763  2 hours ago     162.6 MB
<none>            <none>       6ebd328f833d  5 hours ago     162.6 MB
hello-world       latest       80b84820d442  5 weeks ago     890 B
```
b. Find the local image on the client machine that you want to push to Oracle Cloud Infrastructure Registry.

In the output of the `docker images` command, look for the specific image that you want to push. You'll need to uniquely identify this image later, in one of the following ways:

- using its id
- using its image name (its repository name and image tag separated by a colon)

For example, on the client machine you might have an acme-web-app image. In the output of the `docker images` command, look for the specific acme-web-app image that you want to push. You can uniquely identify that particular image in one of the following ways:

- using its id (for example, 8e0506e14874)
- using its image name (its repository name and image tag separated by a colon, for example `acme-web-app:latest`)

c. Use the `docker tag` command to create a copy of the original image as a new image (the new image is actually just a reference to the existing original image). As a name (or tag) for the new image, you specify the fully qualified path to the target location in Oracle Cloud Registry where you want to push the image, by entering:

```
docker tag <image-identifier> <target-tag>
```

where:

- `<image-identifier>` uniquely identifies the original image, either using the image's id (for example, 8e0506e14874), or the image's name (its original repository name and image tag separated by a colon, for example `acme-web-app:latest`).
- `<target-tag>` is the fully qualified path to the target location in Oracle Cloud Infrastructure Registry where you want to push the image, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>` where:
  - `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, iad. See Availability by Region on page 3508.
  - `ocir.io` is the Oracle Cloud Infrastructure Registry name.
  - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository to which you want to push the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
  - `<repo-name>` is the name of the target repository to which you want to push the image (for example, `project01/acme-web-app`). Note that you'll usually specify a repository that already exists, but that need not always be the case (see Notes about Repository Creation on page 3513).
  - `<tag>` is an image tag you want to give the image in Oracle Cloud Infrastructure Registry (for example, `version2.0.test`).

For example, combining the previous examples, you might enter:

```
docker tag 8e0506e14874 iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

6. Confirm that the Docker image has been correctly tagged on the client machine by entering `docker images` and verifying that the list of images includes an image with the tag you specified.

For example:

```
$ docker images
REPOSITORY TAG IMAGE ID CREATED SIZE
Oracle Cloud Infrastructure User Guide 3515
```
Push the Docker image from the client machine to Oracle Cloud Infrastructure Registry by entering:

```
docker push <target-tag>
```

where `<target-tag>` is in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>` where:

- `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region on page 3508.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository to which you want to push the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
- `<repo-name>` is the name of the target repository to which you want to push the image (for example, `project01/acme-web-app`). Note that you'll usually specify a repository that already exists, but that need not always be the case (see Notes about Repository Creation on page 3513).
- `<tag>` is an image tag you want to give the image in Oracle Cloud Infrastructure Registry (for example, `version2.0.test`).

For example:

```
docker push iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

### Pulling Images Using the Docker CLI

You use the Docker CLI to pull images from Oracle Cloud Infrastructure Registry.

Your permissions control the images you can pull from Oracle Cloud Infrastructure Registry (see Policies to Control Repository Access on page 3527). You can pull images from repositories you've created, from public repositories, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can pull images from any repository in the tenancy.

To pull images from Oracle Cloud Infrastructure Registry using the Docker CLI:

1. If you already have an auth token, go to the next step. Otherwise:

   a. In the top-right corner of the Console, open the Profile menu and then click User Settings to view the details.
   b. On the Auth Tokens page, click Generate Token.
   c. Enter a friendly description for the auth token. Avoid entering confidential information.
   d. Click Generate Token. The new auth token is displayed.
   e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
   f. Close the Generate Token dialog.
2. In a terminal window on the client machine running Docker, log in to Oracle Cloud Infrastructure Registry by entering `docker login <region-key>.ocir.io`, where `<region-key>` corresponds to the key for the Oracle Cloud Infrastructure Registry region you're using. For example, `docker login iad.ocir.io`. See **Availability by Region** on page 3508.

3. When prompted for a username, enter your username in the format `<tenancy-namespace>/<username>`, where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of your tenancy (as shown on the **Tenancy Information** page). For example, `ansh81vru1zp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.

4. When prompted for a password, enter the auth token you copied earlier.

5. Pull the Docker image from Oracle Cloud Infrastructure Registry to the client machine by entering:

```
docker pull <region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>
```

where:
- `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See **Availability by Region** on page 3508.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository from which you want to pull the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
- `<repo-name>` is the name of a repository from which you want to pull the image (for example, `project01/acme-web-app`). Note that your user must have access to the repository (see **Repositories** on page 3509).
- `<tag>` is the tag of the image that you want to pull from Oracle Cloud Infrastructure Registry (for example, `version2.0.test`).

For example:

```
docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

Note that if you don't specify a `<tag>` in the `docker pull` command, Docker pulls the image that has the latest tag.

6. Confirm that the image has been pulled from Oracle Cloud Infrastructure Registry by entering `docker images` and verifying that the list of images on the client machine now includes the image you just pulled.

For example:

```
$ docker images
REPOSITORY                                      TAG                 IMAGE ID          CREATED       SIZE
iad.ocir.io/ansh81vru1zp/project01/acme-web-app version2.0.test 8e0506e14874      1 minute ago  162.6 MB
acme-web-app                                    latest 8e0506e14874      2 hours ago   162.6 MB
acme-web-app                                    version1.0 7d9495d03763      2 hours ago   162.6 MB
<none>                                          <none> 6ebd328f833d      5 hours ago   162.6 MB
hello-world                                     latest 80b84820d442      5 weeks ago   890 B
```
Pulling Images from Registry during Kubernetes Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry, you have to perform two steps:

1. You have to use kubectl to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of kubectl (see the kubectl documentation).
2. You have to specify the image to pull from Oracle Cloud Infrastructure Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.
2. In a terminal window, enter:

```bash
kubectl create secret docker-registry <secret-name> --docker-server=<region-key>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>
```

where:

- `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret. For example, ocirsecret
- `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, iad. See Availability by Region on page 3508.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be ansh81vrulzp. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).
- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-namespace>`. For example, jdoe@acme.com. If your tenancy is federated with Oracle Identity Cloud Service, use the format oracleidentitycloudservice/<oci-username>
- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, k\]j64r(1sJSSF-;)K8
- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, jdoe@acme.com

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```bash
kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vrulzp/jdoe@acme.com' --docker-password='k\]j64r(1sJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.
To specify the image to pull from Oracle Cloud Infrastructure Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Oracle Cloud Infrastructure Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Oracle Cloud Infrastructure Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: ngnix-image
spec:
  containers:
    - name: ngnix
      image: phx.ocir.io/ansh81vru1zp/project01/ngnix-lb:latest
      imagePullPolicy: Always
      ports:
        - name: nginx
          containerPort: 8080
          protocol: TCP
      imagePullSecrets:
        - name: ocirsecret
```

3. Save and close the manifest file.

### Viewing Images and Image Details

To make sure you pull the correct image or to identify images that you no longer need, you can find out detailed information about the images in Oracle Cloud Infrastructure Registry.

Your permissions control the images in Oracle Cloud Infrastructure Registry that you can view information about (see Policies to Control Repository Access on page 3527). You can view information about images in repositories you've created, and in repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can view information about images in any repository in the tenancy.

#### Using the Console

To view images and image details:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of the repository that contains the image you want to see detailed information about. You see all the different images in the repository, along with the tag of each image and when it was pushed to the registry. You can sort the different images by the date they were pushed or by their tag.
5. Click the image for which you want to see detailed information. The Summary page shows you the size of the image, when it was pushed and by which user, and the number of times the image has been pulled. Use the options on the Summary page as follows:
   - Display the Layers tab to see the SHA message digest of each layer in the selected image.
   - Display the Associated Tags tab to see the full path for the image with the tag you select. Note that if you select a different tag, the summary details change accordingly.
6. (Optional) If you want to pull an image, select **Copy Pull Command** from the **Actions** menu button. The command you copy includes the fully qualified path to the image's location in Oracle Cloud Infrastructure Registry, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. For example, `docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`. See **Pulling Images Using the Docker CLI** on page 3516.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

To view details of an image

```
oci artifacts container image get --image-id <image-ocid>
```

For example:

```
oci artifacts container image get --image-id
ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaaalqzjyks...
```

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225. Use the **ListContainerImages** and **GetContainerImage** operations to see image details.

**Deleting and Undeleting an Image**

When you no longer need an old image or you simply want to clean up the list of image tags in a repository, you can delete images from Oracle Cloud Infrastructure Registry.

Your permissions control the images in Oracle Cloud Infrastructure Registry that you can delete (see **Policies to Control Repository Access** on page 3527). You can delete images from repositories you've created, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete images from any repository in the tenancy.

You can undelete an image you've previously deleted, for up to 48 hours after you deleted it. After that time, the image is permanently removed from Oracle Cloud Infrastructure Registry. You use the Oracle Cloud Infrastructure REST API and CLI to undelete images.

In addition to deleting individual images as described below, you can set up image retention policies to delete images automatically based on selection criteria you specify (see **Retaining and Deleting Images Using Retention Policies** on page 3522).

Note that when you delete an image, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting images to release storage, remember that you can also **Contact Us** to obtain more storage.

**Using the Console**

To delete an image from Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Registry**.
2. Choose the registry's region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository from which to delete the image.
5. Click the name of the image that you want to delete.
6. Select **Delete Image** from the **Actions** menu and confirm that you want to delete the image.
You can undelete an image you've previously deleted, for up to 48 hours after you deleted it. After that time, the image is permanently removed from Oracle Cloud Infrastructure Registry.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To delete an image**

```
oci artifacts container image delete --image-id <image-ocid>
```

For example:

```
oci artifacts container image delete --image-id
ocid1.containerimage.oc1.phx.0.ansh81vrulzp.aaaaaaaaalqzjyks...
```

**To undelete an image**

```
oci artifacts container image restore --image-id <image-ocid>
```

For example:

```
oci artifacts container image restore --image-id
ocid1.containerimage.oc1.phx.0.ansh81vrulzp.aaaaaaaaalqzjyks...
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the DeleteContainerImage operation to delete an image.

Use the RestoreContainerImage operation to undelete an image you've previously deleted.

**Untagging Images**

When you want to clean up the list of images in a repository without actually deleting images, you can remove the tags from images in Oracle Cloud Infrastructure Registry (known as 'untagging').

Your permissions control the images in Oracle Cloud Infrastructure Registry that you can untag (see Policies to Control Repository Access on page 3527). You can untag images in repositories you've created, and images in repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can untag images in any repository in the tenancy.

**Using the Console**

To untag an image in Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of the repository containing the image you want to untag.
5. Click the name of the image that you want to untag.
6. Click the tag that you want to remove, select Remove tag from the Actions menu, and confirm that you want to remove the tag.
Tip:
To view the untagged images in a repository, click the name of the repository and then select Untagged under Image Filter.

Using the CLI
For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To untag an image

```bash
oci artifacts container image remove-version --image-id <image-ocid> --image-version <version>
```

For example:

```bash
oci artifacts container image remove-version --image-id ocid1.containerimage.oc1.phx.0.ansh81vrulzp.aaaaaaalqzjyks... --image-version 1.0
```

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the RemoveContainerVersion operation to untag an image.

Retaining and Deleting Images Using Retention Policies
You can set up image retention policies to automatically delete images that meet particular selection criteria, namely:

- images that have not been pulled for a certain number of days
- images that have not been tagged for a certain number of days
- images that have not been given particular Docker tags specified as exempt from automatic deletion

An hourly process checks images against the selection criteria, and any that meet the selection criteria are automatically deleted.

You'll often find image retention policies are a more convenient way to manage the images in a repository than manually deleting individual images (see Deleting and Undeleting an Image on page 3520).

In each region in a tenancy, there's a global image retention policy. The global image retention policy's default selection criteria retain all images, so that no images are automatically deleted. However, you can change the global image retention policy so that images are deleted if they meet the criteria you specify. A region's global image retention policy applies to all repositories in the region, unless it is explicitly overridden by one or more custom image retention policies.

You can set up custom image retention policies to override the global image retention policy with different criteria for specific repositories in a region. Having created a custom image retention policy, you apply the custom retention policy to a repository by adding the repository to the policy. The global image retention policy no longer applies to repositories that you add to a custom retention policy.

If you have manage permission on the tenancy, you can:

- modify each region's own global image retention policy
- create new custom image retention policies
- modify the criteria of existing custom image retention policies
- delete custom image retention policies

If you have manage permission on a repository, you can:
• add the repository to a custom image retention policy
• remove the repository from a custom image retention policy

Note the following:
• Only one custom image retention policy at a time can apply to a repository. If a repository has already been added to a custom retention policy and you want to add the repository to a different custom retention policy, you have to remove the policy from the first retention policy before adding it to the second.
• When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.
• The global image retention policy (and any custom image retention policies you create) are specific to a particular region. To delete images consistently in different regions in your tenancy, set up image retention policies in each region with identical selection criteria.
• When you delete an image, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting images to release storage, remember that you can also Contact Us to obtain more storage.

Using the Console to Edit the Global Image Retention Policy

Provided you have manage permission on the tenancy, you can edit the region’s global image retention policy that applies to all repositories in a region (except for repositories that have been explicitly added to a custom image retention policy).

To edit the global image retention policy:
1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry’s region.
3. Click Settings, and then select Image retention policies.
   You see the current selection criteria of the region’s global image retention policy, along with any custom image retention policies that override the global image retention policy for specific repositories.
4. Click Edit Global Policy.
5. In the Global Image Retention Policy dialog, specify new criteria for the global retention policy:
   • Delete any images that haven't been pulled in n days: Select this option if you want to delete images that have not been pulled for the number of days you specify.
   • Delete any images that haven't been tagged in n days: Select this option if you want to delete images that have not been tagged for the number of days you specify.
   • Exempt Tags: If you want to prevent images from being deleted on the basis of Docker tags they’ve been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify latest,prod-*,*-tail,*.100.*.
6. Click Save Settings.

Going forward, the criteria you entered for the region’s global image retention policy will apply to all repositories in the region, except for repositories that have been explicitly added to a custom image retention policy. Images in repositories that have not been added to a custom image retention policy will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria you specified in the global image retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.
Using the Console to Create a New Custom Image Retention Policy to Override the Global Policy

Provided you have manage permission on the tenancy, you can create a new custom image retention policy to override the region's global image retention policy for the repositories you specify. A custom image retention policy is specific to the region in which you create it.

To create a new custom image retention policy:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.
   
   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.
4. Click Create Policy.
5. In the Create Repository Image Retention Policy dialog, specify criteria for the new retention policy:
   
   • Policy Name: A name of your choice for the policy. Avoid entering confidential information.
   • Delete any images that haven't been pulled in $n$ days: Select this option if you want to delete images that have not been pulled for the number of days you specify.
   • Delete any images that haven't been tagged in $n$ days: Select this option if you want to delete images that have not been tagged for the number of days you specify.
   • Exempt Tags: If you want to prevent images from being deleted on the basis of Docker tags they’ve been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify latest,prod-*,*-.100.*.
6. Click Save Settings.

You can now add repositories to the new custom retention policy.

Using the Console to Remove a Repository from a Custom Image Retention Policy

Provided you have manage permission on a repository, you can remove a repository from a custom image retention policy to which it was previously added.

You might want to remove the repository from a custom image retention policy:

• if you want the region's global image retention policy to apply to the repository
• if you want a different custom image retention policy to apply to the repository (only one custom image retention policy at a time can apply to a repository)

To remove a repository from a custom image retention policy:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.
   
   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.
4. Locate the custom image retention policy to which the repository has been added.
5. Click the delete icon beside the repository name to remove it from the custom image retention policy.

Going forward, the region's global image retention policy will apply to the repository (unless you add the repository to a different custom image retention policy). The images in the repository will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria specified in the global image retention policy.
When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

**Using the Console to Add a Repository to a Custom Image Retention Policy**

Provided you have manage permission on a repository, you can add a repository to an existing custom image retention policy.

Note that if a custom image retention policy already applies to the repository, you'll have to remove the repository from the current policy before adding it to a different policy. Note also that a custom image retention policy is specific to the region in which it was created.

To add a repository to an existing custom image retention policy:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.

   You see the current selection criteria of the region's global image retention policy, along with the custom image retention policies that have been defined to override the global image retention policy for specific repositories.

4. Locate the custom image retention policy to which you want to add the repository.
5. Click Add Repository and select from the list the repository you want to add to the custom image retention policy.

   Note that the repository list includes all repositories in the region, regardless of whether you have permission to add them to a retention policy. You can only add a repository to a retention policy if you have manage permission on that repository.

   If a repository in the list has a policy name beside it, the repository has already been added to a policy. Before you can add the repository to a different policy, you'll have to remove it from the first policy.

Going forward, the custom retention policy to which you added the repository will override the region's global image retention policy. The images in the repository will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria specified in the custom retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

**Deleting a Repository**

There is a limit to the number of repositories you can have in any given region in a tenancy. So when you no longer need a repository, it makes sense to delete it from Oracle Cloud Infrastructure Registry.

Your permissions control the repositories in Oracle Cloud Infrastructure Registry that you can delete (see Policies to Control Repository Access on page 3527). You can delete repositories you've created, and repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete any repository in the tenancy.

Note that when you delete a repository, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting repositories to release storage, remember that you can also Contact Us to obtain more storage.
Using the Console

To delete a repository from Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Registry**.
2. Choose the registry's region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository that you want to delete.
5. Select **Delete Repository** from the **Actions** menu and confirm that you want to delete the repository.

The repository is permanently removed from Oracle Cloud Infrastructure Registry.

Using the CLI

For information about using the CLI, see [Command Line Interface (CLI)](page 4192). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](page 4225).

To delete a repository

```
oci artifacts container repository delete --repository-id <repository-ocid>
```

For example:

```
oci artifacts container repository delete --repository-id ocid1.containerrepo.oc1.us-phoenix-1.0.ansh81vrulzp.aaaaaaaswec83o...
```

Using the API

For information about using the API and signing requests, see [REST APIs](page 4368) and [Security Credentials](page 179). For information about SDKs, see [Software Development Kits and Command Line Interface](page 4225).

Use the **DeleteContainerRepository** operation to delete a repository.

Moving Repositories Between Compartments

When you create a new repository in Oracle Cloud Infrastructure Registry, you specify the compartment in which to create it. Having created the repository in one compartment, you can subsequently move it to a different compartment. For example, to change the users who are authorized to use the repository, or to change how billing for a repository is charged.

Only users with appropriate permissions can access the repository in the compartment that you move it to.

Your permissions control the repositories in Oracle Cloud Infrastructure Registry that you can move, and the compartments that you can move them to (see [Policies to Control Repository Access](page 3527)). You can move repositories you've created (as well as repositories that the groups to which you belong have been granted access by identity policies) to any compartment to which you have access. If you belong to the Administrators group, you can move any repository in the tenancy to any compartment.

Using the Console

To move a repository in Oracle Cloud Infrastructure Registry from one compartment to another:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Registry**.
2. Choose the registry's region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository that you want to move.
5. Select **Move Compartment** from the **Actions** menu.
6. Select the compartment to which you want to move the repository.
7. Click **Submit** to move the repository.

The repository is moved to the compartment you selected.

Only users with appropriate permissions can now access the repository in the compartment that you’ve moved it to.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To move a repository**

```
oci artifacts container repository change-compartment --compartment-id <compartment_ocid_new> --repository-id <repository_ocid>
```

For example:

```
oci artifacts container repository change-compartment --compartment-id ocid1.compartment.oc1..aaaaaaaaswegb83o... --repository-id ocid1.containerrepo.oc1.us-phoenix-1.0.ansh81vrulzp.aaaaaaatxfd94p...
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the ChangeContainerRepositoryCompartment operation to move a repository to a different compartment.

**Getting an Auth Token**

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry, you must already have an Oracle Cloud Infrastructure username and an auth token. If you haven't got an auth token, or you've forgotten it, or you're not sure, you can create a new auth token. You only see the auth token string when you create it, so be sure to copy the auth token to a secure location immediately.

**Tip:**

Each user can have up to two auth tokens at a time. So if you do lose or forget the auth token, you can always create a second auth token.

To create a new auth token:

1. In the top-right corner of the Console, open the **Profile** menu (👤) and then click **User Settings** to view the details.
2. On the **Auth Tokens** page, click **Generate Token**.
3. Enter a friendly description for the auth token. Avoid entering confidential information.
4. Click **Generate Token**. The new auth token is displayed.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

**Policies to Control Repository Access**

You have fine-grained control over the operations that users are allowed to perform on repositories in Oracle Cloud Infrastructure Registry.

A user's permissions to access repositories comes from the groups to which they belong. The permissions for a group are defined by identity policies. Policies define which actions the members of a group can perform. Users access repositories and perform operations based on the policies set for the groups they are members of. Identity policies
to control repository access can be set at the tenancy and at the compartment level. See Details for Registry on page 2335.

Before you can control access to repositories, you must have already created users and already placed them in appropriate groups (see Managing Users on page 2414 and Managing Groups on page 2419). You can then create policies and policy statements to control repository access (see Managing Policies on page 2450).

Note that users in the tenancy’s Administrators group can perform any operation on any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy.

**Common Policies**

**Note:**

The policies in this section use example group names, as follows:

- acme-viewers: A group that you want to limit to just viewing a list of repositories.
- acme-pullers: A group that you want to limit to pulling images.
- acme-pushers: A group that you want to allow to push and pull images.
- acme-managers: A group that you want to allow to push and pull images, delete repositories, and edit repository metadata (for example, to make a private repository public).

Make sure to replace the example group names with your own group names.

**Enable users to view a list of all the repositories belonging to the tenancy or to a compartment**

**Type of access:** Ability to see a list of all repositories in Oracle Cloud Infrastructure Registry belonging to the tenancy (or to a particular compartment). Users will not be able to:

- view the images or layers in a repository
- push or pull images from or to a repository

**Where to create the policy:**

- In the tenancy. For example:
  
  Allow group acme-viewers to inspect repos in tenancy

- In the tenancy or in a compartment. For example:
  
  Allow group acme-viewers to inspect repos in compartment acme-compartment

**Enable users to pull images from any repository belonging to the tenancy or to a compartment**

**Type of access:** Ability to pull images (layers and manifests) from any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy (or to a particular compartment).

**Where to create the policy:**

- In the tenancy. For example:
  
  Allow group acme-pullers to read repos in tenancy

- In the tenancy or in a compartment. For example:
  
  Allow group acme-pullers to read repos in compartment acme-compartment

**Enable users to pull images from specific repositories in the tenancy or in a compartment**

**Type of access:** Ability to pull images (layers and manifests) from any repository in Oracle Cloud Infrastructure Registry that has a name starting with "acme-web-app" and that belongs to the tenancy (or that belongs to a particular compartment).
Where to create the policy:

- In the tenancy. For example:

```plaintext
Allow group acme-pullers to read repos in tenancy where all
   { target.repo.name=/acme-web-app*/ }
```

- In the tenancy or in a compartment. For example:

```plaintext
Allow group acme-pullers to read repos in compartment acme-compartment
   where all { target.repo.name=/acme-web-app*/ }
```

Enable users to push images to any repositories (and create new repositories if necessary) in the tenancy or in a compartment

Type of access: Ability to push images (layers and manifests) to any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy or to a particular compartment.

If the specified repository doesn't exist yet, the REPOSITORY_CREATE permission ensures users are able to create a new repository in the tenancy's root compartment when they push the image. For more information about this unusual scenario, see Notes about Repository Creation on page 3513.

Where to create the policy:

- In the tenancy. For example:

```plaintext
Allow group acme-pushers to use repos in tenancy
```

```plaintext
Allow group acme-pushers to manage repos in tenancy where ANY
   {request.permission = 'REPOSITORY_CREATE', request.permission =
    'REPOSITORY_UPDATE'}
```

- In the tenancy or in a compartment. For example, in a compartment:

```plaintext
Allow group acme-pushers to use repos in compartment acme-compartment
```

Note that if you create the policy in a compartment other than the root compartment as shown above, users cannot push an image to a repository that doesn't exist yet. That's because the above policy does not give users permission to create a new repository in the tenancy's root compartment. For more information about this unusual scenario, see Notes about Repository Creation on page 3513.

Enable managers to perform any operation on any repository belonging to the tenancy or to a compartment

Type of access: Ability to perform any operation on any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy (or to a particular compartment), including:

- Pull an image from any repository.
- Push an image to any repository.
- Create a new repository. That is, either to create an empty repository in any compartment, or to create a repository in the tenancy's root compartment when pushing an image for which no repository exists yet. Note that if you create the policy in a compartment other than the root compartment, users cannot push an image to a repository that doesn't exist yet. That's because the policy does not give users permission to create a new repository in the root compartment. For more information about this unusual scenario, see Notes about Repository Creation on page 3513.
- Delete a repository.
- Change a public repository to a private repository, or a private repository to a public repository.

Where to create the policy:
• In the tenancy. For example:

```
Allow group acme-managers to manage repos in tenancy
```

• In the tenancy or in a compartment. For example:

```
Allow group acme-managers to manage repos in compartment acme-compartment
```

Note that if you create the above policy in a compartment other than the root compartment, users cannot push an image to a repository that doesn't exist yet. That's because the policy does not give users permission to create a new repository in the root compartment. For more information about this unusual scenario, see Notes about Repository Creation on page 3513.
Chapter 30

Resource Manager

This chapter introduces the Oracle Resource Manager service and describes how to use it.

Features

Templates

A template is a Terraform configuration that you can use to manage infrastructure. Templates can help those new to infrastructure as code and those who are updating production workflow configurations. Use templates to try out Resource Manager and to apply proven best practices to your production workflow configuration. For information about Oracle-provided templates, see Templates on page 3588.

Create your own private templates to share with others in the tenancy.
Start with a Resource Creation Page

Save your configuration from a resource configuration page to a stack. Use the stack to install, configure, and manage the resource through the "infrastructure-as-code" model. Supported resource configuration pages: Create Compute Instance.

CI/CD with Resource Manager

Remotely store your Terraform configurations using integrated source code control systems, such as GitHub and GitLab. This integration helps you achieve continuous integration and continuous delivery (CI/CD).

For more information about remotely storing your configurations, see Managing Configuration Source Providers on page 3581.

Resource Discovery

A feature to capture deployed resources as Terraform configuration and state files. With this feature, you can:

- Move from manually managed infrastructure to Resource Manager-controlled infrastructure.
- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
- Duplicate or rebuild existing infrastructure in another compartment.

For more information, see resource discovery and the following instructions:

- To see how Terraform represents your resources on page 3560
- To recreate (clone) existing infrastructure in another compartment on page 3560

Drift Detection

Find out if provisioned resources have different states than those resources defined in the stack's last executed configuration and view detailed drift status for each resource.

You can optionally limit the drift detection to specified resources. Each resource is identified by a resource address, which is a string derived from the resource type and name specified in the stack's Terraform configuration plus an optional index. For example, the resource address for the fourth Compute instance with the name "test_instance" is oci_core_instance.test_instance[3] (resource type of oci_core_instance, a period as delimiter, resource name of test_instance, and index of 3 in brackets). For more details and examples of resource addresses, see the Terraform documentation at https://www.terraform.io/docs/internals/resource-addressing.html#examples.

For more information about drift detection, see drift and the following instructions:

- To detect drift for a stack or selected resources on page 3562
- To view the latest drift detection report on page 3562
- To view an old drift detection report on page 3563

Deploy to Oracle Cloud Button

The Deploy to Oracle Cloud button allows you to launch your remote Terraform configuration using the Create Stack workflow available in Resource Manager.

For more information, see Using the Deploy to Oracle Cloud Button on page 3592.
Overview of Resource Manager

Resource Manager is an Oracle Cloud Infrastructure service that allows you to automate the process of provisioning your Oracle Cloud Infrastructure resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the “infrastructure-as-code” model.

A Terraform configuration codifies your infrastructure in declarative configuration files. Resource Manager allows you to share and manage infrastructure configurations and state files across multiple teams and platforms. This infrastructure management can’t be done with local Terraform installations and Oracle Terraform modules alone. For more information about the Oracle Cloud Infrastructure Terraform provider, see Terraform Provider on page 4275. For a general introduction to Terraform and the "infrastructure-as-code" model, see https://www.terraform.io.

Key Concepts

Following are brief descriptions of key concepts and the main components of Resource Manager.

configuration

Information to codify your infrastructure. A Terraform configuration can be either a template or a set of one or more files that you write. You can either upload your written configuration directly or store it in a source code control system.

Use your configuration to specify the Oracle Cloud Infrastructure resources in a given stack. For example, specify resource metadata, data source definitions, and variable declarations. Each Terraform configuration file is either HashiCorp Configuration Language (HCL) format or JSON format, as indicated by the file’s extension (either .tf or .tf.json, respectively).

For example configurations, see Terraform provider examples and Templates on page 3588. For more information, see Terraform Configurations for Resource Manager on page 3594 and Authoring Configurations on page 4277; see also Hashicorp: Configuration.

configuration source provider

Connection information to a source code control system where your Terraform configuration files are stored. Use a configuration source provider to create a stack from a remote, versioned Terraform configuration file. A configuration source provider has the following types:

• GitHub: Supported products
  • GitHub Enterprise
  • GitHub Enterprise Server
  • GitHub Enterprise Cloud
  • GitHub Free for organizations
  • GitHub Free for user accounts
  • GitHub Team
• GitLab: Supported products
  • GitLab Community Edition
  • GitLab Enterprise Edition
  • GitLab.com

A configuration source provider has the following lifecycle states:

• Active: The configuration source provider is available for use.

For more information, see Managing Configuration Source Providers on page 3581 and To create a stack on page 3557.

drift

Difference between the actual, real-world state of your infrastructure, and the stack’s last executed configuration. For example, drift occurs when a team member adds a production tag to your resources, or when a resource fails. You can run drift detection reports to determine if provisioned resources have different
states than those resources defined in the stack's last executed configuration. You can also view detailed drift status for each resource.

job

Instructions to perform the actions defined in your configuration. Only one job at a time can run on a given stack; further, you can have only one set of Oracle Cloud Infrastructure resources on a given stack. To provision a different set of resources, you must create a separate stack and use a different configuration.

Resource Manager provides the following job types:

- **Plan**: Parses your Terraform configuration and creates an execution plan for the associated stack. The execution plan lists the sequence of specific actions planned to provision your Oracle Cloud Infrastructure resources. The execution plan is handed off to the apply job, which then executes the instructions.
- **Apply**: Applies the execution plan to the associated stack to create (or modify) your Oracle Cloud Infrastructure resources. Depending on the number and type of resources specified, a given apply job can take some time. You can check status while the job runs.
- **Destroy**: Releases resources associated with a stack. Released resources are not deleted. For example, terminates a Compute instance controlled by a stack. The stack's job history and state remain after running a destroy job. You can monitor the status and review the results of a destroy job by inspecting the stack's log files.
- **Import State**: Sets the provided Terraform state file as the current state of the stack. Use this job to migrate local Terraform environments to Resource Manager.

Jobs store history about their associated stack. For example, plan jobs store generated execution plans and apply jobs store configurations (snapshots) and state files. Jobs reside in the same compartment as the stack they are associated with. An OCI ID is assigned to each job.

A job has the following lifecycle states:

- **Accepted**: The job was accepted for processing.
- **In Progress**: The job is currently executing.
- **Failed**: The job did not complete execution.
- **Succeeded**: The job completed execution.
- **Canceling**: The job is being canceled.
- **Canceled**: The job was canceled.

module

A group of related resources. Use modules to create lightweight and reusable abstractions, so that you can describe your infrastructure in terms of its architecture. For more information, see Creating Modules.

package

Typically a .zip file to a Terraform configuration that is stored in a supported provider, such as GitHub. For more information, see Using the Deploy to Oracle Cloud Button on page 3592.

resource discovery

A feature to capture deployed resources as Terraform configuration and state files. With this feature, you can:

- Move from manually managed infrastructure to Resource Manager-controlled infrastructure.
- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
- Duplicate or rebuild existing infrastructure in another compartment.

Resource discovery supports the following Oracle Cloud Infrastructure resources: https://www.terraform.io/docs/providers/oci/guides/resource_discovery.html#supported-resources.

To discover resources, use Resource Manager to create a stack from your compartment. The created stack includes a generated Terraform configuration and state file corresponding to the supported resources in the source compartment.
Resource Manager

Note:
Attributes are missing from some supported resources captured using resource discovery. For more information, see https://docs.cloud.oracle.com/iaas/Content/knownissues.htm#orm-attributes.

Details about undiscoverable attributes

In some cases, a required or optional attribute may not be discoverable from the Oracle Cloud Infrastructure services and may be omitted from the generated Terraform configuration. This omission may be expected behavior from the service, which may prevent discovery of certain sensitive attributes or secrets. In such cases, a placeholder value is set along with a comment like this:

```text
admin_password = "<placeholder for missing required attribute>"
#Required attribute not found in discovery, placeholder value set to avoid plan failure
```

The missing required attributes are also added to lifecycle ignore_changes. This addition is done to avoid Terraform plan failure when moving manually managed infrastructure to Terraform-managed infrastructure. Any changes made to such fields are not reflected in the Terraform plan. If you want to update these fields, remove them from ignore_changes.

Resources that depend on availability domains are generated under availability_domain.tf file. These resources include `oci_core_boot_volume`, `oci_file_storage_file_system`, `oci_file_storage_mount_target`, and `oci_file_storage_snapshot`.

Terraform versions supported: 0.12.x, 0.13.x

Stack

The collection of Oracle Cloud Infrastructure resources corresponding to a given Terraform configuration. Each stack resides in the compartment you specify, in a single region; however, resources on a given stack can be deployed across multiple regions. An `OCID` is assigned to each stack.

You can create stacks from templates, from Terraform configurations stored either remotely or locally, or from existing compartments using resource discovery.

A stack created from a compartment represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.

Stack creation is supported from a single compartment only. Stacks cannot be created from nested compartments.

A stack has the following lifecycle states:

- **Creating**: The stack is being created.
- **Active**: The stack is available for use.
- **Deleting**: The stack is being deleted.
- **Deleted**: The stack was deleted.
- **Failed**: The stack could not be created.

State

The state of your resource configuration, stored in JSON format in a state file (`.tfstate`). The state file maps your stack's resources to your configuration and also maintains essential configuration metadata, such as resource dependencies. For instructions, see To view the state of a stack on page 3564 and To view the state of a job on page 3567. Resource Manager generates and updates state files automatically. You cannot edit the file manually.
Resource Manager supports state locking by allowing only one job at a time to run on a given stack. For more information about state files, see Hashicorp: State.

**template**

A pre-built Terraform configuration that provisions a set of resources used in a common scenario. The template can be provided by either Oracle or someone in your tenancy, as a private template. To create stacks from templates, see To create a stack on page 3557. For reference, see Templates on page 3588.

To create private templates, see Managing Private Templates on page 3578.

**Availability**

The Resource Manager service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

**Generalized Workflow**

The following image represents a generalized view of the Resource Manager workflow.
Links in the following steps reference Console instructions; however, you can do the same tasks using the API (through the CLI or other tool).
1. **Create a Terraform configuration.**

   **Note:**
   You can store your Terraform configuration file locally or remotely, using a source code control system. With remote storage, any job running on the associated stack automatically uses the latest version of your configuration. For more information about remotely storing your file, see Managing Configuration Source Providers on page 3581. You can skip this step if you use a template or create a stack from a compartment.

2. Create a stack.
3. Run a plan job, which produces an execution plan.
4. Review the execution plan.
5. If changes are needed in the execution plan, update the configuration and run a plan job again.
6. Run an apply job to provision resources.
7. Review state file and log files, as needed.
8. You can optionally reapply your configuration, with or without making changes, by running an apply job again.
9. Optionally, to release the resources running on a stack, run a destroy job.

For a detailed walkthrough of the Resource Manager workflow, see Getting Started on page 3541.

**Ways to Access Resource Manager**

You can access the Resource Manager service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

Console: To access Resource Manager using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

API: To access Resource Manager through APIs, use Resource Manager API. To access this API using the Command Line Interface (CLI), use the `oci resource-manager` designation.

**Supported Providers**

In addition to `terraform-provider-oci` (the Terraform provider for Oracle Cloud Infrastructure), Resource Manager supports the following third-party Terraform providers.

<table>
<thead>
<tr>
<th>Third-party Terraform Provider</th>
<th>Supported Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>terraform-provider-ansible</code></td>
<td>1.0.3</td>
</tr>
<tr>
<td><code>terraform-provider-archive</code></td>
<td>1.1.0, 1.2.2</td>
</tr>
<tr>
<td><code>terraform-provider-checkpoint</code></td>
<td>1.0.0</td>
</tr>
<tr>
<td><code>terraform-provider-chef</code></td>
<td>0.2.0</td>
</tr>
<tr>
<td><code>terraform-provider-cloudinit</code></td>
<td>1.0.0</td>
</tr>
<tr>
<td><code>terraform-provider-digitalocean</code></td>
<td>1.13.0</td>
</tr>
<tr>
<td><code>terraform-provider-github</code></td>
<td>2.3.1</td>
</tr>
</tbody>
</table>
### Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to resources in Resource Manager (stacks, jobs, private templates, and configuration source providers), see Policies for Managing Resources Used with Resource Manager on page 2476. For a complete list of Resource Manager permissions, see Details for Resource Manager on page 2336. Policies for managing accessed resource types are also required.

**Important:**

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2142.

### Limits on Resource Manager Resources

See Resource Manager Limits on page 231.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.
Getting Started

This page helps you get started with Resource Manager by providing an end-to-end walkthrough of the tasks required to create and deploy an Oracle Cloud Infrastructure Compute instance using either a pre-built Terraform configuration or your own Terraform configuration. For a brief introduction to Resource Manager, see Overview of Resource Manager on page 3534.

Highlights

In addition to providing a pre-built Terraform configuration for creating a Compute instance, this walkthrough provides samples that demonstrate how to write a Terraform configuration. Whichever configuration you use (pre-built or your own), Resource Manager uses Terraform to provision the defined resources. The resources are organized into stacks, which you create and provision using jobs.

The walkthrough covers the following tasks:

- Select or create a Terraform configuration.
- Provision the infrastructure:
  - Create a stack in which to provision your infrastructure.
  - Run a plan job against your stack, which parses your configuration and creates an execution plan.
  - Review the generated execution plan.
  - Run an apply job against your stack, which provisions your resources. The apply job follows the execution plan, which is based on your Terraform configuration.
  - Review the resulting infrastructure.

Before You Begin

Ensure that you have installed, obtained, or created the prerequisites:

- An Oracle Cloud Infrastructure tenancy
- The OCID for the compartment where you wish to create your stack.
- A user account that includes the following:
  - An API signing key. For guidance, see Required Keys and OCIDs on page 4179.
  - Required IAM permissions. For more information, see How Policies Work on page 2136 and Details for Resource Manager on page 2336.
- If you want to use the Oracle Cloud Infrastructure CLI, install and configure the CLI first. See Quickstart on page 4195 and Configuring the CLI on page 4202

Task 1a: Select a Pre-built Terraform Configuration

You can select the Compute Instance template with its pre-built Terraform configuration instead of writing your own configuration. These steps guide you through the stack creation process.

1. Click the following link to launch the Create Stack page with the Compute Instance template already selected.
   
   Launch stack with Compute Instance template

2. In the Create Stack page, enter a Name for the new stack (or accept the default name provided). Avoid entering confidential information.

3. From the Create in Compartment drop-down, select the compartment where you want to create the stack.
   
   A compartment from the list scope is set by default.

4. Click Next.
   
   The Configure Variables panel displays variables from the Terraform configuration.
5. Review the variables and make changes as necessary.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not add your private key or other confidential information to configuration variables.</td>
</tr>
</tbody>
</table>

6. Click Next.

7. In the Review panel, verify your stack configuration.

8. Click Create to create your stack.

The stack detail page for the new stack appears.

Congratulations! You have created a stack with the pre-built Terraform configuration from the Compute Instance template. The next step is to provision the infrastructure.

**Task 1b: Create Your Own Terraform Configuration**

If you didn't select a pre-built Terraform configuration, then follow these steps to write your own.

A Terraform configuration is a file that codifies your infrastructure. The configuration defines your Terraform provider, the resources you intend to provision, variables, and specific instructions for provisioning the resources.

This page guides you through selecting the Compute Instance template with its pre-built Terraform configuration or alternatively writing your own configuration using several .tf files within a .zip file.

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 3594 and Terraform Configuration.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not provide user credentials or other confidential information in your Terraform configuration.</td>
</tr>
</tbody>
</table>

**Create an Oracle Cloud Infrastructure Provider**

The following code sample creates a basic Oracle Cloud Infrastructure Terraform provider. You can provide values as variables that are defined either in a variables file or in the provider definition (.tf) file. For more information, see Provider Configuration.

```hcl
provider "oci" {
  region = "${var.region}"
}
```

**Define Variables**

Define the variables you want to use when provisioning your resources. A best practice is to create a "variables" file in the configuration package that you upload. Following is an example from a configuration file that we've named variables.tf. For more information about using variables, see Input Variables. See also Configuring Input Variables.

```hcl
variable "compartment_ocid" {
  default = "ocid1.compartment.oc1..uniqueid"
}

variable "region" {
  default = "us-phoenix-1"
}

variable "InstanceImageOCID" {
  type = "map"
  default = {
```

Oracle Cloud Infrastructure User Guide 3542
For more information about variables declared in the preceding examples, see the following:

- **InstanceImageOCID**: Oracle-Provided Images on page 629
- **InstanceShape**: Compute Shapes on page 655
- **region** and **localAD**: Regions and Availability Domains on page 180

### Create a Virtual Cloud Network (VCN)

The following code sample creates an Oracle Cloud Infrastructure virtual cloud network (VCN) named "ExampleVCN."

```hcl
resource "oci_core_virtual_network" "ExampleVCN" {
    cidr_block = "10.1.0.0/16"
    compartment_id = "${var.compartment_ocid}"
    display_name = "TFExampleVCN"
    dns_label = "tfexamplevcn"
}
```

### Create a Subnet in Your VCN

The following code sample creates a subnet named "ExampleSubnet" in the VCN defined in the previous code sample.

```hcl
resource "oci_core_subnet" "ExampleSubnet" {
    availability_domain = "${var.localAD}"
    cidr_block = "10.1.20.0/24"
    display_name = "TFExampleSubnet"
    dns_label = "tfexamplesubnet"
    security_list_ids = ["${oci_core_virtual_network.ExampleVCN.default_security_list_id}
    compartment_id = "${var.compartment_ocid}"```
Create an Internet Gateway

The following code sample creates an internet gateway named "ExampleIG" in the VCN that we created.

```hcl
resource "oci_core_internet_gateway" "ExampleIG" {
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFExampleIG"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"}
```

Create a Core Route Table

The following code sample creates a Oracle Cloud Infrastructure core route table in the VCN and then applies two route rules.

```hcl
resource "oci_core_route_table" "ExampleRT" {
  compartment_id = "${var.compartment_ocid}"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
  display_name = "TFExampleRouteTable"
  route_rules {
    cidr_block = "0.0.0.0/0"
    network_entity_id = "${oci_core_internet_gateway.ExampleIG.id}"  
  }
}
```

Create a Compute Instance

The following extended code example creates an Oracle Cloud Infrastructure Compute instance. The code also references the image on which the Compute instance is created, sets boot volume size, adds essential metadata, and applies both free-form and defined tags.

```hcl
resource "oci_core_instance" "TFInstance" {
  count = "${var.NumInstances}"  
  availability_domain = "${var.localAD}"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFInstance${count.index}"
  shape = "${var.InstanceShape}"
  create_vnic_details {
    subnet_id = "${oci_core_subnet.ExampleSubnet.id}"
    display_name = "primaryvnic"
    assign_public_ip = true
    hostname_label = "tfexampleinstance${count.index}"  
  }
  source_details {
    source_type = "image"
    source_id = "${var.InstanceImageOCID[var.region]}"
    # Apply this to set the size of the boot volume that's created for this instance.
    # Otherwise, the default boot volume size of the image is used.
    # This should only be specified when source_type is set to "image".
    #boot_volume_size_in_gbs = "60"
  }
}
```
# Apply the following flag only if you wish to preserve the attached boot volume upon destroying this instance
# Setting this and destroying the instance will result in a boot volume that should be managed outside of this config.
# When changing this value, make sure to run 'terraform apply' so that it takes effect before the resource is destroyed.
#preserve_boot_volume = true

metadata = {
    sshAuthorizedKeys = "${var.ssh_public_key}"
}

timeouts {
    create = "60m"
}

Finalize the Configuration

Ensure that all of the configuration files are in a single directory. You can store your Terraform configuration file locally or in a source code control system. For more information on storing your file in a source code control system, see Managing Configuration Source Providers on page 3581. Wherever your file is stored, you can select it when creating a stack using the CLI or Console.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Make sure your Terraform configuration file is valid. See Authoring Configurations on page 4277 and Terraform Configurations for Resource Manager on page 3594.</td>
</tr>
</tbody>
</table>

Task 2: Provision the Infrastructure

Use your Terraform configuration to build and deploy your infrastructure by taking the following actions:
1. If you created your own Terraform configuration, follow these steps to create a stack in a tenancy compartment of your choosing. (If you selected a pre-built configuration, skip this step.)

A stack is a collection of resources that you can act on as a group. All of the resources that you specify in your configuration are provisioned in the stack that you create.

You can create a stack from a remote, versioned file in a source code control system or a locally accessed file that you upload.

**To create a stack from your .zip file (Console)**

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click **Create Stack**.

d. On the **Create Stack** page, select **My Configuration**.

   You can either drag and drop your Terraform configuration .zip file onto the control or click **Browse** and navigate to the location of the .zip file. You can also **store your configuration remotely**.

   The dialog box is populated with information contained in the configuration.

e. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.

f. Optionally enter a **Description**.

g. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.

   A compartment from the list scope is set by default.

h. Click **Next**.

   The **Configure Variables** panel displays variables from the selected Terraform configuration file.

i. Review the variables and make changes as necessary.

   **Important:**
   
   Do not add your private key or other confidential information to configuration variables.

j. Click **Next**.

k. In the **Review** panel, verify your stack configuration.

l. Click **Create** to create your stack.

**To create a stack from your .zip file (CLI)**

Use the command related to your file location.

**To create a stack from a remote, versioned file**

Open a command prompt and run `resource-manager stack create-from-git-provider` to create a stack from a file tracked with a configuration source provider:

```
oci resource-manager stack create-from-git-provider --compartment-id <compartment_OCID> --config-source-configuration-source-provider-id <configuration_source_provider_OCID> --config-source-repository-url <repository_url> --config-source-branch-name <branch_name> --display-
```
name "<friendly_name>" --description "<description>" --terraform-version "<version>" --variables <var_file_path> --working-directory "<directory>"

**Note:**

You can return later to update stack settings or add variables after you have created the stack.

For example:

```bash
oci resource-manager stack create-from-git-provider --compartment-id ocid1.tenancy.oc1..uniqueid --config-source-configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --config-source-repository-url https://github.com/user/repo.git --config-source-branch-name mybranch --display-name "My Stack from Git" --description "My Test" --variables file://variables.json --working-directory ""
```

For a complete list of flags and options available for CLI commands, see CLI Help.

**To create a stack from your .zip file**

This section describes how to create a stack from an uploaded configuration file (.zip).

**Note:**

You can also create stacks from configuration files stored in source code control systems, such as Git, and from templates.

On Windows, be sure the .zip file and variables.json files are in the same directory from which you're running the CLI. The CLI currently has a limitation on Windows that prevents correct handling of the files if either one is in a subdirectory.

Open a command prompt and run `oci resource-manager stack create` to create a stack:

```bash
oci resource-manager stack create --compartment-id <compartment_OCID> --config-source <config_file_name> --variables <var_file_path> --display-
name "<friendly_name>" --description "<description>" --working-directory ""

Note:
You can return later to update stack settings or add variables after you have created the stack.

Options
For a complete list of flags and options available for CLI commands, see CLI Help.

• --compartment-id is the OCID of the compartment where you want to create the stack.
• --config-source is the name of a .zip file that contains one or more Terraform configuration files.
• --variables is the path to the file specifying input variables for your resources. Optional.

The Oracle Cloud Infrastructure Terraform provider requires additional parameters when running Terraform locally (unless you are using instance principals). For more information on using variables in Terraform, see Input Variables. See also Input Variable Configuration.
• --display-name is the friendly name for the new stack. Optional.
• --description is the description for the new stack. Optional.
• --working-directory is the root configuration file in the directory. Optional. If not specified, or if null as in this example, then the service assumes that the top-level file in the directory is the root configuration file.

For example:

oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --config-source vcn.zip --variables file://variables.json --display-name "My Example Stack" --description "My Tutorial to Create a VCN" --working-directory ""

Example response

```json
{
   "data": {
      "config-source": {
         "working-directory": null,
         "config-source-type": "ZIP_UPLOAD"
      },
      "defined-tags": {},
      "description": "My Tutorial to Create a VCN",
      "display-name": "My Example Stack",
      "freeform-tags": {},
      "id": "ocid1.ormstack.oc1..uniqueid",
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-04-03T18:26:56.299000+00:00",
      "variables": {
         "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
         "region": "us-phoenix-1"
      }
   }
}
```
2. Generate an execution plan.

The plan job parses your configuration to create an "execution plan," which is a step-by-step representation of the planned deployment in job log entries. Once the plan job has completed, you can evaluate the execution plan by viewing the job's log entries to confirm that it performs the expected operations, and in the intended sequence.

**To run a plan job (Console)**

a. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the stack that you want to use.

   The Stack Details page is displayed.

d. Go to Terraform Actions and select Plan.

e. In the Plan dialog, review the plan job Name and update it if needed.

f. Click Plan.

   The new plan job is listed under Jobs, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

**To run a plan job (CLI)**

Open a command prompt and run `oci resource-manager job create-plan-job` to run a plan job on the specified stack (`--display-name` is optional):

```
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.

**To check the current state of the plan job**

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <plan_job_OCID>
```

**Lifecycle states**

Possible values for lifecycle-state:

- ACCEPTED: The job is queued for execution.
- IN_PROGRESS: The job is running.
- FAILED: The job has failed and stopped running.
- SUCCEEDED: The job has completed successfully.
- CANCELING: The job has been notified to cancel, but has not yet stopped running.
- CANCELED: The job was canceled and has stopped running.

**Example response**

This example shows ACCEPTED for lifecycle-state.

```
{
  "data": {
    "compartment-id": "ocid1.compartment.oc1..uniqueid",
    "defined-tags": null,
    "display-name": "Example Plan Job",
    "freeform-tags": {},
    "id": "ocid1.ormjob.oc1..uniqueid",
    "lifecycle-state": "ACCEPTED",
  }
}
```
3. Review the execution plan to confirm that it represents your intentions.

The execution plan is represented in the log for the plan job you ran previously.

To review an execution plan (the log for the plan job) (Console)

a. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Jobs.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the Job Details page, under Resources, click Logs.

For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

You can also download the job information.

If changes are needed, update your stack to use a revised configuration and then rerun the plan job to obtain an updated execution plan.

To update the configuration for a stack

**Important:**

Ensure that your Terraform configuration file is valid. See Authoring Configurations on page 4277 and Terraform Configurations for Resource Manager on page 3594.

**Note:**

These instructions don't apply to configurations stored in source code control systems. You can store your Terraform configuration file locally or remotely, using a source code control system. With remote storage, any job running on the associated stack automatically uses the latest version of
If you are only editing your configuration source provider settings, skip this step.

Otherwise, ensure you have your revised Terraform configuration (.zip file or folder) ready for upload.

To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration .zip file for the update.

Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

Click the name of the stack that you want to update.

The Stack Details page is displayed.

In the Stack Information tab, next to Terraform Configuration File (.zip), click Upload New File.

In the Edit Stack dialog, either edit your configuration source provider settings (if applicable) or add your revised Terraform configuration (.zip file or folder).

You can either drag and drop it onto the dialog's control or click Browse and navigate to the location of the file or folder.

The dialog box is populated with information contained in the Terraform configuration.

Click Next as needed and then click Save Changes.

Now you can generate a new execution plan using your revised configuration.

To review an execution plan (the log for the plan job) (CLI)

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run oci resource-manager job get-job-logs:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run oci resource-manager job get-job-logs-content:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

If changes are needed, update your stack to use a revised configuration and then rerun the plan job to obtain an updated execution plan.
4. Provision your resources by running an apply job against the execution plan.

When satisfied with the execution plan, we're ready to do the work of provisioning the stack with the resources that we've defined. The apply job takes the execution plan and "applies" it to the stack. The result is a fully provisioned stack.

**To run an apply job (Console)**

- Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
- Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
- Click the name of the stack that you want to use.
  - The **Stack Details** page is displayed.
- Go to **Terraform Actions** and select **Apply**.
- In the **Apply** dialog, review the apply job **Name** and other settings and update it if needed.
- Click **Apply**.
  - The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.
- To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under **Resources**.

**To run an apply job (CLI)**

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use **FROM_PLAN_JOB_ID**:
  ```bash
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job_OCID> --display-name "Example Apply Job"
  ```
- To automatically approve the apply job (no plan job specified), use **AUTO_APPROVED**:
  ```bash
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy AUTO_APPROVED --display-name "Example Apply Job"
  ```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from **IN_PROGRESS** to **SUCCEEDED**.

**To check the current state of the apply job**

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```bash
oci resource-manager job get --job-id <apply_job_OCID>
```

**Lifecycle states**

Possible values for **lifecycle-state**:

- **ACCEPTED**: The job is queued for execution.
- **IN_PROGRESS**: The job is running.
- **FAILED**: The job has failed and stopped running.
- **SUCCEEDED**: The job has completed successfully.
- **CANCELING**: The job has been notified to cancel, but has not yet stopped running.
• CANCELED: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.
5. Review the log entries and state file for the apply job you just ran.

- See the entries in the job log for more details about the job.

**To view the job log (Console)**

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.

    You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the **Job Details** page, under **Resources**, click **Logs**.

   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

   You can also download the job information.

**To view the job log (CLI)**

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

- The job state file represents the job's output in JSON format.

The state file maps your stack's resources to your configuration and also maintains essential configuration metadata, such as resource dependencies. Resource Manager generates and updates state files automatically when you run jobs.

The Resource Manager supports state locking by allowing only one job at a time to run on a given stack. For more information about state files, see Hashicorp: State.

**To view the state of the job (Console)**

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.

    You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the job you want.

d. On the **Job Details** page, click **View State** under **Resources**.

**To view the state of the job (CLI)**
Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

Example response for an apply job

```json
{
    "data": {
        "lineage": "57ef4f0c-c8cd-8a32-d45f-d2c40be7b915",

                                "vcn_domain_name": "myvcntest.oraclevcn.com"
                            },
                            "id": "ocid1.vcn.oc1.phx.uniqueid",
                            "meta": {
                                "e2bfb730-ecaa-11e6-8f88-34363bc7c4c0": {
                                    "create": 300000000000,
                                    "delete": 300000000000,
                                    "update": 300000000000
                                }
                            },
                            "tainted": false
                        },
                    },
                    "provider": "provider.oci",
                    "type": "oci_core_virtual_network"
                }
            }
        ],
        "serial": 4
    }
}
```
6. When you need to release the resources that you provisioned, run a destroy job on the stack.

A destroy job tears down the stack that you created and then cleans up associated resources without deleting them. For example, the destroy job terminates Compute instances associated with the stack.

**To run a destroy job (Console)**

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can also import state files for resources already managed by Terraform.</td>
</tr>
</tbody>
</table>
```

- a. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
- b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
- c. Click the name of the stack that you want to use.
  The Stack Details page is displayed.
- d. Go to Terraform Actions and select Destroy.
- e. Click Destroy again to confirm your action.
  You can monitor the status and review the results of a destroy job by viewing the state or the logs.
- f. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the Job Details page, then click View State under Resources.
- g. To view the logs for the job, click the name of the job to display the Job Details page, then click Logs under Resources.

**To run a destroy job (CLI)**

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we</td>
</tr>
</tbody>
</table>
```
recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and clean up the resources provisioned by the specified stack:

```
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_APPROVED
```

To confirm deletion of the resources, inspect resources in the compartment.

## Managing Stacks and Jobs

This topic describes how to create, edit, and delete stacks as well as work with jobs, including generating and applying execution plans. Drift detection is also covered in this topic.

### Prerequisites

- **IAM policies:** To manage stacks and jobs, you must be given the required type of access in a *policy* written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in.

  Administrators: For common policies that give groups access to resources in Resource Manager (stacks, jobs, private templates, and configuration source providers), see Policies for Managing Resources Used with Resource Manager on page 2476. For a complete list of Resource Manager permissions, see Details for Resource Manager on page 2336. Policies for managing accessed resource types are also required.

  **Important:** Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2142.

- **Terraform configuration file:** To create or update a stack, you must have a valid Terraform configuration file. See Terraform Configurations for Resource Manager on page 3594 and Authoring Configurations on page 4277.

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

### Moving Resources to a Different Compartment

You can move stacks from one compartment to another. When you move a stack to a new compartment, its associated jobs move with it. After you move the stack to the new compartment, inherent policies apply immediately and affect access to the stack and associated jobs through the Console. For more information, see Managing Compartments on page 2431.

### Using the Console

#### Managing Stacks (Console)

**To create a stack**

This section describes how to start from the Create Stack dialog when creating stacks. You can also start your stack creation process from the Create Compute Instance page.
1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click **Create Stack**.
4. In the **Create Stack** dialog, under **Choose the origin of the Terraform configuration**, select the option you want.
   - **My Configuration**: Local folder or .zip file.
     Under **Stack Configuration**, select either **Folder** or **Zip File**.
     You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the folder or file location.
     The dialog box is populated with information contained in the local Terraform configuration.
   - **Template**: Pre-built Terraform configuration (service, architecture, or private template).
     Under **Stack Configuration**, click **Select Template** and then select the template you want. **Private templates** are under the **Private** tab.
     The dialog box is populated with information contained in the Terraform configuration for the selected template.
   - **Source Code Control System**: Remote location using a **configuration source provider**.
     **Steps**
     a. Under **Stack Configuration**, select a **Configuration Source Provider**.
        If you need to create one, see To create a configuration source provider on page 3582.
     b. Select a **Repository**.
        Example: https://gitlab.com/example
     c. Select a **Branch**.
        The list returned is limited to 100 branches.
     d. (Optional) Specify a **Working Directory** for running Terraform.
        Example (one level): Directory
        Example (two levels): Directory/Subdirectory
        If not specified, the root directory is used.
     The dialog box is populated with information contained in the remote Terraform configuration.
   - **Existing Compartment**: Generate a Terraform configuration using **resource discovery**.
     **Steps**
     • Select the **Compartment for Resource Discovery** (the compartment containing the resources that you want to capture).
       A compartment from the list scope is set by default.
     • Select the **Region for Resource Discovery** (the region containing the resources that you want to capture).
     • To filter for specific **Terraform provider services** supported for use with resource discovery, select **Selected** and then select the services you want.
     **Note:**
     This setting cannot be changed when editing the stack later.
5. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.
6. Optionally enter a **Description**.
7. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
   A compartment from the list scope is set by default.
8. Optionally apply tags to the stack.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

9. Click Next.

The Configure Variables panel displays variables from the Terraform configuration.

No variables are listed for the Existing Compartment stack origin because no Terraform configuration exists yet.

10. Review the variables and make changes as necessary.

    | Important: |
    | Do not add your private key or other confidential information to configuration variables. |

11. Click Next.

12. In the Review panel, verify your stack configuration.

13. Click Create to create your stack.

    The stack detail page for the new stack appears.

Existing Compartment stack origin: A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration file for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration. You can recreate these resources in another compartment.

To deploy the defined resources, run an apply job on your new stack.

To begin stack creation from the Create Compute Instance page

You can create a stack using the configuration you specify in the Create Compute Instance page available in the Console. Use the new stack to install, configure, and manage your Compute instance through the "infrastructure-as-code" model.

    | Note: |
    | Before you start, view requirements for creating Compute instances. See Required IAM Policy on page 695 and the prerequisites for Creating a Linux Instance on page 697 or Creating a Windows Instance on page 702. |

1. Open the Create Compute Instance page:

    a. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.

    b. Click Create Instance.

2. Populate configuration fields to specify stack details. For example, select the image you want to use in your stack.

3. Click Create as Stack.

    The Create Stack dialog window appears. The "Compute Instance" stack origin is indicated at the top of the dialog window, along with any provided instance name.
4. In the **Create Stack** dialog window, do the following.
   a. Enter a **Name** for the new stack. Avoid entering confidential information.
      Example: My Compute Instance
   b. Optionally enter a **Description**.
   c. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
      A compartment from the list scope is set by default.
   d. Select a **Terraform Version**.

   **Note:**
   Terraform versions are not backward compatible.

   e. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

   f. Click **Next**.
      The **Configure Variables** panel displays variables from the selected Terraform configuration file.
   g. Review the variables and make changes as necessary.

   **Important:**
   Do not add your private key or other confidential information to configuration variables.

   h. Click **Next**.
   i. In the **Review** panel, verify your stack configuration.
   j. Click **Create** to create your stack.

To deploy the defined Compute *instance*, run an apply job on your new stack.

**To see how Terraform represents your resources**

Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.

1. Capture existing infrastructure by creating a stack from that compartment.

   The stack detail page for the new stack appears. A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration file for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click **Download**.

**To recreate (clone) existing infrastructure in another compartment**

1. Capture existing infrastructure by creating a stack from that compartment.

   The stack detail page for the new stack appears. A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click **Download**.

3. Edit the vars.tf file (variables in the downloaded Terraform configuration file) to specify the destination **compartment_ocid** and **region**.

   Example:

   ```hcl
   variable "compartment_ocid" {
     default = "ocid1.compartment.oc1..uniqueid"
   }
   ```
variable "region" {
    default = "us-phoenix-1"
}

4. If the destination region has more or fewer availability domains than the source region, then edit the vars.tf file to specify the correct number of availability domains.

For example, if you cloned from a region that has 3 availability domains and you want to recreate the infrastructure in a region that has only 1 availability domain, then remove the references to the second and third availability domains.

Example showing 3 availability domains:

```terraform
data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
    compartment_id = var.compartment_ocid
    ad_number      = "1"
}
data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-2 {
    compartment_id = var.compartment_ocid
    ad_number      = "2"
}
data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-3 {
    compartment_id = var.compartment_ocid
    ad_number      = "3"
}
```

Example showing 1 availability domain:

```terraform
data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
    compartment_id = var.compartment_ocid
    ad_number      = "1"
}
```

5. Create a second stack using the edited configuration file.
   a. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
   c. Click Create Stack.
   d. In the Create Stack dialog, click My Configuration.
   e. Add the downloaded Terraform configuration (.zip) file.
      You can leave other fields as is for now. For reference, see To create a stack on page 3557.
   f. For Terraform Version, select a version supported by resource discovery.
      Terraform versions supported: 0.12.x, 0.13.x
   g. Click Next to display the Configure Variables panel.
   h. Update the compartment_ocid variable to specify the destination compartment for the cloned resources.
   i. If you want to clone the resources to a different region, update the region variable.
   j. Click Next to display the Review panel.
   k. Click Create to create your stack.
      The stack detail page for the second stack appears.

6. To confirm that the stack will create resources as expected, run a plan job.

7. Clone resources: Run an apply job on the new stack.
   The resources are cloned in the specified compartment and region.
To view stacks

You can view stack names, descriptions, states, and time created. The detail page for a stack lists its drift status and allows you to view the latest drift detection report.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
3. To display the detail page for a stack, click the stack’s name.

To download the stack’s Terraform configuration file

The Terraform configuration file listed on the stack detail page is the same as the Terraform configuration file listed on the job detail page for the most recent successful job.

Note:

For stacks created using source code control systems, configuration files are not available for download until a job is successfully run on the stack.

To detect drift for a stack or selected resources

You can detect drift for new stacks created from compartments or for stacks where the last job run was Apply or Import State. When detecting drift, you can specify all resources or selected resources.

Drift is the difference between the actual, real-world state of your infrastructure and the stack's last executed configuration. For example, drift occurs when a team member adds a production tag to your resources, or when a resource is deleted.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. In the Stack Information tab, to the right of Terraform Configuration File (.zip), click Download.

To view the latest drift detection report

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack to display its detail page.

   Alternatively go to the Stack Information tab. Under Drift Detection, click View drift detection report.

   A panel lists the drift status of the specified resources defined by the stack. Resources are identified by resource names.

5. To view details of drift status for a resource, click the down arrow.

   Expected and actual properties are listed.

6. (Optional) To make your resources match the properties of your Terraform configuration, run an apply job: In the Stack Details page, go to Terraform Actions and select Apply.

To view an old drift detection report

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack to display its detail page.

4. Click Work Requests.

5. Click the work request for the drift detection report you want.

6. In the Work Requests Information tab, click View Drift Detection Report.

   A panel lists the drift status of the specified resources defined by the stack at the time the drift detection was detected. Resources are identified by resource names.

7. To view details of drift status for a resource, click the down arrow.

   Expected and actual properties are listed.

To view the latest drift detection report, see To view the latest drift detection report on page 3562. To detect drift again, see To detect drift for a stack or selected resources on page 3562.

To edit a stack

You can edit stacks. When editing a stack, you can upload a different configuration and change its name, description, and variables.

Note:

If your configuration is stored in a source code control system, such as GitLab, then commit your changes there. The most recent commit is used when you run jobs on the stack. No configuration file is available for download until a job is successfully run on the stack.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the Actions icon (three dots), and then select Edit.

   You can also edit a stack from its detail page. Click the name of the stack to display its detail page and then click Edit Stack.
4. In the **Edit Stack** dialog, change the properties you want.

**Note:**

The stack's Terraform version cannot be changed.

- To edit the values assigned to variables in a stack, click **Configure Variables**.

You can also edit a stack from its detail page. Click the name of the stack to display the **Stack Details** page, click **Variables** (under **Resources**) and then click **Edit Variables**.

**Important:**

Do not add your private key or other confidential information to configuration variables.

If you want to add, reconfigure, or delete variables in a stack, update the Terraform configuration.

5. Click **Save Changes**.

**To view the state of a stack**

Download the state file corresponding to the most recently run job for the stack.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. Go to **More Actions** and select **Download Terraform State**.

**To manage tags for a stack**

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack you want.

   The **Stack Details** page lists the details about the selected job.
4. Click **Tags** to view or edit existing tags, or click **Add Tags** to add new ones.

**To move a stack to a different compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), and then select **Move Stack**.

   You can also move a stack from its detail page. Click the name of the stack to display the **Stack Details** and then click **Move Stack**.
4. In the **Move Resource To A Different Compartment** dialog box, select the compartment that you want to move the stack to.
5. Click **Move Resource**.

**To delete a stack**

**Note:**

Associated resources persist after stack deletion. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state.
1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), select Delete, and confirm the operation when prompted.

**Note:**
You cannot undo the delete stack operation.

You can also delete a stack from its detail page. Click the name of the stack to display the Stack Details and then click Delete Stack.

**Managing Jobs (Console)**

*To view jobs and job details*

You can view name, type, status, and other key information about jobs for a given compartment or stack. You can view name, type, status, and other key information about a given job. You can also access the job's execution plan (represented by the job log), Terraform configuration, and Terraform state, as well as view the variables used in the job.

For configurations stored in a source code control system, such as GitLab, job details include the relevant commit identifier.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Jobs.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. To view job details, click the name of the job you want.

The Job Details page lists the details about the selected job.

4. To view variables used in the job, click Variables under Resources.

**To manage tags for a job**

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Jobs.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the job you want.

The Job Details page lists the details about the selected job.

4. Click Tags to view or edit existing tags, or click Add Tags to add new ones.

**To generate an execution plan (run a plan job)**

Running a plan job parses your Terraform configuration and converts it into an execution plan listing resources and actions that will result when an apply job is run. For configurations stored in a source code control system, such as GitLab, the job uses the most recent commit. We recommend generating an execution plan before running an apply job.
1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack that you want to use.

   The **Stack Details** page is displayed.

4. Go to **Terraform Actions** and select **Plan**.

5. In the **Plan** dialog, review the plan job **Name** and update it if needed.

6. Click **Plan**.

   The new plan job is listed under **Jobs**, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

### To view the job log

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.

   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the plan job that you ran.

4. On the **Job Details** page, under **Resources**, click **Logs**.

   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

   You can also download the job information.

### To update the configuration for a stack

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure that your Terraform configuration file is valid. See Authoring Configurations on page 4277 and Terraform Configurations for Resource Manager on page 3594.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your configuration is stored in a source code control system, such as GitLab, then commit your changes there. The most recent commit is used when you run jobs on the stack.</td>
</tr>
</tbody>
</table>

1. If you are only editing your configuration source provider settings, skip this step.

   Otherwise, ensure you have your revised Terraform configuration (.zip file or folder) ready for upload.

   To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration .zip file for the update.

2. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

3. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

4. Click the name of the stack that you want to update.

   The **Stack Details** page is displayed.

5. In the **Stack Information** tab, next to **Terraform Configuration File (.zip)**, click **Upload New File**.

6. In the **Edit Stack** dialog, either edit your configuration source provider settings (if applicable) or add your revised Terraform configuration (.zip file or folder).

   You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the location of the file or folder.

   The dialog box is populated with information contained in the Terraform configuration.
7. Click Next as needed and then click Save Changes.

Now you can generate a new execution plan using your revised configuration.

To download job information

You can download files associated with jobs: Terraform configurations, Terraform states, and logs.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Jobs.

   You can also access jobs from a stack detail page. Click Stacks and then click the name of the stack you want.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the job you want.

   The Job Details page appears.

   You can view the log by clicking Logs under Resources.

   You can view the state of your resources (for relevant jobs) by clicking View State under Resources.

4. Download the job information you want:

<table>
<thead>
<tr>
<th>To download this job-associated file</th>
<th>Click</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform configuration (.zip file)</td>
<td>Download Terraform Configuration</td>
</tr>
<tr>
<td>Terraform state (.json file)</td>
<td>Download Terraform State</td>
</tr>
<tr>
<td>Logs (.txt file)</td>
<td>Download Logs (Logs section under Resources)</td>
</tr>
</tbody>
</table>

To run an apply job

When you run an apply job for a stack, Terraform creates the resources and executes the actions defined in your Terraform configuration. For configurations stored in a source code control system, such as GitLab, the job uses the most recent commit. The time required to complete an apply job depends on the number and type of cloud resources to be created.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack that you want to use.

   The Stack Details page is displayed.

4. Go to Terraform Actions and select Apply.

5. In the Apply dialog, review the apply job Name and other settings and update it if needed.

6. Click Apply.

   The new apply job is listed under Jobs. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.

7. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click View State under Resources.

To view the state of a job

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Jobs.

   You can also access jobs from a stack detail page. Click Stacks and then click the name of the stack you want.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the job you want.

4. On the Job Details page, click View State under Resources.

To import an existing Terraform state file (run an import job)

You can import state files for existing resources already managed by Terraform.
1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.

   The **Stack Details** page appears.
4. Go to **Terraform Actions** and select **Import State**.
5. In the **Import State File** dialog, review the job **Name** and update it if needed. Avoid entering confidential information.
6. Add your Terraform state file, either by dragging and dropping it onto the dialog's control, or by clicking **Browse** and navigating to the file location.
7. Click **Import**.

   **To release a stack's resources (run a destroy job)**

   Run a destroy job to tear down the resources and clean up the tenancy.

   **Note:**

   We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.

   The **Stack Details** page is displayed.
4. Go to **Terraform Actions** and select **Destroy**.
5. Click **Destroy** again to confirm your action.

   You can monitor the status and review the results of a destroy job by viewing the state or the logs.
6. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the **Job Details** page, then click **View State** under **Resources**.
7. To view the logs for the job, click the name of the job to display the **Job Details** page, then click **Logs** under **Resources**.

**Using the CLI**

This section provides basic sample CLI commands for managing stacks and jobs. For information about using the CLI, see **Command Line Interface (CLI)** on page 4192. For a complete list of flags and options available for CLI commands, see **CLI Help**.

**Managing Stacks (CLI)**

**To create a stack from a file (CLI)**

Use the command related to your file location.

**Important:**

Ensure your Terraform configuration file is valid. See **Authoring Configurations** on page 4277 and **Terraform Configurations for Resource Manager** on page 3594.

To create a stack from a file hosted on a source code control system
Open a command prompt and run `resource-manager stack create-from-git-provider` to create a stack from a file tracked with a configuration source provider:

```
oci resource-manager stack create-from-git-provider --compartment-id <compartment_OCID> --config-source-configuration-source-provider-id <configuration_source_provider_OCID> --config-source-repository-url <repository_url> --config-source-branch-name <branch_name> --display-name "<friendly_name>" --description "<description>" --terraform-version "<version>" --variables <var_file_path> --working-directory "<directory>"
```

**Note:**
You can return later to update stack settings or add variables after you have created the stack.

For example:

```
oci resource-manager stack create-from-git-provider --compartment-id ocid1.tenancy.oc1..uniqueid --config-source-configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --config-source-repository-url https://github.com/user/repo.git --config-source-branch-name mybranch --display-name "My Stack from Git" --description "My Test" --variables file://variables.json --working-directory ""
```

For a complete list of flags and options available for CLI commands, see [CLI Help](#).

To create a stack from an uploaded file:

This section describes how to create a stack from an uploaded configuration file (.zip).

**Note:**
You can also create stacks from configuration files stored in source code control systems, such as Git, and from templates.

On Windows, be sure the .zip file and variables.json files are in the same directory from which you're running the CLI. The CLI currently has a limitation on Windows that prevents correct handling of the files if either one is in a subdirectory.

Open a command prompt and run `oci resource-manager stack create` to create a stack:

```
oci resource-manager stack create --compartment-id <compartment_OCID> --config-source <config_file_name> --variables <var_file_path> --display-name "<friendly_name>" --description "<description>" --working-directory ""
```

**Note:**
You can return later to update stack settings or add variables after you have created the stack.

**Options**

For a complete list of flags and options available for CLI commands, see [CLI Help](#).

- `--compartment-id` is the OCID of the compartment where you want to create the stack.
- `--config-source` is the name of a .zip file that contains one or more Terraform configuration files.
- `--variables` is the path to the file specifying input variables for your resources. Optional.

The Oracle Cloud Infrastructure Terraform provider requires additional parameters when running Terraform locally (unless you are using instance principals). For more information on using variables in Terraform, see [Input Variables](#). See also [Input Variable Configuration](#).

- `--display-name` is the friendly name for the new stack. Optional.
- `--description` is the description for the new stack. Optional.
• --working-directory is the root configuration file in the directory. Optional. If not specified, or if null as in this example, then the service assumes that the top-level file in the directory is the root configuration file.

For example:

```
oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --config-source vcn.zip --variables file://variables.json --display-name "My Example Stack" --description "My Tutorial to Create a VCN" --working-directory ""
```

Example response

```
{
  "data": {
    "config-source": {
      "working-directory": null,
      "config-source-type": "ZIP_UPLOAD"
    },
    "defined-tags": {},
    "description": "My Tutorial to Create a VCN",
    "display-name": "My Example Stack",
    "freeform-tags": {},
    "id": "ocid1.ormstack.oc1..uniqueid",
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-04-03T18:26:56.299000+00:00",
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To discover resources (create a stack from a compartment)

Open a command prompt and run `oci resource-manager stack create-from-compartment` to create a stack from the specified compartment and region:

```
oci resource-manager stack create-from-compartment --config-source-compartment-id <source_compartment_OCID> --config-source-region <source_region> --config-source-services-to-discover [<services>] --compartment-id <compartment_OCID> --terraform-version <version> --display-name "<friendly_name>" --description "<description>"
```

For example (discovers resources from the core and database Terraform provider services; the source compartment is not a root compartment):

```
oci resource-manager stack create-from-compartment --config-source-compartment-id ocid1.tenancy.oc1..uniqueid1 --config-source-region PHX --config-source-services-to-discover [core, database] --compartment-id ocid1.tenancy.oc1..uniqueid2 --terraform-version 0.13.X --display-name "Stack From Compartment ABC" --description "List of Resources to Duplicate"
```

Example response

```
{
  "data": {
    "config-source": {
      "config-source-type": "COMPARTMENT_CONFIG_SOURCE"
    },
    "defined-tags": {},
    "description": "List of Resources to Duplicate",
    "display-name": "Stack From Compartment ABC",
    "id": "ocid1.ormstack.oc1..uniqueid2",
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-04-03T18:26:56.299000+00:00"
  }
}
```
"display-name": "Stack from Compartment ABC",
"freeform-tags": {},
"id": "ocid1.ormstack.oc1..uniqueid",
"lifecycle-state": "CREATING",
"time-created": "2019-04-03T18:26:56.299000+00:00",
"variables": {
  "compartment_ocid": "ocid1.compartment.oc1..uniqueid1",
  "region": "us-phoenix-1"
}
}

{
"data": {
  "compartment-id": "ocid1.compartment.oc1..uniqueid2",
  "config-source": {
    "compartment-id": "ocid1.compartment.oc1..uniqueid1",
    "config-source-type": "COMPARTMENT_CONFIG_SOURCE",
    "region": "PHX",
    "working-directory": null
  },
  "defined-tags": {},
  "description": "List of Resources to Duplicate",
  "display-name": "Stack From Compartment ABC",
  "freeform-tags": {},
  "id": "ocid1.ormstack.oc1.phx.uniqueid",
  "lifecycle-state": "CREATING",
  "stack-drift-status": "NOT_CHECKED",
  "terraform-version": "0.12.x",
  "time-created": "2020-06-01T18:25:56.102000+00:00",
  "time-drift-last-checked": null,
  "variables": {}
},
"etag": "009010cb57f5162655c6a34f5ef8834f204a734df81e4baa696a7d830488ea25",
"opc-work-request-id": "ocid1.ormworkrequest.oc1.phx.uniqueid"
}

To list resources for discovery

This section describes how to determine which services are supported for resource discovery from a given compartment OCID.

When you create a stack from a compartment, the stack represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.

Open a command prompt and run `oci resource-manager stack list-resource-discovery-services` to retrieve a list of services supported for resource discovery (the compartment OCID is used for authorization only):

```
oci resource-manager stack list-resource-discovery-services --compartment-id <compartment_OCID>
```

To list stacks in a compartment

Open a command prompt and run `oci resource-manager stack list` to list the stacks in a compartment:

```
oci resource-manager stack list --compartment-id <compartment_OCID>
```
To list full details of a stack
Open a command prompt and run `oci resource-manager stack get` to list the details for the specified stack:

```bash
oci resource-manager stack get --stack-id <stack_OCID>
```

To detect drift for a stack
Open a command prompt and run `oci resource-manager stack get` to detect drift for the specified stack:

```bash
oci resource-manager stack detect-drift --stack-id <stack_OCID>
```

To list resource details in the stack's last drift detection report
Open a command prompt and run `oci resource-manager stack get` to list the resource details for the last drift detection report of a specified stack:

```bash
oci resource-manager stack list-resource-drift-details --stack-id <stack_OCID>
```

To delete a stack

**Note:**
Associated resources persist after stack deletion. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager stack delete` to delete the specified stack:

```bash
oci resource-manager stack delete --stack-id <stack_OCID>
```

Managing Jobs (CLI)

To generate an execution plan (run a plan job)
Open a command prompt and run `oci resource-manager job create-plan-job` to run a plan job on the specified stack (---display-name is optional):

```bash
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.

To check the current state of the plan job
Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```bash
oci resource-manager job get --job-id <plan_job_OCID>
```

Lifecycle states
Possible values for lifecycle-state:

- ACCEPTED: The job is queued for execution.
- IN_PROGRESS: The job is running.
- FAILED: The job has failed and stopped running.
• SUCCEEDED: The job has completed successfully.
• CANCELING: The job has been notified to cancel, but has not yet stopped running.
• CANCELED: The job was canceled and has stopped running.

Example response
This example shows ACCEPTED for lifecycle-state.

```json
{
  "data": {
    "compartment-id": "ocid1.compartment.oc1..uniqueid",
    "defined-tags": null,
    "display-name": "Example Plan Job",
    "freeform-tags": {},
    "id": "ocid1.ormjob.oc1..uniqueid",
    "lifecycle-state": "ACCEPTED",
    "operation": "PLAN",
    "jobOperationDetails": {
      "operation": "PLAN"
    },
    "stack-id": "ocid1.ormstack.oc1..uniqueid",
    "time-created": "2019-03-09T20:52:13.922000+00:00",
    "time-finished": null,
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To review an execution plan (view the log for a plan job)

Review the execution plan to ensure that it accurately reflects your intentions. View the log file and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

Open a command prompt and run `oci resource-manager job get-job-logs` to view the log file for the specified job:

```
oci resource-manager job get-job-logs --job-id <plan_job_OCID>
```

If you see problems or errors and wish to make changes, then update the appropriate configuration file (.tf file), update the stack to use the revised configuration, generate a new execution plan, and then review the new execution plan.

Example response

The command returns JSON objects that describe log entries. Each object has a message member with a property that displays one line of the execution plan. In the example shown below, the plan creates a single virtual cloud network (VCN); the remaining members show details about the VCN.

```json
...
  {
    "level": "INFO",
    "message": "Terraform will perform the following actions:",
    "timestamp": "2018-05-24T00:57:14.170000+00:00",
    "type": "TERRAFORM_CONSOLE"
  },
  {
    "level": "INFO",
```
To update an execution plan (update an uploaded configuration for a stack)

**Note:**

These instructions don't apply to configurations stored in source code control systems. You can store your Terraform configuration file locally or remotely, using a source code control system. With remote storage, any job running on the associated stack automatically uses the latest version of your configuration. For more information about remotely storing your file, see Managing Configuration Source Providers on page 3581.
To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration.zip file for the update.

Open a command prompt and run `oci resource-manager stack update` with the option `--config-source` to update the Terraform configuration for the specified stack:

```
oci resource-manager stack update --stack-id <stack_OCID> --config-source <config_file_name>
```

After updating the stack, regenerate and review an execution plan (run a new plan job and then view the log file).

**To run an apply job**

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use `FROM_PLAN_JOB_ID`:

  ```
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job_OCID> --display-name "Example Apply Job"
  ```

  Use this option to "apply" your confirmed execution plan to the stack, execute the instructions, and provision the stack with the specified resources.

- To automatically approve the apply job (no plan job specified), use `AUTO_APPROVED`:

  ```
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy AUTO_APPROVED --display-name "Example Apply Job"
  ```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from `IN_PROGRESS` to `SUCCEEDED`.

**To check the current state of the apply job**

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <apply_job_OCID>
```

**Lifecycle states**

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.

**To download or view job information**

You can download Terraform configurations and Terraform states associated with jobs. You can also view logs associated with jobs.

For configurations stored in a source code control system, such as GitLab, job details include the relevant commit identifier.

To download the configuration for a job
Open a command prompt and run `oci resource-manager job get-job-tf-config` to download the Terraform configuration of the specified job to the specified file:

```bash
oci resource-manager job get-job-tf-config --job-id <job_OCID> --file <output_file_name>
```

To download the state file for a job

Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```bash
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

**Example response for an apply job**

```json
{
  "data": {
    "lineage": "57ef4f0c-c8cd-8a32-d45f-d2c40be7b915",
    "modules": [
      {
        "depends_on": [],
        "outputs": {},
        "path": [
          "root"
        ],
        "resources": {
          "oci_core_virtual_network.vcn1": {
            "depends_on": [],
            "deposed": [],
            "primary": {
              "attributes": {
                "cidr_block": "10.0.0.0/16",

                "id": "ocid1.vcn.oc1.phx.uniqueid",
                "state": "AVAILABLE",
                "time_created": "2018-05-24 01:13:05.855 +0000 UTC",
                "vcn_domain_name": "myvcntest.oraclevcn.com"
              },
              "id": "ocid1.vcn.oc1.phx.uniqueid",
              "meta": {
                "e2bf730-ecaa-11e6-8f88-34363bc7c4c0": {
                  "create": 300000000000,
                  "delete": 300000000000,
                  "update": 300000000000
                }
              }
            },
            "tainted": false
          },
          "provider": "provider.oci",
          "type": "oci_core_virtual_network"
        }
      }
    ]
  }
}
```
To view the log for a job

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```bash
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```bash
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

To import an existing Terraform state file (run an import job)

Open a command prompt and run `oci resource-manager x` to import an existing state file for resources already managed by Terraform:

```bash
oci resource-manager job create-import-tf-state-job --stack-id stack_id --tf-state-file state_file
```

To inspect resources in a compartment

Inspecting resources in a compartment allows you to confirm existence of a resource that you provisioned (by running an apply job) or absence of a resource that you released (by running a destroy job).

Open a command prompt and run the CLI command corresponding to the resources you want to inspect.

For example, run `oci network vcn list` to inspect VCN resources in the specified compartment:

```bash
oci network vcn list --compartment-id <compartment_OCID>
```

To release a stack’s resources (run a destroy job)

**Note:**

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and cleanup the resources provisioned by the specified stack:

```bash
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_APPROVED
```
To confirm deletion of the resources, inspect resources in the compartment.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage stacks:

- ChangeStackCompartment
- CreateStack
- DeleteStack
- DetectStackDrift
- GetStack
- GetStackTfConfig
- GetStackTfState
- ListResourceDiscoveryServices
- ListStackResourceDriftDetails
- ListStacks
- ListTerraformVersions
- UpdateStack

Use these API operations to manage jobs:

- CancelJob
- CreateJob
- GetJob
- GetJobLogs
- GetJobLogsContent
- GetJobTfConfig
- GetJobTfState
- ListJobs
- UpdateJob

Use these API operations to manage work requests:

- GetWorkRequest
- ListWorkRequestErrors
- ListWorkRequestLogs
- ListWorkRequests

**Managing Private Templates**

This topic describes how to create, edit, and delete private templates for reuse of Terraform configurations.

**Prerequisites**

IAM policies: To manage private templates, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Administrators: For common policies that give groups access to resources in Resource Manager (stacks, jobs, private templates, and configuration source providers), see Policies for Managing Resources Used with Resource Manager on page 2476. For a complete list of Resource Manager permissions, see Details for Resource Manager on page 2336. Policies for managing accessed resource types are also required.
Important:

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2142.

Using the Console

To create a private template

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Private Templates.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click Create Private Template.
4. On the Create Private Template panel, do the following.
   • Configuration: Select either Folder or Zip File, then either drag and drop your configuration onto the dialog's control or click Browse and navigate to the folder or file location.
   • If needed, edit the default Name provided for your private template. Avoid entering confidential information.
   • Type a Description.
   • (Optional) In Details, type a detailed description of your private template. This text is displayed in the Console page listing templates when the template is expanded.
5. Optionally do one or more of the following:
   • To add an icon, click Show Advanced Options and then either drag and drop your icon file onto the dialog’s Template Icon control or click Browse and navigate to the file location.
     Template icon file requirements: PNG format, 50 KB maximum, 110 x 110 pixels.
     The icon is displayed in the Console page listing templates when the template is expanded.
   • To choose a different compartment for storing your new private template, click Show Advanced Options and then select the compartment you want from Create in Compartment.
   • To tag the template, click Show Advanced Options and add your tag.
6. Click Create.

   Congratulations, your private template is now created. You can now share the private template with anyone in your tenancy that has sufficient permissions.

   For instructions to create a stack from your private template, see the template step.

To create a stack from a private template

This section provides instructions for starting the stack creation process from the detail page for a private template. You can alternatively select a private template from the Create Stack page.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Private Templates.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the private template you want.
4. On the detail page for the selected private template, click Create Stack.
   The Create Stack page appears, populated with information contained in the Terraform configuration for the selected template.
6. Enter a Name for the new stack (or accept the default name provided). Avoid entering confidential information.
7. Optionally enter a **Description**.
8. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.

   A compartment from the list scope is set by default.
9. Optionally apply tags to the stack.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

10. **Click Next**.

    The **Configure Variables** panel displays variables from the Terraform configuration.

    No variables are listed for the **Existing Compartment** stack origin because no Terraform configuration exists yet.

11. Review the variables and make changes as necessary.

    **Important:**

    Do not add your private key or other confidential information to configuration variables.

12. **Click Next**.
13. In the **Review** panel, verify your stack configuration.
14. **Click Create** to create your stack.

    The stack detail page for the new stack appears.

    To deploy the defined resources, **run an apply job** on your new stack.

**To view private templates**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Private Templates**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

**To edit a private template**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Private Templates**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the private template you want.
4. On the detail page for the selected private template, click **Edit**.
5. In the **Edit Template** panel, update the properties you want.
6. **Click Save**.

**To delete a private template**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Private Templates**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), select **Delete Private Template**, and confirm the operation when prompted.

    **Note:**

    You cannot undo this operation.

You can also delete a private template from its detail page. Click the name of the template to display the **Private Template Details** page and then click **Delete**.
Using the CLI

This section provides basic sample CLI commands for managing private templates. For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see CLI Help.

To create a private template from an uploaded file

This section describes how to create a private template from an uploaded configuration file (.zip).

Open a command prompt and run `oci resource-manager template create` to create a private template:

```
oci resource-manager template create --compartment-id <compartment_OCID> --display-name "<friendly_name_for_template>" --description "<description>" --long-description "<long-description>" --logo-file <icon_file_name> --from-json <config_file_name>
```

For example:

```
oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Template" --description "My Default VCN" --long-description "Use this template to provision the default VCN." --logo-file file://mylogo.png --from-json file://myconfig.json
```

To create a stack from a private template

This section describes how to create a stack from a private template.

Open a command prompt and run `oci resource-manager stack create-from-template` to create a stack from a private template:

```
oci resource-manager stack create-from-template --compartment-id <compartment_OCID> --template-id "<template_OCID>"
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage private templates:

- ChangeTemplateCompartment
- CreateTemplate
- DeleteTemplate
- GetTemplate
- GetTemplateLogo
- GetTemplateTfConfig
- ListTemplateCategories
- ListTemplates
- UpdateTemplate

Managing Configuration Source Providers

This topic describes how to create, edit, and delete configuration source providers for remote Terraform configurations.

Prerequisites

IAM policies: To manage configuration source providers, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.
you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Administrators: For common policies that give groups access to resources in Resource Manager (stacks, jobs, private templates, and configuration source providers), see Policies for Managing Resources Used with Resource Manager on page 2476. For a complete list of Resource Manager permissions, see Details for Resource Manager on page 2336. Policies for managing accessed resource types are also required.

**Important:**

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2142.

### Prerequisites for connecting to GitHub and GitLab

Following are the prerequisites to connect Oracle Cloud Infrastructure Resource Manager to GitHub and GitLab.

- Your GitHub or GitLab server must be accessible over the Internet by Oracle Cloud Infrastructure IP addresses. (This accessibility requirement does not apply to GitLab.com.)
- Make sure Resource Manager can resolve your GitHub or GitLab URL. Make sure that your GitHub or GitLab server is deployed with a well-known root certificate, such as digicert, so that Oracle Cloud Infrastructure can trust its endpoint.
- Configure your network to allow access from Oracle Cloud Infrastructure IP address ranges. Ensure that you include ranges for all relevant services, including the Oracle Services Network (tag: OSN).
- Enable network ingress rules on the VCN where your GitHub or GitLab server is deployed to allow access from Oracle Cloud Infrastructure IP addresses.
- You must have GitHub or GitLab admin or owner permissions for the repository.
- You must have a Personal Access Token (PAT) to your GitHub or GitLab server. The scope read_api is required for use with Resource Manager. For security, we recommend excluding write_repository scope.

To create a PAT, see the relevant documentation:

- GitHub: https://docs.github.com/en/free-pro-team@latest/github/authenticating-to-github/creating-a-personal-access-token
- GitLab: https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html

- You must have Resource Manager permissions required for your task:
  - To create a configuration source provider, you need manage orm-config-source-providers.
  - To create a stack with an existing configuration source provider, you need manage orm-stacks and read orm-config-source-providers.

For more information, see Policies for Managing Resources Used with Resource Manager on page 2476.

For troubleshooting information, see GitHub and GitLab Connection Issues on page 3624.

### Using the Console

**To create a configuration source provider**

**Important:**

To connect to GitHub or GitLab, you must use a Personal Access Token. See Prerequisites for connecting to GitHub and GitLab on page 3582.

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Configuration Source Providers.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click Create Configuration Source Provider.

4. In the Create Configuration Source Provider panel, do the following.
   - Type a Name for your configuration source provider. Avoid entering confidential information.
   - Type a Description.
   - Select the Compartment where you want to create the configuration source provider.
   - Select the Type of configuration source provider you want. Choose from the following options.
     - GitHub: Supported products
       - GitHub Enterprise
         - GitHub Enterprise Server
         - GitHub Enterprise Cloud
         - GitHub Free for organizations
         - GitHub Free for user accounts
         - GitHub Team
     - GitLab: Supported products
       - GitLab Community Edition
       - GitLab Enterprise Edition
       - GitLab.com
   - Paste the Server URL.

   Example URLs:

<table>
<thead>
<tr>
<th>Product</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GitHub Enterprise Cloud</td>
<td><a href="https://github.com/org-name">https://github.com/org-name</a></td>
</tr>
<tr>
<td>GitHub Enterprise Server</td>
<td><a href="https://hostname/api/v3">https://hostname/api/v3</a></td>
</tr>
<tr>
<td>GitHub Free for Organization</td>
<td><a href="https://github.com/org-name">https://github.com/org-name</a></td>
</tr>
<tr>
<td>GitHub Free for User Accounts</td>
<td><a href="https://github.com">https://github.com</a></td>
</tr>
<tr>
<td>GitHub team</td>
<td><a href="https://github.com/team-name">https://github.com/team-name</a></td>
</tr>
<tr>
<td>GitLab.com product</td>
<td><a href="https://gitlab.com/">https://gitlab.com/</a></td>
</tr>
<tr>
<td>GitLab installation (relative URL)</td>
<td><a href="https://example.com/gitlab">https://example.com/gitlab</a></td>
</tr>
<tr>
<td>GitLab installation (subdomain)</td>
<td><a href="https://gitlab.example.com/">https://gitlab.example.com/</a></td>
</tr>
</tbody>
</table>

   - Paste the Personal Access Token.
   - To tag the new configuration source provider, click Show Advanced Options and add your tag.

   For troubleshooting information, see GitHub and GitLab Connection Issues on page 3624.

5. Click Create.

To edit a configuration source provider

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Configuration Source Providers.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the configuration source provider that you want to edit.

4. Click Edit Configuration Source Provider.

5. In the Edit Configuration Source Provider dialog box, update property values as needed.

   For troubleshooting information, see GitHub and GitLab Connection Issues on page 3624.
6. Click Save.

**To delete a configuration source provider**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>A configuration source provider cannot be deleted if it is associated with a stack. To remove the association from the stack, edit the stack.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Configuration Source Providers.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the configuration source provider that you want to delete.
4. Click Delete Configuration Source Provider and then confirm the action.

**Using the CLI**

This section provides basic sample CLI commands for managing stacks and jobs. For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see CLI Help.

**To create a configuration source provider**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To connect to GitHub or GitLab, you must use a Personal Access Token. See Prerequisites for connecting to GitHub and GitLab on page 3582.</td>
</tr>
</tbody>
</table>

Choose the option for the provider type you want:

- **GitHub:**
  
  Open a command prompt and run `resource-manager configuration-source-provider create-github-access-token-provider` to create a GitHub configuration source provider:

  ```
  oci resource-manager stack create-github-access-token-provider --api-endpoint <github_url> --access-token <personal_access_token> --compartment-id <compartment_OCID> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack create-github-access-token-provider --api-endpoint https://api.github.com/ --access-token token --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Configuration Source Provider" --description "Department 80"
  ```

- **GitLab:**
  
  Open a command prompt and run `resource-manager configuration-source-provider create-gitlab-access-token-provider` to create a GitLab configuration source provider:

  ```
  oci resource-manager stack create-gitlab-access-token-provider --api-endpoint <gitlab_url> --access-token <personal_access_token> --compartment-id <compartment_OCID> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack create-gitlab-access-token-provider --api-endpoint https://gitlab.com/api/v3/ --access-token token --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Configuration Source Provider" --description "Department 80"
  ```
For a complete list of flags and options available for CLI commands, see CLI Help.

**To update a configuration source provider**

Choose the option for the provider type you want:

- **GitHub:**

  Open a command prompt and run `resource-manager configuration-source-provider update-github-access-token-provider` to edit the specified configuration source provider:

  ```bash
  oci resource-manager stack update-github-access-token-provider --configuration-source-provider-id <configuration_source_provider_OCID> --api-endpoint <github_url> --access-token <personal_access_token> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```bash
  oci resource-manager stack update-github-access-token-provider --configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --description "Department 99"
  ```

- **GitLab:**

  Open a command prompt and run `resource-manager configuration-source-provider update-gitlab-access-token-provider` to edit the specified configuration source provider:

  ```bash
  oci resource-manager stack update-gitlab-access-token-provider --configuration-source-provider-id <configuration_source_provider_OCID> --api-endpoint <gitlab_url> --access-token <personal_access_token> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```bash
  oci resource-manager stack update-gitlab-access-token-provider --configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --description "Department 99"
  ```

For a complete list of flags and options available for CLI commands, see CLI Help.

**To delete a configuration source provider**

**Note:**

A configuration source provider cannot be deleted if it is associated with a stack. To remove the association from the stack, edit the stack.

Open a command prompt and run `resource-manager configuration-source-provider delete` to delete the specified configuration source provider:

```bash
oci resource-manager configuration-source-provider delete --config-source-provider-id <configuration_source_provider_OCID>
```

For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use these API operations to manage configuration source providers:

- ChangeConfigurationSourceProviderCompartment
- CreateConfigurationSourceProvider
- DeleteConfigurationSourceProvider
- GetConfigurationSourceProvider
- ListConfigurationSourceProviders
- UpdateConfigurationSourceProvider

**Using Remote Exec**

With Resource Manager, you can use Terraform's remote exec functionality to execute scripts or commands on a remote computer. You can also use this technique for other provisioners that require access to the remote resource.

**Prerequisites**

- The location where the script is remotely executed must be an Oracle Cloud Infrastructure resource that has a public IP and supports remote login.
- On Windows, WinRM must be enabled. On Linux or Unix, SSH must be enabled.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 4179.

**Authenticating**

We recommend using one of the following approaches, depending on whether you have access to the Vault service. For more information, see Overview of Vault on page 3952.

**With Vault**

First, use Vault to encrypt your private key. For more information, see Managing Keys on page 3962 and Using Keys on page 3998.

Next, provide the encrypted private key to Resource Manager. You can use the decrypt data source to decrypt it.

The following code sample demonstrates this process.

```hcl
data "oci_kms_decrypted_data" "private_key_decrypted" {
  #Required
  ciphertext = "${file(var.encrypted_private_key_path)}"
  crypto_endpoint = "${var.decrypted_data_crypto_endpoint}"
  key_id = "${var.kms_encryption_key_id}"
}

resource "oci_core_instance" "TFInstance1" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ADs.availability_domains[var.availability_domain - 1],"name")}"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFInstance"
  hostname_label = "instance3"
  shape = "${var.instance_shape}"
  subnet_id = "${oci_core_subnet.ExampleSubnet.id}"
  source_details {
    source_type = "image"
    source_id = "${var.instance_image_ocid[var.region]}"
  }
  extended_metadata {
    ssh_authorized_keys = "${var.ssh_public_key}" 
  }
```
Without Vault

If you do not have access to the Vault service, you can dynamically generate a key pair and store them in the state file.

1. Generate a key pair using a TLS resource.
2. When you launch the Compute instance, use the public key from the TLS resource.
3. When you establish the SSH connection, provide the private key.

| Caution: |
| You should not save your private key in your Terraform configuration file because that is not a secure location. |

The following sample demonstrates how to use the TLS private key resource to provision a Compute instance, then perform a remote execution on that instance.

```terraform
resource "null_resource" "remote-exec" {
  connection {
    agent = false
    timeout = "30m"
    host = "${oci_core_instance.TFInstance1.public_ip}"
    user = "${var.opc_user_name}"
    private_key = "${data.oci_kms_decrypted_data.test_decrypted_data.plaintext}"
  }

  inline = [
    "touch ~/IMadeAFile.Right.Here"
  ]
}
```
depends_on = ["oci_core_instance.TFInstance1"]

provisioner "remote-exec" {
    connection {
        agent       = false
        timeout     = "30m"
        host        = "${oci_core_instance.TFInstance1.public_ip}"
        user        = "${var.opc_user_name}"
        private_key = "${tls_private_key.public_private_key_pair.private_key_pem}" 
    }

    inline = ["touch ~/IMadeAFile.Right.Here"]
}

Connection Construct

This example demonstrates how to use a connection construct for remote exec. Terraform uses a number of defaults when connecting to a resource, but these can be overridden using a connection block in either a resource or provisioner. For more information, see Provisioner Connections.

Templates

This topic describes Oracle-provided templates available for Resource Manager.

Templates are Oracle-provided, pre-built Terraform configurations that provision sets of resources used in common scenarios. You can access templates from the Console.

<table>
<thead>
<tr>
<th>Template</th>
<th>Type</th>
<th>Description</th>
<th>Launch</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Data Warehouse Database</td>
<td>Service</td>
<td>Provision an Autonomous Data Warehouse database</td>
<td>Launch stack</td>
</tr>
<tr>
<td>Autonomous Transaction Processing Database</td>
<td>Service</td>
<td>Provision an Autonomous Transaction Processing database</td>
<td>Launch stack</td>
</tr>
<tr>
<td>Block Volume</td>
<td>Service</td>
<td>Provision a block volume in Oracle Cloud Infrastructure</td>
<td>Launch stack</td>
</tr>
<tr>
<td>Compute Instance</td>
<td>Service</td>
<td>Provision a Compute instance in Oracle Cloud Infrastructure</td>
<td>Launch stack</td>
</tr>
<tr>
<td>Data Science</td>
<td>Service</td>
<td>Provision Data Science and its prerequisites</td>
<td>Launch stack</td>
</tr>
</tbody>
</table>

Note:

Create your own private templates to share with others in the tenancy.

Common uses of templates:

- Test-drive the idea of infrastructure as code.
- Apply proven best practices to your production workflow configuration.
<table>
<thead>
<tr>

</table>

**Preinstalling the Oracle Cloud Development Kit**

This page describes how to provision a Compute instance with the Oracle Cloud Development Kit preinstalled and ready to use.

**What’s Included**

The Oracle Cloud Development Kit template preinstalls the following Oracle Cloud Infrastructure items on the Compute instance:

- Command Line Interface (CLI)
- Terraform Provider on page 4275
- Ansible (includes OCI Ansible modules)
- The following SDKs:
  - Go
  - Java
  - Python
- Git: Use the provided Git command line tool to access any Git-related version control systems, such as Bitbucket, GitHub, and GitLab.

*Instance principal authorization* is set up for installed items and the provisioned Compute instance. An upgrade script is also included.
Steps for Using the Oracle Cloud Development Kit
To provision an instance with the development kit

1. Launch the Create Stack page for the Oracle Cloud Development Kit template by clicking this button:

   ![Deploy to Oracle Cloud](image)

Alternative steps from the Console

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
c. Click **Create Stack**.
d. In the **Create Stack** dialog, click **Template**.
e. Under **Stack Configuration**, click **Select Template** and then select **Oracle Cloud Development Kit**.

2. Follow the prompts to configure and save your new stack

a. In the **Create Stack** dialog, enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.
b. Optionally enter a **Description**.
c. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack. A compartment from the list scope is set by default.
d. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
e. Click **Next**.

The **Configure Variables** panel displays the following variables:

- **Instance Shape**: Select the shape you want to use for the Compute instance.
- **Auto-Generate SSH Key Pair**: Either generates an SSH key pair or allows you to upload a public key.
  - Enabled (selected): Automatically generates an SSH key pair for accessing the instance. The private key is stored in the Terraform state file. You'll use the private key later to connect to the instance.
  
  **Important:**
  Do not use this option in production. The Terraform state file containing the private key is visible to anyone with access to the created stack.
  
  - Disabled (cleared): Allows you to upload a public key. No private key is stored. Keep the corresponding private key in a safe location. You'll use the private key later to connect to the instance.
  
  For instructions on generating SSH key pairs, see **Managing Key Pairs on Linux Instances** on page 693.

- **Compute Instance to Access All Resources at Tenancy Level**: Controls the level used for the **dynamic group policy**, which determines what resources are accessible by users of the Compute instance.
  - Enabled (selected): Tenancy level for access to all resources in the tenancy.
  - Disabled (cleared): Compartment level for access to all resources in the same compartment as the instance.

f. Click **Next**.
g. In the **Review** panel, verify your stack configuration.
h. Click **Create** to create your stack.

The new stack appears in the Stack Details page.
3. Provision the instance by running an apply job on the new stack

   a. On the Stack Details page for your new stack, go to Terraform Actions and select Apply.
   b. In the Apply dialog, review the apply job Name and other settings and update it if needed.
   c. Click Apply.

The new apply job is listed under Jobs. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.

Once the instance is provisioned (indicated by a "Succeeded" status for the apply job), installation of the development kit items begins. The installation process takes a few minutes. If you connect to the instance before the installation finishes, then a warning message indicates that the installation is still in process. Once the items are installed on the instance, you can immediately use them.

d. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click View State under Resources.

Congratulations! You’ve provisioned a Compute instance with the Oracle Cloud Development Kit already installed and ready to use. You can now connect to the instance and use the development kit.

To connect to your newly created instance

Run the following command:

```
ssh -i <private-key> opc@<compute-instance-public-ip>
```

 `<private-key>` is the private key associated with the instance you provisioned from the stack created using the Oracle Cloud Developer Tools template.

 `<compute-instance-public-ip>` is the IP address of the instance.

To retrieve the associated private key and IP address

1. Go to the Stack Details page for your newly provisioned instance:
   a. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
   b. Click the name of the stack to display its detail page.
2. Click the Application Information tab.
3. Copy the value for Compute Instance IP Address.
4. For the private key, follow the steps that correspond to the key option you selected while creating your stack:
   - If you enabled Auto-Generate SSH Key Pair, then retrieve the generated private key: Copy the value for Generated Private Key for SSH Access.
   - If you disabled Auto-Generate SSH Key Pair, then reference the full path and name of the file that contains the private key corresponding to the public key that you uploaded while creating the stack.

   **Note:**

   When you connect to your instance, the private key file permissions are validated. For security, your private key must be accessible by the owner only; otherwise, you won’t be allowed to connect to the instance. (Owner write permissions are required for you to add the private key to the file.)

   For Unix or Linux, use the command `chmod 600 (-rw-------)`.

For general information about connecting to Compute instances, see Connecting to an Instance on page 733.

Once connected to your instance, you can use the installed development kit.

To use the installed development kit

See the following examples:

- CLI: See Using the CLI on page 4207
  Usage: See Easy Provisioning, CLI Updates
Resource Manager

• **Terraform Provider**
  Usage: See Terraform Provider on page 4275.
• **Ansible** (includes OCI Ansible modules)
  Usage: See Writing a Sample Playbook on page 4332.
• **SDKs:**
  • Go
  • Java
    Usage: See Concepts on page 4233.
  • Python
    Setup and usage: See Client-Side Encryption on page 4244.
    Setup and usage for open source SDKs: See Open Source SDKs
  • Git: Use the provided Git command line tool to access any Git-related version control systems, such as Bitbucket, GitHub, and GitLab.
    Usage: To get help on using Git, access the terminal on your new Compute instance and run `git --help`.

To upgrade the installed development kit

1. Connect to the instance that you provisioned from the Oracle Cloud Development Kit template.
2. Run the upgrade command:

```
update-kit.sh
```

Preconfigured Authorization

Instance principal authorization is set up for installed development kit items and the provisioned Compute instance. The template provides the following preconfiguration:

• A **dynamic group**
• An **IAM policy**, with all resource access determined by stack configuration (either tenancy or compartment level)
• Environment variables set in `.bashrc` on the Compute instance for CLI, Terraform, and Ansible

For more information about instance principal authorization, see Calling Services from an Instance on page 2410.

Using the Deploy to Oracle Cloud Button

This page describes the advanced topic of constructing a URL for **Deploy to Oracle Cloud** button.

When properly linked, this button provides a direct option for your users to create stacks with your Terraform configuration.

![Deploy to Oracle Cloud Button](image)

This button takes a user directly to the **Create Stack** page in the Oracle Cloud Infrastructure Console. The button is linked to a Terraform configuration file package that you specify, so the Terraform configuration is already selected for the user when they **create the stack**. You can store Terraform configuration files in a supported provider.

Example of Functioning Deploy Button

The following **Deploy to Oracle Cloud** button is configured to launch the template from [https://github.com/oracle-quickstart/oci-cloudnative](https://github.com/oracle-quickstart/oci-cloudnative).
Supported Providers

The following providers are supported for forming package URLs to use with the **Deploy to Oracle Cloud** button:

- **GitHub**
  
  Example package URL 1: Direct: https://github.com/myrepo/mydirectory/master.zip
  
  Example package URL 2: Release: https://github.com/myrepo/mydirectory/0.0.1.zip
  
  To get the .zip URL to a release in GitHub, see [https://docs.github.com/en/free-pro-team@latest/github/administering-a-repository/linking-to-releases](https://docs.github.com/en/free-pro-team@latest/github/administering-a-repository/linking-to-releases).

- **GitLab**
  
  Example package URL 1: Direct: https://gitlab.com/myrepo/mydirectory/master.zip
  
  Example package URL 2: Release: https://gitlab.com/myrepo/mydirectory/0.0.1.zip

- **Object Storage (pre-authenticated request URL)**
  
  Example package URL: https://objectstorage.region.oraclecloud.com/p/encrypted-string/n/object-storage-namespace/b/bucket/o/filename

To display the linked deploy button

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure that your Terraform configuration file is valid. See <a href="https://docs.oracle.com/en/iaas/Content/Terraform/TerraformConfigurations.htm">Authoring Configurations</a> on page 4277 and <a href="https://docs.oracle.com/en/iaas/Content/Terraform/TerraformConfigurations.htm">Terraform Configurations for Resource Manager</a> on page 3594.</td>
</tr>
</tbody>
</table>

You can display the linked **Deploy to Oracle Cloud** button on repository pages and other web pages.

**Markdown code**

To display the **Deploy to Oracle Cloud** button on a repository page, add the following Markdown code to a README.md file.

```markdown
```

<package-url> is the URL for the .zip file to a Terraform configuration that is stored in a supported provider.

Example Markdown code with a package URL from GitHub:

```markdown
```

**HTML code**

To display the **Deploy to Oracle Cloud** button on a web page, add the following HTML code.

```html
<a href="https://cloud.oracle.com/resourcemanager/stacks/create?zipUrl=<package-url>"
   target="_blank"
   rel="noopener noreferrer">Deploy to Oracle Cloud</a>
```
To create a stack from the linked deploy button

1. Click **Deploy to Oracle Cloud** (the deploy button linked to the Terraform configuration).
2. If you are not yet signed in to the Oracle Cloud Infrastructure Console, then sign in. See [Signing In to the Console](#) on page 41.
   
   The **Create Stack** dialog appears with the selected package identified.
3. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.
4. Optionally enter a **Description**.
5. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
   
   A compartment from the list scope is set by default.
6. Select a **Terraform Version**.
   
   **Note:**
   
   Terraform versions are not backward compatible.
7. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
8. Click **Next**.
   
   The **Configure Variables** panel displays variables from the selected Terraform configuration file.
9. Review the variables and make changes as necessary.
   
   **Important:**
   
   Do not add your private key or other confidential information to configuration variables.
10. Click **Next**.
11. In the **Review** panel, verify your stack configuration.
12. Click **Create** to create your stack.

To deploy the defined resources, run an apply job on your new stack.

**Terraform Configurations for Resource Manager**

This topic describes requirements and recommendations for Terraform configurations used with Resource Manager. For basic information about Terraform configurations, see [Authoring Configurations](#) on page 4277. For instructions on using configurations with stacks and jobs, see [Managing Stacks and Jobs](#) on page 3557.
You can store your Terraform configuration file locally or remotely, using a source code control system. With remote storage, any job running on the associated stack automatically uses the latest version of your configuration. For more information about remotely storing your file, see Managing Configuration Source Providers on page 3581.

In addition to writing your own Terraform configuration file, you also have the option to generate a Terraform configuration from either an existing compartment using resource discovery or a sample template.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not provide user credentials or other confidential information in your Terraform configurations.</td>
</tr>
</tbody>
</table>

Requirements

Terraform configuration files used with Resource Manager must meet the following requirements.

Terraform Provider

When using Resource Manager, the region field in the provider "oci" block is the only required field. For more information about defining providers, see Configuration File Requirements on page 4278.

File Structure

Resource Manager requires the following file structure for the Terraform configuration:

- The working directory must contain at least one .tf file. The working directory cannot contain a .terraform directory.
- The working directory is the path from which to run Terraform. By default, the working directory is the root directory of your configuration (for an uploaded configuration, the root of your .zip file). When using the API, you can specify a different location for the working directory by setting the workingDirectory parameter.
- The configuration must follow guidelines specified in Authoring Configurations on page 4277.
- No Terraform state files (.tfstate) can exist in the configuration.
- If you plan to upload the configuration locally, then bundle all files into a .zip file.

Modules

Resource Manager supports the following Terraform module sources:

- Local paths
- Terraform Registry
- GitHub
- Bitbucket
- Generic Git repositories
- HTTP URLs

Variables

We recommend using a schema document with your Terraform configuration to facilitate user entry in the Oracle Cloud Infrastructure Console.

Resource Manager does not have requirements for variables in Terraform configurations. Resource Manager supports the native Terraform behavior for handling variables. Terraform sets variables from your variable definitions that use supported type constraints.

Example Terraform Configuration for Resource Manager

The following example shows a Terraform configuration that is contained in a single file. This basic sample defines just one Terraform provider, one Oracle Cloud Infrastructure resource, and a set of variables.

```terraform
variable "compartment_ocid" {}
```
More often, Terraform configurations consist of two or more files bundled together (for an uploaded configuration, the files would be bundled in a .zip file). To see more complex, multi-file Terraform configurations, explore the examples at the Oracle Cloud Infrastructure GitHub: terraform-provider-oci/docs/examples.

Schema Documents

Schema documents are recommended for Terraform configurations when using Resource Manager. Including a schema document allows you to facilitate variable entry in the Oracle Cloud Infrastructure Console by surfacing SSH key controls and by naming, grouping, dynamically prepopulating values, and more, including defining text in the Application Information tab displayed for a created stack.

Requirements for Schema Documents

Schema documents for Resource Manager have the following requirements:

- YAML format.
- Placement under the root folder of the Resource Manager Terraform configuration. (By default, the schema document assumes that the root folder is the working directory.)

Supported Types (Dynamic Prepopulation and Controls)

This section lists the types supported by Resource Manager for dynamic prepopulation and controls.

<table>
<thead>
<tr>
<th>Type (rendered as a dynamically prepopulated dropdown field unless otherwise noted)</th>
<th>Resource identifier</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>oci:core:image:id</td>
<td>Image OCID</td>
<td>Mandatory dependsOn field: compartmentId</td>
</tr>
<tr>
<td>oci:core:instanceshape:name</td>
<td>Instance shape name</td>
<td></td>
</tr>
<tr>
<td>oci:core:ssh:publickey</td>
<td>--</td>
<td>Surfaces a control for adding one or more public SSH keys by dropping files or pasting key values. For more information, see SSH key control.</td>
</tr>
<tr>
<td>oci:core:subnet:id</td>
<td>Subnet OCID</td>
<td></td>
</tr>
<tr>
<td>oci:core:vcn:id</td>
<td>VCN OCID</td>
<td></td>
</tr>
<tr>
<td>oci:database:autonomouscontainerdatabase:id</td>
<td>Autonomous container database OCID</td>
<td></td>
</tr>
<tr>
<td>oci:database:autonomousdatabase:id</td>
<td>Autonomous database OCID</td>
<td></td>
</tr>
<tr>

<td>oci:identity:region:name</td>
<td>Region name</td>
<td></td>
</tr>
<tr>
<td>oci:kms:vault:id</td>
<td>Vault OCID</td>
<td></td>
</tr>
</tbody>
</table>

**Meta Schema for Validation**

Use the following meta schema file to confirm that your schema document is using supported variable types.

**Meta Schema**

```json
# Meta JSON Schema.
#
# This is used to validate the Schema file when the package is uploaded/loaded into Resource Manager.
# For marketplace, it is also used to validate the package when the package artifact is created in Partner Portal.
#
# NOTE: additionalProperties are set to true explicitly even though this is the default. It must be set to true in
# cases where we use the allOf. This is a quirk of JSON Schema. During validation, allOf means it has to match all of
# the individual definitions separately. It doesn't mean it has to match a Union of the individual definitions. This
# is a known issue with JSON Schema.

Example Schema Document

Following is an example schema document.

Example

```
# Title shown in Application Information tab.
title: Sample input variable schema
# Sub Title shown in Application Information tab.
description: Sample description...
informationalText: Sample informational text to display in tab...
schemaVersion: 1.1.0
version: "20190304"

# URL of Logo Icon used on Application Information tab. Logo must be 130x130 pixels.
# (Optional)
logoUrl: https://cloudmarketplace.oracle.com/marketplace/content?
contentId=53066708

# Used in Application Information tab to Hyperlink Title and Logo to the Marketplace
# Listing.
# Also used to link to Listing Usage section for "View Instructions".
# (Optional) If it is missing, Application Information uses the "marketplace-listing-id" tag for the same purpose.

# Used to present outputs with more refinement on the Application
# Information tab.
# The Application Information tab is only shown if the schema has a "title",
# "description", and at least one output in this "outputs" section.
#
# type:
# - boolean
# - string
# - number
# - link - contains url that can be hyperlinked. If type is not specified
#   and the
# value is a proper url, this type is assumed.
#ócíd - contains an OCID. An attempt is made to hyperlink it to the designated resource in the console.
#csv - synonym for list. Array of values converted to a comma separated list.
#json - synonym for map. Map of key / values converted to JSON.
#list - array of values converted to a comma separated list.
#map - map of key / values converted to JSON.

#displayText: used in links to give text displayed instead of value
#title: friendly label
#visible: if false, this output is not shown in the outputs section of Application Information.

It can still be used as the `primaryOutputButton`.

```yaml
outputs:
  controlCenterUrl:
    type: link
    title: Control Center
    displayText: Control Center
    visible: false

  schemaRegistryUrl:
    type: link
    title: Schema Registry
    displayText: Schema Registry

  schemaRegistryPublicIps:
    type: csv
    title: Public IPs

  schemaRegistryLoadBalancer:
    type: ocid
    title: Load Balancer

  brokerPublicIps:
    type: csv

  connectUrl:
    type: link
    title: Connect
    displayText: Connect

  connectPublicIps:
    type: csv
    title: Public IPs

  restUrl:
    type: link
    title: Rest API
```

#primaryOutputButton is a reference to a link output that creates a primary button on the Application Information tab.
(Optional) if not provided, no primary button is shown. Also if the output referenced is not a link output, no button is shown.

```
primaryOutputButton: ${controlCenterUrl}
```

# Used to group Outputs. Any outputs not included in these defined groups, are included in a default group labelled "Outputs".
(Optional) if not groups are given, outputs are not grouped at all.

```
outputGroups:
  - title: Schema Registry
```
How to Control Console Items

This section provides instructions and examples for controlling the display of stack variables and stack details page items in the Oracle Cloud Infrastructure Console for stacks created from your Terraform configuration file. Using a schema document, you can define how variables look and behave during stack creation and what text is displayed in the Application Information tab for a created stack.

Following are Console display items that are controlled by the schema document.

Field label and description

To render a field label and description for a variable:

• Add the lines `title: <field_label>` and `description: <field_description>`.

Example image for a variable field label and description:

![Application Name](image)

Example declaration for a variable field label and description:

```yaml
functions_app_name:
  type: string
  # field label, displayed above field
title: "Application Name"
  # field description, displayed below field
description: "Do not use spaces."
```

Default value

To render a variable with a default value:

• Add the line `default: <default-value>`.

Example image for a variable with a default value:

![DataScienceApp](image)

Example declaration for a check box variable:

```yaml
functions_app_name:
  type: string
  title: "Application Name"
  description: "Do not use spaces."
  required: true
  # provide a default value
```
Group and order

To render a group (box) of variables, with the variables in a prescribed sequence:

- Add a `variableGroups` block.
- Add a `title` line to this block.
- Add a `variables` block to `variableGroups`.
- Add variables to the `variables` block in the order you want.

Example image for a group of variables:

```
Network Configuration
```

Example declaration for a group of variables with a prescribed order:

```
variableGroups:
  - title: "Network Configuration"
    variables:
      - ods_vcn_use_existing
      - ods_vcn_existing
      - ods_vcn_name
      - ods_vcn_cidr
      - ods_subnet_public_existing
      - ods_subnet_public_name
      - ods_subnet_public_cidr
      - ods_subnet_private_existing
      - ods_subnet_private_name
      - ods_subnet_private_cidr
```

SSH key control

To render a variable as an SSH key control:

- Add the line `type: oci:core:ssh:publickey`.

Example image for an SSH key control:
Example declaration for an SSH key control:

```yaml
ssh_public_key:
  title: SSH Public Key
  description: The public SSH key for the key-pair that you want to use, if you wish to log in to the instances over SSH
  # renders variable as an SSH key control
  type: oci:core:ssh:publickey
  required: true
  pattern: "((^ssh-rsa AAAAB3NzaC1yc2|ecdsa-sha2-nistp256
  AAAAE2VjZHNhLXNoYT1tbmlzdHAyNT|ecdsa-sha2-nistp384
  AAAAE2VjZHNhLXNoYT1tbmlzdHAzODQAAAAlbmldHAAzOD|ecdsa-sha2-nistp521
  AAAAE2VjZHNhLXNoYT1tbmlzdHA1MjEAAAAIbmldHAA1Mj|ssh-ed25519
  AAAAC3NzaC1lZDI1NTE5|ssh-dss AAAAB3NzaC1kc3}|0-9A-Za-z+\/[=]{0,3})
  (\[^,\]*)?)
  ,((ssh-rsa AAAAB3NzaC1yc2|ecdsa-sha2-nistp256
  AAAAE2VjZHNhLXNoYT1tbmlzdHAyNT|ecdsa-sha2-nistp384
  AAAAE2VjZHNhLXNoYT1tbmlzdHAzODQAAAAlbmldHAAzOD|ecdsa-sha2-nistp521
  AAAAE2VjZHNhLXNoYT1tbmlzdHA1MjEAAAAIbmldHAA1Mj|ssh-ed25519
  AAAAC3NzaC1lZDI1NTE5|ssh-dss AAAAB3NzaC1kc3}|0-9A-Za-z+\/[=]{0,3})
  (\[^,\]*)?)\)*$"
```

Dynamic prepopulation

To dynamically prepopulate variables with values based on dependencies:

- Add the lines `type: <supported-type>` and `dependsOn: <other_variable>`.

  `<supported-type>` is a type listed at Supported Types (Dynamic Prepopulation and Controls) on page 3596.

Example image for a dynamically prepopulated variable:

```
SELECT VCN  OPTIONAL

VCN-20200921-1967
```

Example declaration for a dynamically prepopulated variable:

```yaml
ods_vcn_existing:
  # prepopulates available values for VCN
  type: oci:core:vcn:id
  title: "Select VCN"
  # determines values for prepopulation from selected compartment
  dependsOn:
    compartmentId: compartment_ocid
```
Example declarations for VCN depending on compartment, subnet depending on both compartment and VCN:

```python
vcnCompartment:
    # prepopulates available values for compartment
type: oci:identity:compartment:id

myVcn:
    # prepopulates available values for VCN
type: oci:core:vcn:id
    # determines values for VCN prepopulation from selected compartment
dependsOn:
        compartmentId: ${vcnCompartment}

subnetCompartment:
    # prepopulates available values for compartment
type: oci:identity:compartment:id

mySubnet:
    # prepopulates available values for subnet
type: oci:core:subnet:id
    # determines values for subnet prepopulation from selected compartment
    and VCN
dependsOn:
        compartmentId: ${subnetCompartment}
        vcnId: ${myVcn}
```

Image example declaration 1, where image depends on compartment only (the one mandatory dependsOn field):

```python
instance_image:
    title: Image
description: Image
type: oci:core:image:id
required: true
dependsOn:
    compartmentId: ${compartment_ocid}
```

Image example declaration 2, where image depends on compartment, operating system, operating system version, and shape:

```python
instance_image:
    title: Image
description: Image
type: oci:core:image:id
required: true
dependsOn:
    compartmentId: ${compartment_ocid}
    operatingSystem: "Oracle Linux"
    operatingSystemVersion: "7.8"
    shape: "<shape name>"
```

**Enumerated values**

To render enumerated values for a variable:

- Add the lines `type: enum` and add an `enum` block.

Example image for a variable with enumerated values:
Example declaration for a variable with enumerated values:

```yaml
ods_vault_type:
  type: enum
  title: "Vault Type"
  default: "DEFAULT"
  # enumerated values
  enum:
    - DEFAULT
    - VIRTUAL_PRIVATE
```

Check box

To render a variable as a check box:

- Add the line `type: boolean`.

Example image for a check box variable:

![Check Box](image)

Example declaration for a check box variable:

```yaml
ods_vcn_use_existing:
  # renders variable as a check box
  type: boolean
  title: "Use Existing VCN?"
  required: true
  default: false
```

Visibility dependency

**Note:**

Supported operations include "eq", "and", "or", and "not". Groups have higher priority than the groups' constituent variables. For example, if a variable is visible within a group that is not visible, then the entire group is not visible.

To hide or show variables or variable groups depending on other variables:

- Add the line `visible: <other_variable>`.

Example image for a set of variables, where visibility of the "Application Name" and "API Gateway Name" fields is dependent on the "Provision Functions and API Gateway?" check box:

![Visibility Dependency](image)
Example declarations that show the "Application Name" and "API Gateway Name" fields (functions_app_name and apigateway_name) only when the "Provision Functions and API Gateway?" check box (enable_functions_apigateway) is selected:

```yaml
enable_functions_apigateway:
  type: boolean
  title: "Provision Functions and API Gateway?"
  required: true
  default: true

functions_app_name:
  type: string
  title: "Application Name"
  description: "Do not use spaces."
  required: true
  default: "DataScienceApp"
  pattern: "^[a-zA-Z0-9]+$"
  # show only when enable_functions_apigateway variable is selected
  visible: enable_functions_apigateway

apigateway_name:
  type: string
  title: "API Gateway Name"
  required: true
  default: "Data Science Gateway"
  # show only when enable_functions_apigateway variable is selected
  visible: enable_functions_apigateway
```

**Password**

To render a variable as a password:

- Add the line `type: password`.

To require re-entry for confirmation of the entered password:

- Add the line `confirmation: true`.

Example image for a password variable that requires confirmation:

![Example image for a password variable that requires confirmation](image_url)

Example declaration for a password variable, requiring confirmation:

```yaml
password:
  title: Repository Password
  description: Must match remote repository password
  # renders variable as a password field
  type: password
  # renders a second field to re-enter the password for confirmation
  confirmation: true
  pattern: "^[a-zA-Z-][a-zA-Z0-9]{1,8}$"
  required: true
```
Required variables

To require a value for a variable:
• Add the line required: true.

Example image for a required variable, with validation warning:

![Example declaration for a required variable:]

```yaml
availability_domain:
  type: oci:identity:availabilitydomain:name
  dependsOn:
    compartmentId: compartment_ocid
  # displays validation warning if no value is selected or entered
  required: true
  title: "Available Domain"
  description: "Available Domain"
  default: "tabw:PHX-AD-1"
```

Optional variable

To mark a variable as optional:
• Add the line required: false.

Example image for an optional variable:

![Example declaration for a variable with enumerated values:]

```yaml
volume_group_display_name:
  type: string
  # displays "Optional" marking to right of field label
  required: false
  title: "Block Volume Group Display Name"
  description: "Display name of the Block Volume Group"
```

Validation pattern

To validate the value entered for a variable against a regular expression pattern:
• Add the line pattern: <regular-expression>.
  
  <regular-expression> is the validation pattern specific to the value you want to validate.

  Hyperlink pattern example: ^https?:\/\/(www\.)?[-a-zA-Z0-9@:%._\+~#\=]{2,256}\.[a-z]{2,4}\b([-a-zA-Z0-9@:%_\+.~-?&//=]*)$

Example image for a validation error for an entered value:

![Example image for a validation error for an entered value:]

```yaml
APPLICATION_NAME

Specify a value that satisfies the following regular expression: %[-a-zA-Z0-9\-\=]*$```
Example declaration for a variable with a validation pattern:

```yaml
functions_app_name:
  type: string
  title: "Application Name"
  description: "Do not use spaces."
  required: true
  default: "DataScienceApp"
  # validate entered value against alphanumeric regular expression
  pattern: "^[a-zA-Z0-9]+$"
```

**Application Information tab**

To display the Application Information tab for a stack created from your Terraform configuration:

- Add lines for the schema `title` and `description`.
- Add at least one output in the `outputs` section.

To allow copying of an output variable field value displayed in the Application Information tab:

- Set the type: Add the line `type: copyableString`.

Example image for the Application Information tab:

![Example image for the Application Information tab](image-url)

Example declaration for a schema title, description, and outputs:

```yaml
# heading under Application Information tab
title: "OCI Developer Tools"
# text under heading
description: "OCI Developer Tools like CLI, SDK, Terraform and Ansible are pre-installed on the compute instance."
stackDescription: "OCI Developer Tools are pre-installed on the compute instance."
# text in blue information box
informationText: "The auto-generated SSH private key should not be used for production use, instead, the user should generate the SSH key-pair and upload the public key for the compute instance. To connect to the compute instance, copy the ssh private key pem content into a file on your machine. Run the following command from the terminal [ssh -i <path to the pem file> opc@<Public IP>] ."
```

...
GitHub and GitLab Connection Issues

This topic describes how to troubleshoot connection issues to GitHub and GitLab.

**Symptom**

Can't connect to GitHub or GitLab.

This symptom can occur in the following situations:

- Creating a configuration source provider.
- Creating a stack from a new or existing configuration source provider.
- Running a job on a stack that uses a configuration file stored in GitHub or GitLab.

**Possible causes**

- Your Personal Access Token (PAT) may have been revoked or the required permission scopes changed and are insufficient.
- Your GitHub or GitLab repository permissions may have changed and become insufficient.
- Your GitHub or GitLab server is not accessible over the Internet.

**Resolution**

- Recreate your Personal Access Token (PAT) and ensure the scope for the token includes the required permissions (scopes). See the relevant documentation:
  - GitHub: https://docs.github.com/en/free-pro-team@latest/github/authenticating-to-github/creating-a-personal-access-token
  - GitLab: https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html
- Ensure that your GitHub or GitLab repository permissions meet requirements (admin or owner).
- Review prerequisites to confirm that all requirements are satisfied. See Prerequisites for connecting to GitHub and GitLab on page 3582.
Chapter 31

Search

This chapter explains how to search for resources across compartments.

Overview of Search

Oracle Cloud Infrastructure Search lets you find resources within a tenancy, pages of the Console within services, and documentation within the Oracle Cloud Infrastructure Getting Started Guide and Oracle Cloud Infrastructure User Guide. Search sorts search results by resource, service, or documentation, helping you avoid navigating through menus, the latency associated with loading a long list of results onto a single page, or the inconvenience of viewing a long list that spans multiple pages. You can also filter results by criteria specific to the search category after results are found and sorted by category.

You might find it helpful to use Search to find related resources when creating or deleting another resource. For example, you might want to find what compartments already exist before creating a new one because compartments cannot be deleted. Or, if you want to delete a volume, you can use a query to verify that a backup exists.

Another benefit of Search is that you can find resources that require action. For example, you might want to delete terminated block volumes because you no longer need them and don’t want them to count against your service limits. Or, you can search for all resources that match a specific naming scheme, in case you want to act on a category of associated resources. Sometimes, resources in a specific lifecycle state, such as databases in a failed state, require troubleshooting. With Search, you can quickly identify those resources and resolve problems.

Search can also help you find pages within the Console, even if you can’t recall their location among services in the navigation menu. When you find a page, if you want to know more about its contents, you can use Search to find documentation to help you. For example, you might search for “create virtual cloud network” if you want to read documentation about creating a virtual cloud network.

Search Categories and Ways to Search Them

To search for a resource, you can use a free text search based on keywords. You can also use structured resource query language to build an advanced query based on as little as a single resource attribute, such as the resource's creation date. Results for resource searches are limited to the tenancy and the currently selected region.

To find a named page in the Console without knowing the service or to locate help in the documentation, you can use a free text search. Advanced queries don't work for these types of searches.

Supported Resources

Search supports queries for the Oracle Cloud Infrastructure services and resources listed in this section. The following table will be updated as query support is added for more resources. You can refer to each resource's object reference for information about the resource, including its attributes. In some cases, where indicated, a resource might not support all attributes for search. Often, services index only the required attributes for a given resource. For current information about supported resources and resource attributes, use the ListResourceTypes API.

**Common Resource Attributes**

Although you can use the query language to search fields and values for any supported attribute, query results only provide information about the following resource attributes:

- Resource type
- Oracle Cloud Identifier (OCID)
- Compartment
- Availability domain
- Display name
- Creation date and time
- Lifecycle state
- Tags (visible in the API only)

The preceding attributes are common to most Oracle Cloud Infrastructure resources. Their meaning is consistent across resource types, so they're provided by default for each result when you view a list of query results. Query results do not contain information specific to any resource type except where a matching search term appears. Meaning, you can query for volumes of a certain size. If there's a match, then the search result will display the attribute with the value that matches. In this example, in addition to the common attributes, the result also provides the `Size` attribute if that's where the match was found. You must view the details of a resource to see other resource-specific information.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you use the Console, neither query results nor resource details will include either defined tags or free-form tags, due to display constraints. Any given resource might contain hundreds of tags. If you want to see tags, use the API to view resource details.</td>
</tr>
</tbody>
</table>

### Required IAM Permissions

The resources that you see in search or query results depend on the permissions you have in place for the resource type. You do not necessarily see results for every resource in the compartment or tenancy. For example, if your user account is not associated with a policy that grants you the ability to, at a minimum, inspect the `dbsystem` resource type, then you can’t query for DB systems. (The verb `inspect` lets you list and get resources.) Instead, Search will show no results for queries of DB system resources.

Permissions and policy language applies to resources. Searching for pages across services in the Console or documentation requires no special permissions because they aren't resources. An administrator cannot restrict access to search results of services or documentation.

For more information about policies, see [How Policies Work](#) on page 2136. For information about the specific permissions required for the list API operation for your desired resource type, see the [Policy Reference](#) on page 2167 for the appropriate service.

### Free Text Search

This topic describes how Search handles the search terms that you submit as a free text search.

By default, text entered in the Console search box is interpreted as a free text search. You can use a free text search to conduct a search of any category that Search supports. This includes searches for resources, pages across services in the Console, and documentation.

**Matching**

Search tries to match search terms against the values of indexed fields. For resources, this means that Search evaluates the value of all indexed resource attributes, from [common attributes](#) (except the resource type attribute) to attributes specific to a resource type. For services, this includes all page display names and service groups. For documentation, this includes the title and the contents of the topic. (Search does not query the topic description, topic category, or keyword metadata.)

To provide matching results to the text given in a free text search, Search queries all indexed fields by applying the `=` (equals) operator to text that you specified. If you're familiar with advanced queries, the effect is the same as using a `matching` clause. For example, a free text search for the term "net" queries all resource types, service pages, and documentation for the string "net" in any indexed field. If the string appears as part or the whole of a value anywhere in an indexed field, Search considers the found item a matching result. Search does not require exact matching, but an exact match does improve a result's ranking.

If the free text search includes a delimiting character (for example, a hyphen), the delimiter causes Search to treat the text on either side of the delimiter as an independent search term. For example, a free text search for "2020-04" looks for the string "2020" and the string "04". If a potential result contains either string, then it's a match.
Free text search matches individual terms from the provided text. Search does not try to match specific combinations of characters that you might group by using quotes or by presenting terms in a specific order. Likewise, proximity of search terms does not matter. However, if you have multiple search terms in a free text search, results that contain multiple matches to the search terms have a higher ranking in the search results.

**Ranking of Results**

To rank results, Search evaluates each potential result for how closely it can match the search term or terms provided. Exact matches occupy a higher rank in the results than partial matches. Search also considers how many matches for the exact search term the result contains. Either a close match or multiple matching terms improves the result's ranking.

**Search Language Syntax**

This topic describes the basics of the query language for Search, including an explanation of syntax and rules so you can create your own queries. Queries apply search conditions to specific resource types and let you sort results. If you want to search across all supported resource types and resource attributes and do not need ordered search results, you do not need to construct a query. Instead, you can search for a partial or exact match of free-form text without applying query language syntax to your search.

When you are ready to run a query, see [Querying Resources, Services, and Documentation](#) on page 3642 for instructions.

**Query Basics**

The following examples show the basic syntax of a query:

```plaintext
query <resourceType> resources where <conditions> sorted by <fieldName> <order>
```

Or:

```plaintext
query <resourceType> resources matching <keywords>
```

Search ignores white space, indentation, and line breaks. Sample queries include indentation to improve readability. For the purposes of demonstrating syntax only, angle brackets (<> ) and italicized text indicate variables, which can consist of one or more keywords.

In a query, clauses include the following:

- **query** - (Required) Selects which resources to return based on subsequent clauses. Query statements always begin with the word `query`.
- **where** - Matches resources to the specified `conditions`.
- **matching** - Matches resources to the specified text regardless of whether the text matches exactly, matches the resource type, or appears in an indexed resource attribute.
- **sorted by** - Orders resources according to `fieldName` in the order specified by `order`. If you do not include this clause, Search lists results by creation date in descending order, with the newest resources listed first.

Clauses are optional unless indicated otherwise. For matching purposes, you can use the `where` clause and the `matching` clause either separately or together.

In the `query` clause, you specify the following information:

- **resourceType** - (Required) Specifies the resource type to which the subsequent clauses apply when you run the query. You can specify either the resource type name (for example, `database` or `group`) or `all`. If you specify `all`, Search searches for the `conditions` against all resource types. You can query for individual resource types, but not family types. For a list of supported resource types, see the [Supported Resources](#) section of [Overview of Search](#).
- **resources** - (Required) Specifies that this is a resource query.
**Conditions**

The `where` clause applies conditions that filter the results returned by Search. You can specify one or more condition statements. For more information about multiple conditions, see Grouping Conditions.

In a query, conditions consist of the following:

```
<fieldName> <operation> <value>
```

The `fieldName` keyword is the resource attribute against which the operation and chosen value of that attribute are evaluated. Each field is associated with a field type. The field type tells you the expected format for any value in that field. What kind of operation you can use in a conditions statement depends on the field type.

In query conditions, an operation is a comparison operator that applies to the value in the statement. The `value` keyword refers to the value of the `fieldName` you specified. Search evaluates whether the specified attribute of the chosen resource type matches or does not match the value, according to the operation. In a query, you must enclose any string or date-time value in opening and closing straight single quotes (#) or double quotes (").

The following table describes supported operations for resource queries:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
<th>Supported Field Types</th>
<th>Case-sensitive?</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equals, or exact matching for strings</td>
<td>String, integer, rational, Boolean, date-time</td>
<td>No</td>
<td>If the value was #backUp#, it would match &quot;backup&quot;, &quot;BACKUP&quot;, &quot;BackUp&quot;, &quot;backUp&quot;, or any other variation in casing.</td>
</tr>
<tr>
<td>!=</td>
<td>Does not equal</td>
<td>String, integer, rational, Boolean, date-time</td>
<td>No</td>
<td>If the value was #backUp#, it would match anything that does not equal &quot;backUp&quot;, &quot;backup&quot;, or any other variation in casing. It also would match anything that does not contain the characters 'backup' in that order.</td>
</tr>
<tr>
<td>==</td>
<td>Strictly equals</td>
<td>String</td>
<td>Yes</td>
<td>If the value was #backUp#, it would only match &quot;backUp&quot; and no other variation in casing.</td>
</tr>
<tr>
<td>!==</td>
<td>Strictly does not equal</td>
<td>String</td>
<td>Yes</td>
<td>If the value was #backUp#, it would match &quot;backup&quot;, &quot;BACKup&quot;, or anything except &quot;backUp&quot;, with that exact casing.</td>
</tr>
</tbody>
</table>
The following table lists some examples of resource attributes that belong to each category of supported field types. (As previously described, the field type tells you the expected format for a given field and the kind of operation you can pair it with in a conditions statement.)

The table does not include every possible example for a given field type nor does it include examples from every resource-type. If you want to know what format the Search service expects for a specific resource attribute, you can use the command line interface or API to find out more about resource attributes. You can also consult the API documentation. The API documentation includes a reference for each supported resource type that specifies attributes, their field types, and any restrictions. For more information, see the Supported Resources section of Overview of Search.

<table>

<td>Date-time</td>
<td>Creation dates, last-updated dates, last-indexed dates, and scheduled maintenance reboots</td>
</tr>
</tbody>
</table>

**Grouping Conditions**

By including more than one condition statement in a query, you can refine results according to multiple criteria. You can group multiple conditions by using either the logical operators && (ampersands, to indicate a logical AND) or || (vertical bars, to indicate a logical OR). For example:

```plaintext
licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40 && lifecycleState != 'FAILED'
```

You cannot combine two different logical operators in the same query unless you wrap parentheses around one group of predicates. (Multiple conditions can only use the same logical operator otherwise.) For example:

```plaintext
(licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40) || lifecycleState != 'FAILED'
```

In the preceding example, all results returned will have either “LICENSE_INCLUDED” as the value in the field named “licenseModel” and a value greater than 40 for the field named “dataStoragePercentage” or the value of their “lifecycleState” field name is anything other than “FAILED”.

The following group is also acceptable:

```plaintext
licenseModel = 'LICENSE_INCLUDED' && (dataStoragePercentage > 40 || lifecycleState != 'FAILED')
```

In the preceding example, all results returned will have “LICENSE_INCLUDED” as the value in the field named “licenseModel” and either a value greater than 40 as the value for the field named “dataStoragePercentage” or anything that is not “FAILED” for the value of the field named “lifecycleState”.

Search does not perform left-to-right evaluation to reduce ambiguity or clarify intent.

**Date and Time Values**

You can specify date and time values by using any of the following pattern string formats:

<table>
<thead>
<tr>
<th>Format</th>
<th>Examples</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;yyyy&gt;</code>-<code>&lt;MM&gt;</code>-<code>&lt;dd&gt;</code></td>
<td>'2018-06-19 16:15:41 PDT',</td>
<td>Time Zone is optional. If Time Zone is omitted, UTC is used.</td>
</tr>
<tr>
<td><code>&lt;HH&gt;</code>: <code>&lt;mm&gt;</code>: <code>&lt;ss&gt;</code> <code>&lt;TimeZone&gt;</code></td>
<td>'2018-06-19 16:15:41 -08:00'</td>
<td></td>
</tr>
<tr>
<td><code>&lt;EEE&gt;</code>, <code>&lt;d&gt;</code>, <code>&lt;MM&gt;</code> <code>&lt;yyyy&gt;</code></td>
<td>'Tue, 19 Jun 2018 16:15:41 +0300',</td>
<td>EEE is optional. MMM can also be expressed as MMMM. Time Zone</td>
</tr>
<tr>
<td><code>&lt;HH&gt;</code>: <code>&lt;mm&gt;</code>: <code>&lt;ss&gt;</code> <code>&lt;TimeZone&gt;</code></td>
<td>'19 June 2018 16:15:41'</td>
<td>is also optional. If Time Zone is omitted, UTC is used.</td>
</tr>
</tbody>
</table>
You must observe spacing. Interpret dashes, colons, commas, and the characters 'T' and 'Z' literally. To interpret placeholder values in the preceding table, you can refer to the following pattern syntax:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Date or Time Component</th>
<th>Presentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>Year</td>
<td>Year</td>
</tr>
<tr>
<td>M</td>
<td>Month in year</td>
<td>Month</td>
</tr>
<tr>
<td>d</td>
<td>Day in month</td>
<td>Day</td>
</tr>
<tr>
<td>H</td>
<td>Hour in day (from 00-23)</td>
<td>Number</td>
</tr>
<tr>
<td>m</td>
<td>Minute in hour</td>
<td>Number</td>
</tr>
<tr>
<td>s</td>
<td>Seconds in minute</td>
<td>Number</td>
</tr>
<tr>
<td>E</td>
<td>Day in week</td>
<td>Text</td>
</tr>
</tbody>
</table>

Repeating pattern letters indicate their exact presentation. For example, 'HH' means you must use '00' and not '0' to represent midnight. Similarly, 'EEE' means 'Tue' and not 'Tuesday'. Likewise, 'MM' requires '09' instead of '9' to represent the month of September.

TimeZone is optional, but in your chosen format, you can specify TimeZone in any of the following ways:

- **Name.** You can specify a time zone by its name, such as GMT or PDT. Values are case-insensitive.
- **GMT offset value.** You can specify a time zone according to its GMT offset. For example, GMT-08:00. Values are case-insensitive.
- **ISO 8601 time zone.** You can specify a time zone according to ISO 8601 standards. For example, -08, -0800, or -08:00.

Instead of using one of the preceding formats, you can also specify a date-time value as the constant now. The constant now represents the current time to the level of granularity of seconds in a minute.

Lastly, you can add or subtract time intervals from any date-time values. For example, you can query for resources that were created within five minutes of a specific time. Search supports the following time intervals:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Date or Time Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Seconds</td>
</tr>
<tr>
<td>m</td>
<td>Minutes</td>
</tr>
<tr>
<td>h</td>
<td>Hours</td>
</tr>
<tr>
<td>d</td>
<td>Days</td>
</tr>
<tr>
<td>w</td>
<td>Weeks</td>
</tr>
</tbody>
</table>

To specify a time interval in relation to a date-time value, use one of the following formats:

- now - 3h
- 2018-06-19 16:15:41 PDT + 1h

**Matching**

For matching purposes, instead of or in addition to using a where clause with conditions, you might want to use the matching clause. The matching clause obviates the need to specify conditions (that contain a field name, operation, and value). A matching clause effectively queries all indexed fields by applying the = (equals) operator along with the text you specify. However, it does so without strictly requiring an exact match. For example, the following query uses a matching clause to behave the same way as a free text search: query all resources
matching 'instance'. The query produces results that match all resources and resource attributes that contain the word "instance".

The matching clause queries all indexed fields for matches, but ignores special characters, including any punctuation.

**Sorting**

The last clause of a resource query is the sorted by clause and is optional. The sorted by clause orders the results returned by Search based on the field name and lists them according to the order you specify. By default, if you do not specify sort order, results are always sorted by date-time created in descending order.

In the sorted by clause, you can specify the following:

- **fieldName** - The field that Search uses to sort results. You can specify any field of any resource. Resources that do not contain the field you specify are listed after the resources that do.
- **order** - You can specify either asc or desc. Specifying asc lists results in ascending order. Specifying desc lists results in descending order.

**Querying Multiple Resource Types**

You can query multiple resource types at once by joining queries. Each query can have its own conditional clause. If the queries that you want to join have different "where" conditions, then the syntax is different from when you have queries for multiple resource types that share the same "where" condition.

The basic syntax for a query for multiple resource types is as follows:

```
query <resourceType>,<resourceType> resources
```

For example:

```
query group, user resources
```

The preceding example query returns all groups and all users in the tenancy.

The following shows the syntax for a query for multiple resource types with conditions, but where the conditions are the same for all resource types:

```
query <resourceType>,<resourceType> resources where <conditions>
```

For example:

```
query group, user resources where displayName = 'administrator'
```

The preceding example query returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing.

If you need to apply differing conditions to any resource type, you must use a union keyword instead of comma separation between the joined queries. The following shows the syntax for a query for multiple resource types where some of the resource types share conditions while others do not:

```
query <resourceType>,<resourceType> resources where <conditions>
union <resourceType> resources
```

For example:

```
query group, user resources where displayName = 'administrator' union compartment resources
```
The preceding example returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing, and all compartment resources.

Or, for example:

```
query group resources union user resources where displayName = 'administrator' union compartment resources
```

The preceding example returns all groups and all compartments. It also returns all users with the display name "administrator," with any variation in casing.

Optionally, you can add the `sorted by` clause to the end of the query to order all results in ascending or descending order.

### Sample Queries

This topic provides an explanation of sample queries, including what results to expect from a given sample query. For more information about the syntax for constructing a query, see Search Language Syntax on page 3633.

**Note:**

**Example Values**

Sample queries show example values for resource attributes. Replace those examples with values from your own tenancy.

Search provides the following sample queries in the Console:

- Query for everything
- Query for everything, sorted by time created
- Query for volumes and users
- Query for volumes and users, sorted by time created
- Query for volumes and users that have any indexed field matching “production,” sorted by time created
- Query for all resources that have a specific freeform tag
- Query for all resources that have one of two specific defined tags
- Query for instances in a "Running" state
- Query for instances in either a "Terminated" or "Terminating" state
- Query for all resources in a specific compartment
- Query for all instances due for a maintenance reboot
- Query for all resources that are Always Free

### Query All Resources

**Query name:** Query for everything

**Expected results:** Returns all supported resources in the tenancy across all compartments. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```
query all resources
```

### Query All Resources, Sort by Time Created

**Query name:** Query for everything, sorted by timeCreated

**Expected results:** Returns all supported resources in the tenancy across all compartments, listed in order of time created, from newest to oldest.
Sample query language:
```sql
query
  all resources
  sorted by timeCreated desc
```

**Query Volumes and Users**

**Query name:** Query for volumes and users

**Expected results:** Returns all block volumes and users in the tenancy. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**
```sql
query
  volume, user resources
```

**Query All Volumes and Users, Sort by Time Created**

**Query name:** Query for volumes and users, sorted by timeCreated

**Expected results:** Returns all block volumes and users in the tenancy, listed in order of time created, from newest to oldest

**Sample query language:**
```sql
query
  volume, user resources
  sorted by timeCreated desc
```

**Query Volumes and Users Matching "Production," Sorted by Time Created**

**Query name:** Query for volumes and users, with anything matching production, sorted by timeCreated

**Expected results:** Returns all block volumes and users in the tenancy that have any indexed fields that exactly or partially match the search string "production", irrespective of casing. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**
```sql
query
  volume, user resources
  matching 'production'
  sorted by timeCreated desc
```

**Query All Resources With Specific Freeform Tags**

**Query name:** Query for all resources that have specific freeform tags

**Expected results:** Returns all resources in the tenancy that have a freeform tag of "costcenter" with a value of "1234."

**Sample query language:**
```sql
query
  all resources
  where
    (freeformTags.key = 'costcenter' && freeformTags.value = '1234')
```
Query All Resources According to Defined Tags

Query name: Query for all resources that have one of two specific defined tags

Expected results: Returns all resources in the tenancy that have either a tag with the key “region” and value “phx” in the tag namespace “categorization,” or all resources in the tenancy that have a tag with the key “region” and value “iad” in the namespace “categorization.” Ignores casing for all keys and values.

Sample query language:

```sql
query
  all resources
  where
    (definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'phx') ||
    (definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'iad')
```

Query Instances According to Specific Lifecycle State

Query name: Query for running instances

Expected results: Returns all instances in the tenancy in a "Running" state. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```sql
query
  instance resources
  where lifeCycleState = 'RUNNING'
```

Query Instances According to One of Two Lifecycle States

Query name: Query for instances terminated or terminating

Expected results: Returns all instances in the tenancy in either a "Terminated" or "Terminating" state. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```sql
query
  instance resources
  where lifeCycleState = 'TERMINATED' || lifeCycleState = 'TERMINATING'
```

Query All Resources According to Compartment ID

Query name: Query for all resources in a compartment

Expected results: Returns all resources in the tenancy with a specific compartment ID. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```sql
query
  all resources
  where compartmentId = 'compartmentOcid'
```

Query All Instances Due for Maintenance Reboot

Query name: Query for all instances which have an upcoming scheduled maintenance reboot
Expected results: Returns all instances in the tenancy with a scheduled maintenance reboot time value of "now."
Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
  instance resources
  where timeMaintenanceRebootDue = 'now'
```

Query All Always Free Resources

Query name: Query for all resources that are Always Free

Expected results: Returns all existing resources in the tenancy that are free of charge for the life of the account. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
  all resources
  where
    systemTags.namespace = 'orcl-cloud' &&
    systemTags.key = 'free-tier-retained' &&
    systemTags.value = 'true'
```

Querying Resources, Services, and Documentation

This topic describes different ways you can use Search.

You can find Oracle Cloud Infrastructure resources in your tenancy by performing a free text search or running a query. A free text search locates resources with the desired text anywhere in the resource metadata. An advanced query lets you find resources according to specific fields and conditions. When finding resources, both free text searches and queries rely on resource indexing and the indexed attributes for a given resource type. Search also scopes resource results to the currently selected region.

Although queries can only be used to find resources, you can use free text searches to help you locate pages in the Console or help in the documentation. A free text search looks for search terms in the display names of Console pages and lists pages according to where they appear within services in the tenancy. A free text search can also find search terms in the Oracle Cloud Infrastructure Getting Started Guide and Oracle Cloud Infrastructure User Guide documentation. The results for both these types of searches depend on the language, but not the region.

Note:

Supported Resources and Using Advanced Resource Queries

The search results that you see reflect what Search considers supported resources. To see what Oracle Cloud Infrastructure services and resources Search supports, see the Supported Resources section of Overview of Search.

Furthermore, if you don't find the resource you want or expect when you submit a free text search, you might need to run a query constructed using query language syntax. For more information about syntax for advanced queries, see Search Language Syntax on page 3633. (For a documentation search, if a free text search doesn't produce the content results you expect, you might try a plural or singular form of one or more search terms or a different, supported language.)

Using the Console

You can find resources, services, or documentation by doing one of the following:

- typing free-form text for a free text search
• reusing recent search terms
• typing a query (for resources only)
• modifying a sample query

By default, text entered into the Search for resources, services, and documentation box is interpreted as a free text search.

To perform a free text search

1. In the top navigation bar, click Search for resources, services, and documentation.
2. Type the free-form text you want to search for.
3. Under one of the categories of search results, click a result. (To see all results on a full page instead, click View all next to the category name.)
4. (Optional) If you do not see the results that you expect, you can change to a different region (if searching for a resource), change to a different language (if searching for a service or documentation), view a different category of search results, or edit your search terms. If searching for a resource, you can also refine your search with a query by clicking Advanced Resource Query. Then, follow the instructions in To run a custom, free-form query or To run a sample query.
5. (Optional) If you chose to view results on a full page, the list shows results with the best matches at the beginning of the list. However, you can also do the following:
   • If you chose the Resources category specifically, you can sort results, expand individual results to see the matching text, or you can filter results more specifically. To filter results more specifically, click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include.
   • For the Services category, you can only filter or sort results. To filter results more specifically, click Choose one or more service groups to filter the results, and then type or choose the service group to include.
   • Similarly, for the Documentation category, you can only filter or sort results. To filter results more specifically, click Choose one or more topics to filter the results. (Here, "topic" refers to the subject matter rather than the topic title.)

For any category, filter options only include resource types, service groups, or documentation presented in the full list of results.

Results are eventually consistent, but might not immediately include resources that you created very recently.

To run a custom, free-form query to find a resource

1. In the top navigation bar, click Search for resources, services, and documentation, and then click Advanced Resource Query.
2. In the query text box, type a query using query language syntax, and then click Search.
3. The list shows results in groupings. From here, you can filter results more specifically: click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include in filtered results. Filter options only include resource types present in the full list of results.
4. (Optional) If you do not see the results that you expect, you can change to a different region or edit your query.

Results are eventually consistent, but might not immediately include resources that you created very recently.

To run a sample query to find a resource

1. In the top navigation bar, click Search for resources, services, and documentation, and then click Advanced Resource Query.
2. Click Select Sample Query, and then click one of the listed sample queries. For an explanation of sample queries, see Sample Queries on page 3639.
3. Verify that the query language in the query text box satisfies your needs. Change all example values. Add, delete, or modify clauses, as appropriate, and then click Search.
4. The list shows results in groupings. From here, you can filter results more specifically: click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include in filtered results. Filter options only include resource types present in the full list of results.
5. (Optional) If you do not see the results that you expect, you can change to a different region or edit your query.
Results are eventually consistent, but might not immediately include resources that you created very recently.

**To reuse recent search terms**

1. In the top navigation bar, click **Search for resources, services, and documentation**.
2. Under **Recent searches**, click one of five recent search terms. (Recent searches only include the five most recent free text searches, not advanced searches that use the structured query language.)
3. Under one of the categories of search results, click a result. (To see all results on a full page instead, click **View all** next to the category name.)
4. (Optional) If you do not see the results that you expect, you can change to a different region (if searching for a resource), change to a different language (if searching for a service or documentation), view a different category of search results, or edit your search terms. If searching for a resource, you can also refine your search with a query by clicking **Advanced Resource Query**. Then, follow the instructions in To run a custom, free-form query or To run a sample query.
5. (Optional) If you chose to view results on a full page, the list shows results with the best matches at the beginning of the list. However, you can also do the following:
   - If you chose the **Resources** category specifically, you can sort results, expand individual results to see the matching text, or you can filter results more specifically. To filter results more specifically, click **Choose one or more resource types to filter the results**, and then type or choose one or more resource types to include.
   - For the **Services** category, you can only filter or sort results. To filter results more specifically, click **Choose one or more service groups to filter the results**, and then type or choose the service group to include.
   - Similarly, for the **Documentation** category, you can only filter or sort results. To filter results more specifically, click **Choose one or more topics to filter the results**. (Here, "topic" refers to the subject matter rather than the topic title.)

For any category, filter options only include resource types, service groups, or documentation presented in the full list of results.

Results are eventually consistent, but might not immediately include resources that you created very recently.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en/cloud incontras/oci/service-configuration/ocisearch.html). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](https://docs.oracle.com/en/cloud incontras/oci/service-configuration/ocisearch.html).

**To see what resource-types you can run a query for**

Open a command prompt and run `oci search resource-type list` to see what resource-types you can run a query for:

```bash
oci search resource-type list
```

For example:

```bash
oci search resource-type list --all
```

**To see what resource attributes you can query for a given resource-type**

Open a command prompt and run `oci search resource-type get` to see what attributes you can search for a given resource-type:

```bash
oci search resource-type get --name <resource-type_name>
```

You must specify the resource-type by its indexed name. Pay attention to capitalization. For example:

```bash
oci search resource-type get --name VolumeBackup
```
To perform a free text search

Open a command prompt and run `oci search resource free-text-search` to search the text of all searchable resource-types:

`oci search resource free-text-search`

For example:

`oci search resource free-text-search --text <text_to_search_for>

To run a custom, free-form query to find a resource

Open a command prompt and run `oci search resource structured-search` to run an advanced resource query:

`oci search resource structured-search --query-text "<query_text_using_query_language_syntax>"

For example:

`oci search resource structured-search --query-text "query user resources"

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to search for resources or find out what resources you can search for:

- SearchResources
- ListResourceTypes

In addition to finding supported resources with ListResourceTypes, you can also find what attributes each resource supports for search.

Example: Finding Instance Resources With a Specific Defined Tag

This section describes how to use the API to query for a specific type of resource based on the resource's defined tags.

The following query will find instances with a defined tag within the namespace "rqs", where the tag's key is "costcenter" and the key's value is "1234".

```sql
query
  instance resources
where
  (definedTags.namespace = 'rqs' && definedTags.key = 'costcenter' &&
  definedTags.value = '1234')
```

When you use the SearchResources operation to issue the query, the request will look similar to the following. (This example purposefully omits the authorization header and other headers.)

```json
POST /20180409/resources
Host: query.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "type": "Structured",
  "query": "query instance resources where (definedTags.namespace = 'rqs' &&
  definedTags.key = 'costcenter' &&
  definedTags.value = '1234')",
  "matchingContextType": "HIGHLIGHTS"
}
```
If your query produces results, the response will list the resources that match the resource type and tag that you specified. The response will look similar to the following:

```json
{
    "items" : [
        {
            "resourceType" : "Instance",
            "identifier" : "ocid1.instance.oc1.phx.exampleawcbfhncvbh3siw2svbprg3bopovy6hgnywfauxq037ckdmr6hjya",
            "compartmentId" : "ocid1.tenancy.oc1..examplea46vssm715wsk5qa7cvb163ctajep4bh61v4vaifauxz6ec7jzg4q",
            "displayName" : "service-pkgs",
            "availabilityDomain" : "ABCd:PHX-AD-1",
            "lifecycleState" : "RUNNING",
            "freeformTags" : {},
            "definedTags" : {
                "rqs" : {
                    "costcenter" : "1234"
                }
            },
            "searchContext" : null
        },
        {
            "resourceType" : "Instance",
            "identifier" : "ocid1.instance.oc1.phx.exampleanb3poce6z4omcvbzw66epp3pvbbww6hz7e2jfaux2lxvi3daxhra",
            "compartmentId" : "ocid1.compartment.oc1..examplea43m3udlwrzwmbcvbk5hm3umk2khgfhhjgcdttawjlfiauxuqwsjiya",
            "timeCreated" : "2018-10-09T23:35:30.167Z",
            "displayName" : "prod-test",
            "availabilityDomain" : "ABCd:PHX-AD-2",
            "lifecycleState" : "RUNNING",
            "freeformTags" : {},
            "definedTags" : {
                "rqs" : {
                    "costcenter" : "1234"
                }
            },
            "searchContext" : null
        },
        {
            "resourceType" : "Instance",
            "identifier" : "ocid1.instance.oc1.phx.exampleanb3poce6z4omcvbzw66epp3pvbbww6hz7e2jfaux2lxvi3daxhra",
            "compartmentId" : "ocid1.compartment.oc1..examplea43m3udlwrzwmbcvbk5hm3umk2khgfhhjgcdttawjlfiauxuqwsjiya",
            "timeCreated" : "2018-10-09T23:35:30.167Z",
            "displayName" : "prod-test",
            "availabilityDomain" : "ABCd:PHX-AD-2",
            "lifecycleState" : "RUNNING",
            "freeformTags" : {},
            "definedTags" : {
                "rqs" : {
                    "costcenter" : "1234"
                }
            },
            "searchContext" : null
        },
        {
            "resourceType" : "Instance",
            "identifier" : "ocid1.compartment.oc1..exampleaexfjsiad7gba6ri4hovmcbk3a5h6k5vulswf544ufauxks4p2jasq",
            "compartmentId" : "ocid1.tenancy.oc1..examplea46vssm715cvb5qa7gg563ctajep4bh61v4vauxf4iz6ec7jzg4q",
            "timeCreated" : "2018-06-12T19:45:24.945Z",
            "displayName" : "BackupTest",
            "availabilityDomain" : "ABCd:PHX-AD-3",
            "lifecycleState" : "STOPPED",
            "freeformTags" : {},
            "definedTags" : {
                "rqs" : {
                    "costcenter" : "1234"
                }
            },
            "searchContext" : null
        },
        {
            "resourceType" : "Instance",
            "identifier" : "ocid1.compartment.oc1..exampleaexfjsiad7gba6ri4hovmcbk3a5h6k5vulswf544ufauxks4p2jasq",
            "compartmentId" : "ocid1.tenancy.oc1..examplea46vssm715cvb5qa7gg563ctajep4bh61v4vauxf4iz6ec7jzg4q",
            "timeCreated" : "2018-06-12T19:45:24.945Z",
            "displayName" : "BackupTest",
            "availabilityDomain" : "ABCd:PHX-AD-3",
            "lifecycleState" : "STOPPED",
            "freeformTags" : {},
            "definedTags" : {
                "rqs" : {
                    "costcenter" : "1234"
                }
            },
            "searchContext" : null
        }
    ]
}
With these results, you can take additional action, if needed. For more information about a resource type, such as its attributes, see its reference page in the API Reference Guide. For the reference pages of resource types that have been indexed for Search, see Supported Resources on page 3626.

Troubleshooting Search

This topic covers common issues related to Search and how you can address them:

- Query or Search Results are Not as Expected on page 3647

Query or Search Results are Not as Expected

There are several reasons why you might not see results that you expect from a search or query.

Not all resource types have been indexed for Search. For a list of currently supported resource types, see Supported Resources on page 3626.

You might not have the required permissions for the resource type that you want to view in search or query results. If there's no policy that grants you the permissions you need, then an administrator must create one for you or add you to a group that's already named in a policy. For more information, see Details for Search.

The query syntax you used might need adjustment. Verify that the conditions in your query language haven't restricted the results to a narrower set than you intended.

If you recently created a resource, it might not show up in search results immediately. Similarly, if you recently updated a resource, your changes might not immediately appear. At times, you might see a resource in a list view before you can see it in search results. The Search service is eventually consistent. Wait, and then try again.
This chapter explains how to use Security Zones.

Security Zones

Security Zones let you be confident that your resources in Oracle Cloud Infrastructure, including Compute, Networking, Object Storage, and Database resources, comply with Oracle security principles.

A security zone is associated with a compartment and a security zone recipe. When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the list of policies defined in the security zone recipe. If any security zone policy is violated, then the operation is denied.

For example, a security zone policy forbids the creation of public buckets in Object Storage. If you try to create a public bucket in a security zone that has this policy, or if you try to modify an existing storage bucket and make it public, you receive an error message. Similarly, you can't move an existing resource from a standard compartment to a security zone unless all policies are met.

Security zone

An association between a compartment and a security zone recipe. Resource operations in a security zone are validated against all policies in the recipe.

Security zone recipe

A collection of security zone policies.

Security zone policy

A security requirement for resources in a security zone.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe and you can't modify it.

In general, security zone policies align with these security principles:

• Resources can't be moved from a security zone to a standard compartment because it might be less secure.
• Data in a security zone can't be copied to a standard compartment because it might be less secure.
• All the required components for a resource in a security zone must also be located in a security zone. Resources that are not in a security zone might be vulnerable. For example, a compute instance in a security zone can't use a boot volume that is not in a security zone.
• Resources in a security zone must not be accessible from the public internet.
• Resources in a security zone must be encrypted using customer-managed keys.
• Resources in a security zone must be regularly and automatically backed up.
• Resources in a security zone must use only configurations and templates approved by Oracle.

To learn more, see Security Zone Policies on page 3651.

A security zone policy differs from an IAM policy in the following ways:

• Administrators create IAM policies to grant users the ability to manage certain resources in a compartment.
Security Zones

- A security zone policy ensures that these management operations comply with the Oracle maximum security architecture and best practices.
- A security zone policy is validated regardless of which user is performing the operation.
- A security zone policy denies certain actions; it doesn't grant capabilities.
- Administrators can't create, modify, or disable security zone policies.

To create a security zone, see Managing Security Zones on page 3649.

Managing Security Zones

You can create and delete security zones, and identify the policies enforced in your security zone.

A security zone has the following characteristics:

- Associated with a single compartment that has the same name as the security zone
- Assigned a security zone recipe

As resources are created or modified in the compartment, Oracle Cloud Infrastructure validates these operations against all policies in the security zone recipe.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe, and you can't modify it.

A security zone compartment can only have subcompartments that are also security zone compartments.

- You can create a security zone in an existing security zone compartment.
- You can move a security zone compartment to another security zone compartment.
- You can't create a standard compartment in a security zone compartment.
- You can't move a standard compartment to a security zone compartment.

**Caution:**

To ensure the integrity of your data, you can't move certain resources from a compartment in a security zone to a compartment that isn't in a security zone.

Required IAM Policy

To work with Security Zones, an administrator must grant you access in an IAM policy.

If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted.

For example, the following IAM policy allows users in the group SecurityAdmins to manage security zones in the entire tenancy.

```text
Allow group SecurityAdmins to manage security-zone in tenancy
```

See Security Zone IAM Policies on page 3655.

Creating a Security Zone

Create a security zone by using the Console.

All security zones are assigned the Maximum Security Recipe.

2. Click Create Security Zone.
3. Enter a name and description for the security zone.

Oracle Cloud creates a compartment with the same name and assigns it to this security zone.

Avoid entering confidential information.

4. For Create in Compartment, navigate to the compartment that you want to create the new compartment in.
5. Click Create Security Zone.
To create resources such as networks or compute instances in the new security zone, select the compartment with the same name when you create the resources.

**Viewing the Policies for a Security Zone**

Identify the recipe for an existing security zone, and then view its policies.

1. Open the navigation menu and click **Governance and Administration**. Under **Security**, click **Security Zones**.
2. Click the name of the security zone.
3. Click the recipe for the security zone.

To learn more about a security zone policy in the recipe, see **Security Zone Policies** on page 3651.

**Deleting a Security Zone**

Delete a security zone by using the Console.

To delete a security zone, you delete the compartment that's associated with the security zone.

Before you can delete a compartment, it must be empty of all resources. Ensure that all the compartment's resources have been moved, deleted, or terminated, including any policies attached to the compartment.

- **Note:**
  
  To ensure the integrity of your data, you can't move certain resources from a compartment in a security zone to a compartment that isn't in a security zone.

1. Open the navigation menu and click **Governance and Administration**. Under **Security**, click **Security Zones**.
2. Locate the compartment whose name is the same as the security zone.
3. Click the **Actions** icon (three dots) for this compartment, and then click **Delete Compartment**.
4. At the prompt, click **OK**.

For more information, see **Deleting Compartments**.

**Managing Recipes**

When you create a security zone you assign a recipe to it. A recipe is a collection of security zone policies.

When you perform certain resource operations in a security zone, such as creating a compute instance or a subnet, Oracle Cloud Infrastructure automatically validates the policies within the recipe that is assigned to the security zone.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe, and you can’t modify it.

**Required IAM Policy**

To work with Security Zones, an administrator must grant you access in an **IAM policy**.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted.

For example, the following IAM policy allows users in the group **SecurityAdmins** to manage security zones in the entire tenancy.

```
Allow group SecurityAdmins to manage security-zone in tenancy
```

See **Security Zone IAM Policies** on page 3655.

**Viewing the Policies in a Recipe**

Identify the policies in a security zone recipe by using the Console.

1. Open the navigation menu and click **Governance and Administration**. Under **Security**, click **Security Zones**.
2. Click **Recipes**.
3. Click the name of a recipe.
To learn more about a security zone policy in the recipe, see Security Zone Policies on page 3651.

**Viewing the Security Zones Associated with a Recipe**
Identify the security zones that are associated with a recipe by using the Console.

2. Click Recipes.
3. Click the name of a recipe.
4. Click Associated Security Zones.
To create a security zone, see Managing Security Zones on page 3649.

**Security Zone Policies**
When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the policies associated with the security zone. If any policy is violated, then the operation is denied.

Security zone policies are categorized by security principle. Each policy impacts one or more resources, such as Compute, Networking, Object Storage, and Database resources.

**Note:**
Database policies do not apply to Oracle Exadata Cloud@Customer.

**Restrict Resource Movement**
To ensure the integrity of your data, you can't move certain resources from a security zone to a standard compartment because it might be less secure. You also can't move an existing resource from a standard compartment to a security zone unless all security zone policies are met.

The following table describes the security zone policies that restrict resource movement.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny block_volume_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Block Volume</td>
<td>You can't move a block volume from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny boot_volume_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Block Volume</td>
<td>You can't move a boot volume from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny instance_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Compute</td>
<td>You can't move a compute instance from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny instance_not_in_security_zone_move_to_compartment_in_security_zone</td>
<td>Compute</td>
<td>You can't move a compute instance from a standard compartment to a compartment that is in a security zone.</td>
</tr>
<tr>
<td>deny subnet_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Networking</td>
<td>You can't move a subnet from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny bucket_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Object Storage</td>
<td>You can't move a bucket from a security zone to a standard compartment.</td>
</tr>
</tbody>
</table>
### Security Zones

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny <code>db_instance_move_to_compartment_not_in_security_zone</code></td>
<td>Database (all types)</td>
<td>You can't move a database from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny <code>database_with_dataguard_association_move_to_compartment_in_security_zone</code></td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>You can't move a database from a standard compartment to a security zone if its Data Guard association isn't in a security zone.</td>
</tr>
</tbody>
</table>

### Restrict Resource Association

The components of a resource that impact its security posture must also be located in a security zone. Resources that aren't in a security zone might be vulnerable.

The following table describes the security zone policies that restrict resource association.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny <code>block_volume_not_in_security_zone_attach_to_instance_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>All block storage volumes attached to a compute instance in a security zone must themselves be in a security zone.</td>
</tr>
<tr>
<td>deny <code>block_volume_in_security_zone_attach_to_instance_not_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn't in a security zone can't be attached to block storage volumes that are in a security zone.</td>
</tr>
<tr>
<td>deny <code>boot_volume_not_in_security_zone_attach_to_instance_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>The boot volume for a compute instance in a security zone must also be in a security zone.</td>
</tr>
<tr>
<td>deny <code>boot_volume_in_security_zone_attach_to_instance_not_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn't in a security zone can't be attached to a boot volume that is in a security zone.</td>
</tr>
<tr>
<td>deny <code>instance_in_security_zone_launch_from_boot_volume_not_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>The boot volume for a compute instance in a security zone must also be in a security zone.</td>
</tr>
<tr>
<td>deny <code>instance_not_in_security_zone_launch_from_boot_volume_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn't in a security zone can't use a boot volume that is in a security zone.</td>
</tr>
<tr>
<td>deny <code>attached_block_volume_not_in_security_zone_move_to_compartment_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>A block volume can't be moved to a security zone if it's attached to a compute instance that isn't in a security zone.</td>
</tr>
<tr>
<td>deny <code>attached_boot_volume_not_in_security_zone_move_to_compartment_in_security_zone</code></td>
<td>Compute, Block Volume</td>
<td>A boot volume can't be moved to a security zone if it's attached to a compute instance that isn't in a security zone.</td>
</tr>
<tr>
<td>deny <code>instance_in_security_zone_in_subnet_not_in_security_zone</code></td>
<td>Compute, Networking</td>
<td>A compute instance in a security zone must use subnets that are also in a security zone.</td>
</tr>
<tr>
<td>Policy</td>
<td>Services</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>deny dataguard_association_with_db_instances_not_in_security_zones</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>A database in a security zone can have a Data Guard association with another database (primary/standby) only if it's also in a security zone.</td>
</tr>
<tr>
<td>deny db_instance_subnet_not_in_security_zone</td>
<td>Database (all types)</td>
<td>A database in a security zone must use subnets that are also in a security zone.</td>
</tr>
<tr>
<td>deny db_resource_association_not_in_security_zone</td>
<td>Database (Exadata DB systems)</td>
<td>Exadata Infrastructure resources in a security zone can't be associated with Container Databases or VM clusters that aren't in security zones.</td>
</tr>
</tbody>
</table>

### Deny Public Access

Resources in a security zone must not be accessible from the public internet.

When you create a private subnet, compute instances launched in that subnet can't have public IP addresses. This restriction ensures that compute instances in the subnet have no internet access. For compute instances in a private subnet, a *service gateway* enables private access to public services such as Object Storage. See [Overview of Networking](#).

The following table describes the *security zone policies* that restrict network access.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny public_subnets</td>
<td>Networking</td>
<td>Subnets in a security zone can't be public. All subnets must be private.</td>
</tr>
<tr>
<td>deny internet_gateway</td>
<td>Networking</td>
<td>You can't add an <em>internet gateway</em> to a <em>VCN</em> within the security zone.</td>
</tr>
<tr>
<td>deny public_buckets</td>
<td>Object Storage</td>
<td>Object Storage buckets in a security zone can't be public.</td>
</tr>
<tr>
<td>deny db_instance_public_access</td>
<td>Database (all types)</td>
<td>Databases in a security zone can't be assigned to public subnets. They must use private subnets.</td>
</tr>
</tbody>
</table>

### Require Encryption

Resources in a security zone must be encrypted using customer-managed keys. Data must be encrypted while in transit and at rest.

[Oracle Cloud Infrastructure Vault](#) lets you manage the master encryption keys that protect your data and the secret credentials that you use to securely access resources. You can also regularly rotate encryption keys.

Many services integrate with the Vault service for encryption, including Object Storage and Block Volume.

The following table describes the *security zone policies* that enforce encryption.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny_block_volume_without_vault_key</td>
<td>Block Volume</td>
<td>Block <em>volumes</em> in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
</tbody>
</table>
Security Zones

<table>
<thead>
<tr>
<th>Policy</th>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny boot_volume_without_vault_key</td>
<td>Block Volume</td>
<td>Boot volumes in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
<tr>
<td>deny buckets_without_vault_key</td>
<td>Object Storage</td>
<td>Object Storage buckets in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
</tbody>
</table>

Ensure Data Durability

Automatic backups must be performed regularly for resources in a security zone.

The following table describes the security zone policy that enforces data durability.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny database_without_backup</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>Databases in a security zone must be configured to perform automatic backups. See Backing Up a Database to Oracle Cloud Infrastructure Object Storage.</td>
</tr>
</tbody>
</table>

Ensure Data Security

Data in a security zone is considered privileged and can't be copied to a standard compartment.

The following table describes the security zone policies that enforce data security.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny database_not_in_security_zone_create_from_backup_in_security_zone</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>You can't use a database backup in a security zone to create a database that isn't in a security zone.</td>
</tr>
<tr>
<td>deny database_in_security_zone_create_clone_not_in_security_zone</td>
<td>Database (Virtual machine DB systems, Autonomous Database)</td>
<td>You can't clone a database in a security zone to create a database that isn't in a security zone.</td>
</tr>
</tbody>
</table>

Use Only Configurations Approved by Oracle

Oracle requires certain security features to be enabled and configured for the resources within a security zone. One example is the operating system configuration for a compute instance.

The following table describes the security zone policies that require configurations that are approved by Oracle.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Policy Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny instance_without_sanctioned_image</td>
<td>Compute</td>
<td>All compute instances in a security zone must be created using an Oracle-provided image. You can't create a compute instance from a custom image in a security zone.</td>
</tr>
</tbody>
</table>
Security Zones

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Policy Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny free_database_creation</td>
<td>Database (all types)</td>
<td>You can’t create an <em>Always Free database</em> in a security zone.</td>
</tr>
</tbody>
</table>

Security Zone IAM Policies

Create IAM policies to control who has access to security zones and recipes, and to control the type of access for each group of users.

By default, only users in the Administrators group have access to all security zone resources. If you are new to IAM policies, see Getting Started with Policies.

For a complete list of policies in Oracle Cloud Infrastructure, see the Policy Reference.

Resource-Types

The following resource types are related to security zones.

- security-zone

Supported Variables

Security zone IAM policies support all the general policy variables.

See General Variables for All Requests.

Details for Verb + Resource-Type Combinations

Identify the permissions and API operations covered by each verb for security zones.

The level of access is cumulative as you go from inspect to read to use to manage.

security-zone

<table>
<thead>
<tr>
<th>Verb</th>
<th>Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>SECURITY_ZONE_INSPECT</td>
</tr>
<tr>
<td>read</td>
<td>SECURITY_ZONE_READ</td>
</tr>
<tr>
<td>use</td>
<td>SECURITY_ZONE_ATTACH, SECURITY_ZONE_UPDATE</td>
</tr>
<tr>
<td>manage</td>
<td>SECURITY_ZONE_CREATE, SECURITY_ZONE_DELETE</td>
</tr>
</tbody>
</table>

Policy Examples

Learn about security zone IAM policies using examples.

Allow users in the group SecurityAdmins to create, update, and delete security zones in the entire tenancy:

Allow group SecurityAdmins to manage security-zone in tenancy

Allow users in the group SecurityAuditors to view security zones in the compartment SalesApps:

Chapter 33

Security Guide and Announcements

This section of the Oracle Cloud Infrastructure documentation provides a guide to help you securely configure services and resources, and timely announcements relevant to emerging security issues.

• Oracle Cloud Infrastructure Security Guide on page 3656
• Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 3725
• Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities on page 3731

Oracle Cloud Infrastructure Security Guide

Oracle Cloud Infrastructure enables enterprises to maximize the number of mission-critical workloads that they can migrate to the cloud while continuing to maintain their desired security posture and reduce the overhead of building and operating data-center infrastructure. With Oracle Cloud Infrastructure, enterprise customers get unparalleled control of and transparency into their applications running in the cloud, including:

• Customer isolation that allows you to deploy your application and data assets in an environment that commits full isolation from other tenants and Oracle’s staff, as well as between the same tenant’s workloads.
• Always-on encryption that protects customer data at-rest and HTTPS-only public APIs.
• Easy-to-use IAM policies that allows you to constrain access to your services and segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.
• Security zone policies that allow you to be confident that your resources comply with security principles and best practices related to encryption, network access, and so on.
• Comprehensive log data that allows you to audit and monitor actions on your resources, helping you to meet your audit requirements while reducing security and operational risk.
• Identity federation that allows you to use your existing users and groups in the cloud.
• Support for bringing in third-party software solutions for protecting customer data and resources in the cloud.
• Fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.
• Rigorous internal processes and use of effective security controls in all phases of cloud service development and operation.
• Adherence to Oracle’s strict security standards through third-party audits, certifications, and attestations. Oracle helps customers demonstrate compliance readiness to internal security and compliance teams, their customers, auditors, and regulators.

All of the Oracle Cloud Infrastructure security capabilities have been designed with one goal in mind: allowing you to run your mission-critical workloads in the cloud with complete control and confidence. Oracle continues to invest in the above areas and more to offer unmatched security and assurance to enterprise customers.

For an overview of Oracle Cloud Infrastructure's security, see Security Overview on page 3657.

Security Overview

Oracle’s mission is to build cloud infrastructure and platform services for your business to have effective and manageable security to run your mission-critical workloads and store your data with confidence.

Oracle Cloud Infrastructure’s security approach is based on seven core pillars. Each pillar has multiple solutions designed to maximize the security and compliance of the platform.

CUSTOMER ISOLATION

Allow customers to deploy their application and data assets in an environment that commits full isolation from other tenants and Oracle’s staff.

DATA ENCRYPTION

Protect customer data at-rest and in-transit in a way that allows customers to meet their security and compliance requirements for cryptographic algorithms and key management.

SECURITY CONTROLS

Offer customers effective and easy-to-use security management solutions that allow them to constrain access to their services and segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.

VISIBILITY

Offer customers comprehensive log data and security analytics that they can use to audit and monitor actions on their resources, allowing them to meet their audit requirements and reduce security and operational risk.

SECURE HYBRID CLOUD

Enable customers to use their existing security assets, such as user accounts and policies, as well as third-party security solutions when accessing their cloud resources and securing their data and application assets in the cloud.

HIGH AVAILABILITY

Offer fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.

VERIFIABLY SECURE INFRASTRUCTURE

Follow rigorous processes and use effective security controls in all phases of cloud service development and operation. Demonstrate adherence to Oracle’s strict security standards through third-party audits, certifications, and attestations. Help customers demonstrate compliance readiness to internal security and compliance teams, their customers, auditors, and regulators.

Also, Oracle employs some of the world’s foremost security experts in information, database, application, infrastructure, and network security. By using Oracle Cloud Infrastructure, our customers directly benefit from Oracle’s deep expertise and continuous investments in security.

Basic Security Considerations

The following principles are fundamental to using any application securely:

- Keep software up-to-date. This includes the latest product release and any patches that apply to it.
- Limit privileges as much as possible. Users should be given only the access necessary to perform their work. User privileges should be reviewed periodically to determine relevance to current work requirements.
- Monitor system activity. Establish who should access which system components, and how often, and monitor those components.
- Learn about and use the Oracle Cloud Infrastructure security features. For more information, see Security Services and Features on page 3663.
- Use secure best practices. For more information, see Security Best Practices on page 3673.
- Keep up-to-date on security information. Oracle regularly issues security-related patch updates and security alerts. Install all security patches as soon as possible. See the Critical Patch Updates and Security Alerts website.
Understanding the Oracle Cloud Infrastructure Environment

When planning your Oracle Cloud Infrastructure deployment, consider the following:

**Which resources must be protected?**
- Protect customer data, such as credit card numbers.
- Protect internal data, such as proprietary source code.
- Protect system components from being disabled by external attacks or intentional system overloads.

**Who are you protecting data from?**
For example, you must protect your subscribers’ data from other subscribers, but someone in your organization needs to access that data to manage it. Analyze your workflows to determine who needs access to the data. Consider carefully how much access to give a system administrator; it is possible that a system administrator can manage your system components without needing to access the system data.

**What will happen if protections on a strategic resource fail?**
Sometimes, a fault in your security scheme is nothing more than an inconvenience. In other cases, a fault might cause great damage to you or your customers. Understanding the security ramifications of each resource will help you protect it properly.

**Shared Security Model**
Oracle Cloud Infrastructure offers best-in-class security technology and operational processes to secure its enterprise cloud services. However, for you to securely run your workloads in Oracle Cloud Infrastructure, you must be aware of your security and compliance responsibilities. By design, Oracle provides security of cloud infrastructure and operations (cloud operator access controls, infrastructure security patching, and so on), and you are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

In a shared, multi-tenant compute environment, Oracle is responsible for the security of the underlying cloud infrastructure (such as data-center facilities, and hardware and software systems) and you are responsible for securing your workloads and configuring your services (such as compute, network, storage, and database) securely.

In a fully isolated, single-tenant, bare metal server with no Oracle software on it, your responsibility increases as you bring the entire software stack (operating systems and above) on which you deploy your applications. In this environment, you are responsible for securing your workloads, and configuring your services (compute, network, storage, database) securely, and ensuring that the software components that you run on the bare metal servers are configured, deployed, and managed securely.

More specifically, your and Oracle's responsibilities can be divided into the following areas:
- **Identity and Access Management (IAM):** As with all Oracle cloud services, you should protect your cloud access credentials and set up individual user accounts. You are responsible for managing and reviewing access for your own employee accounts and for all activities that occur under your tenancy. Oracle is responsible for providing effective IAM services such as identity management, authentication, authorization, and auditing.
- **Workload Security:** You are responsible for protecting and securing the operating system and application layers of your compute instances from attacks and compromises. This protection includes patching applications and operating systems, operating system configuration, and protection against malware and network attacks. Oracle is responsible for providing secure images that are hardened and have the latest patches. Also, Oracle makes it simple for you to bring the same third-party security solutions that you use today.
- **Data Classification and Compliance:** You are responsible for correctly classifying and labeling your data and meeting any compliance obligations. Also, you are responsible for auditing your solutions to ensure that they meet your compliance obligations.
- **Host Infrastructure Security:** You are responsible for securely configuring and managing your compute (virtual hosts, containers), storage (object, local storage, block volumes), and platform (database configuration) services. Oracle has a shared responsibility with you to ensure that the service is optimally configured and secured. This responsibility includes hypervisor security and the configuration of the permissions and network access controls.
required to ensure that hosts can communicate correctly and that devices are able to attach or mount the correct storage devices.

- **Network Security:** You are responsible for securely configuring network elements such as virtual networking, load balancing, DNS, and gateways. Oracle is responsible for providing a secure network infrastructure.

- **Client and Endpoint Protection:** Your enterprise uses various hardware and software systems, such as mobile devices and browsers, to access your cloud resources. You are responsible for securing all clients and endpoints that you allow to access Oracle Cloud Infrastructure services.

- **Physical Security:** Oracle is responsible for protecting the global infrastructure that runs all of the services offered in Oracle Cloud Infrastructure. This infrastructure consists of the hardware, software, networking, and facilities that run Oracle Cloud Infrastructure services.

For information about using security credentials to access Oracle Cloud Infrastructure, see Security Credentials on page 179.

**Infrastructure Security**

Our security model is built around people, process, tooling, and a common security “platform” of methodologies and approaches from which we build our products. We apply this model to our core security components of Security Culture, Security Design and Controls, Secure Software Development, Personnel Security, Physical Security, and Security Operations that we use to protect and secure our customers and business.

**Security Culture**

We believe that a dynamic security-first culture is vital to building a successful security-minded organization. We have cultivated a holistic approach to security culture in which all our team members internalize the role that security plays in our business and are actively engaged in managing and improving our products' security posture. We have also implemented mechanisms that assist us in creating and maintaining a security-aware culture.

- **Security-minded leadership:** Our senior leadership is actively involved in our security planning, monitoring and management. We define and measure ourselves against security metrics and include security as a component of our team evaluation processes.

- **Embedded expertise:** To help with driving security practices within our team, we have an embedded security-engineering model with security team members sitting and working with our product development teams. This approach enables our security organization to build deep understanding of the product-development processes and system architectures. We are also able to better assist teams in solving security challenges in real time and drive security initiatives more effectively.

- **Common security standards:** We actively work to integrate security into our products and operations. One way we have done this is to establish a security standards baseline. Our objective in creating this baseline is to provide a single security point of reference for business that establishes clear and actionable guidelines. The security baseline is updated frequently to incorporate learned lessons and reflect emerging business factors. We have also created a series of support materials to assist our teams in implementing security controls including reference architectures, implementation guides, and access to security experts.

- **Values of openness, constructive debate, and encouraged escalation:** Security issues can be addressed only when the people who can fix them are aware of them. We believe that openness and transparency, constructive debate, and encouraged escalation make us stronger. We encourage escalation, and we work to create an environment where raising issues early and often is rewarded.

- **Security training awareness:** We maintain robust security and awareness training programs that raise awareness and reinforce our security culture. We require in-depth security training sessions for all new employees as well as annual refresher trainings, and we provide security training that is tailored to our employees’ specific job roles. All our software developers undergo a secure development training that establishes baseline security requirements for product development and provides best practices. We also work to provide engaging and innovative forms of security awareness training such as guest speakers and interactive forums (and we're not above providing food, drinks, or swag to drive attendance).
Security Designs and Controls

Security is integrated into our products and operations through our Oracle Cloud Infrastructure Methodology. This centralized methodology defines our approach for the core security areas that form the security foundation from which we build our products. This approach lends itself to agility and helps us apply best practices and lessons learned from one product across the business, thus raising the security of all our products.

• **User authentication and access control**: Least-privilege access is used to grant access to production systems, and the approved lists of service team members are periodically reviewed to revoke access when there is no justifiable need. Access to production environments requires multi-factor authentication (MFA). The MFA tokens are granted by the security team, and tokens of inactive members are disabled. All access to production systems is logged, and the logs are stored for security analysis.

• **Change management**: Oracle Cloud Infrastructure follows a defined and rigorous change management and deployment process that uses purpose-built proprietary testing and deployment tools. All changes deployed into our production environment follow a testing and approval process prior to release. This process is designed to ensure that changes operate as intended, and can otherwise be rolled back to a previous known good state to recover gracefully from unforeseen bugs or operational issues. We also track the integrity of critical system configurations to ensure that they align with expected state.

• **Vulnerability management**: We use both internal penetration testing teams and external industry experts to help us identify potential vulnerabilities in our products. These exercises help us improve the security of our products, and we work to incorporate the lessons that we learn into our future development work. Oracle Cloud Infrastructure hosts undergo periodic vulnerability scanning using industry-standard scanners. Scan results are triaged to validate applicability of findings to the Oracle Cloud Infrastructure environment, and that applicable findings are patched by our product teams.

• **Incident response**: We have developed strong processes and mechanisms to enable us to respond to and address incidents as they arise. We maintain 24/7 incident response teams ready to detect and respond to events. Our critical staff members carry paging devices that enable us to call on the expertise needed to bring issues to resolution. We have also built a process to help us learn from our incidents. We perform root cause analysis through our Corrective Action/Preventative Action (CAPA) process. CAPAs are intended to discover process gaps and changes that should be made by the business after an incident. CAPAs act as a common language that we can use to reflect on an issue and capture concrete steps to improve future operational readiness. CAPAs capture the root cause of an issue, what is required to contain or fix the issue, and what steps we must take to ensure that the issue does not recur. Our leadership team reviews all CAPAs, looks for cross-organizational applications for learned lessons, and ensures that actions are implemented in a timely manner.

• **Security logging and monitoring**: We have created automated mechanisms to log various security-relevant events (for example, API calls and network events) in the infrastructure, and monitor the logs for anomalous behavior. Alerts generated by monitoring mechanisms are tracked and triaged by the security team.

• **Network security**: By default, customer communications with Oracle Cloud Infrastructure services are done using the latest TLS ciphers and configuration to secure customer data in transit, and hinder any man-in-the-middle attacks. As a further defense in depth, customer commands to the services are digitally signed using public keys, to prevent any tampering. The services also deploy proven, industry-leading tools and mechanisms to mitigate distributed denial of service (DDoS) attacks and maintain high availability.

• **Control plane security**: Oracle Cloud Infrastructure back-end (control plane) hosts are securely isolated from customer instances by using network ACLs. Provisioning and management of customer instances are done by software agents that must interact with the backend hosts. Only authenticated and authorized software agents can successfully interact with Oracle Cloud Infrastructure back-end hosts. For back-end hosts, pre-production environments (for example, dev, test, and integ) are separated from production environments so that any development and test activities do not have any impact on production systems.

• **Server security and media management**: Oracle has a long history of enterprise-class secure hardware development. Our Hardware Security team is responsible for designing and testing the security of the hardware used to deliver Oracle Cloud Infrastructure services. This team works with our supply chain and tests hardware components to validate them against rigorous Oracle Cloud Infrastructure hardware security standards. This team also works closely with our product development functions to ensure that hardware can be returned to a pristine, safe state after being released by customers.

• **Secure host wipe and media destruction**: Oracle Cloud Infrastructure instances are securely wiped after hardware is released by customers. This secure wipe restores hardware to a pristine state. We have re-engineered
the platform with proprietary hardware components that allow us to wipe and reinitialize the hardware in a secure manner. When the underlying hardware has reached end-of-life, it is securely destroyed. Before leaving our data centers, drives are rendered unusable by using industry-leading media destruction devices.

Secure Software Development

Secure product development requires consistently applied methodologies that conform to clear security objectives and principles. We build security practices into every element of our product development life cycle. Oracle employs formal secure product development standards that are a roadmap and guide for developers. These standards discuss general security knowledge areas such as design principles and common vulnerabilities, and provide specific guidance on topics such as data validation, data privacy, and user management.

Oracle secure product development standards have evolved and expanded over time to address the common issues affecting code, new threats as they are discovered, and new use cases by Oracle customers. The standards incorporate insights and learned lessons; they do not live in a vacuum, nor are they an “after the fact” addendum to software development. They are integral to language-specific standards such as C/C++, Java, PL/SQL, and others, and are a cornerstone to Oracle’s secure development programs and processes.

Security assurance analysis and testing verify security qualities of Oracle products against various types of attacks. There are two broad categories of tests employed for testing Oracle products: static and dynamic analysis. These tests fit differently in the product development lifecycle and tend to find different categories of issues, so they are used together by Oracle product teams.

Personnel Security

Our people make our business. We strive to hire the best, and we invest in and continue to develop our employees. We value training, and we require not only baseline security training for all our employees but also specialized training to keep our teams abreast of the latest security technologies, exploits, and methodologies. In addition to standard annual corporate training programs that cover our information security and privacy programs (among many others), we engage with a broad spectrum of industry groups and send our employees to specialist conferences to collaborate with other industry experts on emerging challenges. The objectives of our security training programs are to help our employees better protect our customers and products, to enable employees to grow in their knowledge areas around security, and to further our mission to attract and retain the best talent.

We work to recruit the best talent for our team as we grow, and we hire people with strong ethics and good judgment. All our employees undergo pre-employment screening as permitted by law, including criminal background checks and prior-employment validation. We also maintain performance evaluation processes to recognize good performance and help our teams and employees identify opportunities for growth. We maintain both team and employee evaluation processes, and we use security as a component of our team evaluation processes. This approach provides our teams and leadership visibility into how our teams are performing against our security standards and enables us to identify best practices and improvement areas for critical security processes.

Physical Security

Oracle Cloud Infrastructure data centers are designed for security and availability of customer data. This approach begins with our site selection process. Candidate build sites and provider locations undergo an extensive risk evaluation process that considers environmental threats, power availability and stability, vendor reputation and history, neighboring facility functions (for example, high-risk manufacturing or high-threat targets), and geopolitical considerations, among other criteria.

Oracle Cloud Infrastructure data centers align with Uptime Institute and Telecommunications Industry Association (TIA) ANSI/TIA-942-A Tier 3 or Tier 4 standards and follow a N2 redundancy methodology for critical equipment operation. Data centers housing Oracle Cloud Infrastructure services use redundant power sources and maintain generator backups in case of widespread electrical outage. Server rooms are closely monitored for air temperature and humidity, and fire suppression systems are in place. Data center staff are trained in incident response and escalation procedures to address security or availability events that may arise.

We take a layered approach to physical security that starts with the site build. Oracle Cloud Infrastructure data center facilities are durably built with steel, concrete, or comparable materials and are designed to withstand impact from a
light vehicle strike. Our sites are staffed with security guards who are ready to respond to incidents 24 hours a day, 7 days a week, 365 days a year. The exterior of the sites is secured with perimeter barriers and vehicle checks are actively monitored by a guard force and cameras that cover the building perimeter.

All persons entering our data centers must first go through a layer of security at the site entrances, which are staffed with security guards. Persons without site-specific security badges entering the site must present government-issued identification and have an approved access request granting them access to the data center building. All employees and visitors must wear visible, official identification badges at all times. There are additional security layers between the entrance and server rooms that vary depending on the site build and risk profile. Data center server rooms are built with additional security layers including cameras that cover server rooms, two-factor access control, and intrusion-detection mechanisms. Physical barriers are in place to create isolated security zones around server and networking racks that span from the floor (including below the raised floor where applicable) to the ceiling (including above ceiling tiles where applicable).

Access to Oracle Cloud Infrastructure data centers is carefully controlled and follows a least-privilege access approach. All access to server rooms must be approved by authorized personnel and is granted only for the necessary period. Access usage is audited, and access provisioned within the system is periodically reviewed by data-center leadership. Server rooms are isolated into secure zones that are managed on a zone-by-zone basis, and access is provisioned only for those zones required by personnel.

Security Operations

The Oracle Cloud Infrastructure Security Operations team is responsible for monitoring and securing the unique Oracle Cloud Infrastructure hosting and virtual networking technologies. The team works and trains directly with the Oracle engineers who develop these technologies to leverage the unique security and introspection capabilities they provide.

We monitor emerging internet security threats daily and implement appropriate response and defense plans to address risks to the business. When we determine that urgent changes are recommended that are within the scope of the customers’ responsibilities, we issue security alert bulletins to those customers to ensure their protection.

In the case of a detected or reported security issue that affects Oracle Cloud Infrastructure servers or networks, Security Operations staff is available 24/7 to respond, escalate, or take required corrective action. When necessary, we will escalate and coordinate with external parties (including network and hosting service providers, hardware vendors, or law enforcement) to protect Oracle Cloud Infrastructure, our customers, and our network's security and reputation.

All actions performed in response to a security issue by the Security Operations team are done according to our documented process, and are logged in accordance with compliance requirements. Care is always taken to protect the goals of service and data integrity, privacy, and business continuity.

Customer Data Protection

Data Rights and Ownership

Oracle Cloud Infrastructure customers retain all ownership and intellectual property rights in and to their content. Customer data protection is critically important, and we strive to be transparent with our data protection processes as well as law enforcement requests that we might receive.

Data Privacy

Oracle complies with the EU-U.S. Privacy Shield Framework as set forth by the U.S. Department of Commerce regarding the collection, use, and retention of personal information transferred from the European Union to the United States. Oracle is also responsible for ensuring that third parties who act as an agent on our behalf do the same.

Oracle has certified to the Department of Commerce that it adheres to the Privacy Shield Principles. If there is any conflict between the terms in our privacy policy and the Privacy Shield Principles, the Privacy Shield Principles shall govern. To learn more about the Privacy Shield program, and to view our certification, visit https://www.privacyshield.gov/list.
For personal information received or transferred pursuant to the Privacy Shield Framework, Oracle is subject to the regulatory enforcement powers of the U.S. Federal Trade Commission.

Oracle continues to adhere to the underlying European privacy principles of the U.S.-Swiss Safe Harbor for the processing of Personal Information received from Switzerland. To learn more about the Safe Harbor program, and to view our certification, visit https://safeharbor.export.gov/swisslist.aspx.

**Law Enforcement Requests**

Except as otherwise required by law, Oracle will promptly notify customers of any subpoena, judicial, administrative or arbitral order of an executive or administrative agency or other governmental authority that it receives and which relates to the personal data Oracle is processing on the customer’s behalf. Upon customer request, Oracle will provide customers with reasonable information in its possession relevant to the law enforcement request and any assistance reasonably required for them to respond to the request in a timely manner.

**Compliance**

Oracle Cloud Infrastructure is built for enterprises. We operate under practices aligned with the ISO/IEC 27002 Code of Practice for information security controls, from which we have identified a comprehensive set of security controls that apply to our business. Oracle Cloud Infrastructure is still a new product line, and we must operate for a period of time in order for these security controls and our operations to undergo external audit. As an enterprise cloud, we plan to pursue a broad suite of industry and government certifications, audits, and regulatory programs.

**Security Services and Features**

A key objective of Oracle Cloud Infrastructure is to allow you to create a logical extension of your on-premises infrastructure and data centers in Oracle Cloud Infrastructure. You can gain the benefits of a modern public cloud without having to compromise or reinvent your existing security posture. This idea was central to the design of all our infrastructure and services.

**Regions and Availability Domains**

To provide data availability and durability, Oracle Cloud Infrastructure enables you to select from infrastructure with distinct geographic and threat profiles. A region is the top-level component of the infrastructure. Each region is a separate geographic area with multiple, fault-isolated locations called availability domains. An availability domain is the subcomponent of a region and is independent and highly reliable. Each availability domain is built with fully independent infrastructure: buildings, power generators, cooling equipment, and network connectivity. With physical separation comes protection against natural and other disasters. Availability domains within the same region are connected by a secure, high-speed, low-latency network, which allows customers to build and run highly reliable applications and workloads with minimum impact to application latency and performance. All links between availability domains are encrypted. Each region has one or more availability domains, each allowing customers to deploy highly available applications.

**Identity and Access Management (IAM) Service**

The Oracle Cloud Infrastructure Identity and Access Management (IAM) service is built to meet the requirements of enterprises, and it provides authentication and authorization for all their Oracle Cloud Infrastructure resources and services. An enterprise can use a single tenancy shared by various business units, teams, and individuals while maintaining security, isolation, and governance.

When a customer joins Oracle Cloud Infrastructure, a tenancy is created. A tenancy is a virtual construct that contains all of the Oracle Cloud Infrastructure resources that belong to the customer. The administrator of the tenancy can create users and groups and assign them least-privileged access to resources that are partitioned into compartments. A compartment is a group of resources that can be managed as a single logical unit, providing a streamlined way to manage large infrastructure. For example, a customer can create a compartment (HR-Compartment) to host a specific set of cloud network, compute instances, and storage volumes necessary to host its HR applications. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating cloud resources. Customers use them to clearly separate resources for the purposes of isolation (separating the resources for...
one project or business unit from another). A common approach is to create a compartment for each major part of an organization. Unlike most Oracle Cloud Infrastructure services that are regionally scoped, the IAM service resources are global. Customers can have a single tenancy across multiple regions.

The following are key IAM primitives:

• **Resource**: A cloud object that a company’s employees create and use when interacting with Oracle Cloud Infrastructure services, for example, compute instances, block storage volumes, virtual cloud networks (VCNs), subnets, and route tables.

• **Policy**: A set of authorization rules that define access to resources within a tenancy.

• **Compartment**: A heterogeneous collection of resources for the purposes of security isolation and access control.

• **Tenancy**: The root compartment that contains all of an organization’s resources. Within a tenancy, administrators can create one or more compartments, create more users and groups, and assign policies that grant groups the ability to use resources within a compartment.

• **User**: A human being or system that needs access to manage their resources. Users must be added to groups in order to access resources. Users have one or more credentials that must be used to authenticate to Oracle Cloud Infrastructure services. Federated users are also supported.

• **Group**: A collection of users who share a similar set of access privileges. Administrators can grant access policies that authorize a group to consume or manage resources within a tenancy. All users in a group inherit the same set of privileges.

• **Identity Provider**: A trusted relationship with a federated identity provider. Federated users who attempt to authenticate to the Oracle Cloud Infrastructure console are redirected to the configured identity provider. After successfully authenticating, federated users can manage Oracle Cloud Infrastructure resources in the console just like a native IAM user. Currently, Oracle Cloud Infrastructure supports the Oracle Identity Cloud Service and Microsoft Active Directory Federation Service (ADFS) as identity providers. Federated groups are mapped to native IAM groups to define the policies apply to a federated user.

All customer calls to access Oracle Cloud Infrastructure resources are first authenticated by the IAM service (or federated provider) and then authorized based on IAM policies. A customer can create a policy that gives a set of users permission to access the infrastructure resources (network, compute, storage, and so on) within a compartment in the tenancy. These policies are flexible and are written in a human-readable form that is easy to understand and audit. A policy contains one or more policy statements that follow this easy-to-understand syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

A verb defines the type of access covered. Oracle defines the following verbs that you can use in your policy statements:

• **inspect**: Provides the ability to list resources, without access to any confidential information or user-specified metadata that might be part of that resource.
• **read**: Includes inspect plus the ability to get user-specified metadata and the actual resource itself.
• **use**: Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource types where the update operation has the same effective impact as the create operation (for example, UpdatePolicy and UpdateSecurityList). In such cases, the update ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.
• **manage**: Includes all permissions for the resource.

The following example policy enables the GroupAdmins group to create, update, or delete any groups:

```
Allow group GroupAdmins to manage groups in tenancy
```

Each user has one or more of the following credentials to authenticate themselves to Oracle Cloud Infrastructure. Users can generate and rotate their own credentials. In addition, a tenancy security administrator can reset credentials for any user within their tenancy.

• **Console password**: Used to authenticate a user to the Oracle Cloud Infrastructure Console.
• **API key**: All API calls are signed using a user-specific 2048-bit RSA private key. The user creates a public key pair, and uploads the public key in the Console.
• **Auth token**: Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. For example, use an auth token to authenticate with a Swift client. To ensure sufficient complexity, the token is created by the IAM service and cannot be provided by a customer.
• **Customer secret key**: Used by Amazon S3 clients to access the Object Storage service’s S3-compatible API. To ensure sufficient complexity, the password is created by the IAM service and cannot be provided by a customer.

### Security Zones Service

Security Zones Service will let you be confident that your Compute, Networking, Object Storage, Database and other resources comply with Oracle security principles and best practices. A security zone is associated with a compartment. When you create and update resources in a security zone compartment, Oracle Cloud Infrastructure validates these operations against security zone policies. If any security zone policy is violated, then the operation is denied.

Here are some examples of security zone policies:

• Subnets in a security zone can't be public. All subnets must be private.
• The boot volume for a compute instance in a security zone must also be in a security zone.
• Object Storage buckets in a security zone must use a customer-managed master encryption key.
• You can't move certain resources like block volumes and compute instances from a security zone to a standard compartment.

For more information, see [Security Zones](#).

### Audit Service

Audit Service Service records all API calls to resources in a customer’s tenancy as well as login activity from the graphical management Console. Using the Audit service, customers can achieve their own security and compliance goals by monitoring all user activity within their tenancy. Because all Console, SDK, and command line (CLI) calls go through our APIs, all activity from those sources is included. Audit records are available through an authenticated, filterable query API or can be retrieved as batched files from Oracle Cloud Infrastructure Object Storage. Audit log contents include what activity occurred, the user that initiated it, the date and time of the request, as well as source IP, user agent, and HTTP headers of the request.

### Compute Service

Compute is a core component of Oracle Cloud Infrastructure and provides on-demand and elastic compute capabilities with enterprise-grade security and performance. Customers can provision thousands of compute instances and scale them up or down through an easy-to-use web-based management console. Programmatic support to do the
same is available through feature-rich SDKs and command-line interfaces (CLIs). All compute instances are hosted in Oracle enterprise-grade data centers.

Compute instances are based on high-performance server hardware that uses latest-generation, multi-core server CPUs, large amounts of memory, and high-throughput NVMe local storage. Oracle Cloud Infrastructure provides bare metal (BM) and virtual machine (VM) instances. Customers can choose instances that fit their performance, cost, and software flexibility requirements.

- **Bare metal instances:** In bare metal instances, physical servers are dedicated to a single customer who has complete control over the server. There is no Oracle-managed hypervisor and Oracle personnel have no access to memory or local (NVMe) storage while the instance is running. All network virtualization is performed off-box and only the Oracle Integrated Lights Out Manager (ILOM) is accessible to the infrastructure (required in order to remotely reboot or reprovision instances). These bare metal instances offer consistent high performance and are immune to any noisy-neighbor issues. Customers have OS-level administrative privileges to the bare metal instance. After a customer terminates their bare metal instance, the server undergoes an automated disk and firmware-level wipe process to ensure isolation between customers.

- **Virtual machine (VM) instances:** Customers with flexibility requirements or those who don't need a dedicated bare metal instance can opt for VMs. Multi-tenant customer VMs in Oracle Cloud Infrastructure are managed by a security hardened hypervisor that provides strong isolation between customers.

Oracle Cloud Infrastructure instances use key-based SSH by default. Customers provide the SSH public keys to Oracle Cloud Infrastructure and securely use the SSH private keys for accessing the instances. Oracle recommends using key-based SSH to access Oracle Cloud Infrastructure instances. Password-based SSH could be susceptible to brute-forcing attacks, and are not recommended.

Oracle Linux images hardened with the latest security updates are available for you to run on Oracle Cloud Infrastructure instances. Oracle Linux images run the Unbreakable Enterprise Kernel (UEK) and support advanced security features such as Ksplice to apply security patches without booting, which allows enterprises to live-update their instances without any disruption. In addition to Oracle Linux, Oracle Cloud Infrastructure makes a growing list of other OS images available, including CentOS, Ubuntu, and Windows Server. You can also bring your own custom images. All Oracle-provided images come with secure defaults including OS-level firewalls turned on by default.

**Networking Service**

High-throughput and reliable networking is fundamental to public-cloud infrastructure that delivers compute and storage services at scale. As a result, we invested significant innovation in Oracle Cloud Infrastructure networking to support requirements of enterprise customers and their workloads. Oracle Cloud Infrastructure regions have been built with a state-of-the-art, non-blocking Clos network that is not over-subscribed and provides customers with a predictable, high-bandwidth, low latency network. The data centers in a region are networked to be highly available and have low-latency connectivity between them.

The Oracle Cloud Infrastructure Networking service offers a customizable private network (a VCN, or virtual cloud network) to customers, which enforces logical isolation of customer Oracle Cloud Infrastructure resources. As with their on-premises network in their data centers, customers can set up a VCN with hosts with private IP addresses, subnets, route tables and gateways using VCN. The VCN can be configured for internet connectivity, or connected to the customer's private data center through an IPSec VPN gateway or FastConnect. FastConnect offers a private connection between an existing network's edge router and Dynamic Routing Gateways (DRG). Traffic does not traverse the internet.

The Networking service also supports bi-directional, stateful and stateless firewalls that allow customers to initialize network security access controls. Firewalls and ACLs specified for a customer VCN are propagated throughout the network topology and control plane, ensuring a multi-tiered and defense-in-depth implementation. Each tenant (customer) can create multiple VCNs to implement logical grouping of their resources.

The following are key networking concepts associated with a VCN:

- **Subnets:** The primary subdivision of a VCN. Subnets have historically been specific to an availability domain, but can now be regional (covering all availability domains in the region). Subnets can be marked as private upon creation, which prevents instances launched in that subnet from having public IP addresses.
Security Guide and Announcements

- **Internet gateway**: A virtual router that provides public internet connectivity from a VCN. By default, a newly created VCN has no internet connectivity.
- **Dynamic routing gateway**: A virtual router that provides a path for private traffic between a VCN and a data center’s network. It is used with an IPSec VPN or Oracle Cloud Infrastructure FastConnect connection to establish private connectivity between a VCN and an on-premises or other cloud network.
- **NAT gateway**: A virtual router that gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.
- **Service gateway**: A virtual router that gives cloud resources private access to Oracle services such as Object Storage without using an internet gateway or NAT gateway.
- **Routing tables**: Virtual routing tables that give the subnets access to the VCN’s gateways (Internet Gateway and Dynamic Routing Gateway). Routes can also use private IPs as a target to implement network functionality such as NAT, firewalls, IDS, and so on.
- **Primary VNICs**: Subnets contain virtual network interface cards (VNICs) that attach to instances. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each instance has a primary VNIC that is created during instance launch and cannot be removed. During instance launch, the Networking service also assigns a public IP address. Customers can override that behavior during instance launch and request to have no public IP address assigned.
- **Secondary VNICs**: VNICs with public and private IP addresses that can be attached to an instance. In a bring-your-own-hypervisor (BYOH) scenario, where customers can run their hypervisor on a BM instance, a secondary VNIC can be assigned to a VM, to allow VCN networking for the VM. This is very useful for running virtual security appliances in a VCN.
- **IPSec VPN connection**: A secure VPN connection between a VCN and a data center.
- **Security lists**: Virtual firewall rules that define allowed ingress and egress to an instance at the packet level. Individual rules can be defined to be stateful or stateless.

Virtual firewalls are implemented by using VCN security lists. Customers can specify a set of firewall rules and associate them with one or more subnets. Associating a security list with a subnet applies those firewall rules to all instances running inside the subnet, at the packet level. There are two types of firewall rules:

- **Ingress rules**: Ingress rules specify the source (IP CIDR and port range), destination port range, and protocol to match on, and are applied to ingress network connections.
- **Egress rules**: Egress rules specify the destination (IP CIDR and port range), source port range, and protocol to match on, and are applied to egress network connections.

Every VCN has a default security list customers may optionally use that allows only SSH and certain types of important ICMP ingress traffic, and all egress traffic. Customers can associate multiple security lists with a subnet. The subnet uses the default security list if the customer doesn’t specify another list for the subnet to use.

For further information about security in the Networking service, see:
- **Ways to Secure Your Network** on page 2830
- **Access Control** on page 2831
- **Security Lists** on page 2850

**Storage Services**

Oracle Cloud Infrastructure offers multiple storage solutions to meet the performance and durability requirements of customers:

- **Local Storage**: NVMe-backed storage on compute instances, offering extremely high IOPS.
- **Block Volumes**: Network-attached storage volumes, attachable to compute instances.
- **Object Storage**: Regional service for storing large amounts of data as objects, providing strong consistency and durability.

The Oracle Cloud Infrastructure Block Volumes service provides persistent storage that can be attached to compute instances using the iSCSI protocol. The volumes are stored in high-performance network storage and support automated backup and snapshot capabilities. Volumes and their backups are accessible only from within a customer's...
VCN and are encrypted at rest using unique keys. For additional security, iSCSI CHAP authentication can be required on a per-volume basis.

The Oracle Cloud Infrastructure Object Storage service provides highly scalable, strongly consistent, and durable storage for objects. API calls over HTTPS provide high-throughput access to data. All objects are encrypted at rest using unique keys. Objects are organized by bucket, and, by default, access to buckets and objects within them requires authentication. Users can use IAM security policies to grant users and groups access privileges to buckets.

To allow bucket access by users who do not have IAM credentials, the bucket owner (or a user with necessary privileges) can create pre-authenticated requests that allow authorized actions on buckets or objects for a specified duration. Alternately, buckets can be made public, which allows unauthenticated and anonymous access. Given the security risk of inadvertent information disclosure, Oracle highly recommends carefully considering the business case for making buckets public. Object Storage enables you to verify that an object was not unintentionally corrupted by allowing an MD5 checksum to be sent with the object (or with each part, in the case of multipart uploads) and returned upon successful upload. This checksum can be used to validate the integrity of the object.

In addition to its native API, the Object Storage service supports Amazon S3 compatible APIs. Using the Amazon S3 Compatibility API, customers can continue to use the existing Amazon S3 tools (for example, SDK clients), and partners can modify their applications to work with Object Storage, with minimal changes to their applications. Their native API can co-exist with the Amazon S3 Compatibility API, which supports CRUD operations. Before customers can use the Amazon S3 Compatibility API, they must create an S3 Compatibility API key. After they've generated the necessary key, they can use the Amazon S3 Compatibility API to access Object Storage in Oracle Cloud Infrastructure.

**Database Service**

Oracle Cloud Infrastructure makes it easy to run, scale, and secure your Oracle databases (DBs) in the cloud. The Oracle Cloud Infrastructure Database service offers three types of DB systems:

- **Bare metal**: Comprising 1-node DB and 2-node Real Application Cluster (RAC) systems, providing exceptional performance at cost-effective pricing.
- **Exadata**: Proven industry-leading Exadata DB systems in quarter, half, and full rack configurations.
- **Virtual machine**: Allows customers to create full-featured Oracle databases on VM shapes with various cores.

DB systems are accessible only from a customer’s VCN, and customers can configure VCN security lists to control network access to their databases. The Database service is integrated with Oracle Cloud Infrastructure IAM for controlling which users can launch and manage DB systems. By default, data is encrypted at rest using Oracle TDE with master keys stored in an Oracle Wallet on each DB system. RMAN backups of DB systems are encrypted and stored in customer-owned buckets in the Object Storage service. Customers need to create a bucket for DB backups and configure the Oracle Database Cloud Backup module with an auth token (to use with the Swift API) and IAM permissions to access the bucket. Alternately, DB backups can be made to local NVMe storage on the DB system.

Each user automatically has the ability to create, update, and delete their own auth tokens in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage auth tokens for other users. Any user of a Swift client that integrates with Object Storage needs permission to work with the service.

**Load Balancing Service**

Oracle Cloud Infrastructure Load Balancing provides automated traffic distribution to compute instances in a customer’s VCN. Load balancers (LBs) can be created as public (accepting traffic from the internet and directing it to private instances) or private (directing traffic between private instances). LBs can be configured for SSL termination using customer-provided certificates; end-to-end SSL, whereby the LB terminates the SSL connection and creates a new SSL connection to the backend; or SSL tunneling, in which the SSL connection is passed through to the backend (TCP load balances only). The Load Balancing service supports TLS 1.2 by default, and prioritizes the following forward-secrecy ciphers in the TLS cipher-suite:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
Managed Domain Name Servers (DNS) Service

The Oracle Cloud Infrastructure DNS service provides dynamic, static, and recursive DNS solutions for enterprise customers. The service connects visitors to customer websites and applications with fast and secure services. The DNS service operates on a global anycast network with 18 points of presence (PoPs) on five continents and offers fully redundant DNS constellations and multiple Tier 1 transit providers per PoP. The solution provides a DNS-based Distributed Denial of Services (DDoS) protection and in-house security expertise that leverages a vast sensor network that collects and analyzes over 240 billion data points per day. The DNS service also fully supports the secondary DNS features to complement the customer’s existing DNS service, providing resiliency at the DNS layer.

Vault Service

The Vault service lets you create and manage the encryption keys and secret credentials that you use to protect your data and connect to secured resources. As customer-managed resources, you have complete control over who has access to vaults, keys, and secrets. You also control what authorized users and services can do with Vault resources. Levels of access might range from something as granular as whether an individual key can be used by a particular service to more broadly impactful lifecycle management activities, like whether a user can delete a key from a vault to prevent its use altogether.

Keys are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. The Vault service uses the Advanced Encryption Standard (AES) as its encryption algorithm and its keys are AES symmetric keys. Secrets and secret versions are base64-encoded and encrypted with master encryption keys, but do not reside within the HSM.

If you use the Security Zones service to improve the tenancy’s security posture, security zones require you to encrypt resources using customer-managed keys where possible. The following services support the use of customer-managed keys for resource encryption:

- Block Volume
- Container Engine for Kubernetes
- File Storage
- Object Storage
- Streaming

For more information, see Overview of Vault on page 3952.

Security Advisor

Security Advisor supports the creation of resources that are encrypted with a customer-managed master encryption key, which is one of the security requirements enforced by security zone policies. You can use Security Advisor to create the following resources:

- Object Storage buckets
- File Storage file systems
- Compute virtual machine instances (and associated boot volumes)
- Block Volume block storage volumes

For more information, see Overview of Security Advisor on page 3738.

Oracle Cloud Testing Policies

This section describes the Oracle Cloud Security Testing and Functional Testing policies, tests involving data scraping tools, and how you can submit a request to schedule tests of our services.
Oracle Cloud Security Penetration and Vulnerability Testing

The Oracle Cloud Security Testing policy describes when and how you may conduct certain types of security testing of Oracle Cloud Infrastructure services, including vulnerability and penetration tests, as well as tests involving data scraping tools. Any such testing of Oracle Cloud services may be conducted only by customers who have an Oracle Account with the necessary privileges to file service maintenance requests, and who are signed-in to the environment that will be the subject of such testing.

Oracle regularly performs penetration and vulnerability testing and security assessments against the Oracle Cloud infrastructure, platforms, and applications. These tests are intended to validate and improve the overall security of Oracle Cloud services.

However, Oracle does not assess or test any components (including, non-Oracle applications, non-Oracle databases or other non-Oracle software, code or data, as may be applicable) that you manage through or introduce into – including introduction through your development in or creation in - the Oracle Cloud services (the “Customer Components”). This policy does not address or provide any right to conduct testing of any third-party materials included in the Customer Components.

Except as otherwise permitted or restricted in your Oracle Cloud services agreements, your service administrator who has system level access to your Oracle Cloud services may run penetration and vulnerability tests for the Customer Components included in certain of your Oracle Cloud services in accordance with the following rules and restrictions.

Permitted Penetration and Vulnerability Testing

The following explains where penetration and vulnerability testing of Customer Components is permitted:

- **IaaS**: Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant Oracle Infrastructure as a Service (IaaS) offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud services including the facilities, hardware, software, and networks owned or managed by Oracle or its agents and licensors.

- **PaaS**: Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant Oracle Platform as a Service (PaaS) offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud services including the facilities, hardware, networks, applications, and software owned or managed by Oracle or its agents and licensors. To be clear, you may not assess any Oracle applications that are installed on top of the PaaS service.

- **SaaS**: Penetration and vulnerability testing is not permitted for Oracle Software as a Service (SaaS) offerings.

Oracle Cloud Security Testing Rules of Engagement

The following rules of engagement apply to cloud penetration and vulnerability testing:

- Your testing must not target any other subscription or any other Oracle Cloud customer resources, or any shared infrastructure components.

- You must not conduct any tests that will exceed the bandwidth quota or any other subscribed resource for your subscription.

- You are strictly prohibited from utilizing any tools or services in a manner that perform Denial-of-Service (DoS) attacks or simulations of such, or any “load testing” against any Oracle Cloud asset including yours.

- Any port scanning must be performed in a non-aggressive mode.

- You are responsible for independently validating that the tools or services employed during penetration and vulnerability testing do not perform DoS attacks, or simulations of such, prior to assessment of your instances. This responsibility includes ensuring any contracted third parties perform assessments in a manner that does not violate this policy.

- Social Engineering of Oracle employees and physical penetration and vulnerability testing of Oracle facilities is prohibited.
You must not attempt to access another customer’s environment or data, or to break out of any container (for example, virtual machine).

Your testing will continue to be subject to terms and conditions of the agreement(s) under which you purchased Oracle Cloud services, and nothing in this policy shall be deemed to grant you additional rights or privileges with respect to such Cloud Services.

If you believe you have discovered a potential security issue related to Oracle Cloud, you must report it to Oracle within 24 hours by conveying the relevant information to My Oracle Support. You must create a service request within 24 hours and must not disclose this information publicly or to any third party. Note that some of the vulnerabilities and issues you may discover may be resolved by you by applying the most recent patches in your instances.

In the event you inadvertently access another customer’s data, you must immediately terminate all testing and report it to Oracle within one hour by conveying the relevant information to My Oracle Support.

You are responsible for any damages to Oracle Cloud or other Oracle Cloud customers that are caused by your testing activities by failing to abide by these rules of engagement.

Notification Process
The process for notifying Oracle of your election to conduct a penetration or vulnerability test as required by this policy can be found in Submitting a Cloud Security Testing Notification on page 3672.

Oracle Cloud Functional Testing

Important:
You must abide by the terms of both this policy and the Oracle Cloud Security Testing policy when performing functional testing.

This policy outlines how and when you may conduct functional testing of Oracle Cloud services. The purpose of functional testing is to validate features of Oracle Cloud services to ensure they meet particular functional requirements or specifications. This is often referred to as black-box testing, regression testing, or unit testing whereby functionality of the application is assessed without the need to scrutinize internal structures or source code.

The following rules apply to functional testing of Oracle Cloud services:

You must not conduct any tests in the production environment. Before deployment, you must test all changes in a test environment.

You can perform functional testing using manual or automated tools.

You can conduct functional tests to validate the main functions of the Oracle Cloud service to meet business requirements including usability, accessibility, and error handling.

You must not use functional testing procedures or tools to test other aspects of the Oracle Cloud service, such as performance, reliability, and scalability.

You can conduct unit tests, user-acceptance tests, regression tests, and black-box tests to test the functionality of the Oracle Cloud services.

Data Scraping Tools
Any use of data scraping tools or technologies with Oracle Cloud services to collect data available through any Oracle user interface or via web service calls requires the express written permission of Oracle. Oracle reserves the right to require that your proposed data scraping tools are validated and tested by Oracle prior to use in production, and are subsequently re-validated and tested annually.

Automated Tools
Oracle doesn't make any recommendation on which third-party automated testing tools you can use.

Load Testing Tools
You can't perform automated load testing of Oracle Cloud services.
**Submitting a Cloud Security Testing Notification**

As a service administrator, you can run tests for some Oracle Cloud services. Before running the tests, you must first review the Oracle Cloud Testing Policies on page 3669 section. Follow the steps below to notify Oracle of a penetration and vulnerability test.

**Note:**

You must have an Oracle Account with the necessary privileges to file service maintenance requests, and you must be signed in to the environment that will be the subject of the penetration and vulnerability testing.

1. Log in to My Services.
2. From the service tile in the dashboard, click the **Action** menu, and then select **Maintenance and Service Requests**.
3. On the Service Request Details page, select **Penetration & Vulnerability Testing** from the **Request Type** list.
4. Review the information and accept the terms and conditions, and then click **Next**.

   The available time slots are identified with the text, “Penetration and Vulnerability Testing”.

   You can switch your view to either daily, weekly, monthly, or a list by using the respective buttons on top of the calendar. The view you select is stored as your preference and you’ll be shown the same when you log in the next time.

5. Select an available slot by clicking **Penetration and Vulnerability Testing** on a specific date.
   
   a. Provide technical contact details. If using a third party for testing, then provide the name and email address of the third party.
   
   b. Specify the testing details, such as duration of testing, purpose, IP addresses, services, and other information. Required fields are marked with an asterisk (*).
   
   c. Click **Submit Request**.

A service maintenance request is created and is automatically approved. In some cases, we may require your approval to confirm the time slots of your maintenance. Such requests are indicated by the phrase **To Review**. The status of each filed service maintenance request is color-coded and displayed in the calendar. To view, edit, or cancel your service maintenance request, see Viewing and Editing Service Maintenance Requests. To request a secondary IDCS instance, contact My Oracle Support.

For more information, see Frequently Asked Questions About Cloud Security Testing.

**Frequently Asked Questions About Cloud Security Testing**

This section provides answers to frequently asked questions (FAQ) related to cloud security testing.

To fully understand how you can conduct cloud penetration and vulnerability testing of the **Customer Components**, you must first review the Oracle Cloud Testing Policies on page 3669 section.

Topics:

- **Do I need Oracle’s permission for all penetration and vulnerability tests?**
- **How can I notify Oracle for penetration and vulnerability tests?**
- **Which instances can I test?**
- **What other actions on my part are required after I receive an authorization to perform my tests?**
- **What do I do when I believe that I have discovered a potential security issue related to Oracle Cloud?**
- **What limitations do I need to be aware of regarding my tests?**
- **Can I conduct any tests that may exceed the bandwidth quota for my subscription?**
- **Can I use my hosted instances to conduct assessments against other services not hosted by Oracle?**

**Do I need Oracle’s permission for all penetration and vulnerability tests?**

No. Per the Oracle Penetration and Vulnerability Testing Policy, you do not need Oracle’s permission to conduct penetration and vulnerability tests of the customer components included in certain Oracle Cloud services. However, you will need to notify Oracle prior to commencing such penetration and vulnerability testing. You may not conduct any penetration and vulnerability testing for Oracle Software as a Service (SaaS) offerings.
How can I notify Oracle for penetration and vulnerability tests?

To notify Oracle, you must log into My Services using your administrator credentials associated with the instances you wish to test. You will need to complete and submit a form with information about the instances you wish to test, the planned start and end dates of your test, as well as the testing tools you want to use. This notification process is explained in more detail in the Oracle Cloud Testing Policies on page 3669 section.

Which instances can I test?

The Oracle Penetration and Vulnerability Testing Policy only permits testing of instances, services, and applications that are customer components. All other aspects and components of the Oracle Cloud Services (including Oracle-managed facilities, hardware components, networks, software, and database instances) must not be tested. You may not conduct any penetration and vulnerability testing of Oracle Software as a Service (SaaS) offerings. In addition, you may not attempt to socially engineer Oracle employees or perform physical penetration and vulnerability testing of Oracle facilities.

What other actions on my part are required after I receive an authorization to perform my tests?

No other actions are required before performing your tests. You may conduct your testing for the duration you requested.

What do I do when I believe that I have discovered a potential security issue related to Oracle Cloud?

If you believe you have discovered a potential security issue related to Oracle Cloud, you must report it to Oracle within 24 hours, by conveying the relevant information to My Oracle Support. You must create a service request (SR) within 24 hours and you must not disclose this information publicly or to any third party. Note that some of the vulnerabilities and issues you discovered may be resolved by you, by applying the most recent patches in your instances.

What limitations do I need to be aware of regarding my tests?

All penetration and vulnerability testing against Oracle Software as a Service (SaaS) instances is prohibited. In addition, the Oracle Penetration and Vulnerability Testing Policy sets forth certain rules applicable to the performance of penetration and vulnerability testing on Oracle Cloud Services. See the policy for limitations.

Can I conduct any tests that may exceed the bandwidth quota for my subscription?

No. You are not allowed to conduct any tests that will exceed the bandwidth quota or any other subscribed resource for your subscription.

Can I use my hosted instances to conduct assessments against other services not hosted by Oracle?

No, all testing must be directed at single-tenant Oracle Infrastructure as a Service (Oracle IaaS) or Oracle Platform as a Service (Oracle PaaS) instances hosted by Oracle. These are not to be used as a platform to test other internet-based services.

Security Best Practices

This guide provides actionable guidance and recommendations to Oracle Cloud Infrastructure customers for securely configuring Oracle Cloud Infrastructure services and resources. Understanding Oracle Cloud Infrastructure services and their security features is an essential prerequisite before reading. As a prerequisite, Oracle recommends that you become familiar with security of services. For more information, see Oracle Cloud Infrastructure Security Guide on page 3656.

Security of an Oracle Cloud Infrastructure tenancy is based on a combination of factors, all of which must be thought through and securely configured. From a practical perspective, take a hierarchical view of Oracle Cloud Infrastructure tenancy security configuration, where we start with addressing the foundational security issues. The following steps provide a roadmap of high-level guidelines to follow when configuring security of a tenancy, where we provide a link to a section enumerating detailed security guidance related to each step.

- **User authentication and authorization:** The initial step in securely configuring a tenancy is to create mechanisms for authenticating users and authorizing users to access tenancy resources in a least-privilege manner.
This step comprises creating Oracle Cloud Infrastructure Identity and Access Management (IAM) users, creating IAM groups, formulating authentication mechanisms (for example, Console access using password, API access using API keys, and auth token for object store) for the IAM users created, grouping customer tenancy resources into logical groups using compartments, and formulating IAM security policies authorizing access of IAM groups to tenancy or compartment resources. For enterprises, federating their on-premises users and groups to their tenancy is an important consideration. IAM allows you to create users, groups, security polices, and federation mechanisms. Security recommendations for configuring IAM are provided in the IAM section.

- **Network security architecture:** After formulating IAM user authentication and authorization, a next step is creating a network security architecture for securely running the customer applications and storing their data in a tenancy. All the customer's compute and storage resources are enclosed in a virtual cloud network (VCN) created for the customer. VCN is a software-defined network, resembling the on-premises physical network used by customers to run their workloads. Formulating a VCN security architecture includes tasks such as:
  - Creating VCN subnets for network segmentation
  - Formulating VCN and load balancer firewalls using VCN security lists
  - Using load balancing for high-availability and TLS
  - Determining type of VCN external connectivity whether internet, on-premises network, peered VCN, or combination of these
  - Using virtual network security appliances (for example, next-generation firewalls, IDs)
  - Creating DNS zones and mappings. An important security consideration in load balancers is using customer Transport Layer Security (TLS) certificates to configure TLS connections to customer's VCN. Security recommendations for VCN are provided in the Networking section.

- **Compute instances security configuration:** Within a customer VCN, the customer applications run on compute instances including Bare Metal (BM) instances, Virtual Machine (VM) instances and GPUs. Compute instances are the basic compute building blocks. Bare metal instances have no Oracle-managed software running on them, with the result that the instances and data stored (in memory and local drives) are completely controlled by the customer. VM instances are architected with least privilege mechanisms, and with corporate industry-leading hypervisor security best-practices. Depending on their security and performance requirements, customers have a choice of using BM and VM instances, to run their application workloads in their tenancy. It is imperative to securely configure compute instances, to maintain security of customer applications running on them. Recommendations related to instance security configuration with respect to instance firewalls, instance credential management, entropy, security patching, and security logging and monitoring are provided in the Compute section.

- **Data storage security configuration:** Depending on the type of data and access required, customers can store data in local drives (attached to compute instances), remote block volumes, object store buckets, databases, or file storage in their tenancy. To handle these data storage requirements, Oracle Cloud Infrastructure offers multiple data storage services such as Block Volume, Object Storage, Database, and File Storage. In order to meet their data security requirements, customers need to formulate a tenancy data storage architecture for storing their data in their tenancy, and securely configure the storage services used. Compliance and regulatory requirements are an important factor in determining an appropriate data storage security architecture. Recommendations related to storage services security configuration are available in Block Volume, Object Storage, Database, and File Storage sections. In addition to these services, customers need to consider security of data stored ephemerally in compute instance memory (DRAM) and local NVMe storage.

API Audit logs record calls to APIs (for example, through the Console, SDKs, CLIs, and custom clients using the APIs) as log events. The API Audit logs are always on by default and can’t be turned off. These logs are available to customers for 90 days, with retention period configurable up to 365 days. Information in the API Audit logs show what time API activity occurred, the source of the activity, the target of the activity, what the action was, and what the response was. Oracle recommends that customers periodically review the OCI API Audit logs to ensure they are in accordance with actions they took on their tenancy resources.

For service-specific best practices, see the following topics:

- Securing Block Volume on page 3675
- Securing Compute on page 3677
- Securing Container Engine for Kubernetes on page 3680
- Securing Data Catalog on page 3684
Security Block Volume

Security Recommendations

- There are two types of volumes: block volumes and boot volumes. Block volumes allow instance storage capacity to be expanded dynamically. A boot volume contains the image used to boot the compute instance. The IAM service groups the family of related volume resource types into a combined resource type called volume-family.
- Assign least privilege access for IAM users and groups to resource types in volume-family. The resource types in volume-family are volumes, volume-attachments, and volume-backups. The volume-family resources are detachable block volume devices that allow dynamic expansion of instance storage capacity or contain the image for booting the instance. The volume-attachments resources are attachments between volumes and instances. The volume-backups resources are point-in-time copies of volumes that can be used to create block volumes or recover block volumes.

Data Durability

To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends giving VOLUME_DELETE, VOLUME_ATTACHMENT_DELETE, and VOLUME_BACKUP_DELETE permissions to a minimum possible set of IAM users and groups. DELETE permissions should be given only to tenancy and compartment administrators.

To minimize loss of data due to deletes or corruption, Oracle recommends that you make periodic backups of volumes. Oracle Cloud Infrastructure allows automated scheduled backups. For more information about scheduled backups, see Policy-Based Backups on page 547.

Data-at-rest Encryption

By default, volumes and their backups are encrypted at rest using AES-256. You can also encrypt your data volumes using tools like dm-crypt, veracrypt, and BitLocker. Instructions on dm-crypt encryption are presented in the next section.

Security Policy Examples

Prevent Delete of Volumes

The following example policy allows group VolumeUsers to perform all actions on volumes and backups, except deleting them.

```plaintext
Allow group VolumeUsers to manage volumes in tenancy
   where request.permission!="VOLUME_DELETE"
Allow group VolumeUsers to manage volume-backups in tenancy
   where request.permission!="VOLUME_BACKUP_DELETE"
```

If VolumeUsers can't detach volumes from instances, you can add the following policy to the previous example.

```plaintext
Allow group VolumeUsers to manage volume-attachments in tenancy
```
Security-related Tasks

Encrypting Non-root Volumes with dm-crypt

dm-crypt is a kernel-level encryption mechanism (part of Linux device mapper framework) to provide encrypted volumes. It encrypts data passed from the filesystem (for example, ext4 and NTFS), and stores it on a storage device in Linux Unified Key Setup (LUKS) format. The encrypted volumes can be stored on a complete disk, disk partition, logical volume, or a file-backed storage created using loopback devices. Cryptsetup is the user-level utility used to manage dm-crypt, and used to encrypt partitions and files. dm-crypt uses the Linux crypto APIs for encryption routines.

1. Attach block storage volume to an instance (for example, /dev/sdb)
2. Format /dev/sdb for LUKS encryption. Enter LUKS passphrase when prompted. The passphrase is used to encrypt the LUKS master key used for encrypting the volume.

   cryptsetup -y luksFormat /dev/sdb

3. Verify that the LUKS formatting is successful.

   cryptsetup isLuks /dev/sdb && echo Success

4. Get encryption information about the device.

   cryptsetup luksDump /dev/sdb

5. Get LUKS UUID of the device. The UUID value is used to configure the /etc/crypttab.

   cryptsetup luksUUID /dev/sdb

6. Create a LUKS container with device name, dev_name. This also creates a device node, /dev/mapper/<dev_name>.

   cryptsetup luksOpen /dev/sdb <dev_name>

7. Get information about the mapped device.

   dmsetup info <dev_name>

8. Format the device node as ext4 filesystem.

   sudo mkfs -t ext4 /dev/sdb

9. Mount the device node.

   mount /dev/mapper/<dev_name> /home/encrypt_fs

10. Add an entry to /etc/crypttab.

    <dev_name> UUID=<LUKS UUID of /dev/sdb> none

All the files copied to /home/encrypt_fs are encrypted by LUKS.

11. Add a keyfile to an available keyslot of the encrypted volume. This keyfile can be used to access the encrypted volume.

    dd if=/dev/urandom of=$HOME/keyfile bs=32 count=1
    chmod 600 $HOME/keyfile
    cryptsetup luksAddKey /dev/sdb ~/keyfile
12. Verify the encryption status of files.

```
cryptsetup status /home/encrypt_fs
```

13. Unmount after you're finished.

```
umount /home/encrypt_fs
cryptsetup luksClose <dev_name>
```

To access the encrypted volume:

```
cryptsetup luksOpen /dev/sdb <dev_name> --key-file=/home/opc/keyfile
mount /dev/mapper/<dev_name> /home/encrypt_fs
```

If you lose the keyfile, or if the keyfile or passphrase gets corrupted, you can't decrypt the encrypted volume. This results in permanent loss of data. Oracle recommends that you store durable copies of the keyfile on an on-premises host.

**Remote Mounting of dm-crypt Encrypted Data Volumes**

The following steps assume that the keyfile is on an on-premises host (SRC_IP) and that `<OCI_SSH_KEY>` is the SSH private key of the instance.

1. Copy keyfile from the on-premises host to an instance.

```
scp -i <OCI_SSH_KEY> keyfile opc@SRC_IP:/home/opc
```

2. Open the encrypted volume.

```
ssh i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksOpen /dev/sdb <dev_name> --key-file=/home/opc/keyfile"
```

3. Mount the volume.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "mount /dev/mapper/<dev_name> /home/encrypt_fs"
```

4. Perform operations on data in the mounted volume.

5. Unmount the encrypted volume.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "umount /home/encrypt_fs"
```

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksClose <dev_name>"
```

6. Delete the keyfile from the instance.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "\rm -f /home/opc/keyfile"
```

**Securing Compute**

**Security Recommendations**

Oracle Cloud Infrastructure Compute provides both bare metal and virtual machine (VM) instances, architected and managed in accordance with security best practices.

**Managing Instances and Credentials**

- To prevent inadvertent or malicious termination of critical instances (for example, production instances), Oracle recommends that you give INSTANCE_DELETE permissions to a minimal set of groups. Give DELETE permissions only to tenancy and compartment administrators.
You can use the Oracle Cloud Infrastructure instance principals feature to authorize instances to access Oracle Cloud Infrastructure services (Compute, Block Volume, Networking, Load Balancing, Object Storage) on behalf of an IAM user. To use this feature, create dynamic groups and grant them access to service APIs. Dynamic groups allow you to group Oracle Cloud Infrastructure computer instances as "principal" actors (similar to user groups). You can then create policies to permit instances to make API calls against Oracle Cloud Infrastructure services.

When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of matching rules to define the group members. A short-lived private key to sign API calls is delivered through the instance metadata service (http://169.254.169.254/opc/v1/identity/cert.pem), and the key is rotated multiple times a day. For more information about accessing services from instances, see Calling Services from an Instance on page 2410.

**Instance Metadata Access Control**

- Instance metadata (http://169.254.169.254) provides predefined instance information, such as OCID and display name, and custom fields. The instance metadata can also provide short-lived credentials, such as dynamic group credentials. Oracle recommends that you limit instance metadata access to privileged users on the instance. The following example shows how to use iptables to restrict instance metadata access to the root user.

```
iptables -A OUTPUT -m owner ! --uid-owner root -d 169.254.169.254 -j DROP
```

- Instances use link local addresses to access the instance metadata service (169.254.169.254:80), DNS (169.254.169.254:53), NTP (169.254.169.254:123), kernel updates (169.254.0.3), and iSCSI connections to boot volumes (169.254.0.2:3260, 169.254.2.0/24:3260). You can use host-based firewalls, such as iptables, to ensure that only the root user is authorized to access these IPs. Make sure these operating system firewall rules are not altered.

**Instance Network Access Controls**

- Harden secure shell (SSH) on all instances. The following table shows some SSH security recommendations. SSH configuration options can be set in the `sshd_config` file (located at `/etc/ssh/sshd_config` in Linux).

<table>
<thead>
<tr>
<th>Security Recommendation</th>
<th>Configuration sshd_config</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use public-key logins only</td>
<td>PubkeyAuthentication yes</td>
<td>Periodically review SSH public keys in the <code>~/.ssh/authorized_keys</code> file.</td>
</tr>
<tr>
<td>Disable password logins</td>
<td>PasswordAuthentication no</td>
<td>Mitigates password brute-force attacks.</td>
</tr>
<tr>
<td>Disable root logins</td>
<td>PermitRootLogin no</td>
<td>Prevents root privileges for remote logins.</td>
</tr>
<tr>
<td>Change SSH port to a non-standard port</td>
<td>Port &lt;port number&gt;</td>
<td>Optional. Verify that this change does not break applications using port 22 for SSH.</td>
</tr>
</tbody>
</table>

- Use secure SSH private keys to access instances and to prevent inadvertent disclosures. For more information about creating an SSH key pair and configuring an instance with the keys, see Managing Key Pairs on Linux Instances on page 693.

- To limit instance access to authorized IP addresses, use VCN network security groups or security lists. Fail2ban is an application that blocklists IP addresses involved in brute-force sign-in attempts (that is, too many failed attempts to sign in to an instance). By default, Fail2ban inspects SSH accesses, and you can configure it to inspect other protocols. For more information about Fail2ban, see Fail2ban Main Page.

- In addition to VCN network security groups and security lists, use host-based firewalls, such as iptables and firewalld, to restrict network access to instances by controlling ports, protocols, and packet types. Use these firewalls to prevent potential network security attack reconnaissance, such as port scanning and intrusion attempts.
Custom firewall rules can be configured, saved, and initialized on every instance boot. The following example shows commands for iptables.

```
# save iptables rules after configuration
sudo iptables-save > /etc/iptables/iptables.rules
# restore iptables rules on next reboot
sudo /sbin/iptables-restore < /etc/iptables.rules
# restart iptables after restore
sudo service iptables restart
```

### Instance Entropy

Both bare metal and VM instances provide high-quality and high-throughput entropy source. Instances have random number generators whose output is fed into the entropy pools used by the operating system to generate random numbers. In Linux instances, `/dev/random` is non-blocking and should be used for security applications requiring random numbers. You can use the following commands to check the throughput and quality of the random numbers generated by `/dev/random` before using the output in applications.

```
# check sources of entropy
sudo rngd -v
# enable rngd, if not already
sudo systemctl start rngd
# verify rngd status
sudo systemctl status rngd
# verify /dev/random throughput and quality using rngtest
cat /dev/random | rngtest -c 1000
```

### Host Security Hardening and Patching

- Establish a baseline for security hardening of Linux and Windows images running on instances. For more information about security hardening of Oracle Linux images, see Tips for Hardening an Oracle Linux Server. The Center for Internet Security Benchmarks provides a comprehensive set of operating system security hardening benchmarks for various distributions of Linux and Windows Server.
- Keep instance software up to date with security patches. Oracle recommends that you periodically apply the latest available software updates to your instances. Oracle Autonomous Linux images are automatically updated with the latest patches. For Oracle Linux images, you can run the `sudo yum update` command (``sudo dnf update`` on Oracle Linux 8). On Oracle Linux, you can get information about available and installed security patches using the `yum-security` plugin. The following example provides commands for `yum-security`. For Oracle Linux instances launched after February 15, 2017, Ksplice support is available for applying patches without rebooting the instance. For more information about using Ksplice on Oracle Cloud Infrastructure instances, see Installing and Running Oracle Ksplice on page 664.

```
# Install yum-security plugin
yum install yum-plugin-security
# Get list of security patches without installing them
yum updateinfo list security all
# Get list of installed security patches
yum updateinfo list security all
```

### Instance Security Logging and Monitoring

- Various security-related events are captured in log files. Oracle recommends that you periodically review these log files to detect any security issues. In Oracle Linux, the log files are located in `/var/log`. Some security-relevant log files are listed in the following table.

<table>
<thead>
<tr>
<th>Log File or Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/var/log/secure</code></td>
<td>Auth log showing failed and successful sign ins.</td>
</tr>
</tbody>
</table>
Log File or Directory | Description
--- | ---
/var/log/audit | Auditd logs capturing system calls issued, sudo attempts, user sign-ins, and so on. ausearch and aureport are two tools used to query auditd logs.
/var/log/yum.log | Lists packages installed or updated on instances with yum.
/var/log/cloud-init.log | During instance boot, cloud-init can run user-provided scripts as a privileged user. For example, cloud-init can introduce SSH keys. Oracle recommends that you review the cloud-init logs for any unrecognized commands.

Security Policy Examples

In all the following examples, the policies are scoped to a tenancy. However, by specifying a compartment name, they can be scoped down to specific compartment in a tenancy.

Restrict Users Ability to Delete Instances

The following example allows the InstanceUsers group to launch instances, but not to delete them.

- Allow group InstanceUsers to manage instance-family in tenancy where request.permission!='INSTANCE_DELETE'
- Allow group InstanceUsers to use volume-family in tenancy
- Allow group InstanceUsers to use virtual-network-family in tenancy

Restrict Ability to Use Instance Console

For security compliance reasons, some customers do not want to expose the instance console to users in their tenancy. The following policy example restricts ability to create or read from consoles.

- Allow group InstanceUsers to manage instance-console-connection in tenancy where all {request.permission!= INSTANCE_CONSOLE_CONNECTION_READ, request.permission!= INSTANCE_CONSOLE_CONNECTION_CREATE}

Securing Container Engine for Kubernetes

This topic provides security recommendations for using Oracle Cloud Infrastructure's Container Engine for Kubernetes (also known as OKE).

Multi-Tenant Clusters

At this time, it is not recommended to run mutually distrusted workloads in the same cluster. For example, you should not run the following workloads in the same cluster:

- Development workloads and production workloads
- Control plane and data plane
- Workloads that run arbitrary customer code

Additionally, you should consider having separate clusters if you have multiple tenants, teams, or users accessing the same cluster with differing levels of trust. As mentioned in subsequent sections, Kubernetes and OKE offer methods to isolate workloads. However, these methods are not currently sufficient for hard multi-tenancy.

Encrypt Secrets at Rest in Etcd

Please review Encrypting Kubernetes Secrets at Rest in Etcd on page 900 for information on configuring secret encryption.
Role-Based Access Control (RBAC)

Kubernetes ships an integrated Role-Based Access Control (RBAC) component that matches an incoming user or group to a set of permissions which are bundled into roles. These permissions combine verbs (get, create, delete) with resources (pods, services, nodes) and can be scoped to a namespace or cluster. A set of preconfigured roles are provided which offer reasonable default separation of responsibility, depending on what actions a client might want to perform.

It is important to understand how updates on one object may cause actions in other places. For example, a user may not be able to create pods directly, but allowing them to create a deployment, which creates pods on their behalf, will let them create those pods indirectly. Likewise, deleting a node from the API will result in the pods scheduled to that node being terminated and recreated on other nodes. The preconfigured roles represent a balance between flexibility and the common use cases, but more limited roles should be carefully reviewed to prevent accidental privilege escalation. You can make roles specific to your use case if the preconfigured roles don't meet your needs.

You should always follow the principle of least privilege to ensure users and Kubernetes Service Accounts have the minimal set of privileges required. By default, any user with USE CLUSTER access in Oracle Cloud Infrastructure IAM or any Kubernetes Service Account will have no access to the Kubernetes API, except to the discovery roles. See About Access Control and Container Engine for Kubernetes to learn how IAM integrates with OKE.

Note that you cannot currently use IAM Groups in RBAC policies. You must use the OCID of the Principal when creating RBAC bindings (for example, user OCID, instance OCID, and service name).

Cluster Security

You can control the operations that pods are allowed to perform on a cluster you've created with Container Engine for Kubernetes by setting up pod security policies for the cluster. Pod security policies are a way to ensure that pods meet security-related conditions before they can be accepted by a cluster. For example, you can use pod security polices to:

- limit the storage choices available to pods
- restrict the host networking and ports that pods can access
- prevent pods from running as the root user
- prevent pods from running in privileged mode

Having defined a pod security policy for a cluster, you have to authorize the requesting user or pod to use the policy by creating roles and bindings. You can then specify whether a cluster enforces the pod security policies defined for it by enabling the cluster's PodSecurityPolicy admission controller.

For more information, see Using Pod Security Policies with Container Engine for Kubernetes on page 905.

Node Pool Security

Node Pool Compartments

Node pools in a cluster can span compartments. However, while using multiple compartments provides a convenient way to group and manage worker nodes, it does not provide any isolation between the worker nodes in the cluster. Any workload can be scheduled across any node pool regardless of the compartment. A valid use case for using more than one compartment for a node pool would be to easily create dynamic groups and IAM policies for worker nodes. An invalid use case for multiple compartments would be putting each node pool running a customer workload in a separate compartment under the assumption that the compartments are providing some type of security boundary or isolation.

Node Pool Subnets

We recommend only using private subnets for node pools. A service gateway should be configured to provide access to Oracle Cloud Infrastructure services. A service gateway cannot be used if the subnets are public with an internet gateway. If your private subnets require access to the internet, use a NAT gateway.
Controlling Which Nodes Pods May Access

By default, a pod may be scheduled on any node in the cluster. Kubernetes offers a rich set of policies for controlling placement of pods onto nodes and the taint based pod placement and eviction that are available to end users. For many clusters, the use of these policies to separate workloads can be a convention that authors adopt or enforce via tooling. These placement controls are not adequate in a multi-tenant environment when users with deployment capabilities are untrusted. If you have untrusted users deploying code then you should consider a cluster per untrusted group.

Limit Access Given to Instance Principals

By default, all pods on a node are able to access the instance principal certificates using the instance metadata endpoint. In order to avoid privilege escalation via instance principals, you should isolate workloads across node pools with different dynamic groups so that pods in a given node pool have the minimal set of privileges required to function.

For example, assume you have the following two workloads, which both require different access:

- LogArchiver - requires access to manage buckets and objects in Object Storage
- HostMonitor - requires access to the Compute API to manage Instances

The simplest approach would be to schedule them in the same node pool and provide the instance principal with all the required access. However, this increases the impact in the event one of the workloads becomes compromised. A better approach would be to schedule the workloads on separate node pools with the limited set of access the instance principals require for the applicable workload.

Block Container Access to Instance Metadata

The preferred way to block access is using a network policy plugin with a default policy of "deny all". Then you would explicitly grant access to pods and networks using NetworkPolicy resources in Kubernetes via label selectors. If you don't have a network policy plugin installed, you can use a IPTables rule to restrict access from all pods on the host. We recommend that you do not use this approach to block a subset of pods on a host.

Important: NetworkPolicies and the following IPTable rule only apply to containers in the pod overlay network. Containers and services running in the host network are not impacted by either option:

```
iptables --insert FORWARD 1 --in-interface veth+ --destination 169.254.0.0/16 --jump DROP
```

Network Security

Pods running in your OKE Cluster often need to communicate with other pods in the cluster or with services outside the cluster. Container Engine for Kubernetes offers multiple options to secure communication to and from the workloads in your cluster. For the best network security posture, you should evaluate using a combination of network policies (to secure pod-level network communication) and security lists (to secure host-level network communication).

Network Policies

Network policies in Kubernetes allow administrators to define how groups of pods are able to communicate with other pods in the cluster. Additionally, network policies allow you to define how groups of pods are able to communicate with services outside the cluster (for example, Oracle Cloud Infrastructure services).

To restrict access using network policies, you need to install a network plugin. Network plugins configure and enforce the network policies defined in Kubernetes. There are numerous network plugin options. You can follow our instructions here to install and configure Calico in your cluster. Network policy plugins work by restricting access on the host. For information on installing Calico into OKE, see Example: Installing Calico and Setting Up Network Policies on page 960.
Node Pool Security Lists

Network administrators can define security list rules on node pool subnets to restrict access to and from worker nodes. Defining security list rules allows administrators to enforce network restrictions that cannot be overridden on the hosts in your cluster.

Because all pod-to-pod communication occurs in a VXLAN overlay network on the worker nodes, you are cannot use security list rules to restrict pod-to-pod communication. However, you can use security lists to restrict access to and from your worker nodes.

Important: There is a minimum set of security list rules that must exist on node pool subnets to ensure that the cluster can function. See Example Network Resource Configurations on page 840 for information on the minimum set of security list rules before making any changes to your security list rules.

Workload Security Best Practices

Use Image Digests Instead of Tags

We recommend that you only pull images using the image digests, and not pull images using tags (because image tags are mutable). Image digests are the sha256 digest of your image, which allows docker to verify the image it downloaded is what you expected.

Example image digest id:

sha256:77af4d6b9913e693e8d0b4b294fa62ade6054e6b2f1ff617ac955dd63fb0182

Pull the image as shown in the following example:

docker pull acme@sha256:77af4d6b9913e693e8d0b4b294fa62ade6054e6b2f1ff617ac955dd63fb0182

You can use the following command to show all the digests for your local images:

docker images --digests

Limit Resource Utilization

Resource quota limits the number or capacity of resources granted to a namespace. This is most often used to limit the amount of CPU, memory, or persistent disk a namespace can allocate, but can also control how many pods, services, or volumes exist in each namespace.

Limit ranges restrict the maximum or minimum size of some of the resources above, to prevent users from requesting unreasonably high or low values for commonly reserved resources like memory, or to provide default limits when none are specified.

Access to resource quotas can be restricted via RBAC policies in Kubernetes. This can help an administrator ensure that users of a cluster are not able to use resources that they should not have access to. See Limiting resource usage in the on a cluster in the Kubernetes documentation for more information.

Disabling the Tiller Add-on

OKE offers an optional Tiller add-on. This provides an easy way to install and use Helm+Tiller, allowing you to quickly provision and run Kubernetes. It is not recommended to use this add-on for production clusters because of the security risks associated with Tiller. Clusters provisioned with Tiller do not have authentication or authorization for API calls made to Tiller, which means they cannot provide attribution for requests. Therefore, any operator or service that can reach Tiller can invoke its APIs with Tiller access.

To solve the security problems associated with Tiller, Helm V3 was developed. The Helm V3 release completely removed Tiller from Helm. We recommend that you consider using Helm V3 if you’d like to utilize the functionality offered by Helm+Tiller.
Disabling the Kubernetes Dashboard Add-on

OKE offers an optional Kubernetes Dashboard add-on, providing an easy way to install the Kubernetes Dashboard. The Kubernetes Dashboard is installed by OKE with the minimal set of privileges required to run. You will not be able to use the dashboard without providing additional credentials. See Accessing a Cluster Using the Kubernetes Dashboard on page 891 for more information.

The dashboard is particularly useful for new Kubernetes users. We do not recommend installing this add-on on production clusters due to the lack of extensible authentication support. If you do install the Kubernetes Dashboard, we recommend that you restrict access within your cluster, instead of exposing it externally via either a load balancer or an ingress controller. The Kubernetes Dashboard is a common attack vector used to gain access to a Kubernetes Cluster.

Note:
To disable the Kubernetes Dashboard add-on on an existing cluster, contact Oracle Support.

Securing Data Catalog

Oracle Cloud Infrastructure Data Catalog provides a collaborative data discovery and governance solution in accordance with industry-leading security best practices.

Security Recommendations

• Assign least privilege access for IAM users and groups to resource types in data-catalog-family.
• To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends giving CATALOG_DELETE permission to a minimum possible set of IAM users and groups. Give CATALOG_DELETE permissions only to tenancy and compartment admins.
• To protect your data sources from any security vulnerability, provide credentials to read-only accounts only. Data Catalog only needs read access to harvest data assets.

Security Policy Examples

Prevent Delete of Data Catalogs

Create this policy to allow group DataCatalogUsers to perform all actions on data catalogs, except deleting them.

Allow group DataCatalogUsers to manage data-catalog-family in tenancy where request.permission! = 'CATALOG_DELETE'

For more information on creating policies, see Data Catalog Policies.

Securing Data Integration

Oracle Cloud Infrastructure Data Integration provides a collaborative data integration solution in accordance with industry-leading security best practices.

Security Recommendations

• Assign least privilege access for IAM users and groups to resource types in dis-family.
• To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends giving DIS_WORKSPACE_DELETE permission to a minimum possible set of IAM users and groups. Give DIS_WORKSPACE_DELETE permissions only to tenancy and compartment admins.
• To protect your data sources from any security vulnerability, provide credentials to read-only accounts only. Data Integration only needs read access to ingest data from data assets.
Security Policy Examples

Prevent Delete of Workspaces
Create this policy to allow group DISUsers to perform all actions on workspaces, except deleting them.

| Allow group DISUsers to manage dis-family in tenancy where request.permission!='DIS_WORKSPACE_DELETE' |

For more information on creating policies, see Data Integration Policies.

Securing Data Transfer

Oracle offers offline data transfer solutions that let you migrate large amounts of data to buckets in a tenancy in Oracle Cloud Infrastructure. Data transfer solutions include:

- Disk-Based Data Import
  For more information about securely transferring data using this service, see Secure Disk Data Transfer to Oracle Cloud Infrastructure on page 972
- Appliance-Based Data Import
  For more information about securely transferring data using this service, see Secure Appliance Data Transfer to Oracle Cloud Infrastructure on page 1020

Securing Database

Security Recommendations

This section lists security recommendations for managing Oracle Cloud Infrastructure Database instances. Recommendations for securely configuring Oracle databases are available in the Oracle Database Security Guide.

Database Access Control

- Users authenticate to the database using their password. Oracle recommends that these passwords be strong. For guidelines on choosing Oracle database passwords, see Guidelines for Securing Passwords. In addition, Oracle database provides a PL/SQL script to verify database password complexity. This script is located at $ORACLE_HOME/rdbms/admin/UTLPWDMG.SQL. For instructions on running UTLPWDMG.SQL script to verify password complexity, see Enforcing Password Complexity Verification.
- In addition to the database password, you can use VCN network security groups or security lists to enforce network access control to database instances. Oracle recommends that you configure VCN network security groups or security lists to allow least privilege access to customer databases in Oracle Cloud Infrastructure Database.
- DB systems created within a public subnet can send outbound traffic directly to the Internet. DB systems created within a private subnet do not have internet connectivity, and internet traffic (both egress and ingress) cannot reach the instance directly. If you try to define a route to a DB system within a private subnet using an internet gateway, the route is ignored.

To perform OS patching and backup for a DB system on private subnet, you can use a service gateway or a NAT gateway to connect to your patching or backup endpoints.

In an virtual cloud network (VCN), you can use security rules along with a private subnet to restrict access to a DB system. In multi-tier deployments, a private subnet and VCN security rules can be used to restrict access to the DB system from the application tiers.

Data Durability

- Oracle recommends that you give database delete permissions (DATABASE_DELETE, DB_SYSTEM_DELETE) to a minimum possible set of IAM users and groups. This minimizes loss of data due to inadvertent deletes by
an authorized user or due to malicious deletes. Only give DELETE permissions to tenancy and compartment administrators.

- You can use RMAN to do periodic backups of Database databases, where encrypted backup copies are stored in local storage (block volumes, for example) or Oracle Cloud Infrastructure Object Storage. RMAN encrypts each backup of a database with a unique encryption key. In transparent mode, the encryption key is stored in the Oracle Wallet. RMAN backups to Object Storage require internet gateway (IGW), and VCN network security groups or security lists need to be configured to allow secure access to Object Storage. For information about setting up the VCN for backing up bare metal databases, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435. For information about backing up and Exadata databases, see Managing Exadata Database Backups by Using bkup_api on page 1323.

**Database Encryption and Key Management**

- All databases created in Oracle Cloud Infrastructure are encrypted using transparent data encryption (TDE). Note that if you migrate an unencrypted database from on-premise to Oracle Cloud Infrastructure using RMAN, the migrated database will not be encrypted. Oracle requires encrypting such databases after migrating them to the cloud.

To learn how to encrypt your database with minimum downtime during migration, see the Oracle Maximum Availability Architecture white paper Converting to Transparent Data Encryption with Oracle Data Guard using Fast Offline Conversion.

Note that virtual machine DB systems use Oracle Cloud Infrastructure block storage instead of local storage. Block storage is encrypted by default.

- User-created tablespaces are encrypted by default in Oracle Cloud Infrastructure Database. In these databases, `ENCRYPT_NEW_TABLESPACES` parameter is set to `CLOUD_ONLY` where tablespaces created in a Database Cloud Service (DBCS) database are transparently encrypted with the AES128 algorithm unless a different algorithm is specified.

- The Database administrator creates a local Oracle Wallet on a newly created database instance, and initializes the Transparent Data Encryption (TDE) master key. Then the Oracle Wallet is configured to be "auto-open". However, a customer can choose to set a password for the Oracle Wallet, and Oracle recommends that you set a strong password (eight characters or more, with at least one capital letter, one small letter, one number, and one special symbol).

- Oracle recommends that you periodically rotate the TDE master key. The recommended rotation period is 90 days or less. You can rotate the TDE master key by using native database commands ("administer key management" in 12c, for example) or dbaascli. All previous versions of TDE master key are maintained in the Oracle Wallet.

- Oracle Key Vault (OKV) is a key management appliance used for managing Oracle TDE master keys. OKV can store, rotate, and audit accesses to TDE master keys. For instructions about installing and configuring OKV in Oracle Cloud Infrastructure, see Managing Oracle Database Encryption Keys in Oracle Cloud Infrastructure with Oracle Key Vault.

**Database Patching**

Applying Oracle database security patches (Oracle Critical Patch Updates) is imperative to mitigate known security issues, and Oracle recommends that you keep patches up-to-date. Patchsets and Patch Set Updates (PSUs) are released on a quarterly basis. These patch releases contain security fixes and additional high-impact/low-risk critical bug fixes.

For information about the latest known security issues and available fixes, see Critical Patch Updates, Security Alerts and Bulletins. If your application does not support the latest patches and needs to use a DB system with older patches, you can provision a DB system with an older version of the Oracle Database edition you are using. In addition to reviewing the critical patch updates and security alerts for your Oracle Database, Oracle recommends that you analyze and patch the operating system provisioned with the DB system.

For information about applying patches to Oracle Cloud Infrastructure Database instances, see Patching a DB System on page 1407 and Patching an Exadata Cloud Service Instance Manually on page 1289.
**Database Security Configuration Checking**

- The Oracle Database Security Assessment Tool (DBSAT) provides automated security configuration checks of Oracle databases in Oracle Cloud Infrastructure. DBSAT performs security checks for user privilege analysis, database authorization controls, auditing policies, database listener configuration, OS file permissions, and sensitive data stored. Oracle database images in Oracle Cloud Infrastructure Database are scanned with DBSAT before provisioning. After provisioning, Oracle recommends that you periodically scan databases with DBSAT, and remediate any issues found. DBSAT is available free of charge to Oracle customers.

**Database Security Auditing**

Oracle Audit Vault and Database Firewall (AVDF) monitors database audit logs and creates alerts. For instructions about installing and configuring AVDF in Oracle Cloud Infrastructure, see Deploying Oracle Audit Vault and Database Firewall in Oracle Cloud Infrastructure.

**Database Backups**

Oracle recommends using Managed backups (backups created using the Oracle Cloud Infrastructure Console or the API) whenever possible. When you use managed backups, Oracle manages the object store user and credentials, and rotates these credentials every 3 days. Oracle Cloud Infrastructure encrypts all managed backups in the object store. Oracle uses the Database Transparent Encryption feature by default for encrypting the backups.

If you are not using managed backups, Oracle recommends that you change the object store passwords at regular intervals.

**Security Policy Examples**

**Prevent Delete of Database Instances**

The following example policy allows the group DBUsers to perform all management actions except delete databases and any artifacts.

```
Allow group DBUsers to manage db-systems in tenancy
   where request.permission!='DB_SYSTEM_DELETE'
Allow group DBUsers to manage databases in tenancy
   where request.permission!='DATABASE_DELETE'
Allow group DBUsers to manage db-homes in tenancy
   where request.permission!='DB_HOME_DELETE'
```

**Securing Email Delivery**

The Email Delivery service offers an SMTP endpoint, secured by a password generated in the Console. The SMTP password is required for sending emails using Email Delivery. Oracle recommends that you create a separate IAM user for SMTP. This user must have manage permissions for approved-senders and suppressions resource types. Oracle recommends that you securely store the SMTP credential, and periodically rotate it. For more information about generating an SMTP credential for Email Delivery, see Generate SMTP Credentials for a User on page 1750.

For Email Delivery best practices, including managing your sender reputation and help for avoiding being blocklisted, see Deliverability Best Practices on page 1780.

**Securing File Storage**

The File Storage Service exposes an NFSv3 endpoint as a mount target in each customer’s VCN subnet. The mount target is identified by a DNS name and is mapped to an IP address. Oracle recommends that you use VCN security lists (of the mount target subnet) to configure network access to the mount target from only authorized IP addresses.

You can mount a file system using the Console or from a Linux command line using NFS utilities. You can authorize users to mount file systems using IAM security policies, but this applies to the console only.
For data durability, Oracle recommends that you take periodic snapshots of the file system. To minimize accidental deletion of data, constrain the set of users having privileges to delete mount targets, file-systems, and snapshots.

All file-system data is encrypted at rest.

Access to mounted NFS file systems from a remote host is determined by POSIX user and group permissions. Oracle recommends that you use well-known NFS security best practices such as the all_squash option to map all users to nfsnobody, and NFS ACLs to enforce access control to the mounted file system.

**Security Policy Examples**

**Prevent Mount Target and File System Deletion**

The following example prevents group FileUsers from deleting mount targets and file-systems.

```plaintext
Allow group FileUsers to manage file-systems in tenancy where request.permission!="FILE_SYSTEM_DELETE"
Allow group FileUsers to manage mount-targets in tenancy where request.permission!="MOUNT_TARGET_DELETE"
Allow group FileUsers to manage export-sets in tenancy where request.permission!="EXPORT_SET_DELETE"
```

**Securing IAM**

**Security Recommendations**

Oracle Cloud Infrastructure Identity and Access Management (IAM) provides authentication of users, and authorization to access resources. Security-relevant IAM concepts include:

**IAM concepts and descriptions**

<table>
<thead>
<tr>
<th>Concept</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compartment</td>
<td>A compartment is a fundamental mechanism to aggregate resources into logical groups. They also provide isolation.</td>
</tr>
<tr>
<td>Tenancy</td>
<td>Oracle Cloud Infrastructure automatically creates a tenancy for an account created by an organization. It is the root compartment that contains all the organization's resources.</td>
</tr>
<tr>
<td>Users and groups</td>
<td>A group is an aggregation of users who need similar access to a group of resources.</td>
</tr>
<tr>
<td>Resource</td>
<td>A resource is an object created in Oracle Cloud Infrastructure services.</td>
</tr>
<tr>
<td>Security policy</td>
<td>A security policy specifies the type of access IAM groups have to resources in a specified aggregation level. An aggregation level can be the tenancy, a compartment, or a service.</td>
</tr>
<tr>
<td>Dynamic groups</td>
<td>A dynamic group allows aggregating Compute instances as principal actors (similar to user groups), in order to authorize instances to make calls to Oracle Cloud Infrastructure APIs.</td>
</tr>
<tr>
<td>Tags</td>
<td>Tags allow you to organize resources across multiple compartments for reporting purposes or for taking bulk actions.</td>
</tr>
</tbody>
</table>
Security Guide and Announcements

<table>
<thead>
<tr>
<th>Concept</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Federation</td>
<td>Mechanism to federate IAM with other identity providers (IdP) used by an organization to authenticate their users.</td>
</tr>
</tbody>
</table>

Oracle recommends that you periodically monitor Audit logs to review changes to IAM users, groups, and security policies.

**IAM Tenancy and Compartments**

- Compartments are unique to IAM, and offer a mechanism that allows an enterprise customer to meet its central needs by having a single account or tenancy. This single account or tenancy provides full central control and visibility while also allowing the account or tenancy to be subdivided to meet the needs of constituent teams, projects, and initiatives.
- For security and governance reasons, users should only have access to resources they need. For example, enterprise users working on a project or belonging to a business unit should have access only to resources belonging to the project or business unit. Compartments provide an effective mechanism to group tenancy resources based on their access privileges and authorize groups of users to access the compartments on as needed basis. In the example above, a compartment can be created to include all resources belonging to a business unit, and authorize only members of the business unit to access the compartment. Similarly, a groups’ access to a compartment can be revoked when they do not need it anymore.
- Keep the following in mind when you create a compartment and assign resources:
  - Every resource should belong to a compartment.
  - A resource can be reassigned to a different compartment after creation. See Managing Compartments on page 2431.
  - A compartment can be deleted after creation. See Managing Compartments on page 2431.
  - Resource tags provide a way to logically aggregate resources distributed across multiple compartments. For example, tenancy resources can be tagged as `test` or `production` depending on their use. For more information about resource tags (free-form and defined tags), see Resource Tags on page 211.
  - Every tenancy comes with a default administrators group. This group can perform any action on all resources in a tenancy (that is, they have root access to the tenancy). Oracle recommends that you keep the group of tenancy administrators as small as possible. Some security recommendations on managing tenancy administrators:
    - Have security policies granting membership of tenancy administrator group strictly on a as-needed basis.
    - Tenancy administrators should use high-complexity passwords, along with MFA, and periodically rotate their passwords.
    - After account set up and configuration, Oracle recommends that you don't use the tenancy administrator account for day-to-day operations. Instead, create less privileged users and groups.
    - Though administrator accounts are not used for daily operations, they are still needed to address emergency scenarios impacting customer tenancy and operations. Specify secure and auditable "break-glass" procedures for using administrator accounts in such emergencies.
    - Disable tenancy administration access immediately when an employee leaves the organization.
    - Because the tenancy administrator group membership is restricted, Oracle recommends that you create security policies which prevent administrator account lock-out (for example, if the tenancy administrator leaves the company and no current employees have administrator privileges).

**IAM Users and Groups**

- Create an IAM user for everyone in the customer organization who needs access to resources. Do not share IAM user accounts across multiple users, especially those with administrative accounts. Using distinct IAM users enables enforcing least privilege access for each user, and captures their actions in audit logs.
- The recommended unit of administration is IAM groups, which makes it easier to manage and keep track of security permissions (as opposed to individual users). Create IAM groups with permissions to do commonly needed tasks (for example, network administration, volume administration), and assign users to these groups on an as-needed basis. IAM permissions can be used to give a group access to resources across multiple compartments in a tenancy.
• Periodically review membership of IAM users in IAM groups, and remove IAM users from groups they do not need access to anymore. Using group membership to manage user access scales well with increasing number of users.
• Deactivate IAM users who do not need access to tenancy resources. Deleting an IAM user removes the user permanently. You can temporarily deactivate an IAM user by doing the following:
  • Rotate the user password and throw it away.
  • Remove all tenancy permissions of the user by removing membership from all groups.

IAM Credentials
IAM user credentials (Console password, API signing key, auth tokens, and customer secret keys) grant access to resources. It is important to secure these credentials to prevent unauthorized access to Oracle Cloud Infrastructure resources. General guidelines for handling credentials include:
• Create a strong console password for each IAM user, with sufficient complexity. Oracle recommends the following for a complex password:
  • Password has a minimum length of 12 characters
  • Password contains at least one uppercase letter
  • Password contains at least one lowercase letter
  • Password contains at least one symbol
  • Password contains at least one number
• Rotate IAM passwords and API keys regularly, every 90 days or less. In addition to a security engineering best practice, this is also a compliance requirement. For example, PCI-DSS Section 3.6.4 states, "Verify that key-management procedures include a defined cryptoperiod for each key type in use and define a process for key changes at the end of the defined crypto period(s)."
• Do not hard code sensitive IAM credentials directly in software or documents accessible to a wide audience. Examples include code uploaded to GitHub, presentations, or documents available on the internet. There have been known, highly publicized cases of hackers breaching customer cloud accounts, using credentials inadvertently disclosed on public sites. When software applications need to access Oracle Cloud Infrastructure resources, Oracle recommends that you use instance principals. If it is not feasible to use instance principals, other recommendations include using user environment variables to store credentials, and using locally stored credential files with API keys to be used by the Oracle Cloud Infrastructure SDK or CLI.
• Do not share IAM credentials between multiple users.
• By federating the Console login through Oracle Identity Cloud Service, customers can use multifactor authentication (MFA) for IAM users, especially administrators.

When rotating API keys, verify that the rotated keys work as expected before disabling older keys. For information about generating and uploading IAM API keys, see Required Keys and OCIDs on page 4179. The high-level steps in rotating an API key are:
1. Generate and upload a new API key.
2. Update the SDK and CLI configuration files with the new API key.
3. Verify that the SDK and CLI calls are working correctly with the new key.
4. Disable the old API key. Use ListApiKeys to list all active API keys.

IAM Security Policies
IAM policies are used to govern access of IAM groups to resources in compartments and in the tenancy. Oracle recommends that you assign least privilege access to IAM groups for accessing resources. The common format for IAM policies is shown in the following example.

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
Allow group <group_name> to <verb> <resource-type> in tenancy
```

IAM policies allow four predefined verbs: inspect, read, use and manage. Inspect allows least privilege and manage allows the maximum. The four verbs are shown in increasing order of privilege in the following table.
### IAM policy verbs

<table>
<thead>
<tr>
<th>Verb</th>
<th>Access Type</th>
<th>Example User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Should only show metadata. This usually results in ability to list resources only</td>
<td>third-party auditor</td>
</tr>
<tr>
<td>read</td>
<td>inspect plus ability to read resource and user metadata. This is the permission most users need to get work done.</td>
<td>internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>read plus ability to work with resources (the actions vary by resource type). Excludes ability to create or delete resource</td>
<td>regular users (software developers, system engineers, dev managers, etc) setting up and configuring tenancy resources, and applications running on them</td>
</tr>
<tr>
<td>manage</td>
<td>All the permissions for all the resources</td>
<td>administrators, executives (for break-glass scenarios)</td>
</tr>
</tbody>
</table>

The resource types of Oracle Cloud Infrastructure resources are shown in the following table.

### IAM resource families, descriptions, and resource types

<table>
<thead>
<tr>
<th>Resource Type Family</th>
<th>Description</th>
<th>Resource Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>all-resources</td>
<td>All resource types</td>
<td>compartments, users, groups, dynamic-groups, policies, identity-providers, tenancy tag-namespaces, tag-definitions</td>

<tr>
<td>dns</td>
<td>Resources in DNS service</td>
<td>dns-zones, dns-records, dns-traffic</td>
</tr>
<tr>
<td>email-family</td>
<td>Resources in email delivery service</td>
<td>approved-senders, suppressions</td>
</tr>
</tbody>
</table>

For more information about IAM verbs and resource type permission mappings, see [Details for the Core Services](#) on page 2181.

IAM security policies can be made fine-grained through conditions. Access specified in the policy is allowed only if the condition statements evaluate to true. Conditions are specified using predefined variables. The variables use the key words request or target, depending on whether the variable is relevant to the request or the resource being acted on, respectively. For information about supported predefined variables, see [Policy Reference](#) on page 2167.

IAM dynamic groups are used to authorize Compute instances to access Oracle Cloud Infrastructure APIs. The instance principals feature can be used by applications, running on the instances, to programmatically access Oracle Cloud Infrastructure services. Customers create dynamic groups, which include instances as members, and authorize access to their tenancy resources using IAM security policies. All access by instances is captured in the audit logs available to customers.

**IAM Federation**

- Oracle recommends that you use federation to manage logins into the Console. Identity federation supports SAML 2.0 compliant identity providers, and can be used to federate on-premises users and groups to IAM users and groups. The enterprise administrator needs to set up a federation trust between the on-premises identity provider (IdP) and IAM, in addition to creating mapping between on-premises groups and IAM groups. Then, on-premises users can single sign-on (SSO) into the Console, and access resources based on authorization of IAM groups they belong to. For more information about federating to the Console, see [Federating with Identity Providers](#) on page 2362. Federation is especially important for enterprises using custom policies for user authentication (for example, multifactor authentication). For more information about managing users and groups under federation, see [Federating with Identity Providers](#) on page 2362.

- When using federation, Oracle recommends that you create a federation administrators group that maps to the federated IdP administrator group. The federation administrators group will have administrative privileges to manage customer tenancy, while being governed by the same security policies as the federated IdP administrator group. In this scenario, it is a good idea to have access to the local tenancy administrator user (that is, member of the default tenancy administrator IAM group), to handle any break-glass type scenarios (for example, inability to access resources through federation). However, you must prevent any unauthorized use of this highly privileged...
local tenancy administrator user. Oracle recommends the following approach to securely managing the tenancy administrator user:

1. Create a local user belonging to the default tenancy administrator group.
2. Create a highly complex Console password or passphrase (18 characters or more, with at least one lowercase letter, one uppercase letter, one number, and one special character) for the local tenancy administrator user.
3. Securely escrow the local tenancy administrator user password in an on-premises location (for example, place the password in a sealed envelope in an on-premises physical safe).
4. Create security policies for accessing the escrowed password only under specific "break-glass" scenarios.
5. Have IAM security policy to prevent the federated administrators IAM group from adding or modifying membership of the default tenancy administrator group to prevent security by-passes.
6. Monitor audit logs for accesses by default tenancy administrator and changes to the administrator group, to alert on any unauthorized actions. For additional security, the local tenancy administrator user password can be rotated after every login, or periodically, based on a password policy.

For an example that shows the way various IAM components fit together, see Example Scenario on page 2126. Periodically monitor Audit logs to review changes to IAM users, groups, policies, compartments, and tags.

**Security Policy Examples**

Common IAM security policy examples are available at Common Policies on page 2142. In all the examples that follow, the policies are scoped to a tenancy. However, by specifying a compartment name, you can scope down the policies to specific compartments in a tenancy.

**Create Service-level Admins for Least Privilege**

To implement security principle of least privilege, you can create service-level admins in the tenancy to further scope down administrative access. This means that service-level administrators can only manage resources of a specific service. For instance, network administrators need administrative (manage) access only to VCN resources, and not to other resources. The following example shows how to create administrator groups for block storage (VolumeAdmins), VCN (NetworkAdmins), databases (DBAdmins), and object storage (StorageAdmins).

| Allow group TenancyAdmins to manage all-resources in tenancy |
| Allow group VolumeAdmins to manage volume-family in tenancy |
| Allow group NetworkAdmins to manage virtual-network-family in tenancy |
| Allow group StorageAdmins to manage object-family in tenancy |
| Allow group DBAdmins to manage database-family in tenancy |

You can further constrain the security policies to a specific compartment. For example, the HR department in an enterprise can create group HRAdmins to manage resources within its compartment, HR-compartment. The HRNetworkAdmins group has administrative access to VCN resources only within the HR-compartment compartment.

| Allow group HRAdmins to manage all-resources in compartment HR-compartment |
| Allow group HRNetworkAdmins to manage virtual-network-family in compartment HR-compartment |

Compliance auditors are tasked with examining cloud resources and verifying for policy violations. The following policy allows group InternalAuditors to inspect (list) all resources in a tenancy.

| Allow group InternalAuditors to inspect all-resources in tenancy |

If you want to limit auditors to only inspect users and groups in a tenancy, you can create a group UserAuditors with the following policy:

| Allow group UserAuditors to inspect users in tenancy |
| Allow group UserAuditors to inspect groups in tenancy |
If you want to create an auditor group that can only inspect VCN firewalls in the tenancy, use the following policy:

```
Allow group FirewallAuditors to inspect security-lists in tenancy
```

In all the policy examples, you can constrain the policies to a compartment by specifying `Compartment <name>` (where `<name>` is the compartment name) in the policy.

**Restrict Ability to Change Tenancy Administrators Group Membership**

Members in the group Administrators can manage all resources in a tenancy. Membership of the Administrators group is controlled by users in the group. Usually, it's convenient to have a group to create and add users in the tenancy, but restrict them from making changes to the Administrators group membership. The following example creates a group UserAdmins to do this.

```
Allow group UserAdmins to inspect users in tenancy
Allow group UserAdmins to inspect groups in tenancy
Allow group UserAdmins to use users in tenancy
  where target.group.name!='Administrators'
Allow group UserAdmins to use groups in tenancy
  where target.group.name!='Administrators'
```

Use verb with conditions (third and fourth policy statements) allows UserAdmins to add users and groups using APIs (UpdateUser, UpdateGroup) to all groups in the tenancy except the Administrators group. However, because `target.group.name!='Administrators'` is not related to the list and get APIs (ListUsers, GetUser, ListGroups, and GetGroup), these APIs will fail. So you must explicitly add the inspect verb (first and second policy statements) to allow UserAdmins to get user and group membership information.

**Prevent Delete or Update of Security Policies**

The following example creates a group PolicyAdmins to be able to create and list security policies created by tenancy administrators, but not delete or update them.

```
Allow group PolicyAdmins to use policies in tenancy
Allow group PolicyAdmins to manage policies in tenancy
  where request.permission='POLICY_CREATE'
```

This security policy statement explicitly only allows POLICY_CREATE permission, and not to POLICY_DELETE and POLICY_UPDATE.

**Prevent Admins from Accessing or Altering User Credentials**

Some compliance requirements need separation of duties, especially where user credential management functionality is separated from tenancy management. In this case, you can create two administration groups, TenancyAdmins and CredentialAdmins where TenancyAdmins can perform all tenancy management functions except user credential management, and CredentialAdmins can manage user credentials. TenancyAdmins can access all APIs except those that list, update, or delete user credentials. CredentialAdmins can only manage the user credentials.

```
Allow group TenancyAdmins to manage all resources in tenancy
  where all {request.operation!='ListApiKeys',
               request.operation!='ListAuthTokens',
               request.operation!='ListCustomerSecretKeys',
               request.operation!='UploadApiKey',
               request.operation!='DeleteApiKey',
               request.operation!='UpdateAuthToken',
               request.operation!='CreateAuthToken',
               request.operation!='DeleteAuthToken',
               request.operation!='CreateSecretKey',
               request.operation!='UpdateCustomerSecretKey',
```
Allow group CredentialAdmins to manage users in tenancy where any request.operation='ListApiKeys', request.operation='ListAuthTokens', request.operation='ListCustomerSecretKeys', request.operation='UploadApiKey', request.operation='DeleteApiKey', request.operation='UpdateAuthToken', request.operation='CreateAuthToken', request.operation='DeleteAuthToken', request.operation='CreateSecretKey', request.operation='UpdateCustomerSecretKey', request.operation='DeleteCustomerSecretKey'}

Useful CLI Commands

In all the following examples, environment variables $T$ and $C$ are set to tenancy OCID and compartment OCID, respectively.

**List Compartments in a Tenancy**

```
# list all compartments (OCID, display name, description) in tenancy $T
oci iam compartment list -c $T
# grep above command for important fields
oci iam compartment list -c $T | grep -E "name\ndescription\nid""
```

**List IAM Users**

```
# lists all users (OCID, display name, description) in tenancy $T
oci iam user list -c $T
# grep above command for important fields
oci iam user list -c $T | grep -E "name\ndescription\nid"
```

**List IAM groups**

```
# lists all groups (OCID, display name, description) in tenancy $T.
oci iam group list -c $T
# grep above command for important fields
oci iam group list -c $T | grep -E "name\ndescription\nid"
```

**List Users in a Group**

The following command is helpful for listing users in groups, especially users with administrative privileges. This command requires the OCID of the group whose users are listed.

```
# list users in group with OCID <GROUP_OCID>
oci iam group list-users -c $T --group-id <GROUP_OCID>
```

**List Security Policies**

```
# lists all policies (OCID, name, statements) in tenancy $T. Remove pipe to
grep to get entire information
oci iam policy list -c $T
# grep above command for important fields
oci iam policy list -c $T | grep -E "name\nAllow\nid"
```
Securing Networking: VCN, Load Balancers, and DNS

Security Recommendations

The Networking service has a collection of features for enforcing network access control and securing VCN traffic. These features are listed in the following table.

<table>
<thead>
<tr>
<th>VCN Feature</th>
<th>Security Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public and private subnets</td>
<td>Your VCN can be partitioned into subnets. Subnets have historically been specific to an availability domain, but can now be regional (covering all availability domains in the region). Instances inside private subnets cannot have public IP addresses. Instances inside public subnets can optionally have public IP addresses at your discretion.</td>
</tr>
<tr>
<td>Security rules</td>
<td>Security rules provide stateful and stateless firewall capability to control network access to your instances. To implement security rules in your VCN, you can use network security groups (NSGs) or security lists. For more information, see Comparison of Security Lists and Network Security Groups on page 2833.</td>
</tr>
<tr>
<td>Gateways</td>
<td>Gateways let resources in a VCN communicate with destinations outside the VCN. The gateways include:</td>
</tr>
<tr>
<td></td>
<td>• Internet gateway: for internet connectivity (for resources with public IP addresses in public subnets)</td>
</tr>
<tr>
<td></td>
<td>• NAT gateway: for internet connectivity without exposing the resources to incoming internet connections (for resources in private subnets)</td>
</tr>
<tr>
<td></td>
<td>• Dynamic routing gateway (DRG): for connectivity to networks outside the VCN's region (for example, your on-premises network by way of an IPSec VPN or FastConnect, or a peered VCN in another region)</td>
</tr>
<tr>
<td></td>
<td>• Service gateway: for private connectivity to Oracle services such as Object Storage</td>
</tr>
<tr>
<td></td>
<td>• Local peering gateway (LPG): for connectivity to a peered VCN in the same region</td>
</tr>
<tr>
<td>Route table rules</td>
<td>Route tables control how traffic is routed from your VCN's subnets to destinations outside the VCN. Routing targets can be VCN gateways or a private IP address in the VCN.</td>
</tr>
<tr>
<td>IAM polices for virtual-network-family</td>
<td>IAM policies specify access and actions permitted by IAM groups to resources in a VCN. For example, IAM polices can give administrative privileges to network administrators who manage the VCNs, and scoped-down permissions to normal users.</td>
</tr>
</tbody>
</table>

Oracle recommends that you periodically monitor Oracle Cloud Infrastructure Audit logs to review changes to VCN network security groups, security lists, route table rules, and VCN gateways.
Network Segmentation: VCN Subnets

• Formulate a tiered subnet strategy for the VCN, to control network access. A common design pattern is to have the following subnet tiers:

1. DMZ subnet for load balancers
2. Public subnet for externally accessible hosts such as NAT instances, intrusion detection (IDS) instances, and web application servers
3. Private subnet for internal hosts such as databases

No special routing is required for the instances in the different subnets to communicate. However, you can control the types of traffic between the different tiers by using the VCN's network security groups or security lists.

• Instances in the private subnet only have private IP addresses and can be reached only by other instances in the VCN. Oracle recommends that you place security-sensitive hosts (DB systems, for example) in a private subnet, and use security rules to control the type of connectivity to hosts in a public subnet. In addition to VCN security rules, configure host-based firewalls such as iptables, firewalld for network access control, as a defense-in-depth mechanism.

• You can add a service gateway to your VCN to enable DB systems in the private subnet to directly back up to Object Storage without the traffic traversing the internet. You must set up the routing and security rules to enable that traffic. For more information for bare metal or virtual machine DB systems, see Network Setup for DB Systems on page 1359. For more information for Exadata DB systems, see Network Setup for Exadata Cloud Service Instances on page 1232.

Network Access Control: VCN Security Rules

• Use your VCN’s security rules to restrict network access to instances. A security rule is stateful by default, but can also be configured to be stateless. A common practice is to use stateless rules for high-performance applications. In a case where network traffic matches both stateful and stateless security lists, the stateless rule takes precedence. For more information about configuring VCN security rules, see Security Rules on page 2833.

• To prevent unauthorized access or attacks on Compute instances, Oracle recommends that you use a VCN security rule to allow SSH or RDP access only from authorized CIDR blocks rather than leave them open to the internet (0.0.0.0/0). For additional security, you can temporarily enable SSH (port 22) or RDP (port 3389) access on an as-needed basis using the VCN API UpdateNetworkSecurityGroupSecurityRules (if you're using network security groups) or UpdateSecurityList (if you're using security lists). For more information about enabling RDP access, see To enable RDP access in Creating an Instance on page 695. For performing instance health checks, Oracle recommends that you configure VCN security rules to allow ICMP pings. For more information, see Rules to Enable Ping on page 2841.

• Oracle recommends bastion hosts as a way to control external access (for example, SSH) to VCN hosts. Usually bastion hosts in a VCN public subnet control access to VCN private subnet hosts. For more information about setting up an SSH bastion host in a VCN, see the white paper Bastion Hosts.

• VCN network security groups (NSGs) and security lists enable security-critical network access control to Compute instances, and it is important to prevent any unintended or unauthorized changes to NSGs and security lists. To prevent unauthorized changes, Oracle recommends that you use IAM policies to allow only network administrators to make NSG and security list changes.

Secure Connectivity: VCN Gateways and FastConnect Peering

• VCN gateways provide external connectivity (internet, on-premises, or peered VCN) to VCN hosts. See the table earlier in this topic for a list of the type of gateways. Oracle recommends that you use an IAM policy to allow only network administrators to create or modify VCN gateways.
• Carefully consider allowing internet access to any instances. For example, you don't want to accidentally allow internet access to sensitive database instances. In order for an instance in a VCN to be publicly accessible from the internet, you must configure the following VCN options:

  • The instance must be in a VCN public subnet.
  • The VCN containing the instance must have an internet gateway enabled and configured to be the routing target for outbound traffic.
  • The instance must have a public IP address assigned to it.
  • The VCN security list for the instance's subnet must be configured to allow inbound traffic from 0.0.0.0/0. Or if you're using network security groups (NSG), the instance must be in an NSG that allows that traffic.

• VPN IPSec provides connectivity between a customer's on-premises network and VCN. You can create two IPSec tunnels for high availability. For more information about creating VPN tunnels to connect VCN DRG to customer CPEs, see VPN Connect on page 2932.

• FastConnect peering allows you to connect your on-premises network to your VCN with a private circuit so that the traffic does not traverse the public internet. You can set up private peering (to connect to private IP addresses), or public peering (to connect to Oracle Cloud Infrastructure public endpoints, such as for Object Storage). For more information about FastConnect peering options, see FastConnect on page 3173.

Virtual Security Appliances in a VCN

• The Networking service lets you implement network security functions such as intrusion detection, application-level firewalls, and NAT (although you can instead use a NAT gateway with your VCN). You can do this by routing all the subnet traffic to a network security host, using route table rules that use a local VCN private IP address as a target. For more information, see Using a Private IP as a Route Target on page 2924. For high availability, you can assign the gateway security host a secondary private IP address, which you can move to a VNIC on a standby host in case of primary host failure. Full network packet capture or network flow logs can be captured on the NAT instances using tcpdump, and the logs can be uploaded periodically to an Object Storage bucket.

• Virtual security appliances can be run as virtual machines (VMs) on a bring-your-own-hypervisor (BYOH) model on a bare metal instance. Virtual security appliance VMs running on the BYOH bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For information about enabling BYOH on a bare metal instance using an open-source KVM hypervisor, see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.

• Virtual security appliances can also be installed on Compute virtual machines (VMs) where VMDK or QCOW2 images of security appliances can be imported using the bring your own image (BYOI) feature. However, due to infrastructure dependencies, the BYOI feature might not work for some appliances, in which case the BYOH model would be another option to use. For more information about importing appliance images into Oracle Cloud Infrastructure, see Bring Your Own Image (BYOI) on page 675.

Load Balancers

• Oracle Cloud Infrastructure load balancers enable end-to-end TLS connections between a client's applications and a customer's VCN. The TLS connection can be terminated at an HTTP load balancer, or on a back-end server by using a TCP load balancer. The load balancers use TLS1.2 by default. For information about configuring an HTTPS listener, see Managing Listeners on page 2522. You can also upload your own TLS certificates. For more information see Managing SSL Certificates on page 2551.

• You can configure network access to load balancers by using VCN network security groups or security lists. This method provides similar functionality to traditional load balancer firewalls. For public load balancers, Oracle recommends that you use a regional public subnet (for example, DMZ subnet) for instantiating the load balancers in a highly available configuration across two different availability domains. You can configure the load balancer firewall rules by setting up the load balancer's network security groups or the subnet's security lists. For more information about creating load balancer security lists, see Update Load Balancer Security Lists and Allow Internet Traffic to the Listener on page 114. Similarly, you must configure the VCN network security groups or security lists for the backend servers to limit traffic only from the public load balancers. For more information
about configuring backend server security lists, see Update Rules to Limit Traffic to Backend Servers on page 116.

**DNS Zones and Records**

DNS zones and records are critical for accessibility of web properties. Incorrect updates or unauthorized deletions could result in outage of services, accessed through the DNS names. Oracle recommends that you limit IAM users who can modify DNS zones and records.

**Security Policy Examples**

**Allow Users to Only View Security Lists**

Your network administrators are the personnel who should have the ability to create and manage network security groups and security lists.

However, you may have network users who need to know what security rules are in a particular network security group (NSG) or security list.

The first line in the following example policy allows the NetworkUsers group to view security lists and their contents. This policy does not let the group create, attach, delete, or modify security lists.

The second line lets the NetworkUsers group view the security rules in NSGs, and also view what VNICs and parent resources are in NSGs. The second line does not let the NetworkUsers group change the security rules in NSGs.

```
Allow group NetworkUsers to inspect security-lists in tenancy
Allow group NetworkUsers to use network-security-groups in tenancy
```

**Prevent Users from Creating External Connection to the Internet**

In some cases, you might need to prevent users from creating external internet connectivity to their VCN. In the following example policy, the NetworkUsers group is prevented from creating an internet gateway.

```
Allow group NetworkUsers to manage internet-gateways in tenancy
where request.permission!='INTERNET_GATEWAY_CREATE'
```

**Prevent Users from Updating DNS Records and Zones**

In the following example policy, the NetworkUsers group is prevented from deleting and updating DNS zones and records.

```
Allow group NetworkUsers to manage dns-records in tenancy
where all {request.permission!='DNS_RECORD_DELETE',
            request.permission!='DNS_RECORD_UPDATE'}
Allow group NetworkUsers to manage dns-zones in tenancy
where all {request.permission!='DNS_ZONE_DELETE',
            request.permission!='DNS_ZONE_UPDATE'}
```

**Useful CLI Commands**

In all the following examples, the environment variables $T, $C and $VCN are set to tenancy OCID, compartment OCID, and VCN OCID, respectively.

**List Open Security Lists in a VCN**

```
# list open (0.0.0.0/0) security lists in VCN $VCN in compartment $C
oci network security-list list -c $C --vcn-id $VCN | grep "source" | grep "\"0.0.0.0/0\""
```
List Gateways in a VCN

```
# list all internet gateways in VCN $VCN in compartment $C
oci network internet-gateway list -c $C --vcn-id $VCN
# list all DRGs in compartment $C
oci network drg list -c $C
# list all local peering gateways in vcn $VCN in compartment $C
oci network local-peering-gateway list -c $C --vcn-id $VCN
```

List Route Table Rules in a VCN

```
# list route table rules in VCN $VCN in compartment $C
oci network route-table list -c $C --vcn-id $VCN
```

Securing Object Storage

Security Recommendations

Assign least privileged access for IAM users and groups to resource types in object-family (buckets and objects). For example, the inspect verb gives the least privilege. Inspect lets you check to see if a bucket exists (HeadBucket) and list the buckets in a compartment (ListBucket). The manage verb gives all permissions on the resource. You can create IAM security policies to give appropriate bucket and object access to various IAM groups. For more information about IAM verbs and permissions for Object Storage buckets and objects, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324. For users without IAM credentials, we recommend that you use pre-authenticated requests (PARs) to give time-bound access to objects or buckets.

Public Buckets Security Controls

- A public bucket allows unauthenticated and anonymous reads to all objects in the bucket. Carefully evaluate the intended use case for public buckets before you enable public buckets. We recommend that you use pre-authenticated requests (PARs) to give bucket or object access (read or write) to users without IAM credentials. By default, buckets are created with no public access (access type is set to NoPublicAccess).
- You can make existing buckets public by updating the bucket access type to ObjectRead or ObjectReadWithoutList. To minimize the possibility of existing buckets being made public inadvertently or maliciously, BUCKET_UPDATE permission should be restricted to a minimal set of IAM groups.

Pre-Authenticated Request (PAR)

- Pre-authenticated requests (PARs) provide a mechanism to provide access to objects stored in buckets, to users who do not have IAM user credentials. In a PAR, an IAM user who has appropriate privileges for accessing objects, can create URLs which grant time-bound read or write access to these objects. For more information about creating PARs, see Using Pre-Authenticated Requests on page 3482.
- The creator of a PAR must have PAR_MANAGE IAM permission. You can create the following PARs:
  - Bucket PAR to allow writes to a bucket
  - Object PAR for reading an object
  - Object PAR for writing an object
  - Object PAR to read or write an object
- A PAR cannot be used to list objects in a bucket.
- PAR accesses to a bucket are logged in Audit logs. PAR accesses to an object are logged in Service logs.
- We recommend that you note down the PAR URL created. By design, it is not possible to retrieve a forgotten PAR URL. If you forget a PAR URL, you must create a new PAR.
**Data Durability**

- Minimize data loss because of inadvertent deletes by an authorized user or malicious deletes. We recommend the following:
  - Use object versioning to automatically create an object version each time a new object is uploaded, an existing object is overwritten, or when an object is deleted.
  - Give BUCKET_DELETE and OBJECT_DELETE permissions to a minimum set of IAM users and groups. Grant delete permissions only to tenancy and compartment administrators.
  - Write once read many (WORM) compliance requires that objects cannot be deleted or modified. Use retention rules to achieve WORM compliance. Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules).

**Data Encryption**

- All data in Object Storage is encrypted at rest by using AES-256. Encryption is on by default and cannot be turned off. Each object is encrypted with its encryption key, and the object encryption keys are encrypted with a master encryption key. In addition, customers can use client-side encryption to encrypt objects with their encryption keys before storing them in Object Storage buckets. An available option for customers is to use the Amazon S3 Compatibility API, along with client-side object encryption support available in AWS SDK for Java. See Amazon S3 Compatibility API on page 3493 for more details about on this SDK.
  - Data in transit between customer clients (for example, SDKs and CLIs) and Object Storage public endpoints is encrypted with TLS 1.2 by default. FastConnect public peering allows on-premises access to Object Storage to go over a private network, rather than the public internet.

**Data Integrity**

- To verify object data integrity, an MD5 checksum is provided for all objects uploaded to Object Storage. We recommend that you verify that the offline MD5 checksum of an object matches the checksum value returned by the Console or API after upload. Oracle Cloud Infrastructure provides the object checksum value in base64 encoding. To covert the base64 encoded checksum value to hexadecimal, use the following command:

  ```
  python -c 'print "BASE64-ENCODED-MD5-VALUE".decode("base64").encode("hex")'
  ```

  Linux provides an md5sum command line utility to compute MD5 checksum value of an object in hexadecimal format.
  - Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. In a multipart upload, a large object is broken up into smaller parts by specifying a part size in MiB. Each part is uploaded separately. Object Storage then combines all the parts to create the original object. If any of the parts fail to upload, only those parts need to be retried for upload, and not the entire object. In a multipart upload, the MD5 checksum values are computed for each part, and an MD5 checksum computed over all the individual checksum values to get the output MD5 value. To verify the MD5 value returned for a multipart upload, follow the same process for offline MD5 checksum calculation. A sample script for the offline calculation of an MD5 checksum value for a multipart upload to Object Storage is available here: https://gist.github.com/itemir/f5bc9f9fed6483cd79c89ebf4ca1cfd30.

**Security Policy Examples**

In the following examples, the policies are scoped to a tenancy. However, specifying a compartment name reduces the scope to a specific compartment in a tenancy.

**Restrict Group Access to Specific Buckets**

You can restrict access by a group to a specific bucket by using the specific bucket name (target.bucket.name), regular expression matching (/^name/, /name*/, /name*/), or defined tags (target.tag.definition.name).
The following is an example of restricting access by groups `BucketUsers` to a specific bucket.

```
Allow group BucketUsers to use buckets in tenancy
where target.bucket.name='BucketFoo'
```

You can modify this policy to restrict access by group `BucketUsers` to all buckets whose names are prefixed with `ProjectA_`.

```
Allow group BucketUsers to use buckets in tenancy
where target.bucket.name=/ProjectA_*/
```

You can also match for post-fix (`/*_ProjectA/`) or substring (`/*ProjectA*/`).

**Restrict Group Access to Read or Write to Objects in a Specific Bucket**

The following example allows listing and reading objects by group `BucketUsers` from a specific bucket named `BucketFoo`.

```
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
where all {target.bucket.name='BucketFoo',
          any {request.permission='OBJECT_INSPECT',
               request.permission='OBJECT_READ'}}
```

The following policy modifies the previous policy to allow listing and writing objects to `BucketFoo`.

```
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
where all {target.bucket.name='BucketFoo',
          any {request.permission='OBJECT_INSPECT',
               request.permission='OBJECT_CREATE'}}
```

You can restrict this policy to read or write access to a set of buckets by using regular expressions or tags rather than a specific bucket.

**Restrict Resource Access to a Particular User**

You can restrict access to Object Storage resources to a specific user by adding a condition to the policy that specifies the user's OCID in a variable.

The following policy restricts access to the resources in `ObjectStorage` compartment to the user OCID specified:

```
Allow any-user to read object-family in compartment ObjectStorage where
request.user.id = 'ocid1.user.oc1..<user_OCID>'
```

**Restrict Access to Requests That Originate From an Allowed IP Address**

You can restrict access only to requests that originate from an allowed IP address. First, you create a `network source` to specify the allowed IP addresses, then you add a condition to your policy to restrict access to the IP addresses in the network source.

The following policy restricts access to only IP addresses in a network source `corpnet` that defines the allowed IP addresses:

```
Allow group CorporateUsers to manage object-family in tenancy where
request.networkSource.name='corpnet'
```

For information on creating network sources and using them in a policy, see Managing Network Sources on page 2427.
**Prevent Delete of Buckets or Objects**

In the following example, the group *BucketUsers* can perform all actions on buckets and objects except delete.

```
Allow group BucketUsers to manage objects in tenancy
  where request.permission!='OBJECT_Delete'
Allow group BucketUsers to manage buckets in tenancy
  where request.permission!='BUCKET_Delete'
```

The following example further restricts object deletion from the specific bucket (*BucketFoo*).

```
Allow group BucketUsers to manage objects in tenancy
  where any {target.bucket.name!='BucketFoo',
              all {target.bucket.name='BucketFoo',
                   request.permission!='OBJECT_Delete'}}
```

**Enable WORM Compliance for Objects**

Use retention rules to achieve WORM compliance. Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules).

The following policies let *BucketUsers* manage the buckets and objects in the tenancy and allow *BucketUsers* to create, manage, and delete retention rules. These policies also let *BucketUsers* lock retentions rules for a specified time.

```
Allow group BucketUsers to manage buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
```

The following more restrictive policies let *BucketUsers* perform all actions on buckets and objects except locking retention rules.

```
Allow group BucketUsers to manage buckets in tenancy
  where request.permission!='RETENTION_RULE_LOCK'
Allow group BucketUsers to manage objects in tenancy
```

**Prevent Public Buckets Configuration**

*BUCKET_CREATE* and *BUCKET_UPDATE* permissions are required to create buckets or make existing private buckets public. Removing these permissions prevents users from creating buckets or making existing buckets public.

```
Allow group BucketUsers to manage buckets in tenancy
  where any {request.permission='BUCKET_INSPECT',
              request.permission='BUCKET_READ',
              request.permission='PAR_MANAGE'}
```

**Useful CLI Commands**

Here are some useful commands to determine if you have public buckets or PARS in your tenancy.

**List of Public Buckets**

The following command returns the public-access-type assigned to a bucket.

```
# "public-access-type" of 'NoPublicAccess' indicates a private bucket, and
# anything else ('ObjectRead') indicates a public bucket
oci os bucket get -ns <your_namespace> --bucket-name <bucket_name> | grep
"public-access-type"
```
List of Bucket Pre-Authenticated Requests (PARs)

The following command returns a list of object PARs in a bucket.

```bash
# list all PARs for objects in bucket $BUCKET_NAME
oci os preauth-request list -ns <your_namespace> -bn <bucket_name>
```

Securing Resource Manager

Resource Manager allows you to automate installing and provisioning Oracle Cloud Infrastructure resources by committing the provisioning instructions to configuration files. These configuration files capture the step-by-step provisioning instructions using a declarative language that follows the "infrastructure-as-code" model. The provisioning instructions are executed as "jobs"; the Oracle Cloud Infrastructure resources that are provisioned when you run the jobs are organized into "stacks."

Executing jobs and provisioning stacks is gated using role-based access control (RBAC), which is enabled by Oracle Cloud Infrastructure Identity and Access Management (IAM). This gives administrators granular control over user access to Oracle Cloud Infrastructure resources and the actions that users can take on these resources.

The Resource Manager security scheme rests on three pillars:

- **Security groups.** Administrator-defined groups that have permission to perform specific operations on stacks and jobs. Individual users are assigned to security groups and can then perform operations that are allowed by that group. For more information about security policies, see [Getting Started with Policies](#) on page 2135. See also [How Policies Work](#) on page 2136 and [Policy Syntax](#) on page 2164. For recommended Resource Manager policies, see [Policies for Managing Resources Used with Resource Manager](#) on page 2476.

- **Permission sets.** Sets of permissions that are specific to jobs and stacks.

- **Operations.** The operations (or actions) that are allowed and the permissions that are required to perform each one.

For permission sets and operations used with Resource Manager, see [Details for Resource Manager](#) on page 2336.

Potential Security Risks and Mitigations

**Terraform State Files**

Terraform state (.tfstate) can contain sensitive data, including resource IDs and in some cases sensitive user data like passwords. HashiCorp provides recommendations for handling Terraform state in the article [Sensitive Data in State](#).

To control access to the Terraform state file, you can create a security policy that limits access to reading jobs, such as the following:

```
Allow group <group_name> to read orm-jobs in compartment
```

**Note:**

Because the permission `read orm-jobs` also affects other operations such as getting logs and Terraform configurations, you should segregate state files in a compartment on which a restrictive policy will not limit the ability to perform other operations.

**Terraform Configurations**

The Resource Manager workflow typically includes writing or generating a Terraform configuration that is then used to manage your stack. Because the Terraform configuration can be accessed using the Resource Manager API `GetJobTfConfig`, we recommend that you do not include sensitive information in your configuration files.

Addressing Basic Configuration Issues

This topic lists procedures to address common configuration issues that affect the security of your cloud resources.
Block Volume
Block volume detached from instance

**Issue:** Ensure that only Oracle Cloud Infrastructure administrators can detach block volumes from instances.

**Basics:** When you detach a block volume it decouples the volume from its associated instance, affecting the data available to the instance. This could impact data availability from business-critical data to the successful completion of scheduled volume backups. To minimize loss of data due to inadvertent volume detachments by an authorized user or malicious volume detachments you should restrict the `VOLUME_ATTACHMENT_DELETE` permission to administrators.

**To prevent detachment of block volumes:**
The following policy allows the group `VolumeUsers` to manage volumes and volume attachments except for detaching volumes:

```
Allow group VolumeUsers to manage volumes in tenancy
Allow group VolumeUsers to manage volume-attachments in tenancy
where request.permission!='VOLUME_ATTACHMENT_DELETE'
```

This change prevents `VolumeUsers` from detaching volumes from instances.

**More information:**
- [Securing Block Volume](#) on page 3675
- [Getting Started with Policies](#) on page 2135
- [How Policies Work](#) on page 2136
- [For volume-family Resource Types](#) on page 2219

Compute
Instance created based on unapproved custom image

**Issue:** An instance was created from a custom image that is unsupported in your environment.

**Basics:** When users create instances they can select from Oracle-provided images, boot volumes from terminated instances, or custom images. Custom images represent a wide variety of images which can include images that aren't approved for your environment. If you use tags in your Oracle Cloud Infrastructure tenancy to identify approved images, verify whether the image the instance is based on is an approved image and terminate the instance if necessary.

**To verify the tags for the image the instance was created from:**
The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.
3. Click the **Image** link to view the source image.
4. Click the **Tags** tab to view the tags applied to this image.

If the custom image does not have an approved tag, and the instance needs to be terminated, see [Terminating an Instance](#) on page 783.

**More information:**
- [Securing Compute](#) on page 3677
- [Resource Tags](#) on page 211
- [Creating an Instance](#) on page 695
- [Image Import/Export](#) on page 670
- [Bring Your Own Image (BYOI)](#) on page 675
I AM

Member of the Administrators group used API keys

Issue: A user who is a member of the Administrators group accessed resources using an API key.

Basics:

• API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
• For security and governance reasons, users should only have access to resources they need to interact with.
• For individuals who are members of the Administrators group who also need access to resources through the API, create another user in IAM to which you attach the API keys. Grant the user with the API keys permissions to only the resources they need to interact with programatically.

To create a user, group, and policy with limited permissions:

The following set of procedures shows you how to set up an example user with limited permissions. In this example, the user needs to be able to launch instances in a specific compartment.

The following procedure is for the Oracle Cloud Infrastructure Console.

Create a User

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users.
2. Click Create User.
3. In the New User dialog:
   • Name: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   • Description: Enter a description (required).
4. Click Create User.

Create a Group

Next, create the group ("InstanceLaunchers") that you will create the policy for.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups.
2. Click Create Group.
3. In the Create Group dialog:
   • Name: Enter a unique name for your group, for example, "InstanceLaunchers".
     Note that the name cannot contain spaces.
   • Description: Enter a description (required).
4. Click Create Group.

Create a Policy

In this example, the policy grants members of the group InstanceLaunchers permissions to launch instances in a specific compartment (CompartmentA).

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
2. Click Create Policy.
3. Enter a unique Name for your policy, for example, "InstanceLaunchersPolicy".
   Note that the name cannot contain spaces.
4. Enter a Description (required), for example, "Grants users permission to launch instances in CompartmentA".
5. Enter the following Statement:

   Allow group InstanceLaunchers to manage instance-family in compartment CompartmentA

This statement grants members of the InstanceLaunchers group permissions to launch and manage instances in the compartment called CompartmentA.
6. Click **Create Policy**.

**Add the User to the Group**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
2. In the **Users** list, find the user and click the name.
3. On the user detail page, click **Groups** (on the left side of the page). The list of groups that the user belongs to is displayed.
4. Click **Add User to Group**.
5. From the **Groups** list, select **InstanceLaunchers**.
6. Click **Add**.

**Upload an API signing key for the user**

The following procedure works for a regular user or an administrator. Administrators can upload an API key for either another user or themselves.

---

**Important:**

The API key must be an **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY-----
```

For more information about generating a public PEM key, see **Required Keys and OCIDs** on page 4179.

---

1. View the user's details:
   - If you're uploading an API key for your **self**:
     
     Open the **Profile** menu (🔍) and click **User Settings**.
   - If you're an administrator uploading an API key for another **user**: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add Public Key**.
3. Paste the key's value into the window and click **Add**.

**More information:**

- **Securing IAM** on page 3688
- **How Policies Work** on page 2136 and **Common Policies** on page 2142
- **Managing User Credentials** on page 2456
- **Managing Groups** on page 2419
- **Managing Users** on page 2414

**Policy grants broad permissions**

**Issue:** A policy grants full management permissions for at least one service in a compartment or in the tenancy.

**Basics:**

- Access to resources is controlled through policies. A **policy** is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a **group** to work in certain ways with specific types of **resources** in a particular **compartment**.
- For security and governance reasons, users should only have access to resources they need.
Consider carefully the access level a user needs. Policy language provides a default set of verbs (manage, use, read, inspect) that allow you to easily scope users' permissions to a set of common tasks. For example, if a user needs to be able to update resources, but does not need to create or delete them, grant them the use permission, rather than the manage permission.

The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the permissions in the statement. For more fine-grained access control, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

Wherever possible, scope access to the specific compartments a user needs access to, rather than scoping it to the full tenancy.

**Tips for writing least-privilege policies:**

**Scope the policy to a compartment instead of the tenancy**

Each policy consists of one or more policy statements that follow a basic syntax. Where possible, scope policies to compartments, rather than to the tenancy. For example, update a policy like this:

```
Allow group <group_name> to <verb><resource-type> in tenancy
```

to include just the compartments needed:

```
Allow group <group_name> to <verb><resource-type> in compartment <compartment_name>
```

If the user needs access to multiple compartments, create a policy statement for each compartment. It is then easy to remove access to individual compartments, if necessary.

**Scope permissions to those required to perform a job function**

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource.</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td>read</td>
<td>Includes inspect plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>Includes read plus the ability to work with existing resources (the actions vary by resource type). In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td>manage</td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

Users who don't need to create or delete resources generally don't need manage permissions. If you have a policy like

```
Allow group <group_name> to manage <resource-type> in compartment <compartment_name>
```

but the user will never create or delete the resource-type, consider rewriting the policy to

```
Allow group <group_name> to use <resource-type> in compartment <compartment_name>
```

The Policy Reference on page 2167 includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.
**Service-specific links**

- Details for the Search Service

**For fine-grained access control, scope access using conditions and API operations**

In a policy statement, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (change their description), but not delete them. To list, get, create, and update groups, you need a policy with manage groups as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations on page 2281, the permissions covered are:

- GROUP_INSPECT
- GROUP_UPDATE
- GROUP_CREATE
- GROUP_DELETE

To restrict access to only the desired permissions, you could add a condition that explicitly states the permissions you want to allow:

```
Allow group XYZ to manage groups in tenancy

where any 
{ request.permission='GROUP_INSPECT',
  request.permission='GROUP_CREATE',
  request.permission='GROUP_UPDATE'
}
```

An alternative would be a policy that allows all permissions except GROUP_DELETE:

```
Allow group XYZ to manage groups in tenancy where request.permission != 'GROUP_DELETE'
```

Another alternative would be to write a condition based on the specific API operations. Notice that according to the table in Permissions Required for Each API Operation on page 2288, both ListGroups and GetGroup require only the GROUP_INSPECT permission. Here's the policy:

```
Allow group XYZ to manage groups in tenancy

where any 
{ request.operation='ListGroups',
  request.operation='GetGroup',
  request.operation='CreateGroup',
  request.operation='UpdateGroup'
}
```

It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-based policy above, that policy will already control XYZ group's access to that new API operation.
But notice that you can further scope a user's access to a permission by also specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to ListGroups.

Allow group XYZ to manage groups in tenancy

where all {request.permission='GROUP_INSPECT', request.operation='ListGroups'}

API signing keys over 90 days old

**Issue:** A user's API signing keys are older than 90 days. Oracle recommends that you rotate API keys at least every 90 days.

**Basics:**
- API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
- It is a security engineering best practice and compliance requirement to rotate API keys regularly, every 90 days or less.
- Ensure that you test the new keys before you deactivate the old keys.

**To generate and upload new API keys:**

The following procedure is for the Oracle Cloud Infrastructure Console.

**Generate new API keys**

You can use the following OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool.

1. If you haven't already, create a .oci directory to store the credentials:

   ```bash
   mkdir ~/.oci
   ```

2. Generate the private key with one of the following commands.

   - Recommended: To generate the key, encrypted with a passphrase you provide when prompted:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```
     
     **Note:** For Windows, you may need to insert `-passout stdin` to be prompted for a passphrase. The prompt will just be the blinking cursor, with no text.
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 -passout stdin 2048
     ```

   - To generate the key with no passphrase:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Ensure that only you can read the private key file:

   ```bash
   chmod go-rwx ~/.oci/oci_api_key.pem
   ```
4. Generate the public key:

```bash
openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
```

**Note:** For Windows, if you generated the private key with a passphrase, you may need to insert `-passin stdin` to be prompted for the passphrase. The prompt will just be the blinking cursor, with no text.

```bash
openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem -passin stdin
```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:

```bash
cat ~/.oci/oci_api_key_public.pem | pbcopy
```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

**Get the key's fingerprint**

You can get the key's fingerprint with the following OpenSSL command.

**For Linux and Mac OS X:**

```bash
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

**For Windows:**

**Note:**

If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.

```bash
openssl rsa -pubout -outform DER -in \.\/oci\api_key.pem | openssl md5 -c
```

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: `12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef`

**Upload the API signing key for the user**

You can upload the PEM public key in the Console, located at [https://cloud.oracle.com](https://cloud.oracle.com). If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
   - If you're signed in as this user, click your username in the top-right corner of the Console, and then click **User Settings**.
   - If you're an administrator doing this for another user: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.
3. Click **Add Public Key**.
4. Paste the contents of the PEM public key in the dialog box and click **Add**.

The key's fingerprint is displayed (for example, `12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef`). Notice that after you've uploaded your first public key, you can also use the **UploadApiKey** API operation to upload additional keys.
You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

**Test the new key**

Test the key in a sample API call against Oracle Cloud Infrastructure.

**Delete the old key**

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.

1. View the user's details:
   - If you're deleting an API key for *yourself*:
     
     Open the **Profile** menu (🔗) and click **User Settings**.  
   - If you're an administrator deleting an API key for *another user*:
     
     Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. For the API key you want to delete, click **Delete**.

3. Confirm when prompted.

The API key is no longer valid for sending API requests.

**More information:**

- Securing IAM on page 3688
- API Signing Key on page 179

**Tenancy administrator privilege grant to an IAM group**

**Issue:** A group other than the Administrators group has been granted administrator privileges.

**Basics:**

- Granting the tenancy administrator privilege *(manage all-resources in tenancy)* to a group enables the members to have full access to all resources in the tenancy.
- This high-privilege entitlement must be controlled and restricted to only the users who need it to perform their job function.
- Verify with the Oracle Cloud Infrastructure administrator that this entitlement grant was sanctioned and that the membership of the group remains valid after the grant of the administrator privilege.
- Rather than create an alternative group with administrator privileges, consider instead adding users needing administrator privileges to the default Administrators group.

**To resolve this issue:**

Add users who need administrator privileges to the Administrators group:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
2. In the **Groups** list, click **Administrators**.
3. Click **Add User to Group**.
4. In the **Add User to Group** dialog, select the user from the **User** list.
5. Click **Add User**.

Remove the policy or policy statement that grants the (non-Administrators) group administration privileges.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
   
   If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the policy you want to update.
   
   The policy's details and statements are displayed.
3. Find the statement that grants administrator privileges to the group. This policy will look like:

```plaintext
Allow group <group_name> to manage all-resources in tenancy
```

Click the the Actions icon (three dots) and then click **Delete**.

4. If the policy has no other statements, you can delete the policy by clicking **Delete** next to the policy name.

**More information:**
- [Securing IAM](#) on page 3688
- [Managing Policies](#) on page 2450

**Networking: VCN, Load Balancers, and DNS**

**No ingress rules in security lists**

**Issue:** A VCN's security lists have no ingress rules. This means that the instances in the VCN can't receive incoming traffic.

**Basics:**
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

**To add an ingress rule to an existing security list:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Add at least one ingress rule:
   a. In the **Allow Rules for Ingress** section, click **+ Rule**.
   b. Choose whether it's a stateful or stateless rule (see [Stateful Versus Stateless Rules](#) on page 2839). By default, rules are stateful unless you specify otherwise.
   c. Enter the source CIDR. Typical CIDRs you might specify in a rule are the CIDR block for your on-premises network or a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see [Task 3: (Optional) Update security rules](#) on page 3261.
   d. Select the protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).
   e. Enter further details depending on the protocol:
      - If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20-22).
      - If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.
8. When you're done, click **Save Security List Rules**.
This change enables ingress access from the source CIDR block listed in the rule. Add additional rules if you want to allow ingress from other known sources.

More information:
- Securing Networking: VCN, Load Balancers, and DNS on page 3696
- Security Lists on page 2850
- UpdateSecurityList

Security list allows traffic from any IP address (open source)

Issue: A security list has at least one rule with an open source (0.0.0.0/0). This means that traffic could come from any source and is not controlled.

Basics:
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

To change the source of a security list rule:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
5. Click the security list you're interested in.
6. Click Edit All Rules.
7. Locate the rule that lists 0.0.0.0/0 as the source CIDR.
8. For that rule, change 0.0.0.0/0 to the CIDR block of a known source.

This change restricts ingress so packets are allowed only from a specific CIDR block. Add additional rules if you want to allow ingress from other known sources.

More information:
- Securing Networking: VCN, Load Balancers, and DNS on page 3696
- Security Lists on page 2850
- UpdateSecurityList

Security list allows traffic to sensitive ports

Issue: A security list has at least one rule that enables access to a sensitive port.

Basics:
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
• For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
• You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

Recommendation: Update the subnet's security list to enable access to instances through SSH (TCP port 22) or RDP (TCP port 3389) on a temporary, as-needed basis, and only from authorized CIDR blocks (not 0.0.0.0/0). To perform instance health checks, update the security list to allow ICMP pings.

**To change an existing security list:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Make one or more of these changes:
   • Delete an existing rule by clicking the X next to the rule.
   • Change an existing rule in the list. For example: change the source from 0.0.0.0/0 to the CIDR block of a known source.
   • Add a new rule by clicking + Rule and entering values for the new rule.
8. Click **Save Security List Rules**.

**More information:**

- [Securing Networking: VCN, Load Balancers, and DNS](#) on page 3696
- [To enable RDP access](#)
- Security Lists on page 2850
- UpdateSecurityList

**Internet gateway attached to VCN**

**Issue:** A VCN has an internet gateway. The gateway must be authorized to be attached to the VCN and must not unintentionally expose resources to the internet.

**Basics:**

• Gateways provide external connectivity to hosts in a VCN. For example: an internet gateway enables direct internet connectivity for instances that are in a public subnet and have a public IP address. A dynamic routing gateway (DRG) enables connectivity with the on-premises network over an IPSec VPN or FastConnect.
• To enable traffic through the internet gateway from a particular subnet in the VCN, there must be a rule in the subnet's route table that lists the internet gateway as a route target. To delete the internet gateway from the VCN, you must first delete any route rules that specify the internet gateway as the target.
• You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted VCNs.

**To remove an internet gateway from a VCN:**

Prerequisite: Ensure that there are no route rules that specify the internet gateway as a target.

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Internet Gateways**.
5. Click the Actions icon (three dots) for the internet gateway, and then click **Terminate**.
6. Confirm when prompted.

This change disables direct internet connectivity for the VCN.
Instance has a public IP

**Issue:** An instance has a public IP address. This means the instance could be publicly addressable if other required components are present and configured correctly in the VCN.

**Basics:**

- Carefully consider allowing internet access to any instances. For example, don't accidentally allow internet access to sensitive DB systems.
- For an instance to be publicly addressable:
  - The instance must have a public IP address and reside in a public subnet in the VCN (instances in private subnets cannot have public IP addresses).
  - The subnet's security list must be configured to allow traffic for all IPs (0.0.0.0/0) and all ports.
  - The VCN must have an internet gateway and be configured to route outbound traffic from the subnet to the internet gateway.
  - An instance can have more than one public IP address. A given public IP is assigned to a private IP on a particular VNIC on the instance. An instance can have more than one VNIC, and each VNIC can have more than one private IP.

**To remove a public IP address from an instance:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Confirm you're viewing the compartment that contains the instance you're interested in.
3. Click the instance to view its details.
4. Click **Attached VNICS**.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
   - The VNIC's primary private IP and any secondary private IPs are displayed.
6. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
7. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
8. Click **Update**.

The public IP is unassigned from the instance.

**More information:**

- Securing Networking: VCN, Load Balancers, and DNS on page 3696
- Internet Gateway on page 3243
- DeleteInternetGateway
- Public IP Addresses on page 2875

Load balancer has no inbound rules or listeners

**Issue:** A load balancer's subnet security lists have no ingress rules, or a load balancer has no listener. In this case, the load balancer can't receive incoming traffic.

**Basics:**

- Load balancers provide automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). Each load balancer exists in a subnet governed by security list rules. A load balancer receives incoming data traffic from one or more listeners.
- Security lists provide stateful and stateless firewall capability to control network access to your load balancer and backend servers.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, configure ingress security list rules to state a specific known source and not an open source (0.0.0.0/0).
- A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.
- To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.
- You can apply path route rules to a listener to route traffic to the correct backend set without using multiple listeners or load balancers. A path route is a string that the listener matches against an incoming URI to determine the appropriate destination backend set.
- Ensure that your Oracle Cloud Infrastructure load balancers use inbound rules or listeners to allow access only from known resources.
- Exceptions can be configured in CASB to reduce alerts from exempted load balancers.

To enable a listener to accept traffic:

The following procedure is for the Oracle Cloud Infrastructure Console.

To enable a listener to accept traffic, you must update your VCN's security list rules:

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   The list of VCNs in the current compartment appears.
2. Click the name of the VCN containing your load balancer, and then click Security Groups or Security Lists.
   A list of the security groups or lists in the cloud network appears.
3. Click the name of the NSG or security list that applies to your load balancer.
4. Add or edit the existing rules to allow access from the appropriate resources.
   An NSG's security rules appear on the Network Security Group Details page. From there you can add, edit, or remove rules.
   The Security List Details page provides access to separate tables in which you can add or edit Ingress Rules or Egress Rules.

   For details on rule configuration, see Security Rules on page 2833.

To create a listener:

Usually, you create a listener as part of the load balancer creation workflow. To create a listener for an existing load balancer:

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click Listeners under the Resources menu, then click Create Listener.
   The Create Listener dialog box appears.
4. Enter the following:

- **Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.
- **Hostname:** Optional. Select up to 16 virtual hostnames for this listener.

  | Important: |
  |
  | To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated hostnames, you can create one on the Hostnames page. |

- **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.
- **Port:** Required. Specify the port on which to listen for incoming traffic.
- **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the listener. The following settings are required to enable SSL handling. See Managing SSL Certificates on page 2551 for more information.

  - **Certificate Name:** The friendly name of the SSL certificate bundle to use.
  - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.
  - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.
- **Backend Set:** Required. Specify the default backend set to which the listener routes traffic.
- **Idle Timeout in Seconds:** Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

  | Tip: |
  |
  | The maximum value is 7200 seconds. For more information, see Connection Management on page 2489. |

- **Path Route Set:** Optional. Specify the name of the set of path-based routing rules that applies to this listener's traffic.

  | Important: |
  |
  | To apply a path route set to a listener, the set must be part of the load balancer's configuration. |
  | To remove a path route set from an existing listener, choose None as the Path Route Set option. The path route set remains available for use by other listeners on this load balancer. |

- **Show Advanced Options:** Click to display the following options:

  - **TLS Version:** Specify the Transport Layer Security (TLS) version(s):
    - 1.0
    - 1.1
    - 1.2 (recommended)

    You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

    - **Select Cipher Suite** - Select a set of cipher suites from the list. (default).
      
      All choices present in the list have at least one cipher associated with each TLS version you selected.

    - Click Show Cipher Suite Details to display the individual ciphers the selected cipher suite contains.
    - **Server Order Preference:** Select Enable to give preference to the server ciphers over the client.

5. Click Create.

When you create a listener, you must also update your VCN's security list rules to allow traffic to that listener.

More information:
Load balancer has no backend sets

**Issue:** A load balancer has no backend set. In this case, the load balancer has no place to distribute incoming data and no means to monitor backend server health.

**Basics:**
- A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers.
- The backend set determines the load balancer's traffic distribution policy, such as:
  - IP Hash
  - Least Connections
  - Weighted Round Robin
- You specify the test parameters to confirm the health of backend servers when you create a backend set.
- If you have an existing load balancer with no backend set, you can specify the backend servers that receive traffic from the load balancer after you create a backend set.
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

**To create a backend set:**

The following procedure is for the Oracle Cloud Infrastructure Console.

Usually, you create a backend set as part of the load balancer creation workflow. To create a backend set for an existing load balancer:

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click **Backend Sets** under the **Resources** menu, then click **Create Backend Set**.

   The **Create Backend Set** dialog box appears.
4. Enter the following:

- **Name:** Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.
  
  Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Traffic Distribution Policy:** Required. Choose the load balancer policy for the backend set. The available options are:
  
  - IP Hash
  - Least Connections
  - Weighted Round Robin

  For more information on these policies, see How Load Balancing Policies Work on page 2488.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot add a backend server marked as Backup to a backend set that uses the IP Hash policy.</td>
</tr>
</tbody>
</table>

- **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the backend set.
  
  If there are no certificate bundles attached to the load balancer, this option is disabled.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you check Use SSL, the SSL Policies fields appear at the bottom of the page.</td>
</tr>
</tbody>
</table>

  - **Certificate Name:** Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See Managing SSL Certificates on page 2551 for more information.

  - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.

  - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.

  - **Session Persistence:** Optional. Specify how the load balancer manages session persistence.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>See Session Persistence on page 2491 for important information on configuring these settings.</td>
</tr>
</tbody>
</table>

  - **Disable Session Persistence:** Choose this option to disable cookie-based session persistence.

  - **Enable Application Cookie Persistence:** Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a Set-cookie header with the cookie name you specify.

  - **Cookie Name:** The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.

  - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.

  - **Enable Load Balancer Cookie Persistence:** Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.

  - **Cookie Name:** Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is X-Oracle-BMC-LBS-Route.

    Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.

  - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.

  - **Domain Name:** Optional. Specify the domain in which the cookie is valid.

    This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.
• **Path:** Optional. Specify the path in which the cookie is valid. The default value is /.

• **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

• **Attributes**
  - **Secure:** Specify whether the Set-cookie header should contain the Secure attribute. If selected, the client sends the cookie only using a secure protocol.
    
    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.

  - **HTTP Only:** Specify whether the Set-cookie header should contain the HttpOnly attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

• **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.

  - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure your health check protocol to match your application or service.</td>
</tr>
</tbody>
</table>

  - **Port:** Optional. Specify the backend server port against which to run the health check.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can enter the value '0' to have the health check use the backend server's traffic port.</td>
</tr>
</tbody>
</table>

  - **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.

  - **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

  - **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

  - **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. The default is '3'.

  - **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.

  - **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

• **SSL Policy:** Optional. Specify the type of cipher suite to use:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You must check Use SSL for the SSL Policy features to be displayed.</td>
</tr>
</tbody>
</table>

  - **TLS Version:** Optional. Specify the Transport Layer Security (TLS) version(s):

    - 1.0
    - 1.1
    - 1.2 (recommended)

    You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

  - **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

    All choices present in the list have at least one cipher associated with each TLS version you selected.

    - Click Show Cipher Suite Details to display the individual ciphers the selected cipher suite contains.

5. **Click Create.**
After your backend set is provisioned, you must specify backend servers for the set. See Managing Backend Servers on page 2515 for more information.

More information:

- Securing Networking: VCN, Load Balancers, and DNS on page 3696
- Managing Backend Sets on page 2510
- Editing Health Check Policies on page 2558
- Managing Load Balancers on page 2494

Load balancer SSL certificate expires in X days

Issue: A load balancer's SSL certificate expires soon. When the certificate expires, data traffic can be interrupted and security compromised.

Basics:

- To ensure continuous security and usability, SSL certificates must be rotated on a timely basis.
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

To rotate a load balancer's certificate bundle:

The following procedure is for the Oracle Cloud Infrastructure Console.

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

Note:
The steps to update your client or backend server are unique to your system.
2. Upload the new SSL certificate bundle to the load balancer

   a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

   b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

   c. Click the load balancer you want to configure.

   d. In the **Resources** menu, click **Certificates**, and then click **Add Certificate**.

   e. In the **Add Certificate** dialog box, enter the following:

      - **Certificate Name**: Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.

      - **Choose SSL Certificate File**: Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field. Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

      - **Specify CA Certificate**: Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.

         - **Choose CA Certificate File**: Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field. Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.

      - **Specify Private Key**: Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.

         - **Choose Private Key File**: Drag and drop the private key, in PEM format, into the **Private Key** field. Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.

      - **Enter Private Key Passphrase**: Optional. Specify the private key passphrase.

   f. Click **Add Certificate**.
3. Edit listeners or backend sets (as needed) so they use the new certificate bundle

   Editing a listener:
   a. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
   b. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. In the Resources menu, click Listeners.
   d. For the listener you want to edit, click the Actions icon (three dots), and then click Edit Listener.
   e. In the Certificate Name drop-down list, choose the new certificate bundle.
   f. Click Submit.

   Editing a backend set:
   Caution:
   Updating the backend set temporarily interrupts traffic and can drop active connections.

   a. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
   b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. In the Resources menu, click Backend Sets, and then click the name of the backend set you want to edit.
   d. Click Edit Backend Set.
   e. In the Edit Backend Set dialog box, select (check) Use SSL.
   f. In the Certificate Name drop-down list, choose the new certificate bundle.
   g. Click Save Changes.

4. (Optional) Remove the expiring SSL certificate bundle

   Important:
   You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.

   a. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
   b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. Click the load balancer you want to configure.
   d. In the Resources menu, click Certificates.
   e. For the certificate you want to delete, click the Actions icon (three dots), and then click Delete.
   f. Confirm when prompted.

More information:

- Securing Networking: VCN, Load Balancers, and DNS on page 3696
- Managing SSL Certificates on page 2551

Object Storage

Public buckets detected

**Issue:** Public buckets were detected in your tenancy. Confirm that the creation of each public bucket is intentional and authorized. If the bucket is not sanctioned for public access, follow the procedure for changing the visibility of a bucket and make the bucket private.

**Basics:**

- Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, users can obtain object metadata, download bucket objects, and optionally list bucket contents.
- Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
- Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

**To change the visibility of a bucket (private or public):**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the bucket name to see the bucket details.

   **Visibility:** shows the current bucket setting, which is **Private** by default.

3. Click **Edit Visibility**.

4. In the **Edit Visibility** dialog box, edit the visibility settings:

   - **Visibility**
     - **Public**
     - **Private**
   - If you select **Public** to enable public access, decide whether you want to let users list the bucket contents. To set the visibility of bucket object lists, click **Allow users to list objects from this bucket**.

5. Click **Save Changes**.

**More information:**

- [Securing Object Storage](#) on page 3700
- [Managing Buckets](#) on page 3398
- [Using Pre-Authenticated Requests](#) on page 3482

**Oracle Cloud Security Response to Intel L1TF Vulnerabilities**

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see [Vulnerability Note VU#584653](#). These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

However, vulnerability CVE-2018-3620 could enable a rogue user mode process to read privileged kernel memory within the same virtual machine. As a result, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

Oracle Cloud Infrastructure Compute

For details and required actions related to the Compute service's VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service on page 3726.

Oracle Cloud Infrastructure Database

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to Oracle Cloud Infrastructure offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service on page 3730.

Platform Service and Kubernetes Services on Oracle Cloud Infrastructure

Oracle has deployed technical mitigations designed to prevent malicious attacker’s VM instance from accessing data from other VM instances on the same hypervisor.

However, vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems you're advised to keep up with the OS security patches to address this vulnerability.

Other Oracle Cloud Infrastructure Services

Mitigations designed to protect all other Oracle Cloud Infrastructure services have been deployed. Oracle will notify and coordinate directly with customers for any additional required maintenance activities.

Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic

For more information see Oracle Cloud Infrastructure Classic.

Oracle is deploying technical mitigations designed for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic. Some customers may experience reboots or downtime associated while deploying these mitigations.

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems you're advised to keep up with the OS security patches to address this vulnerability.

Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
• CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
• CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 3725 for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

You should be aware that the vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system (OS). As a result, you are advised to keep up with OS security patches to address this vulnerability. See Protecting your Compute Instance Against the L1TF Vulnerability on page 3727 for instructions to patch the OS on the instances you manage.

Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances

Bare metal instances in Oracle Cloud Infrastructure offer you full control of a physical server. Oracle Cloud Infrastructure’s network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

If you're running your own virtualization stack or hypervisors on bare metal instances, the L1TF vulnerability allows a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. You should review the Intel recommendations about vulnerabilities CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646, and make changes to your configurations as you deem appropriate.

Protecting your Compute Instance Against the L1TF Vulnerability

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors, for more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

• CVE-2018-3615 which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
• CVE-2018-3620 which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
• CVE-2018-3646 which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 3725 for more information.

Recommended Action

Oracle recommends that you patch the operating systems for your existing bare metal and virtual machine (VM) instances, and verify that this includes the patch for the CVE-2018-3620 vulnerability. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate the CVE-2018-3646 vulnerability. For bare metal instances using virtualization technology, you should also follow these instructions to ensure that they are mitigated against the CVE-2018-3646 vulnerability.

If you're running your own virtualization stack or hypervisors on bare metal instances, you should apply the patch for the CVE-2018-3646 vulnerability.

The following Oracle-provided image releases have been updated with the recommended patches, so instances created from these images or new image releases include the recommended patches for the L1TF vulnerability.

Oracle-provided images updated with recommended patches for the L1TF vulnerability:
Note:

Protections against the L1TF vulnerabilities are enabled by default in Oracle Linux 8, CentOS 8, and Windows Server 2019.

- Oracle-Linux-7.5-2018.08.14-0
- Oracle-Linux-7.5-Gen2-GPU-2018.08.14-0
- Oracle-Linux-6.10-2018.08.14-0
- CentOS-7-2018.08.15-0
- CentOS-6.10-2018.08.15-0 (end of support)
- Canonical-Ubuntu-18.04-2018.08.15-0
- Canonical-Ubuntu-16.04-2018.08.15-0
- Canonical-Ubuntu-16.04-Gen2-GPU-2018.08.15-0
- Canonical-Ubuntu-14.04-2018.08.15-0 (end of support)
- Windows-Server-2016-Standard-Edition-VM-Gen2-2018.08.16-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-2018.08.16-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-DenseIO-2018.08.16-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-2018.08.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-DenseIO-2018.08.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-2018.08.15-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-2018.08.15-0 (end of support)
- Windows-Server-2008-R2-Enterprise-Edition-VM-Gen2-2018.08.15-0 (end of support)

For your running instances created from imported custom images, refer to the operating system (OS) vendor's guidance to patch the OS for the L1TF vulnerability.

**Patching Oracle Linux Instances**

For Oracle Linux, the patches for the CVE-2018-3620 and CVE-2018-3646 vulnerabilities are addressed by the same set of patches.

Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances.

To install the latest microcode updates, run the following command:

```
# sudo yum update microcode_ctl
```

The microcode RPM should be greater than or equal to microcode_ctl-2.1-29.2.0.4.e17_5.x86_64.rpm. This is the version of the microcode package that shipped for the Spectre v3a and Spectre v4 updates. No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

**To patch the OS for bare metal and VM instances with downtime**

The yum-plugin-security package allows you to use yum to obtain a list of all of the errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the **yum-plugin-security** package, run the following command:

```
# sudo yum install yum-plugin-security
```
2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

```
# sudo yum updateinfo list --cve CVE-2018-3620
# sudo yum update --cve CVE-2018-3620
```

A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using `yum update`, visit Installing and Using the Yum Security Plugin.

3. After the system reboots, ensure that the following file is populated.

```
cat /sys/devices/system/cpu/vulnerabilities/l1tf
```

Patching Windows Instances

Protecting New Windows VM and Bare Metal Instances

When you create a new VM or bare metal instance based on the latest Oracle-provided Windows images, the image includes the Microsoft-recommended patches to protect against the L1TF vulnerability. Windows bare metal instances also include the latest microcode updates from Intel.

There is no further action required from you to protect your new Windows-based VM or bare metal instances from the L1TF vulnerability. You should ensure that you keep the your instances updated with the latest patches as recommended by your OS vendor.

Protecting Existing Windows VM and Bare Metal Instances

To update the microcode for existing bare metal instances

Bare metal instances launched before the Oracle-provided Windows images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images on page 668 for more information.
2. Terminate your existing Windows bare metal instance.
3. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images. Find the custom image you want to use.
4. Click the Actions icon (three dots), and then click Create Instance.
5. Provide additional launch options as described in Creating an Instance on page 695.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft.

To patch the OS for bare metal and VM instances with downtime

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images on page 636 and Security Lists on page 2850 for more information.

1. Verify that you have installed the latest Windows OS security update from Microsoft.
   a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
   b. To manually check for the latest update, select Start.
   c. In Settings select Updates & security and then select Windows Update.
   d. In Windows Update, click Check for updates.
   e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see Windows Update: FAQ.
For additional details see Windows Server guidance to protect against L1 terminal fault.

**Patching Ubuntu or CentOS Instances**

When you create a new VM or bare metal instance based on the latest Oracle-provided Ubuntu or CentOS images, the image includes the recommended patches to protect against the L1TF vulnerability, see for more information L1 Terminal Fault (L1TF) and L1TF - L1 Terminal Fault Attack - CVE-2018-3620 & CVE-2018-3646.

For existing VM or bare metal instances you should follow the guidance provided by the OS vendor for patching systems.

**Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service**

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 3725 for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

**Autonomous Data Warehouse and Autonomous Transaction Processing**

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads. Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads. Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by the L1TF vulnerabilities, CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646. No further action is required by customers.

**Guidance for the Database Service on Bare Metal Instances**

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access from other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

**Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems**

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system. As a result, you need to patch these systems once these patches are available. These patches will be available shortly and Oracle will update this page when the operating system (OS) patches are published. Oracle will update the Database base images with the latest patches for new instance launches.

Once the patches are available, use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in Updating a DB System on page 1397.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure Database service, apply the OS patches following the instructions in Updating a DB System on page 1397.
- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in Applying Linux OS Security Patches by Using the dbaascli Utility.
For Exadata DB systems, apply the OS patches following the instructions in Updating an Exadata Cloud Service Instance on page 1274.

Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

However, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

Oracle Cloud Infrastructure Compute

For details and required actions related to the Compute service’s VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service on page 3732.

Oracle Cloud Infrastructure Database

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service on page 3735.

Oracle Cloud Infrastructure Container Engine for Kubernetes

To help secure your existing worker nodes for the Oracle Cloud Infrastructure Container Engine for Kubernetes Oracle recommends replacing your current node pools with new node pools. Please follow the instructions described in Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 930. All worker nodes created or upgraded after May 14th, 2019 are not impacted by this security issue.

Other Oracle Cloud Infrastructure Services

Technical mitigations designed to protect all other Oracle Cloud Infrastructure services against the MDS processor vulnerabilities have been deployed. Oracle will notify customers if additional maintenance activities are required.

Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic

For more information see Oracle Cloud Infrastructure Classic.

In response to the MDS processor vulnerabilities, Oracle is performing mandatory maintenance for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic.
Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems, you are advised to keep up with the appropriate OS security patches to address these vulnerabilities.

**Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service**

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see [https://blogs.oracle.com/security/intelmds](https://blogs.oracle.com/security/intelmds).

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

You are advised to keep up with OS security patches to address this vulnerability. See Oracle Cloud Infrastructure Compute Content Impact on page 3732 for instructions to patch the OS on the instances you manage.

**Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances**

Bare metal instances in Oracle Cloud Infrastructure offer customers full control of a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

However, for customers running their own virtualization stack on bare metal instances, the MDS vulnerabilities could allow a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. These customers should review Intel’s recommendations about these MDS vulnerabilities and make the recommended changes to their configurations, [https://www.intel.com/content/www/us/en/security-center/advisory/intel-sa-00233.html](https://www.intel.com/content/www/us/en/security-center/advisory/intel-sa-00233.html).

**Oracle Cloud Infrastructure Compute Content Impact**

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see [https://blogs.oracle.com/security/intelmds](https://blogs.oracle.com/security/intelmds).

**Recommended Action**

Oracle recommends that customers patch the operating systems for their existing bare metal and virtual machine (VM) instances and verify that these OS updates include the patch for the MDS vulnerabilities. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate for the MDS vulnerabilities. For bare metal instances using virtualization technology, you should also follow the following instructions:

If you are running your own virtualization stack or hypervisors on bare metal instances, you should apply the appropriate patch required to address the MDS processor vulnerabilities.

The information in the following sections detail the commands needed to update your running instances created with Oracle-Provided Images on page 629.
The following Oracle-provided image releases have been updated with the recommended patches, as a result instances created using these images or subsequent images include the recommended patches for the MDS vulnerabilities.

Oracle-provided images updated with recommended patches for the MDS vulnerability

<table>

- Canonical-Ubuntu-16.04-Gen2-GPU-2019.05.15-0
- Canonical-Ubuntu-16.04-Minimal-2019.05.15-0
- Canonical-Ubuntu-18.04-2019.05.15-0
- Canonical-Ubuntu-18.04-Minimal-2019.05.15-0

Customers running instances created from imported third-party images should refer to the operating system (OS) vendor's guidance to patch the OS for the MDS vulnerability.

Patching Oracle Linux Instances

Oracle has released security patches for Oracle Linux 6, Oracle Linux 7, and Oracle VM Server for X86 products. In addition to the OS patches, customers should run the latest version of the microcode from Intel to mitigate these issues. For both bare metal and VM instances, please install the latest Ksplice via uptrack-upgrade.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>See Installing Ksplice Utrack Within the Oracle Cloud Infrastructure for how to install Ksplice.</td>
</tr>
</tbody>
</table>

For Oracle Linux, the patches for the MDS vulnerabilities are addressed by the same set of patches. For further information please see the following:

Oracle Cloud Infrastructure User Guide 3733
Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances. To install the latest microcode updates on bare metal instances, run the following command:

```
# sudo yum update microcode_ctl
```

The required versions of microcode_ctl rpms are:

- **Oracle Linux 7**: microcode_ctl 2.1-47.0.4
- **Oracle Linux 6**: microcode_ctl 1.17-1002

No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

**To patch the OS for bare metal and VM instances with downtime**

The `yum-plugin-security` package allows you to use yum to obtain a list of all errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the `yum-plugin-security` package, run the following command:

   ```
   # sudo yum install yum-plugin-security
   ```

2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

   ```
   # sudo yum updateinfo list --cve CVE-####-####
   # sudo yum update --cve CVE-####-####
   ```

   Replace `####-####` in the above commands with the relevant CVE numbers.

3. A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using yum update, visit Installing and Using the Yum Security Plugin.

4. After the system reboots, ensure that the following file is populated:

   ```
   cat /sys/devices/system/cpu/vulnerabilities/mds
   ```

**Patching Windows Instances**

**Protecting New Windows VM and Bare Metal Instances**

When you create a new VM or bare metal instance based on the latest Oracle-provided Windows images, the image includes the Microsoft-recommended patches to protect against the MDS vulnerability. Windows bare metal instances also include the latest microcode updates from Intel. To apply the MDS patch install the latest Windows updates and reboot the instance. You should ensure that you keep your instances updated with the latest patches as recommended by your OS vendor.

**Protecting Existing Windows VM and Bare Metal Instances**

To update the microcode for existing bare metal instances

Bare metal instances launched before the Oracle-provided Windows images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images on page 668 for more information.
2. Terminate your existing Windows bare metal instance.
3. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images. Find the custom image you want to use.
4. Click the Actions icon (three dots), and then click Create Instance.
5. Provide additional launch options as described in Creating an Instance on page 695.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft.

To patch the OS for bare metal and VM instances with downtime:

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images and Security Lists for more information.

1. Verify that you have installed the latest Windows OS security update from Microsoft.
   a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
   b. To manually check for the latest update, select Start.
   c. In Settings select Updates & security and then select Windows Update.
   d. In Windows Update, click Check for updates.
   e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see Windows Update: FAQ.

For additional details see Windows Server guidance to protect against speculative execution side-channel vulnerabilities.

Patching Ubuntu or CentOS Instances

The recommended patches to protect against the MDS vulnerabilities are included when you create a new VM or bare metal instance based on the latest Oracle-provided Ubuntu or CentOS images, see Microarchitectural Data Sampling (MDS) and MDS - Microarchitectural Store Buffer Data - CVE-2018-12130, CVE-2018-12126, CVE-2018-12127, and CVE-2019-11091. For existing VM or bare metal instances you should follow the patching guidance provided by the original OS vendor.

Note:

Any images published after May 14, 2019 listed in the image release notes will include the MDS patches. If using earlier images already launched, follow patching instructions.

Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service

Intel disclosed 4 new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

Autonomous Data Warehouse and Autonomous Transaction Processing

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads.
Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads.

Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by MDS vulnerabilities. These services do not run on their own hypervisor and they do not allow for the execution of untrusted code in their services enclave. Customers can execute code within their own instances and each customer instance is isolated from that of another customer. No further customer action is currently required.

**Guidance for the DatabaseService on Bare Metal Instances**

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access from other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances. As a result, the Database service on bare metal instances are not affected by the MDS vulnerabilities.

**Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems**

Customers are advised to apply available patches at the earliest possible time. Use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in Updating a DB System on page 1397.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure Database service, apply the OS patches following the instructions in Updating a DB System on page 1397.
- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in Applying Linux OS Security Patches by Using the dbaascli Utility.
- For Exadata DB systems, apply the OS patches following the instructions in Updating an Exadata Cloud Service Instance on page 1274.
Chapter 34

Security Advisor

This chapter explains how to use Security Advisor to create more secure resources.

Overview of Security Advisor

Oracle Cloud Infrastructure Security Advisor supports and reinforces what's required of the tenancy by Security Zones configurations. It does this by combining and streamlining existing workflows to efficiently create resources that meet baseline security requirements from the outset. Specifically, you can assign a new customer-managed encryption key to a resource at the time that you create the resource, even if you've never created a vault or encryption key before. Security zones require encryption using customer-managed keys where possible because no one but an authorized user can access the keys, thereby resulting in sensitive data that can only be decrypted and read by those explicitly allowed.

Streamlined workflows reduce complexity and decision-making. Where you would otherwise need to choose between configuration settings, Security Advisor provides only the more secure option. For example, Security Advisor only allows you to create master encryption keys that are 256 bits in length. Longer encryption keys provide greater security than shorter ones.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Security Advisor leverages the functionality of existing workflows, so the tenancy might not need new policies to grant permissions beyond what's already in place. To be sure, you can compare the tenancy's existing policies with the example permissions described in the chosen workflow. In particular, confirm that you have policies that grant access to Vault resources, especially if you haven't used the service previously.

The example policy statements make it possible for the specified groups to do anything allowed by Security Advisor. If, instead, you wanted to limit the creation of new vaults, you can write a policy that grants permission only to use vaults, rather than the level of access required to manage vaults. With permission to use vaults, a user can select an existing vault, but cannot create a new one. This does not change the options that Security Advisor presents, but it does affect whether all operations succeed when submitted.
Regions and Availability Domains

You can use Security Advisor in all Oracle Cloud Infrastructure commercial regions. For a list of regions, along with associated locations, region identifiers, region keys, and availability domains, see About Regions and Availability Domains on page 180.

Each service that integrates with Security Advisor has a single regional endpoint for all API operations, with one exception. The Vault service has one regional endpoint for the provisioning service that handles create, update, and list operations for vaults. For create, update, and list operations for keys, service endpoints are distributed across multiple independent clusters.

Limits on Resources

Security Advisor does not introduce resources and does not impose restrictions on your usage level of any resource. Security Advisor does, however, respect the limits instituted by other services.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

For instructions to view your usage level against the tenancy's resource limits, see Viewing Your Service Limits, Quotas, and Usage on page 216. For vaults, you can also get each individual vault's usage against key limits by viewing key and key version counts in the vault details.

Creating a Secure Bucket

This topic describes how to use Security Advisor to create a secure bucket. In this context, a secure bucket is one that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the bucket, but also the Vault key that you want to use to encrypt the bucket, and then assigning the key to the bucket. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Object Storage security features and best practices, and then implement them with your newly created resource. For more information, see Securing Object Storage on page 3700 and Using Your Own Keys for Server-Side Encryption on page 3491.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators:

- The following policy lets the specified group do everything with buckets and objects in the specified compartment:

  Allow group CreateSecureOSBucketGroup to manage object-family in compartment CompartmentABC

- The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the bucket compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

  Allow group CreateSecureOSBucketGroup to manage vaults in compartment CompartmentDEF
The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```
Allow group CreateSecureOSBucketGroup to manage keys in compartment CompartmentDEF
```

The following policy lets the Object Storage service list, view, and perform cryptographic operations with all keys in the specified compartment:

```
Allow service ObjectStorage-<region_name> to use keys in compartment CompartmentDEF
```

In the preceding example, replace `<region_name>` with the appropriate region identifier, for example:

- objectstorage-us-phoenix-1
- objectstorage-us-ashburn-1
- objectstorage-eu-frankfurt-1
- objectstorage-uk-london-1
- objectstorage-ap-tokyo-1

To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 180.

For more information about how policies work, see How Policies Work on page 2136.

**Using the Console**

**To create a secure bucket**

1. Open the navigation menu. Under the Governance and Administration group, go to Security, and click Overview.
2. Click Create Secure Bucket.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault, click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 3953.
6. When you're ready, click Next.
7. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
9. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 3986.
10. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure
if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.

10. On the Create Bucket page, specify the attributes of the bucket:

- **Bucket Name:** The system generates a default bucket name that reflects the current year, month, day, and time, for example `bucket-20190306-1359`. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.

- **Create in Compartment:** The compartment where you want the bucket to reside. This does not need to be the same compartment as the vault and key.

- **Storage Tier:** Select the tier in which you want to store your data. Available tiers include:
  - **Standard** is the primary, default Object Storage tier for storing frequently accessed data that requires fast and immediate access.
  - **Archive** is a special tier for storing infrequently accessed data that requires long retention periods. Access to data in the Archive tier is not immediate. Archived data must be restored before the data is accessible. For more information, see “Overview of Archive Storage on page 484” in the Oracle Cloud Infrastructure User Guide.
  - **Object Events:** Select Emit Object Events if you want to enable the bucket to emit events for object state changes. For more information about events, see Overview of Events on page 1784.
  - **Object Versioning:** Select Enable Object Versioning if you want Object Storage to create an object version each time the content changes or the object is deleted. For more information, see Using Object Versioning on page 3446.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

When you're ready, click **Next**.

11. Review the summary of the resources that Security Advisor will create, and then click **Create Secure Bucket**.

### Creating a Secure File System

This topic describes how to use Security Advisor to create a secure file system. The process involves creating not only the file system, but also the Vault key that you want to use to encrypt the file system, and then assigning the key to the file system. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a file system comes with some limitations. You cannot use Security Advisor to create a file system with a new mount target. You must reuse an existing mount target.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure File Storage security features and best practices, and then implement them with your newly created resources. For more information, see Securing File Storage on page 3687 and About Security on page 1925.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators:

- The following policy lets the specified group do everything with file systems and mount targets in the specified compartment:

```plaintext
Allow group CreateSecureFileStorageGroup to manage file-family in compartment CompartmentABC
```
The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the file system compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

```
Allow group CreateSecureFileStorageGroup to manage vaults in compartment CompartmentDEF
```

The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```
Allow group CreateSecureFileStorageGroup to manage keys in compartment CompartmentDEF
```

The following policy lets the File Storage service list, view, and perform cryptographic operations with all keys in the specified compartment:

```
Allow service FssOciProd to use keys in compartment CompartmentDEF
```

In the preceding example, the policy refers to the File Storage service by the service principal name FssOciProd.

For more information about how policies work, see How Policies Work on page 2136.

**Using the Console**

**To create a secure file system**

1. Open the navigation menu. Under the Governance and Administration group, go to Security, and click Overview.
2. Click Create Secure File System.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 3953.
6. When you're ready, click Next.
7. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
9. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 3986.
10. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.
10. On the **Create File System** page, specify the attributes of the file system:

- **File System Information:**
  - **Compartment:** The compartment where you want the file system to reside. You must choose a compartment where you have the required existing mount target.
  - **Name:** File Storage creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system. Avoid entering confidential information.
  - **Availability domain:** The availability domain within the current region where you want to place the file system.
  - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Export Information**
  Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.

  - **Export Path:** The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

    **Important:**
    The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

    Acceptable:
    
    `/example` and `/path`
    `/example` and `/example2`

    Not Acceptable:
    
    `/example` and `/example/path`
    `/ and /example`
    `/example/`
    `/example/path/ ../example1`

    **Caution:**
    If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

    **Note:**
    Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the
For more information, see Paths in File Systems on page 2006.

- **Use Secure Export Options:** Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options on page 1934 for more information.

  **Caution:** Leaving the Use Secure Export Options setting unselected lets unprivileged users read and modify any file or directory on the target file system.

- **Mount Target Information:**

  File systems must be associated with a mount target to be mounted by an instance. If you don't have a mount target in the selected availability domain in the compartment, you must choose a different availability domain or create the file system in a compartment and availability domain where you do have a mount target.

  When you're ready, click **Next**.

11. Review the summary of the resources that Security Advisor will create, and then click **Create Secure File System**.

**Creating a Secure Virtual Machine Instance**

This topic describes how to use Security Advisor to create a secure virtual machine (VM) instance. In this context, a secure instance is one with a boot volume that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the instance and associated boot volume, but also the Vault key that you want to use to encrypt the volume, and then assigning the key to the volume. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a virtual machine instance comes with some limitations. They include the following:

- You cannot configure private or public IP addresses for an instance.
- You cannot change the image build. It will always use the latest version.
- You cannot launch the instance on a dedicated virtual machine host, which lets you run the instance in isolation so that it is not running on shared infrastructure.
- You cannot specify the volume performance settings for the boot volume.
- You cannot use Security Advisor to generate SSH keys for you if you want to remotely connect to the instance by using Secure Shell (SSH). You must generate your own SSH keys and have the public key available when you create the instance.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Compute and Oracle Cloud Infrastructure Block Volume security features and best practices, and then implement them with your newly created resources. For more information, see Securing Compute on page 3677, Securing Block Volume on page 3675, and Best Practices for Your Compute Instance on page 594.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators:
Security Advisor

- The following policy lets the specified group list and use all components in Networking in the specified compartment. This includes virtual cloud networks (VCNs), subnets, gateways, virtual circuits, security lists, route tables, and so on.

```
Allow group CreateSecureVMGroup to use virtual-network-family in compartment CompartmentABC
```

- The following policy lets the specified group create and manage instance images in the specified compartment:

```
Allow group CreateSecureVMGroup to manage instance-family in compartment CompartmentABC
```

- The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the instance compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

```
Allow group CreateSecureVMGroup to manage vaults in compartment CompartmentDEF
```

- The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```
Allow group CreateSecureVMGroup to manage keys in compartment CompartmentDEF
```

- The following policy lets the Block Volume service list, view, and perform cryptographic operations with all keys in the specified compartment. The Block Volume service is responsible for the boot volume attached to the instance.

```
Allow service blockstorage to use keys in compartment CompartmentDEF
```

For more information about how policies work, see How Policies Work on page 2136.

Using the Console

To create a secure virtual machine instance

1. Open the navigation menu. Under the Governance and Administration group, go to Security, and click Overview.
2. Click Create Secure Bucket.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 3953.
6. When you're ready, click Next.
7. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
8. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 3986.

9. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.

10. On the Create Compute Instance page, specify the attributes of the instance:

   - **Name**: A display name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.
   - **Create in Compartment**: The compartment where you want to create the instance. This does not need to be the same compartment as the vault and key.
   - **Image or Operating System**: By default, an Oracle Linux 7.x image is used to boot the instance. You cannot use Security Advisor to create a virtual machine instance with a different image.
   - **Availability Domain**: The availability domain where you want to create the instance.
   - **Shape**: The default shape for the selected image and availability domain combination. You cannot use Security Advisor to create a virtual machine instance with a different shape. For more information about shapes, see Compute Shapes on page 655.

11. In the Configure networking section, configure the network details for the instance:

   - **Virtual cloud network compartment**: The compartment containing the network in which to create the instance.
   - **Virtual cloud network**: The network in which to create the instance. You can only choose an existing virtual cloud network (VCN). You cannot use Security Advisor to create a new VCN. If you have a VCN in a different compartment, click Change compartment, and then select a different compartment.
   - **Subnet**: A subnet within the cloud network to attach the instance to. Subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For a more secure instance, we recommend that you choose a private subnet. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.
   - **By default, when you create an instance in a public subnet, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. You cannot use Security Advisor to create a virtual machine instance with a public IP address.**

12. In the Boot volume section, configure the size and encryption options for the instance's boot volume:

   - **To specify a custom size for the boot volume, select the Specify a custom boot volume size check box. Then, enter a custom size from 50 GB to 32 TB.** The specified size must be larger than the default boot volume size for the selected image. See Custom Boot Volume Sizes on page 610 for more information.
   - **To encrypt data while the data is in transit between the instance and the attached boot volume, select the Use in-transit encryption check box.** The Vault service encryption key that you use to encrypt the boot volume data at rest will also be used for in-transit encryption. For more information, see Block Volume Encryption on page 504. Security zones require data to be encrypted in-transit, so you must select this check box to comply with security zone requirements.
13. In the **Add SSH keys** section, generate an SSH key pair or upload your own public key. Select one of the following options:

- **Choose SSH key files**: Upload the public key portion of your key pair. Either browse to the key file that you want to upload, or drag and drop the file into the box. To provide multiple keys, press and hold down the Command key (on Mac) or the CTRL key (on Windows) while selecting files.
- **Paste SSH keys**: Paste the public key portion of your key pair in the box.
- **No SSH keys**: Select this option only if you do not want to connect to the instance using SSH. You cannot provide a public key or save the key pair that is generated by Oracle Cloud Infrastructure after the instance is created.

14. Optionally, to configure tags, click **Show Tagging Options**. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

15. Review the summary of the resources that Security Advisor will create, and then click **Create Secure Instance**.

### Creating a Secure Block Volume

This topic describes how to use Security Advisor to create a secure block volume. In this context, a secure block volume is one that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the block volume, but also the Vault key that you want to use to encrypt the volume, and then assigning the key to the volume. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a block volume comes with some limitations. You cannot use Security Advisor to create a block volume with a backup policy. See **Policy-Based Backups** on page 547 for more information about backup policies.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Compute and Oracle Cloud Infrastructure Block Volume security features and best practices, and then implement them with your newly created resources. For more information, see **Securing Compute** on page 3677, **Securing Block Volume** on page 3675, and **Best Practices for Your Compute Instance** on page 594.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators:

- The following policy lets the specified group do everything with block storage volumes, volume backups, and volume groups in the specified compartment:

  ```
  Allow group CreateSecureBlockVolumeGroup to manage volume-family in compartment CompartmentABC
  ```

- The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the volume compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

  ```
  Allow group CreateSecureBlockVolumeGroup to manage vaults in compartment CompartmentDEF
  ```
The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```plaintext
Allow group CreateSecureBlockVolumeGroup to manage keys in compartment CompartmentDEF
```

The following policy lets the Block Volume service list, view, and perform cryptographic operations with all keys in the specified compartment:

```plaintext
Allow service blockstorage to use keys in compartment CompartmentDEF
```

For more information about how policies work, see How Policies Work on page 2136.

**Using the Console**

**To create a secure block volume**

1. Open the navigation menu. Under the Governance and Administration group, go to Security, and click Overview.
2. Click Create Secure Bucket.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 3953.

When you're ready, click Next.

6. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.

7. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.

8. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 3986.

9. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.

10. On the Create Block Volume page, specify the attributes of the volume:
   - **Block Volume Name**: A user-friendly name or description. Avoid entering confidential information.
   - **Compartment**: The compartment where you want to create the volume.
   - **Availability Domain**: Must be in the same availability domain as the instance you plan to use this block volume with.
   - **Volume Size and Performance**: The volume size must be between 50 GB and 32 TB. You can choose in 1 GB increments within this range. The default is 1024 GB. If you choose a size outside of your service limit, you may be prompted to request an increase. For more information, see Service Limits on page 215. The
default option for performance settings is **Balanced**. See [Block Volume Elastic Performance](#) on page 581 for more information about volume performance options.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

When you're ready, click **Next**.

11. Review the summary of the resources that Security Advisor will create, and then click **Create Secure Block Volume**.
Chapter 35

Service Connector Hub

This chapter explains how to move data between Oracle Cloud Infrastructure services using Service Connector Hub.

Service Connector Hub Overview

Service Connector Hub is a cloud message bus platform that offers a single pane of glass for describing, executing, and monitoring movement of data between services in Oracle Cloud Infrastructure.

Note:
Service Connector Hub is not available in Oracle Cloud Infrastructure Government Cloud realms.

How Service Connector Hub Works

Service Connector Hub orchestrates data movement between services in Oracle Cloud Infrastructure.

Data is moved using service connectors. A service connector specifies the source service that contains the data to be moved, tasks to run on the data, and the target service for delivery of data when tasks are complete.

Service Connector Hub Concepts

The following concepts are essential to working with Service Connector Hub.

service connector
The definition of the data to be moved. Specifies a source service, target service, and optional tasks.

source
The service containing the data to be moved according to specified tasks. Example: Logging.

target
The service receiving the data from the source, according to specified tasks. A given target service may process, store, or deliver received data. Functions processes received data while Logging Analytics, Monitoring, Object Storage, and Streaming store received data. Notifications delivers received data.

task
Optional filtering to apply to the data before moving it from the source service to the target service.

trigger
The condition that must be met for the service connector to run. Currently the trigger is continuous; that is, service connectors run continuously.

Flow of Data

When a service connector runs, it receives data from the source service, completes optional tasks on the data (such as filtering), and then moves the data to the target service.
Availability

The Service Connector Hub service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Service Connector Hub

You can access the Service Connector Hub service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

Console: To access Service Connector Hub using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Open the navigation menu. Under Data and AI, click Service Connector Hub.

You can also access Service Connector Hub from Logging in the Console: Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Service Connectors.

API: To access Service Connector Hub through API, use Service Connector Hub API. To access this API using the Command Line Interface (CLI), use the designation for service connectors: oci sch service-connector. For more details about the CLI, see Command Line Reference for Service Connector Hub.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).
An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Access to Service Connector Hub

Administrators: For common policies that give groups access to Service Connector Hub, see Allow a group to manage service connectors on page 2160.

Write Access to Target Services

Note: Make sure any policy you create complies with your company guidelines.

To move data, you must give your service connector the required authorization to write to the specified target resource in the target service. (Service connectors can read all supported source services.)

A default policy providing the required authorization is offered when you use the Console to define the target service for a service connector. This policy is limited to the context of the service connector. You can either accept this default policy or make sure you have the proper authorizations in a group-based policy.

Default Policies for Target Services

This section details the default policies offered when you define a target service in a new or updated service connector in the Console.

Functions

Where this policy is created: The compartment where the function resides. The function is selected when you create or edit service connector.

```
ALLOW any-user TO use fn-function IN COMPARTMENT ID <target_function_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
ALLOW any-user TO use fn-invocation IN COMPARTMENT ID <target_function_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

Logging Analytics

Where this policy is created: The compartment where the log group resides. The log group is selected or entered when you create or edit a service connector.

```
ALLOW any-user TO use loganalytics-log-group IN COMPARTMENT ID <target_log_group_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    target.loganalytics-log-group.id=<log_group_OCID>,
    request.principal.compartment.id=<serviceconnector_compartment_OCID>
}
```
Monitoring

Where this policy is created: The compartment where the metric namespace resides. The metric namespace is selected or entered when you create or edit a service connector.

```plaintext
ALLOW any-user TO use metrics IN COMPARTMENT ID <target_metric_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    target.metrics.namespace='<metric_namespace>',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

Notifications

Where this policy is created: The compartment where the topic resides. The topic is selected when you create or edit service connector.

```plaintext
ALLOW any-user TO use ons-topics IN COMPARTMENT ID <target_topic_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

Object Storage

Where this policy is created: The compartment where the bucket resides. The bucket is selected when you create or edit service connector.

```plaintext
ALLOW any-user TO manage objects IN COMPARTMENT ID <target_bucket_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    target.bucket.name='<bucket_name>',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

Streaming

Where this policy is created: The compartment where the stream resides. The stream is selected when you create or edit service connector.

```plaintext
ALLOW any-user TO use stream-push IN COMPARTMENT ID <target_stream_compartment_OCID>
WHERE ALL {
    request.principal.type='serviceconnector',
    target.stream.id='<stream_OCID>',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

When reviewing group-based policies for required authorization to write to a target service, reference the default policy offered for that target service (see previous section) or see the policy details for the target service at Policy Reference on page 2167.

**Note:**
To accept the default policy for an existing service connector, simply edit the service connector. The default policy is offered whenever you create or edit a
service connector (the only exception is when the exact policy already exists in IAM, in which case the default policy is not offered).

For troubleshooting information, see Troubleshooting Service Connectors on page 3775.

**Limits on Service Connector Hub**

See Service Connector Hub Limits on page 231. Logging Limits on page 226 apply when service connectors read from Logging.

See ServiceLimits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Managing Service Connectors**

This section describes how to manage service connectors.

A service connector defines the flow of data between a source and target service.

**Prerequisites**

IAM policies: To use Service Connector Hub, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.

To move data, you must give your service connector the required authorization to write to the specified target resource in the target service.

A default policy providing the required authorization is offered when you use the Console to define the target service for a service connector. This policy is limited to the context of the service connector. You can either accept this default policy or make sure you have the proper authorizations in a group-based policy.

For more information about service connector authorization, see Write Access to Target Services on page 3752.

If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may need to check the policy for the current compartment. For more information on user authorizations, see Authentication and Authorization on page 3751.

**Using the Console**

**To create a service connector**

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
3. Click Create Service Connector.
4. On the **Create Service Connector** page, fill in the settings:
   
   - **Connector Name**: User-friendly name for the new service connector. Avoid entering confidential information.
   - **Description**: Optional identifier.
   - **Resource Compartment**: The compartment where you want to store the new service connector.
   - **Configure Service Connector**:
     
     - **Source**: Select the service containing the data you want to transfer from the following options.
       - **Logging**: Transfer log data from the Logging service. See [Logging Overview](#) on page 2574.
     - **Target**: Select the service that you want to transfer the data to.
       - **Functions**: Send data to a **function**.
       - **Logging Analytics**: Send data to a **log group**.
       - **Monitoring**: Send **metric** data points to the Monitoring service.
       - **Notifications**: Send data to a **topic**.
       - **Object Storage**: Send data to a **bucket**.
       - **Streaming**: Send data to a **stream**.
     - **Configure your source and task**:

   **Note:**

   By default, this page uses Basic mode. To toggle between Basic Mode and Advanced Mode, click **Switch to Advanced mode** (to the right of **Configure source connection**) or **Switch to Basic mode** (to the right of **Configure source and task**). Complex queries cannot be displayed in Basic mode. See [I can't view my query in Basic mode](#).
• Configure source connection:

<table>
<thead>
<tr>
<th>Source service</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logging</td>
<td>Compartment</td>
</tr>
<tr>
<td>See Logging Overview on page 2574.</td>
<td>Log Group</td>
</tr>
<tr>
<td></td>
<td>Logs</td>
</tr>
</tbody>
</table>

• Configure task:

<table>
<thead>
<tr>
<th>Source service</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logging</td>
<td>Audit Logs on page 2617: When _Audit is selected for Log Group:</td>
</tr>
<tr>
<td>See Logging Overview on page 2574.</td>
<td>• When Attribute is selected for Filter Type:</td>
</tr>
<tr>
<td></td>
<td>• Filter Type: Attribute</td>
</tr>
<tr>
<td></td>
<td>• Attribute Name</td>
</tr>
<tr>
<td></td>
<td>• Attribute Values</td>
</tr>
<tr>
<td></td>
<td>• When Event type is selected for Filter Type:</td>
</tr>
<tr>
<td></td>
<td>• Filter Type: Event type</td>
</tr>
<tr>
<td></td>
<td>• Service Name</td>
</tr>
<tr>
<td></td>
<td>• Event Type</td>
</tr>
<tr>
<td>Service Logs on page 2591, Custom Logs on page 2619: When another log group (not _Audit) is selected for Log Group:</td>
<td>• Property</td>
</tr>
<tr>
<td></td>
<td>• Operator</td>
</tr>
<tr>
<td></td>
<td>• Value</td>
</tr>
</tbody>
</table>

• Click Advanced Mode or Switch to Advanced Mode to view and edit the source connector and task using the Query Code Editor.

• Configure target connection: Select the Service Compartment (where the target service resides) and fill in additional fields as needed:
### Target service

<table>
<thead>
<tr>
<th>Additional fields</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function Application</strong>: Select the name of the function application that includes the function you want.</td>
</tr>
<tr>
<td><strong>Function</strong>: Select the name of the function you want to send the data to.</td>
</tr>
</tbody>
</table>

#### Note:

- Functions are invoked synchronously with 6MB of data per invocation. If data exceeds 6MB, then the service connector invokes the function again to move the over-limit data. Such over-limit invocations are handled sequentially.
- Functions execute for two minutes.
- Do not return data from functions to service connectors. Returned data is not read.

### Logging Analytics

| Log Group: Select the log group you want. |
## Target service
### Monitoring

<table>
<thead>
<tr>
<th>Additional fields</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Namespace</strong>: Select the <a href="#">metric namespace</a> that includes the metric you want. It can be an existing or new namespace.</td>
</tr>
</tbody>
</table>

**Note:**
When typing a new metric namespace, press ENTER to submit it.

**Metric Name**: Select the name of the [metric](#) that you want to send the data to. It can be an existing or new metric.

The following dimensions are included with your metric:

- **connectorId**: The OCID of the service connector that the metrics apply to.
- **connectorName**: The name of the service connector that the metrics apply to.
- **connectorSourceType**: The source service that the metrics apply to.

The timestamp of each metric data point is the timestamp of the corresponding log message.

## Notifications

<table>
<thead>
<tr>
<th>Additional fields</th>
</tr>
</thead>
</table>
| **Note:**

Log Group for Notifications is limited to _Audit_. |

**Topic**: Select the name of the [topic](#) that you want to send the data to.

**Message Format**: Select the option you want:

- **Send formatted messages**: Simplified, user-friendly layout.

  **Note:**
  To view supported subscription protocols and message types for formatted messages, see [Friendly Formatting](#).

- **Send raw messages**: Raw JSON blob.
Service Connector Hub

<table>
<thead>
<tr>
<th>Target service</th>
<th>Additional fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Storage</td>
<td><strong>Bucket</strong>: Select the name of the bucket that you want to send the data to.</td>
</tr>
</tbody>
</table>

**Note:**
- Batch rollover details:
  - Batch rollover size: 100 MB
  - Batch rollover time: 7 minutes
- Files saved to Object Storage are compressed using gzip.

| Streaming | **Stream**: Select the name of the stream that you want to send the data to. |

- To accept the default policy allowing this service connector to write to the target service, click **Create**. A link is provided for you to view the newly created policy.

You can get that authorization through this default policy or through a group-based policy. The default policy is offered whenever you use the Console to create or edit a service connector (the only exception is when the exact policy already exists in IAM, in which case the default policy is not offered). For more information about this authorization requirement, see **Write Access to Target Services** on page 3752.

**Note:**
- If you don't have permissions to accept the default policy, contact your administrator.

- **Show Advanced Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

**To edit a service connector**

1. Open the navigation menu. Under **Data and AI**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click **Edit**.
5. Make your changes.

**Note:**
- If you did not previously create the default access policy to allow this service connector to write to the target service, you can do so now. You can get that authorization through this default policy or through a group-based policy. The default policy is offered whenever you use the Console to create or edit a service connector (the only exception is when the exact policy already exists in IAM, in which case the default policy is not offered). For more information about this authorization requirement, see **Write Access to Target Services** on page 3752.
6. Click **Save Changes**.

   If you updated the source service or tasks, then data movement may pause for a few minutes, as indicated by **Data Freshness metrics**. Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

**To update your service connector to use friendly message formats**

Friendly message formats are available with service connectors that use Notifications as target.

1. Open the navigation menu. Under **Data and AI**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click **Edit**.
5. Under **Configure target connection**, select the **Message Format** you want:
   - **Send formatted messages**: Simplified, user-friendly layout.
     - **Note**: To view supported subscription protocols and message types for formatted messages, see **Friendly Formatting**.
   - **Send raw messages**: Raw JSON blob.
     - **Note**: If you did not previously create the default access policy to allow this service connector to write to the target service, you can do so now. You can get that authorization through this default policy or through a group-based policy. The default policy is offered whenever you use the Console to create or edit a service connector (the only exception is when the exact policy already exists in IAM, in which case the default policy is not offered). For more information about this authorization requirement, see **Write Access to Target Services** on page 3752.

6. Click **Save Changes**.

   If you updated the source service or tasks, then data movement may pause for a few minutes, as indicated by **Data Freshness metrics**. Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

**To activate a service connector**

1. Open the navigation menu. Under **Data and AI**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to activate.
4. Click **Activate** and then confirm.

   The service connector immediately begins moving data according to its configuration, applying tasks to data in the source service and then moving the data to the target service.

**To deactivate a service connector**

1. Open the navigation menu. Under **Data and AI**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to deactivate.
4. Click **Deactivate** and then confirm.

   The service connector stops moving data.
To move a service connector to another compartment

**Note:**

Default policies stop working for moved service connectors. To give a moved service connector the required authorization, edit the service connector using the Console and accept the offered default policy. For more information about service connector authorization, see Write Access to Target Services on page 3752.

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To delete a service connector

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment containing the service connector.
3. Click the name of the service connector you want to deactivate.
4. Click Delete and then confirm.

The service connector stops moving data.

**Using the Command Line Interface (CLI)**

**To list service connectors**

Open a command prompt and run `oci sch service-connector list` to list service connectors in the specified compartment:

```bash
oci sch service-connector list --compartment-id <compartment_OCID>
```

**To get a service connector**

Open a command prompt and run `oci sch service-connector get` to get the specified service connector:

```bash
oci sch service-connector get --service-connector-id <service_connector_OCID>
```

**To create a service connector**

Open a command prompt and run `oci sch service-connector create` to create a service connector:

```bash
oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
```

**To edit a service connector**

Open a command prompt and run `oci sch service-connector update` to edit a service connector:

```bash
oci sch service-connector update --service-connector-id <service_connector_OCID> --display-name "<display_name>" --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
```
To activate a service connector

Open a command prompt and run `oci sch service-connector activate` to activate the specified service connector:

```
oci sch service-connector activate --service-connector-id <service_connector_OCID>
```

To deactivate a service connector

Open a command prompt and run `oci sch service-connector deactivate` to deactivate the specified service connector:

```
oci sch service-connector deactivate --service-connector-id <service_connector_OCID>
```

To move a service connector to another compartment

Open a command prompt and run `oci sch service-connector change-compartment` to move the service connector to the specified compartment:

```
oci sch service-connector change-compartment --service-connector-id <service_connector_OCID> --compartment-id <destination_compartment_OCID>
```

To delete a service connector

Open a command prompt and run `oci sch service-connector delete` to delete the specified service connector:

```
oci sch service-connector delete --service-connector-id <service_connector_OCID>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage service connectors:

- ActivateServiceConnector
- ChangeServiceConnectorCompartment
- CreateServiceConnector
- DeactivateServiceConnector
- DeleteServiceConnector
- GetServiceConnector
- ListServiceConnectors
- UpdateServiceConnector

Use these API operations to manage work requests:

- GetWorkRequest
- ListWorkRequests
- ListWorkRequestErrors
- ListWorkRequestLogs

Service Connector Hub Scenarios

Here are a few basic scenarios to help you understand the Service Connector Hub service and generally how the components work together.
Scenario: Alarm on Log Data

This topic explains how to set up alarms for log data.

This scenario involves creating a service connector and an alarm. The service connector (Service Connector Hub) processes and moves log data from Logging to Monitoring while the alarm fires when triggered by received log data.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring and Notifications.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This section walks through creating a service connector and an alarm using the Console and then updating the topic created with the alarm.

Note:

Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775 and Troubleshooting Notifications on page 3385.

Task 1: Create the service connector

This example walks through using the Console to create a service connector that filters VCN flow log data from Logging for rejected traffic and then moves this log data to a new metric in Monitoring.

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the **Create Service Connector** page, filter **VCN flow log data** to a new metric:
   - Type a **Connector Name** such as "VCN Flow Log Errors." Avoid entering confidential information.
   - Select the **Resource Compartment** where you want to store the new service connector.
   - Under **Configure Service Connector**, select your source and target services to move log data to a metric:
     - **Select Source:** Logging
     - **Select Target:** Monitoring
   - Under **Configure source connection**, select your **VCN flow log**:
     - **Compartment:** The compartment containing the VCN flow log data.
     - **Log Group:** The log group containing the VCN flow log data.
     - **Logs:** The log object name for your VCN flow logs.
   - Under **Configure task**, filter the log data to rejected traffic:
     - **Property:** data.action
     - **Operator:** =
     - **Value:** REJECT
     - If you are interested in rejected traffic for a particular port or address, add another filter. For example, select the property **data.destinationPort** or **data.destinationAddress**.
   - Under **Configure target connection**, enter the metric namespace and metric name that you want to use for the filtered log data:
     - Select the **Service Compartment** where you want to store the metric data points corresponding to the VCN flow log data for rejected traffic.
     - Enter a new **Namespace:** vcnlogs.
     - **Enter a new Metric Name:** rejectedtraffic
     - [Note:]
       
       When typing a new metric namespace, press ENTER to submit it.

5. If prompted to create a policy (required for access to create or update a service connector), click **Create**.
6. Click **Create**.

**Task 2: Create the alarm**

This example walks through using the Console to create an alarm that sends a message when Monitoring receives metric data points corresponding to VCN flow log data for rejected traffic. During this process, you'll create a topic and an email subscription.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.
3. On the **Create Alarm** page, under **Define alarm**, set up your threshold:
   - **Metric description:**
     - **Compartment:** (select the **compartment** specified in the previous task, where you are storing the metric data points corresponding to the VCN flow log data)
     - **Metric Namespace:** (enter the metric namespace that you specified in the service connector)
     - **Metric Name:** (enter the metric name that you specified in the service connector)
     - **Interval:** 1m
     - **Statistic:** Count
   - **Trigger rule:**
     - **Operator:** greater than
     - **Value:** 0
     - **Trigger Delay Minutes:** 1
4. Under Notifications, Destinations, set up an email notification:
   - Destination Service: Notifications Service
   - Compartment: (select the compartment where you want to create the topic and associated subscriptions)
   - Topic: Click Create a topic
     
     | Note: |
     |-------|
     | If you already created your topic and email subscription, you can select that topic here instead of creating a new one. |
   
   - Topic Name: Rejected Traffic Topic
   - Subscription Protocol: Email
   - Email Addresses: (type your email address here)
5. Click Save alarm.

Using the CLI

This section walks through creating the service connector, topic, subscriptions, and alarm using the CLI.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

1. Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

   ```bash
   oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
   ```

2. Create a topic: Open a command prompt and run the `oci ons topic create` command:

   ```bash
   oci ons topic create --name "Alarm Topic" --compartment-id "<compartment_ocid>"
   ```

3. To this topic, add a subscription referencing your email address. Open a command prompt and run the `oci ons subscription create` command:

   ```bash
   oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
   ```

4. Create an alarm that defines the error threshold and references this topic as the destination: Open a command prompt and run the `oci monitoring alarm create` command:

   ```bash
   oci monitoring alarm create --display-name "My Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --namespace "oci_computeagent" --query-text "<yourmetric>[1m].count() > 0" --severity "INFO" --destinations "<topic-ocid>" --is-enabled true
   ```

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775 and Troubleshooting Notifications on page 3385.

Using the API

This section walks through creating the service connector, topic, subscription, and alarm using the API.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:
1. **CreateServiceConnector**: Create a service connector.

   **Example CreateServiceConnector request**

   ```
   POST /20200909/serviceConnectors
   Host: service-connector-hub.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
       "compartmentId": "<compartment_OCID>",
       "description": "My service connector description",
       "displayName": "My Service Connector",
       "source": {
           "kind": "logging",
           "logSources": [
               {
                   "compartmentId": "<compartment_OCID>",
                   "logGroupId": "<log_group_OCID>",
                   "logId": "<log_OCID>"
               }
           ],
           "target": {
               "compartmentId": "<compartment_OCID>",
               "kind": "metrics",
               "metric": "<yourmetric>",
               "metricNamespace": "<yournamespace>"
           },
           "tasks": [
               {
                   "condition": "data.action='REJECT'",
                   "kind": "logRule"
               }
           ]
       }
   }
   ```

2. **CreateTopic**: Create a topic.

   **Example CreateTopic request**

   ```
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
       "name": "Alarm Topic",
       "compartmentId": "<compartment_OCID>"
   }
   ```

3. **CreateSubscription**: To this topic, add a subscription referencing your email address.

   **Example CreateSubscription request: Email**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
       "topicId": "<topic_OCID>",
       "compartmentId": "<compartment_OCID>",
       "protocol": "EMAIL",
       "endpoint": "john.smith@example.com"
   }
   ```
4. **CreateAlarm**: Create an alarm that defines the memory threshold and references this topic.

**Example CreateAlarm request**

```
POST /20180401/alarms
Host: telemetry.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "displayName": "My Alarm",
    "compartmentId": "<compartment OCID>",
    "metricCompartmentId": "<compartment OCID>",
    "namespace": "<yournamespace>",
    "query": "<yourmetric>[1m].count() > 0",
    "severity": "INFO",
    "destinations":
        [
            "<topic OCID>"
        ],
    "isEnabled": true
}
```

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775 and Troubleshooting Notifications on page 3385.

**Scenario: Send Log Data to an Autonomous Database**

This topic explains how to send log data from Logging to an Autonomous Database using a function (Functions service).

This scenario involves creating a function and then referencing that function in a service connector (Service Connector Hub) to process and move log data from Logging to an Autonomous Database.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Functions.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

**Setting Up This Scenario**

This scenario involves creating a service connector (Service Connector Hub) to send log data from Logging to an Autonomous Database (JSON).

Before you can create the service connector, you must set up an Autonomous JSON Database that you want to receive the log data and set up the function to copy that log data.

Autonomous JSON Database setup details:

- **Create the Autonomous JSON Database**
- Copy the ORDS base URL: From the detail page for the Autonomous Database, click Service Console, click Development, and then click Copy URL under RESTful Services and SODA.
• Create a "logs" collection to store the log data that will be moved by the function and service connector:

1. Go to the detail page for the Autonomous Database.
2. Click Tools and then click Open SQL Developer Web.
3. Log in with the admin user and the password you set when you created the database.
4. In SQL Developer Web, enter the following command:

   soda create logs

5. Click Run Statement.

To query documents in the collection after the service connector copies log data, enter the following command:

   soda get logs -f {}

Function setup details:

• Create the function
• Deploy the function
• Set the configuration values as follows:

  • ordsbaseurl
    Use the ORDS base URL you copied during setup of the database.
  • dbschema
  • dbuser
  • dbpwd
  • collection

  For more information, see Passing Custom Configuration Parameters to Functions on page 2085.

• (Optional) Invoke the function

Once the database and function are set up, you're ready to create the service connector. Creating the service connector is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Function code sample

The following code sample is for a function to send log data from the Logging service to an Autonomous Database. For instructions on creating and deploying functions, see Creating and Deploying Functions on page 2063.

Note:
The following code sample is not meant for production workloads. Update it for your production environment.

```python
import io
import json
import logging
import requests
from fdk import response

# soda_insert uses the Autonomous Database REST API to insert JSON documents
def soda_insert(ordsbaseurl, dbschema, dbuser, dbpwd, collection, logentries):
    auth=(dbuser, dbpwd)
    sodaurl = ordsbaseurl + dbschema + '/soda/latest/
    bulkinserturl = sodaurl + 'custom-actions/insert/' + collection + "/"
    headers = {'Content-Type': 'application/json'}
    resp = requests.post(bulkinserturl, auth=auth, headers=headers, data=json.dumps(logentries))
    return resp.json()
```
def handler(ctx, data: io.BytesIO=None):
    logger = logging.getLogger()
    logger.info("function start")

    # Retrieving the Function configuration values
    try:
        cfg = dict(ctx.Config())
        ordsbaseurl = cfg["ordsbaseurl"]
        dbschema = cfg["dbschema"]
        dbuser = cfg["dbuser"]
        dbpwd = cfg["dbpwd"]
        collection = cfg["collection"]
    except:
        logger.error('Missing configuration keys: ordsbaseurl, dbschema, dbuser, dbpwd and collection')
        raise

    # Retrieving the log entries from Service Connector Hub as part of the Function payload
    try:
        logentries = json.loads(data.getvalue())
        if not isinstance(logentries, list):
            raise ValueError
    except:
        logger.error('Invalid payload')
        raise

    # The log entries are in a list of dictionaries. We can iterate over the list of entries and process them.
    # For example, we are going to put the Id of the log entries in the function execution log
    logger.info("Processing the following LogIds:")
    for logentry in logentries:
        logger.info(logentry["oracle"]["logid"])

    # Now, we are inserting the log entries in the JSON Database
    resp = soda_insert(ordsbaseurl, dbschema, dbuser, dbpwd, collection, logentries)
    logger.info(resp)
    if "items" in resp:
        logger.info("Logs are successfully inserted")
        logger.info(json.dumps(resp))
    else:
        raise Exception("Error while inserting logs into the database: " + json.dumps(resp))

    # The function is done, we don't return any response because it would be useless
    logger.info("function end")
    return response.Response(ctx,
                            response_data="",
                            headers={"Content-Type": "application/json"})

Using the Console
This section walks through creating a service connector using the Console. Your function must be deployed.

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775.
Create a service connector

This example walks through using the Console to create a service connector. In this example, the service connector moves log data from Logging to an Autonomous Database using the function you created using the function code sample.

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the Create Service Connector page:
   - Type a Connector Name such as "Send Logs to My Autonomous Database." Avoid entering confidential information.
   - Select the Resource Compartment where you want to store the new service connector.
   - Under Configure Service Connector, select your source and target services to move log data to a metric:
     - Select Source: Logging
     - Select Target: Functions
   - Under Configure source connection, select a Compartment Name, Log Group, and Log.
   - Under Configure target connection, select the Function Application and Function corresponding to the function you created using the function code sample.
5. If prompted to create a policy (required for access to create or update a service connector), click Create.
6. Click Create.

Using the CLI

This section walks through creating a service connector using the CLI that moves log data to your function (which then moves the data to an Autonomous Database).

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

- Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

```
oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
```

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775.

Using the API

This section walks through creating the service connector using the API.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:
- CreateServiceConnector: Create a service connector that moves log data to your function (which then moves the data to an Autonomous Database).

Example CreateServiceConnector request

```
POST /20200909/serviceConnectors
Host: service-connector-hub.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "compartmentId": "<compartment_OCID>",
  "description": "My service connector description",
  "displayName": "My Service Connector",
  "source": {
```
Scenario: Archive Logs to Object Storage

This topic explains how to archive log data to a bucket in Object Storage.

This scenario involves creating a service connector. The service connector processes and moves log data from Logging to Object Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring, Notifications, and Object Storage.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This example walks through using the Console to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775.

Create the service connector

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the **Create Service Connector** page, send subnet log data to a bucket:
   - Type a **Connector Name**, such as "Archive Logs." Avoid entering confidential information.
   - Select the **Resource Compartment** where you want to store the new service connector.
   - Under **Configure Service Connector**, select your source and target services to move log data to a metric:
     - **Select Source**: Logging
     - **Select Target**: Object Storage
   - Under **Configure source connection**, select your subnet log:
     - **Compartment**: The compartment containing the log data you want.
     - **Log Group**: The log group containing the log data you want.
     - **Logs**: The log object name for the log data you want.
   - Under **Configure target connection**, select the bucket where you want to archive this log data:
     - **Select the Service Compartment** where you want to store the received (filtered) log data.
     - **Select the Bucket** you want.

5. If prompted to create a policy (required for access to create or update a service connector), click **Create**.
6. Click **Create**.

**Using the CLI**

This example walks through using the CLI to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

- **Create a service connector**: Open a command prompt and run the `oci sch service-connector create` command:

```bash
oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source ["<source_in_JSON>"] --target ["<targets_in_JSON>"]
```

For help with troubleshooting, see [Troubleshooting Service Connectors](#) on page 3775.

**Using the API**

This example walks through using the API to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use the following operations:

- **CreateServiceConnector**: Create a service connector.

**Example CreateServiceConnector request**

```
POST /20200909/serviceConnectors
Host: service-connector-hub.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "compartmentId": "<compartment_OCID>",
    "description": "My service connector description",
    "displayName": "My Service Connector",
    "source": {
        "kind": "logging",
        "logSources": [
            {
                "compartmentId": "<compartment_OCID>",
                "logGroupId": "<log_group_OCID>"
            }
        ]
    },
    "target": {
        "serviceCompartment": "<service_compartment_OCID>",
        "bucket": "<bucket_name>",
        "isPublic": false
    }
}
```
Scenario: Analyze Logs

This topic explains how to send log data to Logging Analytics.

This scenario involves creating a log group and a service connector. The service connector (Service Connector Hub) processes and moves log data from Logging to the log group in Logging Analytics.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Logging Analytics to create the log group and access to Service Connector Hub to create the service connector.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This section walks through creating a log group and a service connector using the Console.

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775.

Task 1: Create the log group

Use Logging Analytics to create the log group. For instructions, see Create Log Groups.

Task 2: Create the service connector

This example walks through using the Console to create a service connector that sends log data from Logging to the log group you created using Logging Analytics. In this example, the service connector filters VCN flow log data.

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the Create Service Connector page, filter VCN flow log data to your log group:
   - Type a Connector Name such as "VCN Flow Log Error Analysis."
   - Select the Resource Compartment where you want to store the new service connector.
   - Under Configure Service Connector, select your source and target services to move log data to the log group:
     - Select Source: Logging
     - Select Target: Logging Analytics
   - Under Configure source connection, select your VCN flow log:
     - Compartment: The compartment containing the VCN flow log data.
     - Log Group: The log group containing the VCN flow log data.
     - Logs: The log object name for your VCN flow logs.
   - Under Configure task, filter the log data to rejected traffic:
     - Property: data.action
     - Operator: =
     - Value: REJECT
     If you are interested in rejected traffic for a particular port or address, add another filter. For example, select the property data.destinationPort or data.destinationAddress.
   - Under Configure target connection, enter the log group that you want to send the filtered log data to:
     - Select the Service Compartment containing the log group.
     - Select the Logging Analytics Log Group (the log group you created).
5. If prompted to create a policy (required for access to create or update a service connector), click Create.
6. Click Create.

Using the CLI

This section walks through creating the log group and service connector using the CLI.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

1. Create a log group: Open a command prompt and run the `oci log-analytics log-group create` command:

   ```bash
   oci log-analytics log-group create --display-name "<display_name>" --compartment-id <compartment_OCID> --namespace-name "<namespace_name>"
   ```

2. Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

   ```bash
   oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
   ```

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775 and Troubleshooting Notifications on page 3385.

Using the API

This section walks through creating the log group and service connector using the API.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:
1. **CreateLogAnalyticsLogGroup**: Create a log group.

   **Example CreateLogAnalyticsLogGroup request**

   ```
   post /20200601/namespaces/<namespaceName>/logAnalyticsLogGroups
   Host: loganalytics.us-phoenix-1.oci.oraclecloud.com
   <authorization and other headers>
   {  
       "compartmentId": "<compartment_OCID>",
       "displayName": "My Log Group"
   }
   ```

2. **CreateServiceConnector**: Create a service connector.

   **Example CreateServiceConnector request**

   ```
   POST /20200909/serviceConnectors
   Host: service-connector-hub.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {  
       "compartmentId": "<compartment_OCID>",
       "description": "My service connector description",
       "displayName": "My Service Connector",
       "source": {  
           "kind": "logging",
           "logSources": [  
               {  
                   "compartmentId": "<compartment_OCID>",
                   "logGroupId": "<log_group_OCID>",
                   "logId": "<log_OCID>"
               }
           ],
           "target": {  
               "compartmentId": "<compartment_OCID>",
               "kind": "loggingAnalytics",
               "logGroupId": "<logging_analytics_log_group_OCID>"
           },
           "tasks": [  
               {  
                   "condition": "data.action='REJECT'",
                   "kind": "logRule"
               }
           ]
       }
   }
   ```

For help with troubleshooting, see Troubleshooting Service Connectors on page 3775 and Troubleshooting Notifications on page 3385.

**Troubleshooting Service Connectors**

This topic covers troubleshooting techniques for Service Connector Hub.

**No data is being moved**

This section provides troubleshooting information for service connectors that don't appear to be moving data. For example service connectors, see Service Connector Hub Scenarios on page 3762.

Check these items:
• **Error metrics**: Determine if errors exist at the source service, target service or Service Connector Hub service.

**To view error metrics for a service connector**

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the **Compartment** that contains the service connector you want to view, and then click the service connector's name.
3. In the Resources menu, click Metrics (if necessary).
   
   The Metrics page displays a default set of charts for the current service connector.
4. Review the following metric charts:
   - Errors at Source
   - Errors at Target
   - Service Connector Hub Errors

**Authorization to write to the target service**: Make sure you have authorization, either through the default policy offered when creating or updating the service connector or through a group-based policy. See Write Access to Target Services on page 3752.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your accepted default policy may take a few minutes to propagate to regions that are not your home region. The service connector does not move data until the policy is propagated.</td>
</tr>
</tbody>
</table>

**I can’t view my query in Basic mode**

Check these items:

• **Query simplicity**: Update the query so that it only includes elements supported in Basic mode:
  
  • **Audit logs only**: Type-based filters can use the OR operator. Other filters must use the AND operator.
    
    Example:
    
    ```
    ((type = value1 OR type = value2) AND field = value3 AND field1 = value4)
    ```
  
  • **Any combination of logs (Service logs, custom logs, and Audit logs)**: Filters joined with the AND operator.
    
    Example:
    
    ```
    (field = value AND field1 != value1)
    ```

Examples of query complexity that are not supported in Basic mode:

• OR operator (except with type-based filters when only Audit logs are used)
• Functions (for example: `isNull()`)
• `select`
• `summarize`

**How do I know when issues occur?**

Check these items:
• **Data freshness**: Look for unexpected lapses of time between data movement.

**To view data freshness for a service connector**

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment that contains the service connector you want to view, and then click the service connector's name.
3. In the Resources menu, click Metrics (if necessary).
   
   The Metrics page displays a default set of charts for the current service connector.
4. Review the following metric charts:
   
   • Data Freshness

**To view data freshness for all service connectors in the tenancy**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Metric Namespace, select oci_service_connector_hub.
3. Review the following metric charts:
   
   • Data Freshness

### Viewing the State of a Work Request

This topic describes how to view the state of work requests associated with a given service connector.

**Note:**

The Service Connector Hub service does not use the common Work Requests API to support work request operations. Instead, Service Connector Hub work requests are supported by the Service Connector Hub API. See Using the Console to View Work Requests on page 260 for information on viewing work requests for other services.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

### Monitoring Work Requests

Many of the Service Connector Hub service requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment. To provide visibility for in-progress workflows, the Service Connector Hub service creates a work request object.

The work request states are:

**ACCEPTED**

The request is in the work request queue to be processed.

**IN_PROGRESS**

A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.

**SUCCEEDED**

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.
FAILED
A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

CANCELING
The work request is in the process of canceling.

CANCELED
The work request has been canceled.

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these operations to monitor the state of work requests:

- GetWorkRequest
- ListWorkRequests
- ListWorkRequestErrors
- ListWorkRequestLogs

Example Messages
This topic shows examples of messages sent by service connectors that use Notifications as target.

A service connector with a Notifications target sends messages to all subscriptions for the specified topic. The contents and appearance of each message depends on the subscription protocol, such as Email.

For friendly formatting of email messages, select Formatted for the service connector's message format.

Email (Raw) and Slack

Please do not reply directly to this email. If you have any questions or comments regarding this email, contact your account administrator.
Service Connector Hub Metrics

You can monitor the health, capacity, and performance of your service connectors by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the Service Connector Hub service in the oci_service_connector_hub metric namespace.

Resources: Service connectors.

Overview of the Service Connector Hub Service Metrics

The Service Connector Hub service metrics help you measure the number and type of connections between services in Oracle Cloud Infrastructure. You can use metrics data to diagnose and troubleshoot service connector issues.

To view a default set of metrics charts in the Console, navigate to the service connector you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.
**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Administrators: For common policies that give groups access to Service Connector Hub, see Allow a group to manage service connectors on page 2160.

**Available Metrics: oci_service_connector_hub**

The metrics listed in the following tables are automatically available for any service connectors you create. You do not need to enable monitoring on the resource to get these metrics.

Service Connector Hub service metrics include the following dimensions:

- **connectorId**
  
  The OCID of the service connector that the metrics apply to.

- **connectorName**
  
  The name of the service connector that the metrics apply to.

- **errorType**
  
  The type of error.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For information about common errors, see API Errors on page 4372.</td>
</tr>
</tbody>
</table>

- **region**
  
  The region that the metrics apply to.

- **sourceName**
  
  The name of the source service that the metrics apply to.

- **targetName**
  
  The name of the target service that the metrics apply to.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>BytesReadFromSource</td>
<td>Bytes Read from Source</td>
<td>Bytes</td>
<td>Number of bytes read from the source</td>
<td>connectorId, connectorName, region, sourceName</td>
</tr>
</tbody>
</table>

**Note:**

- The value for this metric is cumulative. For example, when a service connector reads 1MB from the source, the service connector emits a `BytesReadFromSource` metric with a value of 1MB. However, let's say that the service connector is unable to write to the target. The next time the service connector reads (1MB) from the source, it will emit a `BytesReadFromSource` metric with a cumulative value of 2MB, which includes the 1MB from the first read. Let's say the service connector successfully writes to the target. The third time the service connector reads (1MB) from the source, it will emit the `BytesReadFromSource` metric with a cumulative value of 1MB.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>BytesWrittenToTarget</td>
<td>Bytes Written to Target</td>
<td>Bytes</td>
<td>Number of bytes written to the target</td>
<td>connectorId, connectorName, region, targetName</td>
</tr>
</tbody>
</table>

**Note:**

Use this metric as a general indicator of success. BytesWrittenToTarget may not match BytesReadFromSource for data read from Logging to the following target services.

- Monitoring may translate multiple records into a single metric data point.
- Object Storage compresses data. For example, 10MB read may be converted into 1MB written.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFreshness</td>
<td>Data Freshness</td>
<td>Milliseconds</td>
<td>Indicates age of the oldest processed record of the most recent set</td>
<td>connectorId&lt;br&gt;connectorName&lt;br&gt;region&lt;br&gt;sourceName&lt;br&gt;targetName</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For example, let's say you check this metric at 10:30. At 10:00, you received your last set of records at 10:00. Of the five records, three have a 10:00 timestamp while two have a 9:55 timestamp. In this example, the most recent set was received at 10:00; the oldest processed record had a 9:55 timestamp. At 10:35, the age is 35 minutes.</td>
<td></td>
</tr>
<tr>
<td>ErrorsAtSource</td>
<td>Errors at Source</td>
<td>Count</td>
<td>Number of errors that affect retrieving data from source</td>
<td>connectorId&lt;br&gt;connectorName&lt;br&gt;errorType&lt;br&gt;region&lt;br&gt;sourceName</td>
</tr>
<tr>
<td>ErrorsAtTarget</td>
<td>Errors at Target</td>
<td>Count</td>
<td>Number of errors that affect writing data to target</td>
<td>connectorId&lt;br&gt;connectorName&lt;br&gt;errorType&lt;br&gt;region&lt;br&gt;sourceName</td>
</tr>
<tr>
<td>LatencyAtSource</td>
<td>Latency at Source</td>
<td>Milliseconds</td>
<td>Time-to-first-byte when retrieving data from source. Useful for customers to troubleshoot with complex tasks (log rules).</td>
<td>connectorId&lt;br&gt;connectorName&lt;br&gt;region&lt;br&gt;sourceName</td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Dimensions</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------</td>
<td>------------</td>
<td>----------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>LatencyAtTarget</td>
<td>Latency at Target</td>
<td>Milliseconds</td>
<td>Time-to-first-byte when writing data to target</td>
<td>connectorId, connectorName, region, targetName</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Dimensions</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>MessagesReadFromSource</td>
<td>Messages Read from Source</td>
<td>Count</td>
<td>Number of records read from the source</td>
<td>connectorId, connectorName, region, sourceName</td>
</tr>
</tbody>
</table>

**Note:**
The value for this metric is cumulative. For example, when a service connector reads a single message from the source, the service connector emits a `MessagesReadFromSource` metric with a value of 1. However, let's say that the service connector is unable to write to the target. The next time the service connector reads (1 message) from the source, it will emit a `MessagesReadFromSource` metric with a cumulative value of 2, which includes the message from the first read. Let's say the service connector successfully writes to...
<table>
<thead>
<tr>

<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServiceConnectorHubErrors</td>
<td>Service Connector Hub Errors</td>
<td>Count</td>
<td>Number of errors in Service Connector Hub that affect moving data from source to target</td>
<td>connectorId, connectorName, region</td>
</tr>
</tbody>
</table>
Using the Console
To view default metric charts for a single service connector

1. Open the navigation menu. Under Data and AI, click Service Connector Hub.
2. Choose the Compartment that contains the service connector you want to view, and then click the service connector's name.
3. In the Resources menu, click Metrics (if necessary).

The Metrics page displays a default set of charts for the current service connector.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for multiple service connectors

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Metric Namespace, select oci_service_connector_hub.

The Service Metrics page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoringservice to create custom queries.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

Using the API
Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Query Reference for Service Connector Hub
Service Connector Hub supports a subset of the Logging Query Language Specification on page 2639.

Stream expressions are limited to following streaming operators:

- search

  Constructs a log stream from actual log objects.

  Example:

  ```
  search "<compartment_OCID>/loggroup1/logname1" "<compartment_OCID>/loggroup2/logname2" "<compartment_OCID>/loggroup3/logname3"
  ```

- where

  Filters the current log stream using a Boolean expression.

  Example 1:

  ```
  search "<compartment_OCID>/Audit" 
  | where type = 'com.oraclecloud.objectstorage.deleteobject'
  output: 
  {"specversion": "1.0", "type": 
   "com.oraclecloud.objectstorage.deleteobject", "source": 
   "<compartment_OCID>/myBucket",......}
  ```

  Example 2: Complex Boolean expression:

  ```
  search "<compartment_OCID>/Audit" 
  | where type = 'com.oraclecloud.objectstorage.deleteobject' or '
  'com.oraclecloud.objectstorage.getobject'
  ```
| where source = 'myBucket'
output:
{"specversion": "1.0", "type": "com.oraclecloud.objectstorage.deleteobject", "source": "<compartment_OCID>/myBucket"},.....
{"specversion": "1.0", "type": "com.oraclecloud.objectstorage.getobject", "source": "<compartment_OCID>/myBucket"},.....

Example 3: search without where:

search "<compartment_OCID>/application" | level = 'ERROR'

Example 4: Full text search. You can perform a full text search by specifying a filter on the entire content of the log. A search on logContent returns any log line where a value matches your string. This functionality supports wildcards:

search "<compartment_OCID>/application"
| where logContent = 'ERROR'  -- returns log lines with a value matching "ERROR"

search "<compartment_OCID>/application"
| where logContent = '*ERROR*'  -- returns log lines with a value containing "ERROR"

Functions are limited to scalar functions.
Chapter 36

Storage Gateway

This chapter explains how to use Storage Gateway to connect your on-premise applications with Oracle Cloud Infrastructure.

Overview of Storage Gateway

Storage Gateway is a cloud storage gateway that lets you connect your on-premises applications with Oracle Cloud Infrastructure. Applications that can write data to an NFS target can also write data to the Oracle Cloud Infrastructure Object Storage, without requiring application modification to uptake the REST APIs.

Important:

Storage Gateway is the evolution of the Storage Software Appliance that was launched with Oracle Cloud Infrastructure Classic. By migrating to Oracle Cloud Infrastructure Object Storage, you are using Storage Gateway with its enhanced file-to-object transparency and improved scale and performance.

Availability

The Storage Gateway service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Storage Gateway and Oracle Cloud Infrastructure Concepts

The following concepts are essential to working with Oracle Cloud Infrastructure Storage Gateway.

FILE SYSTEM

A Storage Gateway file system on a local host maps its files and directories to objects with the same names in a corresponding Oracle Cloud Infrastructure Object Storage bucket.

FILE SYSTEM CACHE

Storage Gateway's configurable file system cache enables asynchronous and optimized movement of data to the cloud. The file system cache serves as both a write buffer and a read cache for data storage and retrieval. The write buffer contains data that copied to the disk cache and queued for upload to Oracle Cloud Infrastructure. The read cache contains frequently retrieved data that’s accessible locally for read operations. Proper file system cache configuration is critical to Storage Gateway performance. See Configuring the Cache for File Systems on page 3797 for details.

METADATA

The metadata associated with a Storage Gateway file is stored as custom metadata for the corresponding object in Oracle Cloud Infrastructure Object Storage. Examples of file metadata include object id, creation date, modification date, size, and permissions. Storage Gateway caches all metadata for the file system locally.
NFSV4
NFS is an established and widely adopted distributed file system protocol for handling network storage. NFS lets client computers mount file systems on remote servers and access those remote file systems over the network as though they were local file systems. Storage Gateway performs the NFS to REST API translation needed to interact with Oracle Cloud Infrastructure Object Storage.

ORACLE CLOUD INFRASTRUCTURE
Oracle Cloud Infrastructure is a set of complementary cloud services that lets you build and run a wide range of applications and services in a highly available hosted environment. Oracle Cloud Infrastructure offers high-performance compute capabilities (as physical hardware instances) and storage capacity in a flexible overlay virtual network that is securely accessible from your on-premises network.

TENANCY
A tenancy is a secure and isolated partition within Oracle Cloud Infrastructure where you can create, organize, and administer your cloud resources.

OBJECT STORAGE AND ARCHIVE STORAGE
Oracle Cloud Infrastructure offers two distinct storage tiers for you to store your unstructured data. Use the Object Storage Standard tier for data to which you need fast, immediate, and frequent access. Use the Archive Storage service’s Archive tier for data that you access infrequently, but which must be preserved for long periods of time. Both storage tiers use the same manageable resources (for example, objects and buckets). The difference is that when you upload a file to Archive Storage, the object is immediately archived. Before you can access an archived object, you must first restore the object to the Standard tier.

Note:
In the Storage Gateway documentation, generic references to Object Storage encompass both the Standard and Archive storage tiers.

Both storage tiers are simple to use, perform well, and scale to an unlimited capacity.

bucket
An Object Storage bucket is a logical container for storing objects. A file system created in Storage Gateway maps to a corresponding bucket by the same name in Object Storage. A bucket is associated with a single Oracle Cloud Infrastructure compartment. The compartment has policies that determine what actions a user can perform on the bucket the objects it contains.

object
An individual file or directory written to a Storage Gateway file system on an NFS share creates an identically named object in the target Object Storage bucket. An object is composed of the object itself and metadata about the object.

NAMESPACE
A logical entity that serves as a top-level container for all Oracle Cloud Infrastructure Object Storage buckets and objects. The namespace enables you to control bucket naming within your tenancy. Each tenancy has one unique and uneditable Object Storage namespace that is global, spanning all compartments and regions. Bucket names must be unique within your tenancy.

COMPARTMENT
A collection of Oracle Cloud Infrastructure-related resources. Only users and groups with access permissions explicitly granted by an administrator can access the resources. Compartments help you organize resources and make it easier to control access to those resources. Oracle Cloud Infrastructure automatically creates a root compartment when a tenancy is provisioned. An administrator can then create more compartments within the root compartment and add access rules for those compartments. A bucket can exist in only one compartment.
How Storage Gateway Works

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through file systems that you create in Storage Gateway.

Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket.

There is file-to-object transparency between Storage Gateway and Object Storage:

- A Storage Gateway file system directory on a local host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage.
- Any file written to a Storage Gateway file system is written as an object with the same name in the associated Object Storage bucket. The system stores associated file attributes as object metadata.
- You can access Object Storage objects directly using native APIs, SDKs, third-party tools, the HDFS connector, and the Oracle Cloud Infrastructure CLI and Console. You use the Refresh operation in Storage Gateway to ingest any data that was added or modified directly in Object Storage.

Enterprise applications typically work with files in nested directories. Object Storage buckets, and the objects within those buckets, exist in a flat hierarchy. Storage Gateway flattens the directory hierarchy into nested object prefixes in Object Storage. See Interacting With Object Storage on page 3805 for details.

Recommended Uses and Workloads

The following summarizes some of the ways that you can use Storage Gateway.

DATA TRANSFER

Use Storage Gateway to move data from your on-premises host to Oracle Cloud Infrastructure. Storage Gateway is not a replacement for general-purpose network attached storage (NAS), though it behaves similarly to NAS. Use Storage Gateway’s integrated Cloud Sync feature to transfer and synchronize data to Oracle Cloud Infrastructure.

CLOUD TIERING

Use Storage Gateway to expand the capacity of on-premises storage solutions without capital expenditures. Configuring and connecting a Storage Gateway file system with a large cache to Oracle Cloud Infrastructure Object Storage provides unlimited scale to create a workflow in which files get automatically moved to the cloud and retrieved only on demand. Even though on-demand retrieval is slower than access to local storage, capital expenditures or changes to existing tools and software are not required.

BACKUPS

Use Storage Gateway to move files to Oracle Cloud Infrastructure Archive Storage as a cost-effective backup solution. You can move individual files and compressed or uncompressed ZIP or TAR archives. Storing secondary copies of data is an ideal use case for Storage Gateway.

ARCHIVAL

Storage Gateway is ideal for archive use cases.

DISASTER RECOVERY

Storage Gateway lets traditional applications move data to highly durable object storage. When you need to recover data, create a fresh instance of Storage Gateway to return the data from Object Storage.

Uses and Workloads Not Supported

Storage Gateway does not support the following uses and workloads.

WINDOWS OPERATING SYSTEM

Storage Gateway does not currently support the Windows operating environment or Windows solutions.
GENERAL-PURPOSE NETWORK STORAGE

Storage Gateway isn't a general-purpose storage filer and must not be used as a replacement for traditional network storage appliances.

FILE SYNC AND SHARE

Though Storage Gateway is an effective data mover, it’s not a replacement for file sync and share services. Evaluate Oracle services like Oracle Document Cloud service if you need file sync and share functionality.

CONTENT COLLABORATION

Storage Gateway does not support multiple Storage Gateway instances simultaneously reading from and writing to a single Object Storage bucket. Do not use Storage Gateway as a tool for distributed teams to collaborate on creating and managing content.

FREQUENTLY MODIFIED FILES

Do not use Storage Gateway if you expect your data to be modified frequently. Each time a file is modified and closed, Storage Gateway creates an updated version and uploads it to Object Storage as a new object. Frequently modified data results in substantial inefficiency, in terms of both bandwidth consumption and capacity utilization.

renaming large directory trees

Renaming directories in the Storage Gateway works well for a small directory tree. However, renaming a parent directory with many children can be slow. The service updates the object ID of every corresponding child object in the object store to reflect the new path. If you do start a rename, ensure that the action finishes by monitoring the Pending Uploads field in the Storage Gateway user interface.

Security Considerations

ADMIN PASSWORD

Because Storage Gateway administrators can create, modify, and delete file systems, follow these password guidelines:

• Set a strong password.
• Ensure that the password is secure.
• Share passwords with others only on a need-to-know basis.

DOCKER

Storage Gateway runs inside a Docker container for security and isolation. Follow these Docker-related guidelines and recommendations:

• Avoid or minimize Docker instance operations.
• Avoid logging in to the Docker container. If there is a genuine requirement to log in to the Docker container, use extreme caution to avoid service disruption. Do not change the Docker configuration or the Docker instance unless instructed to do so by Oracle support personal.
• Although the NFS protocol controls access to the file system from clients, Storage Gateway file systems are also locally mounted inside the Docker container. To prevent unauthorized access to file system data, ensure that a Docker container is accessible only by an administrator or an authorized user.
• Configure the Docker host to limit user access to the Storage Gateway Docker container.
• Files and directories in a Docker container are also visible in the Docker host - typically file systems and directories that are provisioned in the Docker host and mapped to the container. Set the appropriate
ownership and modes to ensure that only an administrator or an authorized user can access these folders. We recommend the following:

- A dedicated Storage Gateway host.
- Limit who can access the Storage Gateway host.
- Set firewall rules to limit access to the Docker host and Docker container.
- Implement backup and retention policies for the files associated with Storage Gateway.

ACCESS CONTROL

Default file system export options are too permissive. Set more restrictive export options so that only trusted NFS clients can access the file system data and metadata. Modify the advanced file system settings for NFS Allowed Hosts and NFS Export Options to restrict access to a file system. In addition to NFS protocol security, you can also set up and configure a firewall on the host to further control access to the file system. UID/GID/modes control access to files and directories. Set the appropriate ownership mode to protect sensitive data.

OBJECT STORAGE

Files in a file system are uploaded to Oracle Cloud Infrastructure and stored as objects in an Object Storage bucket. Associated file attributes are stored as object metadata. Access control for Object Storage is different from access control for a traditional file system. Anyone with permission to read or modify any object in the bucket can read or modify all objects in the bucket. To protect sensitive data, set up Oracle Cloud Infrastructure IAM policies to limit who can access objects in the bucket.

Storage Gateway transfers data to Oracle Cloud Infrastructure using HTTPS, which encrypts data packets in flight between Storage Gateway and the cloud. Data written to Object Storage is always automatically encrypted in the cloud.

Limits on Storage Gateway Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- Ensure that the number of file systems per Storage Gateway doesn't exceed 10. For best performance, host each file system on a dedicated Storage Gateway.
- Ensure that the number of objects stored in a Storage Gateway file system doesn't exceed 100 million. For datasets that consist of more than 100 million objects, distribute the objects across multiple Storage Gateways.
- Ensure that you configure adequate local storage for file system cache. Storage Gateway warns you if you have configured less than the recommended 500 GB.
- The minimum amount of memory required for any Storage Gateway file system is 16 GB.
  - File systems with up to 50 million files require 32 GB of memory.
  - Large file systems with up to 100 million files require 64 GB of memory.
- The number of files in the cache is limited to 20,000 regardless of the specified cache size in bytes.
- To improve the efficiency of file ingestion, cloud upload operations, and to reduce the number of objects in the namespace, bin-pack or zip small files before writing them to Storage Gateway.

Storage Gateway Release Notes

Release notes provide version-specific release information and important Storage Gateway issues that you need to be aware of:

https://docs.cloud.oracle.com/iaas/releasenotes/services/storage-gateway/

Features of Storage Gateway

This topic highlights key features of Storage Gateway.
POSIX-Compliant NFS Access to Oracle Cloud Infrastructure Object Storage

Using Storage Gateway, your applications can interact with Oracle Cloud Infrastructure Object Storage through standard NFSv4 protocols. You connect Storage Gateway file systems to Object Storage buckets. Storage Gateway stores files as objects in an Oracle Cloud Infrastructure Object Storage bucket and supports multipart uploads for large objects. Object Storage does not, however, support symbolic links, hard links, or special device files.

Note:
Storage Gateway does not support the setgid POSIX function.

Data Integrity with Checksum Verification

The built-in data integrity checks ensure that data is validated as it moves through the data path from Storage Gateway to Oracle Cloud Infrastructure Object Storage. Checksum verification helps ensure data integrity. Metadata integrity checks ensure that the metadata is in a consistent state. The checksum for each file can be read using a custom interface.

Large File Support

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for faster, more efficient, and resilient uploads. Storage Gateway can use multipart upload for files larger than 128 MB. With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload. See Using Multipart Uploads on page 3477 for details.

Beginning with version 1.3, Storage Gateway provides partial update capabilities to:

- Reduce upload latency.
- Improve the use of available network bandwidth.
- Reduce the minimum required cache size.
- Enable ingestion of single files that are larger than the Storage Gateway cache size.

Storage Gateway's partial update capability leverages the Object Storage service multipart upload functionality to break a large file into smaller parts, and then upload the parts in parallel. After uploading, the service reconstructs them as a single object. With partial update, the service can upload only the modified file parts and reconstruct the object using the unchanged parts that already exist in Object Storage. The service does not need to overwrite the existing object by uploading the entire file.

Since the full file does not have to exist within the Storage Gateway cache at one time, partial update enables the service to ingest single files that are larger than the allocated cache size.

The default file part size is 1GB, with a maximum size of 10TB for the full file. Although the part size is configurable per file system, Oracle does not recommend that you use custom sizes. Custom part sizes do not improve upload performance, but can reduce the maximum supported full file size. The maximum file size is 10,000 times the file part size, with a hard cap of 10TB. If you customize the file part size, you do not need to restart the Storage Gateway, but you must reconnect to the affected file system.

All file parts in the cache are managed by the least recently used (LRU) cache management policy.

To use partial update for objects stored in the Archive Storage tier, you must first restore the object. See Upgrading Storage Gateway on page 3845 for information about upgrading your Storage Gateway system to use partial update.

Support for Data Archival

In addition to uploading to buckets in the Object Storage Standard tier, Storage Gateway supports uploading to and restoring objects from buckets in the Archive Storage tier.

When you create a file system, you specify the storage tier in which to create the corresponding Object Storage bucket.
• The default Standard Object Storage tier is used for storing data to which you need fast, immediate, and frequent access.
• The Archive Storage tier is used for storing data that is accessed infrequently and requires long retention periods.

While Archive Storage is more cost effective than Object Storage for preserving cold data, you must first restore the objects before you can access them. The restoration process can take up to four hours depending on the size of the object. See Overview of Archive Storage on page 484 and Restoring Files and Objects from Archive Storage on page 3832 for details.

Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management on page 3466 for details.

Automated Object Deletion

When you delete a Storage Gateway file from a file system, the corresponding object in Object Storage is automatically deleted.

Quick Access to Select Files with Cache Pinning

Storage Gateway lets you pin files to the file system cache for quick access. You can pin files to the cache for file systems connected to either the Object Storage Standard or Archive tier.

When you write a file to your Storage Gateway file system, the file is initially stored in the file system cache, and then asynchronously uploaded to your Oracle Cloud Infrastructure bucket. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the Least Recently Used (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can pin the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them.

Storage Gateway Health Check

The Storage Gateway performs automated "health checks" on the system to monitor the status of the following:

• Storage Gateway services and resources
• Local storage, file system cache, metadata storage, and log storage

Integrated Cloud Transfer and Synchronization (Cloud Sync)

Storage Gateway provides an integrated cloud transfer and synchronization feature called Cloud Sync that lets you back up and transfer files on local storage to and from Oracle Cloud Infrastructure Object Storage buckets. This new feature replaces the independent, downloadable cloud sync utility that was available in the previous Storage Gateway version.

You can use the Storage Gateway management console or CLI to create, monitor, and manage Cloud Sync jobs similar to other enterprise NAS backup/replication offerings. Cloud Sync runs as part of the Storage Gateway software inside the Docker instance on the host.

Getting Started With Storage Gateway

This topic provides recommendations for getting started with Storage Gateway.
Recommended Reading

- If you have not done so already, read Overview of Storage Gateway on page 3790. That topic describes:
  - Key concepts for understanding both Storage Gateway and Object Storage.
  - Important security considerations.
  - Recommended uses and workloads.
  - Uses and workloads to avoid.
- Configuring the cache for file systems is key to Storage Gateway. Read Configuring the Cache for File Systems on page 3797 to understand the importance of the file system cache and the guidelines for configuring the cache when you add a file system.
- To understand the prerequisite tasks and requirements for interacting with Object Storage, read Interacting With Object Storage on page 3805.

Next Steps for Setting Up Storage Gateway

Key topics for setting up Storage Gateway include:

- Installing Storage Gateway on page 3807
- Logging In to the Storage Gateway Management Console on page 3815
- Creating Your First File System on page 3816
- Mounting File Systems on Clients on page 3823

Next Steps for Using Storage Gateway

Key topics for using and managing Storage Gateway include:

- Managing File Systems on page 3820
- Managing Storage Gateway on page 3828
- Monitoring Storage Gateway on page 3834

Configuring the Cache for File Systems

Storage Gateway caches frequently retrieved data on the local host, minimizing the number of REST API calls to Oracle Cloud Infrastructure Object Storage and enabling faster data retrieval. You configure the cache for a file system when you create the file system. See Creating Your First File System on page 3816 and Adding a File System on page 3820.

About File System Cache

The file system cache serves as both a read cache and a write buffer for data storage and retrieval. The read cache contains frequently retrieved data that’s accessible locally for read operations. The write buffer contains data that has been copied to the disk cache and queued for upload to your Oracle Cloud Infrastructure tenancy.

When you retrieve data from Oracle Cloud Infrastructure, the data is stored in the Storage Gateway read cache. The read cache allows subsequent I/O operations to that data at local disk speed.

When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

For more information on how to preserve files in the read cache, see Preserving Files in the File System Cache on page 3801.

When an application transfers files through an NFS share, the files are written to the write buffer. The write buffer can contain many files that are queued and pending upload. If the host on which Storage Gateway is installed fails or Storage Gateway stops abruptly, the pending upload operations persist on the local disk. When Storage Gateway restarts, the pending upload operations resume and the data is uploaded to Oracle Cloud Infrastructure.
Configuring Local Storage for File Systems and Cache

Storage Gateway uses local storage attached to the server (or virtual server) for hosting the file systems and cache. Files written to a file system in Storage Gateway are uploaded to the associated Object Storage bucket, with a portion of the file set maintained locally in the file system as a warm cache.

For optimal performance, reliability, and fault tolerance, follow these guidelines when configuring the local Storage Gateway storage:

• Allocate dedicated local storage for each Storage Gateway file system, and associated metadata and logs.
• Multiple disks (hard disk drives or solid-state drives) in a RAID10 set provide an optimal balance of performance, reliability, and fault tolerance. Alternatively, you can use RAID6.

  Important:
  Avoid RAID0 or single disk (no RAID) because of the potential for data loss upon disk failure.

• Provision sufficient space to accommodate the read cache and the write buffer (for ingesting new files) without ever becoming more than 80% full.

  In general, provision file system cache storage that is at least 1.5 times the size of the file set that you want to hold in the read cache. For example, assume that the entire file set requires 50 TB of space. You expect frequent access to 10% (5 TB) of that file set. Ensure that the file system cache storage has at least 7.5 TB of usable capacity. If the cache size reaches a near-full threshold, any data ingestion results in an out of space error in Storage Gateway.

• When you provision local storage at installation time, Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size. If the file system cache is less than 300 GB, Storage Gateway generates a warning message.

Determining File System Cache Size

The Storage Gateway file system cache serves as both a read cache and a write buffer. You can specify the maximum size of the read cache. The write buffer uses any remaining available space in the file system cache. You do not explicitly specify a size for the write buffer.

  Important:
  Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size.

Read Cache Size

The default maximum read cache size is 300 GB if the file system cache size is greater than 300 GB. Changing the default maximum read cache size is optional. The appropriate size depends on Storage Gateway workload. While the default setting for the read cache is appropriate for most workloads, consider increasing the size if Storage Gateway must retrieve a significant amount of data from the cloud.

Use the following guidelines to determine the appropriate setting for the read cache size:

• Do not set the read cache maximum equal to the size of the file system cache. Doing so allocates 100% of the space for the read cache and leaves no capacity for ingesting new files. If there is no available space for new file ingestion, Storage Gateway stops ingesting data and begins evicting files from the read cache to create space. Always preserve some space in the file system cache for ingestion.

• Set the read cache size to equal the amount of data that you anticipate to be accessed frequently, while leaving enough capacity for the write buffer.

  Note:
  If the total file system cache size is less than 300 GB, Storage Gateway automatically sets the read cache maximum size to 20% of the file system cache. The system does not honor custom read cache configuration settings for a file system cache less than 300 GB.
After you calculate the optimal file system cache size, you can configure the read cache when creating the file system or adjust it after monitoring the workload. See Adding a File System on page 3820 and Changing the Properties of a File System on page 3826.

**Write Buffer Size**

Optimizing the space available for the write buffer is an important part of determining the appropriate file system cache size. The write buffer size increases when data is ingested in Storage Gateway and decreases after the data is uploaded to the cloud.

**Important:**
- When the write buffer uses all available file system cache space, further data ingestion is blocked until a portion of the existing files are uploaded and evicted from the cache.
- Oracle recommends that you allow a minimum of 300 GB for the write buffer under any circumstances.

Use the following guidelines to determine the space needed for the write buffer:

- Identify the amount of data to be uploaded in Storage Gateway. If a large amount of data is uploaded, the Storage Gateway write buffer can reach its maximum size. Exceeding the write buffer leads to I/O failure as the file system cache has no space available. If you cannot regulate data ingestion, you can increase the file system cache space to avoid I/O failure. You can regulate I/O by pausing after a certain amount of data is ingested or by periodically allowing uploads to complete before ingesting more data. For example, you can use this approach for backups run as cron jobs when the file system cache space is less than the amount of data to be ingested.
- Calculate the amount of data that is ingested on any typical day or week in Storage Gateway. Also, calculate the amount of data that is uploaded over a time period, based on the available bandwidth or historical data. Ensure that the difference between these calculations does not exceed the write buffer size.
- Some applications can handle I/O failure, and then resume writing data. In this case, consider setting the cache size to the amount of data that you’d like the application to tolerate before the cache space can be reclaimed.

As stated earlier, you want to avoid completely filling the file system cache. The write buffer grows by the difference between the ingest rate and the upload rate. The file system cache size must be larger than the read cache plus the total number of bytes buffered at any point during the job. If you have workloads that upload large amounts of data in parallel, you can use the following equation to determine the amount of space needed by the write buffer.

\[
WB \geq D \times (1 - UR/IR) + E
\]

**WB** = Recommended write buffer size  
**D** = Total uploaded dataset size  
**UR** = Upload rate (The upload rate is the lesser of the actual upload rate or the disk read speed.)  
**IR** = Ingestion rate (disk write speed)  
**E** = Extra margin (Oracle recommends at least 50 GB.)

**Note:**  
This equation applies only if the upload rate is less than the ingest rate.

Run the following command to measure your system's ingestion rate:

```
sudo docker exec -it ocisg python /opt/oracle/gateway/python/packages/ocisg_helper/disk_speed_test.py
```

**Example output:**

```
Write speed:
2.1 GB copied in 9.4 seconds (228 MB/s)
```
Read speed:
2.1 GB copied in 6.8 seconds (315 MB/s)

If read and writes occur in parallel during the job, the read and write speeds are about 50% of the returned values.

Run the following command to measure your system's upload rate:

```
sudo docker exec ocisg cat /mnt/gateway/cache-phoenix/:::diag:oci-network-speed-test
```

Example output:

```
Average Upload Speed = 125 MB/s
```

**Example 1**

Daily dataset is 500 GB
Upload rate = 2 MB/s
Disk read = 600 MB/s
Ingestion rate (Disk write) = 600 MB/s
Apply the equation:
WB >= 500 GB * (1 - (2/600)) + 50 GB
WB >= 549 GB
In this case, the upload rate is very slow compared to the ingestion rate, so the entire dataset needs to fit in the write buffer.

**Example 2**

Daily dataset is 1 TB
Upload rate = 300 MB/s
Disk read = 400 MB/s
Ingestion rate (Disk write) = 100 MB/s
In this case, we recommend the minimum write buffer size of 300 GB, since the upload rate is higher than the ingestion rate.

**Example 3**

Daily dataset is 5 TB
Upload rate = 250 MB/s
Disk read = 400 MB/s
Ingestion rate (Disk write) = 300 MB/s
Apply the equation:
WB >= 5 TB * (1 - (250/300)) + 50 GB
WB >= 0.88 TB
WB is 880 GB.
Note:

Storage Gateway begins throttling I/O when the free cache space falls below 15 GB. Determine if the application is able to handle the throttling or if you want to provision more cache space.

Preserving Files in the File System Cache

When you write a file to your file system, the file is initially stored in the file system cache, and then uploaded to your Oracle Cloud Infrastructure tenancy. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the Least Recently Used (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can pin the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them. You can view the Maximum Read Cache Size in GiB for a selected file system in the management console under Settings.

You can pin files connected to both Standard and Archive storage tiers to file system cache. Files that you write to a file system are always uploaded to your tenancy, regardless of whether the files are pinned to the cache.

If the file that you want to pin to cache is not present in the cache, the file is automatically downloaded to the cache if the file system is connected to a Standard storage tier. If that file belongs to a file system connected to an Archive storage tier, you must first restore the file before the file can be downloaded to the cache. See Restoring Files and Objects from Archive Storage on page 3832 for details.

Important:

- By default, the cache pinning feature is enabled on all file systems.
- When selecting the files for cache pinning, consider the overall cache threshold and calculate the residual cache space that remains available for normal cache operations. For example, assume that your cache threshold is 1 TB and you estimate that the files you want to pin to cache occupy 300 GB. That leaves 700 GB of usable space in your cache after pinning the files.
- When you restore a file from the Archive storage tier, the file moves to the Standard storage tier. The file remains in Standard storage for 24 hours or the retention duration you specify. The continued availability of the file in the cache depends on the LRU operation. However, if you pin such a file to the cache, the restored file remains in the cache until you unpin the file.

Enabling and Managing Cache Pinning

To perform cache pinning operations for a file system, run the following command from the NFS client on which the file system is mounted:

```
cat /path/to/mountpoint/<file_path>:::cache:cache_command[:argument]
```

The following table lists the cache pinning operations and the corresponding command and argument for each operation:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Cache Command</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable cache pinning for a file system. By default, cache pinning is enabled for all file systems.</td>
<td>set-preserve-option</td>
<td>true</td>
</tr>
<tr>
<td>Operation</td>
<td>Cache Command</td>
<td>Argument</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>--------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>Get the cache pinning status for a file system.</td>
<td>get-preserve-option</td>
<td>No argument</td>
</tr>
<tr>
<td>Disable cache pinning for a file system.</td>
<td>set-preserve-option false</td>
<td></td>
</tr>
<tr>
<td>List the files that are pinned to the cache.</td>
<td>list-preserve</td>
<td>No argument</td>
</tr>
<tr>
<td>Remove deleted files from the preserve list.</td>
<td>list-preserve-update</td>
<td>No argument</td>
</tr>
<tr>
<td>Add a file to the preserve list.</td>
<td>add-preserve</td>
<td>No argument</td>
</tr>
<tr>
<td>Remove a file from the preserve list.</td>
<td>remove-preserve</td>
<td>No argument</td>
</tr>
<tr>
<td>Clear the preserve list.</td>
<td>clear-preserve</td>
<td>No argument</td>
</tr>
</tbody>
</table>

**Example Commands**

- To enable cache pinning for the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:set-preserve-option:true
  ```

- To get the cache pinning status for myFS:

  ```
  cat /mnt/gateway/myFS/:::cache:get-preserve-option
  ```

  If cache pinning is enabled for the file system, the output of this command is `true`. Otherwise, the output is `false`.

- To disable cache pinning for the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:set-preserve-option:false
  ```

- To add a file `myFile` of the myFS file system to the preserve list:

  ```
  cat /mnt/gateway/myFS/myFile:::cache:add-preserve
  ```

- To find out which files are added to the preserve list of the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:list-preserve
  ```

  Sample output of the preceding command:

  ```
  ["/doNotDelete.txt", "/myFileMetadata", "/myFile"]
  ```

- To remove the file `myFile` from the preserve list:

  ```
  cat /mnt/gateway/myFS/myFile:::cache:remove-preserve
  ```
To update the preserve list when the output of the `cache:list-preserve` command indicates that a pinned file has been removed from the file system:

```
cat /mnt/gateway/myFS/:::cache:list-preserve-update
```

Sample of the original preserve list:

```
["/doNotDelete.txt", "/myFileMetadata"]
```

Output of the `cache:list-preserve` command after the file `myFileMetadata` is removed from the cache:

```
["/doNotDelete.txt", "Status: 1 files appear to no longer exist. Please run list-preserve-update"]
```

Output of the `cache:list-preserve-update` command:

```
["/doNotDelete.txt"]
```

To clear the preserve list for a file system:

```
cat /mnt/gateway/myFS/:::cache:clear-preserve
```

**Understanding Storage Gateway Performance**

This topic covers the performance characteristics of Storage Gateway and the ways you can maximize its efficiency.

**Performance Characteristics**

It is important to understand the basic performance characteristics of Storage Gateway:

- Because there is transactional overhead for each file, Storage Gateway generally exhibits better performance with large files than with small files. Storage Gateway can only upload data as fast as your connection and the storage host allows. Storage Gateway buffers the data in local disk storage while waiting to upload to Oracle Cloud Infrastructure. Once a file is uploaded, the file's local copy can be removed from the cache to free up space. If file system cache space falls below 10 GB, application I/O and file/directory creation can fail.
- Storage Gateway does not support frequently modified files such as logs, databases, or virtual disks. Storage Gateway depends on the closing of a file to trigger an upload of that file. If a file never closes or is modified frequently, the upload event cannot successfully occur.
- Upload throughput to Object Storage (WAN) is typically slower than NFS client throughput (LAN). As a result, Storage Gateway can accumulate a large amount of data that is pending upload.
- You can attach Storage Gateway to an existing Object Storage bucket that contains data. The service is optimized for this type of initialization. Storage Gateway can initialize about 700 thousand files per hour with a hard disk drive-based cache. It can initialize about 7 million files per hour with an NVMe SSD-based cache.

**Factors That Affect Performance**

To get the maximum performance benefits from Storage Gateway, follow the practices documented at Best Practices for Using Storage Gateway on page 3842.

In addition to having sufficient memory and file system cache space, Oracle recommends that you use SSDs to help improve NFS ingestion rate.

Storage Gateway is tuned for maximum upload and download performance by default. No additional tuning is needed.
Performance Testing

While measuring performance is complex and open to variability, we have observed the following in performance benchmark tests with 10-Gb/s link speed:

<table>
<thead>
<tr>
<th>Workload (Upload/Download)</th>
<th>Configuration</th>
<th>Average Upload Throughput</th>
<th>Average Download Throughput</th>
</tr>
</thead>
</table>
| Single large file of 400 GB | CPU: 8 cores  
Memory: 32GB  
Disk Read: 340 MB/s  
Disk Write: 234 MB/s  
Link Speed: 10 Gb/s (1.25 GB/s) | 239 MB/s | 195 MB/s |
| Multiple files of 10-50 GB (Total data = 400GB) | CPU: 8 cores  
Memory: 32GB  
Disk Read: 340 MB/s  
Disk Write: 234 MB/s  
Link Speed: 10 Gb/s (1.25 GB/s) | 260 MB/s | 225 MB/s |

Note:
Using FastConnect with Storage Gateway makes optimal use of full link speed. We have customers using FastConnect with 10-Gb/s link speed and have seen each gateway achieve 400–450 MB/s uploads to Oracle Cloud Infrastructure. See FastConnect Overview on page 3173 for more information.

Testing Network Bandwidth

Storage Gateway provides a diagnostic command that you can use to test the bandwidth in your environment and ensure that you get the expected upload and download speeds. The amount of data transferred depends on these factors:

Bandwidth * Delay Product (bits) = total_available_bandwidth (bits/sec) x round_trip_time (sec)

Note:
Different buckets can have different upload and download speeds. The round_trip_time can vary by region.

To run the diagnostic command:
You need root permissions to run the diag command.
1. Using SSH, log in to the host on which you installed Storage Gateway.
2. Run the `diag` command, specifying the Storage Gateway file system name:

```
[root@ocisg-ashburn opc]# sudo docker exec ocisg cat /mnt/gateway/<file_system_name>/:::diag:oci-network-speed-test
```

The `diag` command responds with the average upload speed, for example:

```
Average Upload Speed = 217 MB/s
```

## Interacting With Object Storage

This topic helps you understand the Oracle Cloud Infrastructure Object Storage environment and how it interacts with a Storage Gateway.

### Creating the Required IAM Users, Groups, and Policies

An Oracle Cloud Infrastructure administrator must perform prerequisite tasks in preparation for data movement between Storage Gateway and Object Storage. If you are new to Oracle Cloud Infrastructure, we recommend that you read Setting Up Your Tenancy on page 122.

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. For details on creating groups, see Managing Groups on page 2419.

For Storage Gateway, an administrator creates these groups with the following policies:

<table>
<thead>
<tr>
<th>Allow group <code>&lt;group_name&gt;</code> to manage buckets in compartment <code>&lt;compartment_name&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group <code>&lt;group_name&gt;</code> to manage objects in compartment <code>&lt;compartment_name&gt;</code></td>
</tr>
</tbody>
</table>

### Content Consistency Between Storage Gateway and Object Storage

Changes to the files in Storage Gateway, including create, write, update, and delete, eventually are consistent with Object Storage. Uploads are asynchronous and buffered for performance, so Storage Gateway file changes might not yet be reflected in Object Storage.

You can access, modify, and upload objects directly to a bucket using Object Storage native APIs, SDKs, the CLI, the Console, or the HDFS connector. Objects modified in these ways do not appear as files in Storage Gateway until you click **Refresh** in the Storage Gateway management console.

### Name Restrictions

Storage Gateway file and file system names must adhere to Object Storage bucket and object name restrictions and guidelines.

Use the following guidelines for naming file systems:

- Use from 1 to 256 UTF-8 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Names cannot contain a slash (/) character because this character delimits Object Storage bucket and object names.</td>
</tr>
</tbody>
</table>
- Avoid entering confidential information.
• Make the name unique within a Storage Gateway instance.

Use the following guidelines for naming files:
• Use from 1 to 1024 characters.
• Valid characters are letters (upper or lower case), numbers, and characters other than linefeed, newline, and NULL.
• Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
• Avoid entering confidential information.
• Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

Custom Metadata
POSIX file and directory attributes are stored in custom metadata. These attributes include uid, gid, mode, atime, ctime, and mtime. If existing objects in Object Storage are missing the required custom metadata, Storage Gateway assigns the following default values:
• uid=0
• gid=0
• mode=0644 for file and 0755 for directory

The custom metadata is not updated in Object Storage until a file operation triggers Storage Gateway to update the file in Object Storage. Timestamp metadata (atime, ctime, and mtime) are expressed in milliseconds. Access modes are expressed in octal and include file/directory bit.

The custom metadata names follow these guidelines:
• Only ASCII characters.
• A maximum of 128 bytes.

The custom metadata values follow these guidelines:
• Only UTF-8 characters.
• A maximum of 256 bytes.

Understanding Directory and File Hierarchy Translations in Object Storage
Within an Object Storage namespace, buckets and objects exist in a flat hierarchy. Storage Gateway flattens the file system directory hierarchy into nested object prefixes in Object Storage.

For directories:
• A Storage Gateway file system called myFS that contains a directory called myDir, appears in Object Storage as:

n/<os_namespace>/b/myFS/o/myDir/

• A Storage Gateway file system called myFS that contains a myDir subdirectory called mySubDir, appears in Object Storage as:

n/<os_namespace>/b/myFS/o/myDir/mySubDir/

You can distinguish a Storage Gateway directory from a Storage Gateway file in the following ways:
• Directories have a trailing slash /.
• Directory size or length is 0 (zero).

For files:
• A Storage Gateway file system called `myFS` that contains a directory called `myDir` with a file called `file1`, appears in Object Storage as:

```
/n/<os_namespace>/b/myFS/o/myDir/file1
```

• A Storage Gateway file system called `myFS` that contains a `myDir` subdirectory called `mySubDir` with a file called `file2`, appears in Object Storage as:

```
/n/<os_namespace>/b/myFS/o/myDir/mySubDir/file2
```

You can distinguish a Storage Gateway file from a Storage Gateway directory in the following ways:

• Directories have a trailing `/` and files do not.
• File length can be 0 (zero) or non-zero, but directory length is always 0 (zero).

### Internal Storage Gateway Objects

Storage Gateway creates some special internal objects in Object Storage. These objects have a `/gateway` directory prefix. For example:

```
/n/<object_storage_namespace>/b/<bucket>/o///gateway
```

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not modify or remove the objects in the special <code>/gateway</code> directory. These objects are critical for Storage Gateway operation.</td>
</tr>
</tbody>
</table>

### Installing Storage Gateway

This topic provides instructions for installing the Storage Gateway software.

### Prerequisites

These instructions assume that you are familiar with the administration and configuration commands of the operating system on your host machine. To install Storage Gateway, your host system must meet certain hardware and software requirements.

### Hardware Recommendations and Requirements

To run Storage Gateway, the host machine must meet the following requirements:

• Two dual-core CPUs or better. Oracle recommends 4-core CPUs.
• Minimum memory requirements:
  • 16 GB for required for any Storage Gateway file system.
  • 32 GB for file systems up to 50 million files.
  • 64 GB for file systems up to 100 million files.
• The recommended local storage disk size is 600 GB, which includes 500 GB for the file system cache, 80 GB for metadata storage, and 20 GB for log storage.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provision local storage before installing Storage Gateway. For best performance, allocate dedicated local storage file systems for the Storage Gateway cache, the metadata, and the logs. The installation script prompts you for the paths to your Storage Gateway file system cache, metadata storage, and log storage locations. Follow the disk size recommendations provided by the installer.</td>
</tr>
</tbody>
</table>
Oracle recommends that you use the XFS file system for the file system cache, metadata, and logs. XFS is a 64-bit file system designed for parallel I/O. Parallel I/O allows a system to scale based on the number of I/O threads and file system bandwidth.

## Software Requirements

- Oracle Linux 7 with UEK Release 4 or later.

**Note:**
If you create an Oracle Cloud Infrastructure Compute instance to host Storage Gateway, the instance creation wizard provides an option to choose the operating system image.

- Docker 1.12.6 or newer. Docker is an open platform for building, shipping, and running distributed applications. For more information, see [https://www.docker.com/](https://www.docker.com/).
- NFSv4.

**Note:**
The Storage Gateway installation software automatically installs Docker and the NFS protocol.

## Hosting Storage Gateway on an Oracle Cloud Infrastructure Compute Instance

To host Storage Gateway on an Oracle Cloud Infrastructure Compute instance, you need:

- An SSH key pair in PEM format.
  - To create a key pair, see [Managing Key Pairs on Linux Instances](#) on page 693.
  - If your public key is not in PEM format, use the following command to convert it:

```
ssh-keygen -f <key_name>.pub -e -m pem
```

- An Oracle Cloud Infrastructure user account with an API signing key (the public key from your SSH key pair).
  - If you need to create a user account, see [To create a user](#) on page 2417.
  - To upload an API signing key to an existing user account, see [To add an API signing key](#) on page 2461.
- A virtual cloud network (VCN) and related resources. For help with creating a VCN, see [VCNs and Subnets](#) on page 2821.

The following configuration points apply to your VCN:

- Do not select the **Use DNS Hostnames in this VCN** check box unless you plan to use DNS hostnames for your Storage Gateway Compute instance.
- The security list must include a rule to allow SSL (443) ingress.
- After you install the Storage Gateway software your host machine, you must add a security list rule to allow communication with the management console port. More information appears on this page after the Storage Gateway installation instructions.
- A Compute instance. See [Creating an Instance](#) on page 695.

The VM.Standard2.4 Compute shape meets the minimum required specifications for Storage Gateway. Large file systems might require an image with more resources.

- A Block Volume. See [Creating a Volume](#) on page 515.
  - The recommended disk size is 600 GB.
  - Attach the volume to your Compute instance. See [Attaching a Volume](#) on page 517.
  - If you specify **Volume Attachment Types** on page 501 as the volume attachment type, you must also connect and mount the volume from the instance for the volume to be usable. For more information, see [Volume Attachment Types](#) on page 501 and [Connecting to a Volume](#) on page 524.
Installing Storage Gateway

You can install Storage Gateway on an Oracle Cloud Infrastructure Compute instance or an on-premises host that meets the hardware and software requirements.

To install the Storage Gateway software

1. Connect to your Compute instance or on-premises host.
   
   For help with connecting to an Oracle Cloud Infrastructure Compute instance, see Connecting to an Instance on page 733.

2. If your host volume is new, you might need to format and mount the disk.

   Tip:
   
   This task describes the simplest way to create a functional file system to host a Storage Gateway. It uses one device and file system to host the cache, metadata, and log volumes. You specify the paths to those volumes later in this procedure. To optimize performance for your system, you can:
   
   • Create a separate device and file system for each of the cache, metadata, and log volumes.
   • Create a single device, but create logical volumes and file systems for the cache, metadata, and log volumes.

To format the disk and create a file system:

   a. Run fdisk:

      ```
      sudo fdisk /dev/sdb
      ```

      (Optional) Press **m** to view the *fdisk* options.

   b. Choose command **g** - create a new empty GPT partition table.

   c. Choose command **w** - write table to disk and exit.

   d. Create an XFS (file system).

   To make file system volume extensive, we recommend using LVM to create logical partitions that can span across one or more physical hard drives. First, the hard drives are divided into physical volumes, then those
physical volumes are combined to create the volume group and finally the logical volumes are created from
volume group. Follow these steps:

1. Create a volume group.

   ```bash
   sudo vgcreate <volume_group_name> <device>
   ```

2. Create a logical volume.

   ```bash
   sudo lvcreate -l 100%FREE -n <logical_volume_name> <volume_group_name>
   ```

3. Create an XFS file system.

   ```bash
   sudo mkfs.xfs /dev/<volume_group_name>/<logical_volume_name>
   ```

4. Mount the XFS file system.

   ```bash
   sudo mount /dev/<volume_group_name>/<logical_volume_name> <directory_path>
   ```

To mount the formatted volume:

a. Create a mount directory:

   ```bash
   sudo mkdir /ocisg
   ```

b. Mount the drive:

   ```bash
   sudo mount /dev/sdb /ocisg
   ```

3. Download the Storage Gateway 1.3 tar archive.

4. Use the SFTP tool of your choice to copy the tar archive into the /tmp folder of the host machine.

5. On the host machine, change directory to /tmp and extract the files from the tar archive:

   ```bash
   cd /tmp
   sudo tar xvfz ocisg-1.3.tar.gz
   ```

   This command extracts the files from the tar archive into a subdirectory named ocisg-1.3.

6. Change directory to ocisg-1.3 and run the installation script as sudo or root user:

   ```bash
   cd ocisg-1.3
   ```
sudo ./ocisg-install.sh

Optionally, you can specify the following `ocisg-install.sh` script flags:

- **-a** Runs the installation in advanced configuration mode, which lets you specify ports and the Docker network mode.

  In addition to prompting you for the paths to the metadata storage, cache storage, and log storage, advanced configuration mode also prompts you for:

  - The Docker network mode (host or bridge).
    
    Bridge mode is the default. It allows multiple instances of Storage Gateway to run on the same host.
    Host mode improves network performance. If you plan to run only one instance of Storage Gateway on the host, Oracle recommends host mode. If you encounter issues with host mode, try bridge mode or contact [My Oracle Support](https://support.oracle.com).
  
  - The host port to use for the management console.
  
  - The host port to use for NFS access.
  
  - The host port to use for the HTTP REST service.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For each host port specification, you can designate a port or press Enter to let Storage Gateway dynamically allocate the port. You can use the <code>ocisg configure port</code> command to change the ports</td>
</tr>
</tbody>
</table>
• **-d** Installs Storage Gateway at the location you specify instead of the default location of /opt/ocisg. For example:

```bash
sudo ./ocisg-install.sh -d /opt/storagegateway
```

• **-h** Displays the installation script help information.

• **-p** Specifies that Storage Gateway is running behind a proxy server. You can specify multiple proxy arguments. For example:

```bash
```

• **-q** Runs the installation in quiet mode.

If you supply the paths to the Storage Gateway cache, metadata, and log storage locations using `-m <path_to_metadata_storage>`, `-c <path_to_cache_storage>`, and `-l <path_to_log_storage>`, you are not prompted for input. For example:

```bash
sudo ./ocisg-install.sh -q -m /ocisg/metadata -c /ocisg/cache -l /ocisg/log
```

**Note:**

Ignore the devicemapper warning message if it appears during the installation.

The script guides you through the Storage Gateway installation. Depending on your host machine configuration, some steps can require your input:

1. Docker does not appear to be installed. Do you want to install docker engine with yum? [y/N]
   
   Press y, and then press Enter.

   The installation script automatically installs Docker and configures the storage driver for use with Storage Gateway.

**Important:**

If Docker is already installed on your system, the installation script does not automatically configure the storage driver and returns a warning message:

```
Checking that docker is installed and using the correct version
Found docker version Docker version 18.03.1-01, build 0d51d18
The storage appliance requires to set devicemapper as the docker storage driver.
Please follow the setup link below to enable devicemapper and rerun the install.
```
b. **NFS server does not appear to be enabled. Do you want to enable NFS?** [y/N]

Press y, and then press **Enter**.

c. When prompted, press **Enter** accept the default installation location.

d. When prompted, specify the paths to your Storage Gateway cache, metadata, and log storage locations.

The following examples represent paths for a simple system. Your setup might include paths to separate devices and file systems for each location.

1. Enter a path for the file system cache. For example:

   /oci$g/sg/cache

2. Enter the path for metadata storage. For example:

   /oci$g/sg/metadata

3. Enter the path for log storage. For example:

   /oci$g/sg/log

If you receive warnings about cache, metadata, and log storage existing on the same volume, enter y to proceed with the installation.

After a successful installation, the script provides the following information:

- The URL to log in to the Storage Gateway management console.
- The NFS port number.
- An example command for mounting your Storage Gateway file systems.

If you installed Storage Gateway on a Compute instance, see **Security List Requirements for Compute Instance Installations** on page 3813.

### Security List Requirements for Compute Instance Installations

If you installed Storage Gateway on an Oracle Cloud Infrastructure Compute instance, that instance must be able to receive HTTPS connections from other hosts and allow communication with the Storage Gateway management console. To open the necessary port, add an ingress rule to the security list governing the instance's host subnet. To learn about VCN security control, see **Security Lists** on page 2850.

**Important:**

This installation task assumes that your existing security list already allows traffic to port 443, as described in the **Prerequisites** on page 3807 section of this page. If port 443 is not open, you must add a security list rule to open it.

**To add a security list rule**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the name of the cloud network (VCN) that hosts your Compute instance.
3. Click **Security Lists**.
4. Click the name of the security list that governs the subnet hosting your Compute instance.
5. Click **Edit All Rules**.
6. Add an ingress rule:
   
a. Leave **Stateless** unmarked.
   
b. Select CIDR for the **Source Type**.
   
c. Enter `0.0.0.0/0` to indicate all IP addresses.
   
d. Select **TCP** as the **IP Protocol**.
   
e. Enter **All** in the **Source Port Range** field.
   
f. Specify your Storage Gateway management console port in the **Destination Port Range** field. For example:

   ```
   32769
   ```

   If you do not know the management console port for your Storage Gateway installation, run the following command on the host machine:

   ```
   sudo ocisg info
   ```

   The management console port appears at the end of the management console URL:

   ```
   Management Console: https://exampleCompute:32769
   ```

7. Click **Save Security List Rules**.

   You can now connect to the compute instance using the public IP address (https://<public_IP_address>). See [Getting the Instance Public IP Address and Initial Windows Password](#) on page 78 for details.

### Verifying and Updating the Storage Driver in Docker

To verify the storage driver in Docker:

1. **Start docker:**

   ```
   sudo systemctl start docker
   ```

2. **Verify the information in docker:**

   ```
   sudo docker info
   ```

3. **Look for Storage Driver in the output. For example:**

   ```
   Containers: 0
   Running: 0
   Paused: 0
   Stopped: 0
   Images: 0
   Server Version: 18.03.1-ol
   Storage Driver: overlay2
     Backing Filesystem: xfs
     Supports d_type: true
     Native Overlay Diff: false
   Logging Driver: json-file
   Cgroup Driver: cgroupfs
   Plugins:
     Volume: local
     Network: bridge host macvlan null overlay
     Log: awslogs fluentd gcplogs gelf journald json-file logentries splunk syslog
   Swarm: inactive
   Runtimes: runc
   Default Runtime: runc
   Init Binary: docker-init
   containerd version: 773c489c9c1b21a6d78b5c538cd395416ec50f88
   runc version: 4fc53a81fb7c994640722ac585fa9ca548971871
   ```
init version: 949e6fa
Security Options:
seccomp
Profile: default
selinux
Kernel Version: 4.1.12-124.15.4.el7uek.x86_64
Operating System: Oracle Linux Server 7.5

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore the devicemapper warning message if it appears.</td>
</tr>
</tbody>
</table>

If Storage Driver is not devicemapper, do the following:

a. Stop docker:

```
sudo systemctl stop docker
```

b. Look for /etc/docker/daemon.json in the host.

If the file daemon.json does not exist, create it.

c. In the daemon.json file, set the storage-driver variable to devicemapper:

```
{
   "storage-driver": "devicemapper"
}
```

d. Restart docker:

```
sudo systemctl start docker
```

e. Verify the information in docker:

```
sudo docker info
```

Look for Storage Driver in the output and verify that the storage driver is devicemapper.

**Next Step**

[Logging In to the Storage Gateway Management Console on page 3815]

**Logging In to the Storage Gateway Management Console**

Use the Storage Gateway management console to create, manage, and monitor file systems.
Storage Gateway provides the URL to access the management console after a successful installation. When you access the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

**Note:**

Storage Gateway uses a self-signed certificate for the HTTPS connection. Your browser might warn that the SSL certificate couldn’t be verified. If you entered the correct public IP address of the Storage Gateway instance, you can safely ignore this warning. The steps to ignore this warning and go to the management console vary depending on the browser you use.

**To log in to the management console:**

1. Enter one of the following URLs in a supported web browser:
   - If you installed the software on an on-premises host, enter the URL provided at the end of the Storage Gateway installation script:
     ```
     https://<storagegateway_hostname>:<port_number>
     ```
     For example:
     ```
     https://myStorageGatewayHost:3775
     ```

     **Note:**
     If you cannot access Storage Gateway using the hostname, contact your network administrator. Depending on your network configuration, your Storage Gateway hostname might need to be added to DNS or you might need to use an IP address rather than the hostname.
   - If you installed the software in an Oracle Cloud Infrastructure compute instance, enter the URL as follows:
     ```
     https://<instance_public_IP_address>:<port_number>
     ```
     For example:
     ```
     https://192.168.14.5:3775
     ```

     **Note:**
     See [Getting the Instance Public IP Address](#) on page 67 for details.

   The console log-in page appears. The page prompts you to set and confirm a password for the Storage Gateway admin user.

2. Enter a password that meets the following requirements:
   - From 8 to 32 characters.
   - At least one special character, one numerical character, one uppercase character, and one lowercase character.

**Next Step**

[Creating Your First File System](#) on page 3816

**Creating Your First File System**

This topic guides you through creating your first Storage Gateway file system.

Think of a file system as a namespace containing a dataset that’s accessible through Storage Gateway. A Storage Gateway file system in this context represents a mapping between a directory on your on-premises host and a bucket
in Oracle Cloud Infrastructure Object Storage. When you create a Storage Gateway file system, you define the connection credentials that Storage Gateway uses to connect to your Oracle Cloud Infrastructure tenancy.

When you log in to the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

To create your first file system

1. Log in to the management console.
2. Click **File Systems** on the upper-right area of the management console.
3. Click **Create File System**.
4. Enter the required information in **Create a File System**:

   - **File System Name**: A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
     - Use from 1 to 256 characters.
     - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

   **Important**: The name cannot contain the following:
   - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
   - The strings "pub" or "priv"

   If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.

   If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

   - **Select the Object Storage tier in which you want to store your data**

   **Important**: Once set, you cannot change the storage tier in which a bucket resides.

   You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See **Using Object Lifecycle Management** on page 3466 for details.

   - **Standard**: The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See **Overview of Object Storage** on page 3392 for more information.
   - **Archive**: The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See **Overview of Archive Storage** on page 484 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see **Restoring Files and Objects from Archive Storage** on page 3832).

   - **Object Storage endpoint**: Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

   **Important**: The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See **Required Keys and**
OCIDs on page 4179 for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
- **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

**Note:**

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. **Click Save.**

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.

Enter the required configuration information or click **Use Default** to accept the default values:

- **NFS Allowed Hosts**: A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64, 192.0.2.0/24

- **NFS Export Options**: The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

  **Important:**

  Do not specify the fsid option.

- **Concurrent Uploads**: The number of concurrent uploads to Oracle Cloud Infrastructure.
  
  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

  The allowed range is from 1 to 30.

- **Sync Policy**: The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead**: The number of blocks to be downloaded and used to **read ahead** when reading files for improved performance.

  Default value: 50

- **Maximum Read Cache Size in GiB**: The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  **Note:**

  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

  See [Configuring the Cache for File Systems](#) on page 3797 for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

**Next Steps**

Connect the file system to a directory on the Storage Gateway host. For more information, see [Connecting a File System](#) on page 3822.

You can also do the following in the management console:

- Set up the NFS export. This directory acts as a mount point. For more information, see [Mounting File Systems on Clients](#) on page 3823.
- Add more file systems. For more information, see [Adding a File System](#) on page 3820.
- View the details of a file system. For more information, see [Viewing the Details of a File System](#) on page 3825.
Managing File Systems

A Storage Gateway file system connects a directory on a local host to an Object Storage bucket in Oracle Cloud Infrastructure. This topic describes how to manage Storage Gateway file systems.

Adding a File System

You can add file systems in Storage Gateway and connect each file system to an Object Storage bucket in your tenancy.

To add a file system

1. Log in to the management console.
2. Click File Systems on the upper-right area of the management console.
3. Click Create File System.
4. Enter the required information in Create a File System:
   - **File System Name**: A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
     - Use from 1 to 256 characters.
     - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.
     - **Important**: The name cannot contain the following:
       - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
       - The strings "pub" or "priv"
   
   If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.
   
   If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.
   
   - **Select the Object Storage tier in which you want to store your data**
     - **Important**: Once set, you cannot change the storage tier in which a bucket resides.
     - You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management on page 3466 for details.
     - **Standard**: The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage on page 3392 for more information.
     - **Archive**: The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage on page 484 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see Restoring Files and Objects from Archive Storage on page 3832).
     - **Object Storage endpoint**: Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.
     - **Important**: The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and
OCIDs on page 4179 for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
- **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

**Note:**

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.

Enter the required configuration information or click **Use Default** to accept the default values:

- **NFS Allowed Hosts**: A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64,192.0.2.0/24

- **NFS Export Options**: The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not specify the fsid option.</td>
</tr>
</tbody>
</table>

- **Concurrent Uploads**: The number of concurrent uploads to Oracle Cloud Infrastructure.

  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

  The allowed range is from 1 to 30.

- **Sync Policy**: The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead**: The number of blocks to be downloaded and used to *read ahead* when reading files for improved performance.

  Default value: 50

- **Maximum Read Cache Size in GiB**: The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.</td>
</tr>
</tbody>
</table>

  See **Configuring the Cache for File Systems** on page 3797 for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

### Connecting a File System

After you create a file system, you must connect the file system to an Oracle Cloud Infrastructure Object Storage bucket before you can store and retrieve data through the file system.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If network connectivity with Oracle Cloud Infrastructure is lost, your file system is disconnected.</td>
</tr>
</tbody>
</table>

**To connect a file system**

1. Log in to the Storage Gateway management console.
2. On the **Dashboard** tab, identify the file system that you want to connect to your Object Storage bucket.
3. Click Connect.

If a bucket with the same name as the file system exists in Object Storage, the file system is connected to that bucket. Any existing data cached in the Storage Gateway file system is deleted to ensure consistency with the data stored in the bucket. If a bucket by that name doesn’t exist, the bucket is created and the file system is connected to the bucket. If the compartment OCID was specified during file system creation, then the bucket is created in that compartment. Otherwise, the bucket is created in the root compartment by default.

**Important:**

You can mount a read/write file system on only one Storage Gateway at a time.

If the file system that you're importing is connected to another Storage Gateway, the **File System: Claim Ownership** window appears. You can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information, and then click **Claim Ownership**:

- Public key finger print
- Private key
- Private key passphrase

Claiming ownership ensures that you don't inadvertently connect a new file system to a bucket that's already connected to another Storage Gateway file system.

### Mounting File Systems on Clients

Each Storage Gateway file system maps a directory to an Oracle Cloud Infrastructure Object Storage bucket. To establish the connection between Storage Gateway and an NFS client, you must mount the Storage Gateway file system on the NFS client.

Any Linux/UNIX NFS client certified to work with NFSv4 server running on Oracle Linux 7.x is compatible with Storage Gateway.

**Note:**

Storage Gateway does not currently support NFS clients running on Windows or Mac OS.

### To mount a Storage Gateway file system

1. Log in to the Storage Gateway host.
2. Start Storage Gateway:

   ```
   sudo ocisg up
   ```

3. Find the NFS port number:

   ```
   sudo ocisg info
   ```

   Note the NFS port number from the output. For example:

   **Management Console:** https://myStorageGatewayHost.example.com:32775

   **If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.**

   **NFS Port:** 32774
Example: mount -t nfs -o vers=4, port=32774
myStorageGatewayHost.example.com:/<OCISG File System name> /local_mount_point

In the sample output:

- myStorageGatewayHost.example.com is the Storage Gateway host name.
- 32775 is the management console port number.
- 32774 is the NFS port number.

4. Log in to the NFS client from which you want to access your service instance through Storage Gateway.
5. Create a directory on the NFS client.
6. Mount the file system on the directory that you created on the NFS client:

```
sudo mount -t nfs -o vers=4, port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file_system_name> /<local_mount_point>
```

In this command:

- Replace `<NFS_port_number>` with the NFS port number you noted earlier.
- Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
- Replace `<ocisg_file_system_name>` with the file system name that you want to mount.
- Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

For example:

```
sudo mount -t nfs -o vers=4, port=32774 myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
```

In this example,

- 32774 is the NFS port.
- myStorageGatewayHost.example.com is the Storage Gateway host name.
- myFirstFS is the file system name.
- /home/xyz/abc is the path to the directory abc on the NFS client.

The Storage Gateway file system is now mounted on the NFS client directory. You can now access the Storage Gateway file system from the NFS client.

For more information, see Using Storage Gateway File Management Operations on page 3831.

**To mount a Storage Gateway file system automatically after a reboot**

You can mount a Storage Gateway NFS share either on directly to the host or remotely. When Storage Gateway restarts, the mount point may encounter residual file handle issues depending on the readiness of the fuse mount. The fuse mount takes some time to be available for a Storage Gateway restart.

Using an `/etc/fstab` entry to automount a Storage Gateway file system is **not supported**. Instead, you can set up an optional `cron` job for this purpose.

The `cron` job ensures the NFS share to be mounted only when the fuse mount is ready. However, this solution only works when the mount point is on the same Storage Gateway host. You must remount the NFS share to address file handling issues if it is mounted remotely.

1. Log in to the Storage Gateway host.
2. Create an executable script called `mountSgFilesystem.sh` and save it to an accessible location:

```
#!/bin/sh
#$1 - ip address
#$2 - nfs port
```

Oracle Cloud Infrastructure User Guide 3824
Viewing the Details of a File System

You can view the configuration details of a file system and monitor the upload activity through the management console of Storage Gateway.

To view the details of a file system

1. Log in to the management console.
2. Click the name of the file system.
   - The Details tab displays the Oracle Cloud Infrastructure service type, storage tier, and the identity domain associated with your tenancy. If the file system is connected, you can see mount point connection information to help you with mounting that file system. For example:

   **NFS Client Mount Command:** `mount -t nfs -o vers=4,port=\$1:/$3 $1:/$3 $4
break
fi
sleep 30
done`

   - The Settings tab displays the following details:
     - Details of the tenancy and scope specified for the file system.
     - File system properties.
     - NFS and cache settings for the file system.

   You can edit these settings. If you make changes, remember to click **Save**.

   If your file system is connected, you can also see:
   - The Activity tab, which shows ongoing and pending file upload activity.

   If you contact Oracle Support Services about any issue with the file system, you might need to provide the file system log to help diagnose the issue. To view or download the file system log, click **View Streaming Logs** near the lower-right corner of the Details tab.

   - The Completed Uploads tab, which shows the last 100 files that were uploaded to Oracle Cloud Infrastructure Object Storage during the current browser session.

   **Note:**

   The file list doesn’t persist across browser sessions. If you refresh the page or open the Completed Uploads tab in another browser after the files are uploaded, the list will be empty.

   - You can also disconnect the file system. See **Disconnecting a File System** on page 3826.
Changing the Properties of a File System

You can change the properties of a file system using the Storage Gateway management console.

To change the properties of a file system

1. Log in to the management console.
2. In the Dashboard, click the name of the file system that you want to edit.
3. In the Settings tab, edit the file system properties and advanced settings, such as the cache limits.
4. Click Save.
5. For the changes to take effect, disconnect and reconnect the file system.

Refreshing a File System

The auto-refresh feature triggers file system refreshes based on a time interval you specify. The system schedules the next refresh after any in-progress refresh completes. That means the elapsed time between the beginning of any two successive refreshes is equal to the specified auto-refresh interval plus the time required to run a file system refresh.

Use the following command to configure the auto-refresh feature:

```
ocisp set <file_system_name> dataset.refreshInterval=<interval_in_minutes>
```

The configuration command works on created and connected file systems. The configuration does not take effect until the file system is disconnected and reconnected or the Storage Gateway application restarts. To apply the changes, run:

```
ocisp down
cocisp up
```

Attribute caching can cause NFS clients to be unaware of files, corresponding to new objects in the bucket, that are created in a Storage Gateway file system during a refresh. You can use the noac mount option to turn off attribute caching. Turning off attribute caching can affect system performance.

When you run a refresh, the system reads attributes and fetches information about all objects in the corresponding bucket. Use a larger refresh interval for buckets with many objects.

**Note:**

After you refresh a file system, or create one for a bucket that already contains objects, Oracle recommends that you check for any files that might have been missed due to network connectivity issues.

To check for missing files, run the following command:

```
zgrep -ni "failed to get the object for" <path_to_gateway_logs>/<file_system_name>.*
```

For example, if the path to the gateway logging directory is `/ocisp/log` and the file system name is `my-fs-1`, the command is:

```
zgrep -ni "failed to get the object for" /ocisp/log/my-fs-1.*
```

Files listed in the output of this command were not successfully registered with the gateway. If any file names appear in the list, refresh the file system again.

Disconnecting a File System

When a file system is disconnected, no one can access or modify that file system.
We recommend disconnecting file systems that are not in use. Disconnecting a file system frees up the resources associated with that file system, making those resources available to file systems that are active (connected).

**To disconnect a file system**

1. Log in to the management console.
2. In the **Dashboard**, click the name of the file system that you want to disconnect.
3. Click **Disconnect**.

   When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.
4. For the changes to take effect, disconnect and reconnect the file system.

You can resume storing and retrieving data by connecting the file system again. You can delete the disconnected file system when you no longer need it. For more information, see [Deleting a File System](#) on page 3828.

**Importing an Existing File System**

Before you import an existing file system from another Storage Gateway, ensure that any pending file uploads to Oracle Cloud Infrastructure Object Storage are complete.

**To import an existing file system**

1. Log in to the management console.
2. Click the **Create File System** navigation link.
3. Click **Create File System** in the navigation pane on the left.

   The **Create a File System** page appears.
4. Enter the required information in **Create a File System**.
   For the file system name, enter the name of the existing file system that you want to import to this Storage Gateway.
5. Click **Save**.
6. Select the options that you’d like to enable in the file system.
7. Click **Show Advanced** and enter the required information.
8. Click **Save**.

   The file system is created and appears on the **Dashboard** tab.
9. Click **Connect** for the file system that you want to import.

   a. If the file system that you’re importing is connected to another Storage Gateway, the **File System: Claim Ownership** window appears so you can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information and click **Claim Ownership**:
   
   - Public key finger print
   - Private key
   - Private key passphrase

   b. If you connect to a file system that previously belonged to a different gateway, you must restart the new owning gateway:

```
oci_sg down
oci_sg up
```
10. Mount the file system to a directory on the Storage Gateway host and set up the NFS export. For example:

```bash
sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file_system_name> /<local_mount_point>
```

In this command:
- Replace `<NFS_port_number>` with the NFS port number you noted earlier.
- Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
- Replace `<ocisg_file_system_name>` with the file system name that you want to mount.
- Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

**Deleting a File System**

You can delete a file system from Storage Gateway when you no longer need it.

**To delete a file system:**

1. Log in to the management console.
2. On the **Dashboard**, identify the file system that you want to delete.
   
   **Important:**
   When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.
   Deleting a file system does not automatically delete the objects in the bucket. If you want to remove objects from the Object Storage bucket, set the **Delete Old File Versions** property for the file system and delete all the files before disconnecting the file system.

3. Ensure that the file system is disconnected. If it’s still connected, click **Disconnect**.
4. After the file system is disconnected, click its name.
   The details of the file system appear.
5. Click **Delete**.
   The file system is deleted from Storage Gateway.

**Managing Storage Gateway**

This topic describes some basic Storage Gateway management tasks.

**Managing Storage Gateway Using the CLI**

You can use the `ocisg` command line interface (CLI) to manage Storage Gateway. To use the CLI, open an `ssh` connection and log in to the host on which you installed Storage Gateway.

**Note:**
You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Storage Gateway Cloud Sync jobs. See **Using Storage Gateway Cloud Sync** on page 3837 for details.

The CLI supports the following Storage Gateway management tasks:
- **To start Storage Gateway:**

  ```bash
  sudo ocisg up
  ```
• To stop Storage Gateway:

```
sudo ocisg down
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the server with a Storage Gateway system fails, you can reinstall and start a new one. All the configuration and system data is automatically downloaded and applied. The pending upload and download activities resume when the new Storage Gateway system runs.</td>
</tr>
<tr>
<td>If a disk cache is unrecoverable on the Storage Gateway server, data might be lost since the file might not have been transferred to the bucket in your tenancy. To ensure efficient data protection, see Best Practices for Using Storage Gateway on page 3842.</td>
</tr>
</tbody>
</table>

• To view details about Storage Gateway and how to access the management console:

```
sudo ocisg info
```

• To find the version of Storage Gateway:

```
sudo ocisg version
```

• To configure Storage Gateway to use a proxy server for connections to Oracle Cloud Infrastructure Object Storage:

```
sudo ocisg configure proxy <proxy_server_URL>
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>After configuring the proxy server, you must stop and restart Storage Gateway.</td>
</tr>
</tbody>
</table>

By default, no proxy server is specified.

• To remove previously configured proxy server details in Storage Gateway:

```
sudo ocisg configure proxy [remove]
```

• To configure Storage Gateway to use SSL when communicating with the management console and REST APIs:

```
sudo ocisg configure ssl true
```

SSL is enabled by default.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>After configuring Storage Gateway to use SSL, you must stop and restart Storage Gateway.</td>
</tr>
</tbody>
</table>

To disable SSL:

```
sudo ocisg configure ssl false
```
To specify ports for the Storage Gateway services:

```bash
sudo ocisg configure port <service> <port_number>
```

- `<service>`: Specify `admin`, `nfs`, or `rest`.
- `<port_number>`: Ensure that the port number you specify is not already in use on the Storage Gateway host.

By default, the port number is assigned dynamically for the Storage Gateway services when you start Storage Gateway.

**Note:**
For the port assignment to take effect, you must stop and start Storage Gateway.

To remove the static port assignment for a service:

```bash
sudo ocisg configure port <service> remove
```

To allocate memory for the Storage Gateway host:

```bash
sudo ocisg configure memory <memory_in_GB>
```

To remove the memory allocation:

```bash
sudo ocisg configure memory remove
```

By default, Storage Gateway uses 4 GB of the available memory on the host server. You can delete the memory information by using the `remove` parameter.

**Note:**
After configuring memory for Storage Gateway, you must stop and restart Storage Gateway.

To specify the docker network mode:

```bash
sudo ocisg configure network mode
```

The mode can be either `host` or `bridge`.

The default mode is `bridge`. In this mode, you can run multiple instances of Storage Gateway on your host.

In the `host` mode, you can run only a single instance of Storage Gateway. Network performance is better in `host` mode.

**Note:**
After specifying the docker network mode, you must stop and restart Storage Gateway.

To change the Storage Gateway admin password:

```bash
sudo ocisg do password:reset
```

Set a new password:

```bash
sudo ocisg password:set <new_password>
```

Enter a password that meets the following requirements:

- Uses from 8 to 32 characters.
- Includes at least one special character, one numerical character, one uppercase character, and one lowercase character.
• To view help for the available commands:
  
  `sudo ocisg help`

**Using Storage Gateway File Management Operations**

This topic describes how to use the Storage Gateway file management operations.

**Important:**

Exercise caution when using the REST API, Java library, or any other client to retrieve, create, update, or delete objects directly in a bucket that’s mapped to a file system in Storage Gateway. Until you **Refresh** the Storage Gateway file system, Storage Gateway is not aware of the changes and data is inconsistent between Storage Gateway and Object Storage.

**Uploading Files to Buckets**

Before you connect the file system to the Oracle Cloud Infrastructure Object Storage bucket, make a note of the Oracle Cloud Infrastructure Object Storage tenancy details such as namespace, tenant OCID, and compartment OCID.

Copy the files to the mounted directory on the Storage Gateway or the NFS client host. Storage Gateway writes the files to the disk cache. The system queues and asynchronously uploads the files to an Object Storage bucket. Corresponding objects are created in the storage tier you specified during file system creation, either **Standard** or **Archive**. See Creating Your First File System on page 3816 or Managing File Systems on page 3820 for details.

**Note:**

Storage Gateway automatically performs multipart upload for files larger than 128 MB. See Using Multipart Uploads on page 3477 for details.

You can view files uploaded to your tenancy during the current browser session. See the **Completed Uploads** tab in Viewing the Details of a File System on page 3825.

**Reading Files**

When you write a file to a Storage Gateway file system, the system stores the file in the local disk cache. You can read the file directly from the mounted directory. Storage Gateway asynchronously copies the file to the corresponding Object Storage bucket in your tenancy. To retrieve the data from the bucket using Storage Gateway, read the files from the mounted directory.

If space is available, Storage Gateway automatically places the files in the read cache. If the file is in the read cache, you can retrieve the file immediately. If the file is not available in the read cache and it is stored in the **Archive** tier, you must restore the object. For more information, see Restoring Files and Objects from Archive Storage on page 3832.

**Note:**

You cannot read or write to a file that is stored in the **Archive** tier and does not exist in the read cache. This action returns an Input/Output error.

Storage Gateway checks data integrity using checksum verification on uploads. The system might not be able to perform data integrity validation on a partial read, since checksum verification works only on a whole file or object.

To read the upload checksum for a file in a file system, run the following command from the NFS client on which the file system is mounted:

```
sudo docker exec ocisg bash -c "cd /mnt/gateway/${filesystem} && cat ${filepath}:::meta:csm"
```
Restoring Files and Objects from Archive Storage

You can initiate a file restore from the Storage Gateway command line. You can also initiate an object restore from Archive Storage in Oracle Cloud Infrastructure. You can read the corresponding file using Storage Gateway after the object has been restored to Object Storage.

Note:

Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management on page 3466 for details.

Restoring Archived Files Using the Storage Gateway Command Line

To restore one or more archived files

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore` command. Specify the full path to a directory or to a file.

```
ocisg archive restore <file_system_name> <full/path/to/directory/or/file> [<#_of_hours>]
```

By default, the file remains restored for 24 hours after restoration. However, you can optionally specify `[<#_of_hours>]` with an integer value of from 1 to 240 hours.

For example, to restore all the files in a directory:

```
ocisg archive restore myFS myDir/mySubDir 240
```

For example, to restore a single file:

```
ocisg archive restore myFS myDir/mySubDir/file2 240
```

To check the archive status of one or more files

You can get the archive status for all files in a file system, for all files in a directory, or for an individual file.

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore-status` command.

```
ocisg archive restore-status <file_system_name> [<full/path/to/directory/or/file>]
```

The status can be one of the following:

- Archived
- In progress
- Restored

For example, to check the archive status for all files in a file system:

```
ocisg archive restore-status myFS
```
To check the archive status for all files in directory:

```
ocissg archive restore-status myFS myDir/mySubDir
```

To check the archive status for an individual file:

```
ocissg archive restore-status myFS myDir/mySubDir/file2
```

To check the restoration job status for a file system

You can get the status for all restoration jobs that have been initiated for a file system.

Open a command prompt on the Storage Gateway host and run the `ocissg archive restore-jobs` command.

```
ocissg archive restore-jobs <file_system_name>
```

For example:

```
ocissg archive restore-jobs myFS
```

### Restoring Archived Files Using Oracle Cloud Infrastructure

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you use Oracle Cloud Infrastructure to restore archived objects, use the Refresh operation in Storage Gateway to display the data that was added or modified directly in Object Storage.</td>
</tr>
</tbody>
</table>

To restore an archived object using the Oracle Cloud Infrastructure Console

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_RESTORE permissions to restore Archive Storage objects.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders (if enabled) and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to restore.
6. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.
7. Optionally, specify the **Time Available for Download in Hours**.
   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object Details or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.
   After the allotted download time expires, the object returns to Archive Storage.
8. Click **Restore Objects**.
   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option**.
Storage Gateway

**To check the status of an object restoration using the Oracle Cloud Infrastructure Console**

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of objects in the bucket is displayed.
5. Click the Actions icon (three dots) to the right of the object you want to check the restoration or download status of, then click Details.
6. Check the Status.
   Status displays one of the following:
   - Archived
   - Restoring
   - Restored

**To restore an archived object using the Oracle Cloud Infrastructure CLI**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_RESTORE permissions to restore Archive Storage objects.</td>
</tr>
</tbody>
</table>

```
oci os object restore --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]
```

By default, you have 24 hours to download an object after restoration. However, you can optionally specify --hours with an integer value of download time of from 1 to 240 hours.

**To check the status of an object restoration using the Oracle Cloud Infrastructure CLI**

```
oci os object restore-status --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name>
```

**Deleting Files**

Remove the files that you no longer need from the NFS client by deleting them from the directory on which the file system is mounted.

**Monitoring Storage Gateway**

This topic describes how to monitor Storage Gateway file system upload activity, system health, and storage usage. The topic also describes how to view system notifications and how to receive notifications in email.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitoring file system activity in the Storage Gateway management console consumes system resources. Monitoring file system activity is not recommended when Storage Gateway is under high load.</td>
</tr>
</tbody>
</table>

**Monitoring Upload Activity**

When you upload a file to a file system, you can view the status of the upload activity. The Activity tab shows the ongoing and pending upload activity in a file system.
To monitor upload activity

1. Log in to the management console.
2. Click File Systems in the upper-right corner of the management console.
3. On the File Systems page, select a file system.
4. Click Activity.

You can see the upload progress of the file in the Uploading pane.

Monitoring System Health Status

You can monitor the overall system health status using System Status on the right side of the management console.

Storage Gateway performs an automated "health check" on the system to monitor the status of:

- Storage Gateway resources and services.
- Local storage, file system cache, metadata storage, and log storage.

System Status shows the result of Storage Gateway health analysis, either Healthy or Unhealthy.

System Status also provides information on:

- Any system warnings or errors.
- Local I/O Mode, which depends on local disk usage:
  - Normal
    The available disk space is greater than 10 GB in Storage Gateway. You can upload files in Storage Gateway and upload them to your Oracle Cloud Infrastructure tenancy.
  - Rejecting I/O
    The available disk space is less than 10 GB in Storage Gateway. Storage Gateway runs in protection mode and does not allow any writes to its local disk. All read operations work normally. All Storage Gateway metadata operations fail except for deletions and truncation.
    To return to Normal mode, you must wait until all ongoing upload activities complete and the files are removed from the read cache.
  - Throughput
    The approximate upload throughput to Object Storage. If there is no recent activity, Throughput shows Idle.
  - Available Read Cache
    The amount of read cache available. For optimal performance, reliability, and fault tolerance, follow the guidelines for configuring cache storage. See Configuring Local Storage for File Systems and Cache on page 3798 for details.
  - Pending Uploads
    The number of files or directories, for all file systems, awaiting upload to Object Storage. If Pending Uploads is 0 (zero), all files and directories have been uploaded.

Monitoring Storage Usage

You can track the storage usage and availability.

To monitor storage usage

1. Log in to the management console.
2. Click System in the upper-right corner of the management console.
3. Click **System Stats**.

   The system data appears in three panes:
   
   • **Local Storage**
   • **Local I/O**
   • **Local Resources**

**Local Storage**

This pane provides a graphical representation of the amount of storage being used and the available free storage on the Storage Gateway host. You can see:

• Available local storage.
• Storage used for pending uploads and preserved cache files.
• Storage used for metadata.
• Storage used for logging.
• Storage used for other applications.

**Local I/O**

This pane displays the local I/O mode of Storage Gateway based on the local disk space usage on the Storage Gateway host.

**Local Resources**

This pane shows the overall memory usage and availability for Storage Gateway from the following fields:

• **Available Cores**: The number of CPUs being used by Storage Gateway.
• **Maximum Memory Available to Storage Gateway**: The total RAM available for Storage Gateway.
• **Memory Used by Storage Gateway**: The amount of memory being used by the file systems in Storage Gateway.
• **Free Memory**: The amount of free RAM available in Storage Gateway host.

**Viewing System Notifications**

The **System Notifications** tab shows system notifications and helps you track overall system performance.

**To view system notifications**

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.

   You can view a list of warnings or critical system notifications.

**Configuring Email Notification**

You can configure Storage Gateway to notify you by email about system health and Cloud Sync job completion.

**To configure email notification**

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.
4. If email notifications are not yet configured, click **Click here to configure**.
5. Enter the required information for the following fields:
   
   • SMTP server.
   • Email addresses to receive notifications.
6. Click **Show Advanced Options** and enter the required information in the advanced configuration fields:
   - SMTP port.
   - SMTP User name.
   - SMTP Password.
   - Sender’s Email Address.

   The default value is: noreply@oracle.com

7. Click **Save**.

8. Click **Test Email Notification** to verify that the specified email address receives a system notification email.

**Using Storage Gateway Cloud Sync**

Use Cloud Sync to move on-premises datasets from a local NFS-mounted file system to Storage Gateway, where the data is then moved asynchronously to Oracle Cloud Infrastructure Object Storage. You can also use Cloud Sync to synchronize Storage Gateway file system changes back to the local file system.

Cloud Sync generates the following for each sync job:

- Sync status (Created, Running, Completed, Failed, or Canceled).
- Number of files and directories to be copied from the source to the target.
- File and directory upload progress.
- Number of files and directories uploaded to the target.
- Time the job started, the time the job ended, and the run duration.
- The number of files skipped. (Cloud Sync skips non-regular files, such as symlinks, in the source directory.)
- A list of skipped files.

You can use the Storage Gateway management console or the command line interface (CLI) to create, manage, and monitor Cloud Sync jobs.

**About Cloud Sync**

Cloud Sync is an enhanced wrapper around the Linux `rsync` command and relies on `rsync` to detect new and changed files using size and modification time. Cloud Sync also relies on `rsync` to verify the files once the data transfer is complete using checksums of the files. Cloud Sync calls the Storage Gateway diagnostic commands to provide detailed data movement progress and status between your local server, Storage Gateway, and Oracle Cloud Infrastructure.

**Understanding Failure Behavior**

Because the file system is mounted over NFS locally, the NFS client running on the host handles any issues resulting from file system availability or connectivity.

Cloud Sync does the following:

- Reports and logs any failures to list or copy specific files (for example, resulting from permission issues).
- Monitors and reports on the pending and completed uploads to Object Storage.

Storage Gateway handles any connectivity and access issues to Object Storage and performs retry operations as needed.

**Prerequisites for Cloud Sync**

- Create the Storage Gateway file system that serves as either the source or target destination for the sync operation. A file system on the Storage Gateway host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage. See Creating Your First File System on page 3816 or Adding a File System on page 3820 for details.
- Obtain the proper credentials to mount the file system share from the local server.
The local server source must:

- Have names services set up correctly so that UIDs and GIDs are preserved and are not remapped to nobody.
- Be exported with root permissions to read and traverse the entire source tree.
- The filesystem to be synced needs to be NFS mounted to a mount point under `/cloudsync/mounts/`

### Important:

If a Storage Gateway file system serves as the source, set the auto-refresh for new objects in the bucket to be synced using CloudSync. Use the following command to set the file system refresh at regular intervals:

```
ocisg set file_system_name
    dataset.refreshInterval=interval_in_minutes
```

Restart Storage Gateway, then run the following commands to apply the changes:

```
ocisg down
ocisg up
```

See [Managing File Systems](#) on page 3820 for more information.

## Using the Management Console

You can use the Storage Gateway management console to create, manage, and monitor Cloud Sync jobs.

**To create a Cloud Sync job that syncs all files and directories at the specified source location**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.

   By default, a list of all the Cloud Sync jobs that have already been created is displayed.

3. Click **Create Cloud Sync Job**.
4. In **Create Cloud Sync Job** page, specify the attributes of the job:
   - **Job Name**: Required. A unique, user-friendly name for the job. Avoid entering confidential information.
   - **Source Path**: Path to the Cloud Sync source directory containing the files to sync.
     - If you are syncing a local file system to Oracle Cloud Infrastructure, specify the source path as:
       ```plaintext
       /cloudsync.mounts/<user_mount>[/<path_to_directory>]
       ```
     - If you are syncing Oracle Cloud Infrastructure to a local file system, specify the source path as:
       ```plaintext
       <storage_gateway_file_system>/<path_to_directory>
       ```
   - **Target Path**: Path to the Cloud Sync target directory for the synced files.
     - If you are syncing a local file system to Oracle Cloud Infrastructure, specify the target path as:
       ```plaintext
       <storage_gateway_file_system>/<path_to_directory>
       ```
     - If you are syncing Oracle Cloud Infrastructure to a local file system, specify the target path as:
       ```plaintext
       /cloudsync.mounts/<user_mount>[/<path_to_directory>]
       ```
   - **Enable Auto-Deletion**: Enable this option if you want Cloud Sync to automatically delete files from the target when:
     - Files are deleted from the source.
     - Source files have been renamed.
     
     By default, when a file is deleted on the source, Cloud Sync does not automatically delete the file on the target unless you enable **Enable Auto-Deletion**. Also, when a source file is renamed, the file with the old name is deleted and a file with the new name is created. By default, Cloud Sync does not delete the file with the old name on the target (retaining both a file with the old name and a file with the new name) unless you choose **Enable Auto-Deletion**.
     
     The names of all deleted files are stored in a job-specific log directory.

5. Click **Create Cloud Sync Job**.

A Cloud Sync job is created and displayed in the list of jobs.

**To list Cloud Sync jobs**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
   
   By default, a list of all the Cloud Sync jobs is displayed.
3. Optionally, you can filter the job listing by status (Created, Running, Completed, Failed, or Canceled) and type of Cloud Sync job (upload or download) by clicking one of the **Quick Filters**.

**To run a Cloud Sync job**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job that you want to run.
4. Click **Run** to the right of the job name.

Cloud Sync runs the job. The management console displays the status of the job just below the job name.

**To get the status of a Cloud Sync job**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job for which you want status.

   The management console displays the status of the job (Created, Running, Completed, Failed, or Canceled) just below the job name.

**To cancel a Cloud Sync job**

You can only cancel a job if it is running.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job that you want to cancel.

   **Tip:**
   
   Use **Quick Filters** to get a list of **Running** jobs.

4. Click **Cancel** to the right of the job name.

**To delete a Cloud Sync job**

You cannot delete a running job.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the created, canceled, or failed Cloud Sync job that you want to delete.
4. Click **Delete** to the right of the job name.

**Using the CLI**

You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Cloud Sync jobs. Using `ssh`, log in to the host on which you installed Storage Gateway to use the CLI.

**To create a Cloud Sync job that syncs all files and directories at the specified source location**

Open a command prompt and run `ocisg cloudsync create` to create a job:

```bash
```

--schedule is an option to automate the Cloud Sync job so it runs according to the specified schedule. Set the schedule value using the format used for cron jobs. For example, `--schedule="*/5 * * * *"` runs the job every five minutes.

--auto-delete is an option to direct Cloud Sync to automatically delete files from the target when files are deleted from the source, and old names of files that have been renamed. By default, Cloud Sync does not automatically delete the files on the target unless you specify this option. The names of all deleted files are stored in a job-specific log directory.

--parallel=<number> is an option to specify the number of processes for data synchronization. By default, the number of processes is set to one. With a single process using a hard disk drive, you can expect a sync rate of 60-70 MB/s. If your system has higher disk throughput, you can use the number of processes that is proportional to the available bandwidth. Oracle recommends from two to five processes for optimal performance. The maximum number of processes allowed is 10.

--files-from=<file> is an option to specify a set of files that you want to sync to the target. If you do not set this option, the service syncs all files. The `<file>` should be a file under the `/cloudsync/` directory. For example, `--files-from="/cloudsync/files.list"`. 
--exclude-from=<file> is an option to specify a set of files that you want to exclude from the Cloud Sync job. The <file> should be a file under the /cloudsync/ directory. For example, `--exclude-from="/cloudsync/exclude.list"`.

--verify-contents is an option to enable verification of the destination contents against the source. If you do not explicitly enable verification, new files added to Cloud Sync sources after the job has started are not reported as errors when they do not appear in the destination.

Avoid entering confidential information.

The Cloud Sync job is created and displayed in the list of jobs.

**To list Cloud Sync jobs**

Open a command prompt and run `ocisg cloudsync list` to list jobs:

```
sudo ocisg cloudsync list [-s <status>] [<job_name_or_type>]
```

Optionally, you can filter the list of jobs by specifying job status (Created, Running, Completed, Failed, or Canceled). You can also list a single job by specifying the name of that job.

For example:

```
sudo ocisg cloudsync list sync_to_os1
```

**To run a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync run` to run a job:

```
sudo ocisg cloudsync run <job_name>
```

For example:

```
sudo ocisg cloudsync run sync_to_os1
```

**To get the status of a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync status` to get the status of a job:

```
sudo ocisg cloudsync status <job_name>
```

For example:

```
sudo ocisg cloudsync status sync_to_os1
```

**To cancel a Cloud Sync job**

You can cancel a job only if the job is in progress.

Open a command prompt and run `ocisg cloudsync cancel` to cancel a job:

```
sudo ocisg cloudsync cancel <job_name>
```

For example:

```
sudo ocisg cloudsync cancel sync_to_os1
```

**To delete a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync delete` to delete a job:

```
sudo ocisg cloudsync delete <job_name>
```
For example:

```
sudo ocisg cloudsync delete sync_to_os1
```

### Best Practices for Using Storage Gateway

Apply the recommendations found in the following topics to optimize the manageability, performance, reliability, and security of your Storage Gateway.

- [Security Considerations](#) on page 3793
- [Understanding Storage Gateway Performance](#) on page 3803
- [Configuring Local Storage for File Systems and Cache](#) on page 3798
- [Determining File System Cache Size](#) on page 3798
- [Recommended Uses and Workloads](#) on page 3792
- [Uses and Workloads Not Supported](#) on page 3792
- [Renaming Directory Trees](#)
- [Limits on Storage Gateway Resources](#) on page 3794

### Troubleshooting Storage Gateway

This topic covers some common Storage Gateway issues and how to address them.

**I installed docker and NFS on my host, but I can’t install Storage Gateway**

1. Add the docker group to the existing groups in your host:
   ```
sudo groupadd docker
   ```
2. Add your user id to the docker group:
   ```
   usermod -a -G docker <username>
   ```
3. Shut down your host:
   ```
   shutdown -r now
   ```
4. Log in to your host and run the Storage Gateway installation script:
   ```
   sudo ./ocisg-install.sh
   ```

**I can’t access the management console**

1. Run the `ocisg info` command:
   ```
   sudo ocisg info
   ```
   If Storage Gateway is not running, start Storage Gateway:
   ```
   sudo ocisg up
   ```
2. Make a note of the management console port number from the output:
   ```
   Management Console: https://myStorageGatewayHost.example.com:32775
   ```
   If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.
   ```
   NFS Port: 32774
   ```
Example: `mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/<OCISG File System name> / local_mount_point`

In the example, `myStorageGatewayHost.example.com` is the Storage Gateway host name and 32775 is the management console port number.

3. Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
4. Check that the management console port number in the output from `ocisg info` matches the port you’re using to access the management console.
5. Ensure that you are using `https` if you have enabled SSL. SSL is enabled by default.

I am unable to mount a file system

1. Run the `ocisg info` command:

   `sudo ocisg info`

   If Storage Gateway is not running, start Storage Gateway:

   `sudo ocisg up`

2. Make a note of the management console port number and NFS port number from the output:

   Management Console: https://myStorageGatewayHost.example.com:32775

   If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.

   NFS Port: 32774
Example: mount -t nfs -o vers=4,port=32774
myStorageGatewayHost.example.com:/<OCISG File System name> /local_mount_point

In the sample output:
• myStorageGatewayHost.example.com is the Storage Gateway host name.
• 32775 is the management console port number.
• 32774 is the NFS port number.
• Log in to the NFS client from which you want to access your service instance through Storage Gateway.
• Create a directory on the NFS client.
• Mount the file system on the directory that you created on the NFS client:

```
sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file_system_name> /<local_mount_point>
```

In this command:
• Replace `<NFS_port_number>` with the NFS port number.
• Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
• Replace `<ocisg_file_system_name>` with the name of the file system you want to mount.
• Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

For example:

```
sudo mount -t nfs -o vers=4,port=32774
myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
```

In this example,
• 32774 is the NFS port number.
• myStorageGatewayHost.example.com is the Storage Gateway host name.
• myFirstFS is the file system name.
• /home/xyz/abc is the path to the directory abc on the NFS client.
• Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
• Ensure that the NFS protocol is running:

```
sudo systemctl enable nfs-server
```

• Check that the NFS port number in the output from `ocisg info` matches the port you’re using to connect to with your NFS client.

### I cannot delete a bucket after canceling a Cloud Sync job

If you cancel an active or stalled Cloud Sync job and disconnect the file system, you might not be able to delete the associated Object Storage bucket. If file uploads were in progress when you canceled the job, the Object Storage service might expect a commit that never completed. In this case, the service does not allow bucket deletion and returns the error "multipart upload pending". You can use the CLI to resolve the issue.

1. List the bucket’s pending multipart uploads:

```
oci os multipart list -bn <bucket_name>
```

Be sure to note the relevant object names and upload IDs.
2. Delete all pending uploads:

   ```sh
   oci os multipart abort -bn <bucket_name> --object-name <object_name> --upload-id <upload_id>
   ```

3. Delete the bucket:

   ```sh
   oci os bucket delete -ns <object_storage_namespace> --name <bucket_name>
   ```

### Additional NFS Troubleshooting

The Storage Gateway installation software installs the NFS, if needed, and automatically configures it. After the installation, the NFS is configured and a file system created. You can then mount the filesystem from a remote client. Sometimes this mount can fail.

To troubleshoot a mount failure:

1. Ensure that the NFS port is included in the Storage Gateway's subnet security list and that it is available there. If the port does not appear in the subnet security list, add it and retry the mount.
2. Run `rpcinfo -p`. The command should return:

   ```
   100003 4 tcp 2049 nfs
   ```

   This result means that NFS is ready, available, and the mount succeeds.
3. If `nfs` does not appear in the response to the `rpcinfo -p` command, enable and restart both `rpcbind` and `NFS`:

   ```
   sudo systemctl enable rpcbind
   sudo systemctl enable nfs
   sudo systemctl start rpcbind
   sudo systemctl start nfs
   ```

4. Run the `rpcinfo -p` command again to verify that NFS is now available.
   
   a. If NFS still is not available, reboot the Storage Gateway.
   b. Run the `rpcinfo -p` command again to confirm.
5. If you remain unable to mount the file system, contact My Oracle Support.

### Contacting Oracle Support

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Creating a Service Request Using the Console on page 126 for information.

### Upgrading Storage Gateway

Storage Gateway notifies you when there is a new version available for you to download and install:

- A pop-up notification appears in the management console after you log in.
- A small banner notification appears at the top of the Dashboard.
- If you have configured email notifications, the system sends an email notification. See Configuring Email Notification on page 3836 for details.

**Important:**

If you are upgrading from Storage Gateway 1.0, underlying database and schema changes require you to recreate your Storage Gateway file systems. See Recreating Your File Systems on page 3846 for details.
Before You Begin

- Plan for downtime appropriately since the upgrade takes some time to complete. The downtime varies depending on the system resources, the number of file systems, and the number of files.
- Wait for any pending or ongoing write operations from the NFS client instances to complete, then unmount all file systems.
- Wait for pending uploads to Oracle Cloud Infrastructure Object Storage to complete. On the Dashboard under System Status, ensure that the Pending Uploads field shows 0.
- Disconnect all of the file systems.
- Ensure that there is no ongoing activity in the Activity tab for each file system in the management console.

Important:

To enable partial update capabilities in Storage Gateway, there must be no pending uploads for any associated file systems before the upgrade. The upgrade process purges the existing local cache across all Storage Gateway file systems.

Upgrading Storage Gateway

To upgrade to Storage Gateway 1.3

1. Log in to your Storage Gateway host.
2. Download the Storage Gateway 1.3 tar archive.
3. Extract the files from the downloaded ocisg-1.3.tar.gz file:

```bash
  tar xzvf ocisg-1.3.tar.gz
```

This command extracts the file's contents to a subdirectory named ocisg-1.3.
4. Change directory to ocisg-1.3:

```bash
  cd ocisg-1.3
```
5. Run the installation script as sudo or root user:

```bash
  sudo ./ocisg-install.sh
```

If you encounter any interruption during the upgrade, such as lost connectivity, rerun the installation script to resume the upgrade.

If you are upgrading from Storage Gateway 1.0, you must recreate the file systems that were created in the 1.0 version of the Storage Gateway software. Connect the file systems in the management console and claim ownership if there’s a bucket ownership prompt. Storage Gateway version 1.3 rebuilds the local metadata for existing buckets in Object Storage. The more objects there are in the buckets, the more time it takes to rebuild the metadata.

Recreating Your File Systems

When you created file systems in Storage Gateway 1.0, corresponding Oracle Cloud Infrastructure Object Storage buckets were created. Recreate those file systems in Storage Gateway so that you can connect to the same buckets and automatically see the files that have already been uploaded to Object Storage.

When you recreate Storage Gateway file systems, data that you already uploaded to Oracle Cloud Infrastructure Object Storage is automatically included in the newly created file system.

To recreate your file systems

1. Log in to the management console.
2. Click File Systems on the upper-right area of the management console.
3. Click Create File System.
4. Enter the required information in **Create a File System**:

- **File System Name**: A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
  - Use from 1 to 256 characters.
  - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

**Important:**

The name **cannot** contain the following:

- A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
- The strings "pub" or "priv"

If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.

If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

- **Select the Object Storage tier in which you want to store your data**

**Important:**

Once set, you cannot change the storage tier in which a bucket resides.

You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management on page 3466 for details.

- **Standard**: The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage on page 3392 for more information.
- **Archive**: The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage on page 484 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see Restoring Files and Objects from Archive Storage on page 3832).

- **Object Storage endpoint**: Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

**Important:**

The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and OCIDs on page 4179 for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
- **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

**Note:**

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair
Storage Gateway

5. Click Save.

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click Save again.

6. Click Show Advanced File System Configuration.

Enter the required configuration information or click Use Default to accept the default values:

- **NFS Allowed Hosts**: A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64, 192.0.2.0/24

- **NFS Export Options**: The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

  **Important:**

  Do not specify the fsid option.

- **Concurrent Uploads**: The number of concurrent uploads to Oracle Cloud Infrastructure.
  
  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.
  
  The allowed range is from 1 to 30.

- **Sync Policy**: The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only Posix Standard is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead**: The number of blocks to be downloaded and used to read ahead when reading files for improved performance.
  
  Default value: 50

- **Maximum Read Cache Size in GiB**: The maximum read cache.
  
  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  **Note:**

  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

See Configuring the Cache for File Systems on page 3797 for details.

The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click Save.

The file system is created and appears in the File Systems listing.

Uninstalling Storage Gateway

This topic describes how to uninstall Storage Gateway.

Uninstalling

To uninstall Storage Gateway
1. Log in to the on-premises host or compute instance from which you want to uninstall Storage Gateway.
2. Stop Storage Gateway:
   
   ```
   sudo ocisg down
   ```
3. If the ocisg_data container exists in docker ps -a output, remove it:
   
   ```
   sudo docker rm -v ocisg_data
   ```
4. Delete the image in docker:
   
   ```
   sudo docker rmi $(sudo docker images| grep ocisg | awk '{print $3}')
   ```
5. Delete all the files in /usr/bin/ that begin with ocisg:
   
   ```
   sudo rm /usr/bin/ocisg*
   ```
6. View the contents of the file gateway_config:
   
   ```
   cat /etc/gateway_config
   ```

   **Sample output:**

   ```
   $ cat /etc/gateway_config
   DATASTORAGE=/ocisg/cache
   MDSTORAGE=/ocisg/metadata
   LOGSTORAGE=/ocisg/log
   PROXY=
   USE_SSL=
   MEMORY=
   NETWORK=bridge
   HTTP_FRAMEWORK=
   ADMINPORT=443
   NFSPORT=32769
   RESTPORT=32768
   ```

   • Delete the DATASTORAGE directory, for example:
     
     ```
     sudo rm -rf /ocisg/cache
     ```
   • Delete the MDSTORAGE directory, for example:
     
     ```
     sudo rm -rf /ocisg/metadata
     ```
   • Delete the LOGSTORAGE directory, for example:
     
     ```
     sudo rm -rf /ocisg/log
     ```
   • Delete the gateway_config file:
     
     ```
     sudo rm /etc/gateway_config
     ```
   • Delete the Storage Gateway installation directory ocisg:
     
     ```
     sudo rm -rf /opt/ocisg
     ```

**Getting Help with Storage Gateway**

This topic provides information about getting help with Oracle Cloud Infrastructure Storage Gateway.
Contacting Oracle Support

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Creating a Service Request Using the Console on page 126 for information.

Downloading the Support Bundle

If you contact Oracle Support about any issue with Storage Gateway, you might need to provide a support bundle to help the Oracle Support technicians diagnose the issue.

1. Log in to the management console.
2. Click System in the upper-right corner of the management console.
3. Click Help.
4. Click Download Support Bundle in System Logs.
   You can download and save the support bundle.

Contents of the Support Bundle

The support bundle contains the following information:

- All of the logs needed for diagnostics.
- Local storage usage information.
- Basic system information such as memory size, Docker version, and the Storage Gateway version.
- A list of file systems.
- Cloud Sync job details.
The Oracle Cloud Infrastructure Streaming service provides a fully managed, scalable, and durable solution for ingesting and consuming high-volume data streams in real-time.

Use Streaming for messaging, ingesting application logs, operational telemetry, web click-stream data, or any other use cases in which data is produced and processed continually and sequentially in a publish-subscribe messaging model.

About Streaming

Here's how Streaming works: a producer publishes messages to a stream, which is an append-only log. These messages are distributed among Oracle-managed partitions using the message's key for scalability.

Partitions allow you to distribute a stream by splitting messages across multiple nodes (or brokers). Each partition can be placed on a separate machine to allow multiple consumers to read a stream in parallel. Consumers can read from any partition regardless of where the partition is hosted. All partitions associated with a stream are deleted when the stream is deleted.

A consumer reads messages from one or more partitions. Each message within a stream is marked with an offset value, so a consumer can pick up where it left off if it is interrupted. Consumers can read messages individually, or as a member of a consumer group.

You can use Streaming for:

**Messaging**

Use Streaming to decouple the components of large systems. Producers and consumers can use Streaming as an asynchronous message bus and act independently and at their own pace.

**Metric and log ingestion**

Use Streaming as an alternative for traditional file-scraping approaches to help make critical operational data more quickly available for indexing, analysis, and visualization.

**Web or mobile activity data ingestion**

Use Streaming for capturing activity from websites or mobile apps, such as page views, searches, or other user actions. You can use this information for real-time monitoring and analytics, and in data warehousing systems for offline processing and reporting.
Infrastructure and apps event processing

Use Streaming as a unified entry point for cloud components to report their lifecycle events for audit, accounting, and related activities.

Benefits of Streams

Streams have several advantages over traditional messaging queues. Such as:

Configurable message persistence

You control how long your data is retained. Messages in a stream are available for the entirety of the stream's configured retention time.

Replay

Because a stream's messages are not removed immediately when processed by consumers, you can replay any and all messages in the stream at any time within the configured retention limit.

Message guarantees

Each message is guaranteed to be delivered at least once. In some cases, such as a consumer's failure to commit messages before going offline, messages may be delivered multiple times.

Order guarantees

Messages within a stream, per partition, are always delivered in the same order that they were produced.

Client-side cursors

Your client applications control and track which messages are read and can move the cursor as needed for maximum flexibility.

Horizontal scale

Partitions provide an opportunity to scale up throughput to meet the needs of multiple consumers, resulting in increased flexibility.

Consumer groups

Consumer groups handle all of the coordination that is required to deliver messages to multiple consumers in a balanced manner. Because this management is handled by a consumer group on behalf of all of its members, you can enjoy reduced overhead and operational ease.

Streaming Concepts

The following concepts are essential to understanding and working with Streaming.

stream

A partitioned, append-only log of messages.

stream pool

A grouping that you can use to organize and manage streams, including any shared Kafka or security settings.

partition

A section of a stream. Partitions allow you to distribute a stream by splitting messages across multiple nodes. Each partition is typically placed on a separate virtual machine in order to provide durability of data. This also allows multiple consumers to read from a stream in parallel.

cursor

A pointer to a location in a stream. This location could be a pointer to a specific offset or time in a partition, or to a groups' current location.
**message**
A Base64-encoded message that is published to a stream.

**producer**
An entity that publishes messages to a stream.

**consumer**
An entity that reads messages from one or more streams.

**consumer group**
A set of instances which coordinates messages from all of the partitions in a stream. At any given time, the messages from a specific partition can only be consumed by a single consumer in the group.

**instance**
A member of a consumer group. Instances are defined when a group cursor is created. Group membership is maintained through interaction; lack of interaction results in a timeout, removing the instance from the consumer group.

**topic/key**
An identifier used to group related messages.

**offset**
The location of a message within a partition. Each message within the partition is identified by its offset. Consumers can read messages starting from any chosen offset. You can use the offset to restart reading from a stream if interrupted.

**permissions**
You can use IAM to set permissions on the following operations: list, get, update, create, and delete streams.

### Streaming Features
Streaming provides the following features:

**Fully managed**
Streaming is fully managed, from the underlying infrastructure to its provisioning, deployment, maintenance, security patching, and replication. Integration with Monitoring and default metrics make operations easy.

Oracle manages stream partitions and consumer groups can handle your message offsets.

**Durability and Availability**
Messages published to the Streaming service are synchronously replicated across three availability domains when available. In regions with a single availability domain, the data is replicated across multiple fault domains. This ensures that even the failure of an availability domain or fault domain does not result in data loss. The result is highly durable data.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for Streaming. Refer to the Oracle Cloud Infrastructure Service Level Agreement page for details.

**Security**
Streaming data is encrypted both at rest and in transit, ensuring message integrity. You can let Oracle manage encryption, or use the Oracle Cloud Infrastructure Vault service to securely store and manage your own encryption keys if you need to meet specific compliance or security standards.

Integration with Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who and what services can access which keys and what they can do with those resources.

Private endpoints restrict access to a specified virtual cloud network (VCN) within your tenancy so that its streams cannot be accessed through the internet.
For more information, see Stream Security on page 3858.

Kafka compatibility

Streaming makes it possible to offload the setup, maintenance, and management of the infrastructure that hosting your own Apache Kafka cluster requires.

Streaming is compatible with most Kafka APIs, allowing you to use applications written for Kafka to send messages to and receive messages from the Streaming service without having to rewrite your code. See Using Kafka APIs on page 3881 for more information.

Streaming also takes advantage of the Kafka Connect ecosystem to interface directly with first-party and third-party products by using out-of-the-box Kafka source and sink connectors. See Using Kafka Connect on page 3883 for more information.

Ways to Access Streaming

You can access Streaming using any of the following options, based on your preference and use case.

- Oracle Cloud Infrastructure REST APIs provide the most functionality, but require programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs on page 4368. The Streaming service is accessible with the Streaming API.

  Tip:

  Because Streaming is compatible with the Apache Kafka API, applications written for Kafka can also access Streaming.

- Oracle Cloud Infrastructure provides SDKs so that you can interact with Streaming without having to create a framework. Basic Streaming usage examples are included with our SDKs. For more information about using the SDKs, see the SDK Guides.

- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Using the CLI on page 4207.

- The Console is an easy-to-use, browser-based interface. You can use the Console to create and manage streams, stream pools, and Kafka Connect configurations, but you cannot publish or consume messages using the Console.

  To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Using Streaming

To get started with Streaming, see the following topics:

- For instructions on how to create and manage streams, see Managing Streams on page 3856 and Managing Stream Pools on page 3864.
- For information about publishing messages to a stream, see Publishing Messages on page 3870.
- For information on how to consume messages, see Consuming Messages on page 3873.
- For information on Apache Kafka compatibility, see Using Streaming with Apache Kafka on page 3880.
- For API reference documentation, see Streaming API.
- For SDK and CLI information, see Software Development Kits and Command Line Interface on page 4225.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).
An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize Streaming users, see Common Policies on page 2142.

For in-depth information on granting users permissions for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

Limits on Streaming Resources

The Streaming service has the following limits:

- The maximum retention period for messages in a stream is seven days. The minimum retention period is 24 hours. All messages in a stream are deleted after the retention period passes, whether or not they have been read.
- The retention period for a stream cannot be changed after creation of the stream.
- A tenancy has a default limit of five partitions (Monthly Universal Credits) or zero partitions (Pay-as-You-Go or Promo). If your throughput requires additional partitions, you can request more.
- The number of partitions for a stream cannot be changed after creation of the stream.
- A single stream can support up to 50 consumer groups reading from the stream.
- Each partition can support:
  - A total data write rate of 1 MB per second. There is no limit on the number of PUT requests, provided the limit of 1 MB per second per partition is not exceeded.
  - 5 GET requests per second per consumer group. Since a single stream can support up to 50 consumer groups, and a single partition in a stream can be read by at-most one consumer in a consumer group, a partition can support up to 250 GET requests per second (5 GET requests per second per consumer in all 50 consumer groups).
- The maximum size of a unique message that producers can publish to a stream is 1 MB.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing Streams

Before publishing messages to a stream, or consuming messages from a stream, you must first create a stream. You can use the Oracle Cloud Infrastructure Console or the Streaming API to create your stream.

When creating a stream, consider the expected stream throughput, message retention period, partition key strategy, and how your stream will be consumed. Most configuration values cannot be changed after the stream has been created. For example, after a stream is created, you can't change the message retention time or number of partitions.

Partitioning a Stream

To take full advantage of the Streaming service's ability to operate at scale, configure the number of partitions in the stream based on the following considerations.

Partitions and Throughput

When you create a stream, you must specify how many partitions the stream has. The expected throughput of your application can help you determine the number of partitions for your stream.

Multiply the average message size by the maximum number of messages written per second to estimate your expected throughput. Since a single partition is limited to a 1 MB per second data write rate, and 5 GET requests per second per consumer group, a higher throughput requires additional partitions to avoid throttling. Keep additional Streaming limits in mind when making your design decisions.
Streaming Service Overview

Tip:
To help you manage application spikes, we recommend allocating partitions slightly higher than your maximum throughput.

Publishing to Partitions
The content of the messages you intend to publish to a stream can also help you determine how many partitions your stream should have.

A message is published to a partition in the stream. If there is more than one partition, the partition where the message is published is calculated using the message's key.

For more information, see Publishing Messages on page 3870.

Key to partition mapping
Messages with the same key go to the same partition. Messages with different keys might go to different partitions or to the same partition. If you do not specify a key, Streaming recognizes the null key and generates a random key on the behalf of the user. If a user publishes the same message twice, it could go to different partitions, since a completely new key is generated. Do not expect all messages with a null key to go to the same partition.

By default, Streaming provides uniform and predictable distribution of messages to a stream's partitions. Streaming APIs do not let you specify exactly which partition data is published to, since this can introduce a risk of hotspotting a single partition if a user is not aware of the nuances of Streaming. However, if you use Kafka APIs to interact with Streaming, you may choose to do custom partitioning and explicitly map messages to partitions, although we do not recommend it.

Effective partitioning keys
To ensure uniform distribution of messages, you need effective values for your message keys. To create an effective value, consider the selectivity and cardinality of your Streaming data.

Cardinality: Consider the total number of unique keys that could potentially be generated based on the specific use case. Higher key cardinality generally means better distribution.

Selectivity: Consider the number of messages with each key. Higher selectivity means more messages per key, which can lead to hotspots.

Always aim for high cardinality and low selectivity.

Ordering
Messages with the same key are guaranteed to be stored in the order they are published, and delivered to consumers in the same order they were produced. Because messages with the same key go to the same partition, this guarantee only applies at the partition level.

Partitions and Consumer Groups
If your stream will be consumed by one or more consumer groups, you should factor that into your decision on how many partitions it should have. Partition reads are balanced among the instances in a consumer group.

Consumer groups can only utilize a single instance at a time if the stream has only one partition. If your stream has multiple partitions, you can scale the number of instances up to the number of the partitions and have one instance in the group reading from one partition in the stream.

For more information, see Using Consumer Groups on page 3876.

Stream Pooling
When you create your stream, you need to specify whether it should become a member of an existing stream pool, or a member of a new, automatically created stream pool. See Managing Stream Pools on page 3864 for more information.
Stream Security

Streaming data is encrypted both at rest and in transit. Private endpoints within your virtual cloud network (VCN) can be used to restrict access to your streams so they cannot be accessed through the internet.

Both encryption and private access are configured at the stream pool level to make managing groups of streams easier.

Encryption

By default, all encryption-related matters are handled by Oracle, but you can manage your own encryption keys using Oracle Cloud Infrastructure Vault. Vault allows you to bring your own Advanced Encryption Standard (AES) symmetric keys and manage, rotate, disable, and delete them as needed.

Because encryption keys are managed at the stream pool level, you can use a different encryption key for each logical stream grouping or virtual Kafka cluster.

To use your own encryption key:

• Ensure that you have the required IAM policies.
• Import your key.
• Change the master encryption key assigned to the stream pool.

For more information, see Overview of Vault on page 3952 and Managing Keys on page 3962.

Private Endpoints

Private endpoints associate a private IP address within a VCN to the stream pool, allowing Streaming traffic to avoid traversing the internet.

To create a private endpoint for Streaming, you need access to a VCN with a private subnet when you create the stream pool. See About Private Endpoints on page 3254 and VCNs and Subnets on page 2821 for more information.

To use private endpoints:

• Ensure you have the required IAM policies.
• Select Private Endpoint and provide the required information when you create your stream pool.

Because streams using private endpoints are not accessible from the internet, you cannot use the Console to show their latest messages.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 3895.

Using the Console

To create a stream

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.

   A list of existing streams is displayed.

2. Click Create Stream at the top of the list.

3. **Stream Name**: Required. Specify a friendly name for the stream. It does not have to be unique within the compartment, but it must be unique to the stream pool. The stream name cannot be changed. Avoid entering confidential information.
4. **Compartment**: Choose the compartment in which the stream will be created. To change the compartment, select a different compartment from the drop-down list.

5. **Stream Pool**: Choose the stream pool that will contain your stream.
   a. If your chosen compartment has an existing stream pool, you can select it from the drop-down list or click Create new stream pool and configure the stream pool manually.
   b. If no stream pool exists in the chosen compartment, select Auto-create a default stream pool or click Create a new stream pool and configure the stream pool manually.

6. In the Define Stream Settings panel:
   a. **Retention (in Hours)**: Enter the number of hours (from 24 to 168) to retain messages. The default value is 24.
   b. **Number of Partitions**: Enter the number of partitions for the stream. The maximum number is based on the limits for your tenancy.

   **Tip:**
   The maximum **Total Write Rate** and **Total Read Rate** of your stream are displayed as you adjust the number of partitions.

7. Click **Show Advanced Options** to optionally define Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

8. Click **Create**.

**To delete a stream**
1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. You can delete a stream in two ways:
   a. Click the the Actions icon (three dots) on the right side of the stream you want to delete and select **Delete Stream**.
   b. Click the stream you want to delete. The stream details screen displays. Click **Delete**.
3. Confirm when prompted.

**To produce a test message**
1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click a stream to display the stream details page.
3. Click **Produce Test Message**.
4. On the Test Stream dialog, enter the text-only message to produce in the **Data** text box.
5. Click **Produce**.

**To show recent messages on a stream**
1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click a stream to display the stream details page.
3. In the **Recent Messages** panel, click **Load messages**.

Streams using private endpoints are not accessible from the internet, so their messages do not display in the Console.

**To move a stream to a different compartment**
1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click a stream to display the stream details page.
3. Find the stream you want to move in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.
Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**

The examples in this section use the full syntax for all parameters, for example `--compartment-id`. For some parameters, there are shortened versions that you can use instead, like `-c`. See the CLI online help for instances of a shortened parameter associated with a command.

To get a list of streams in a compartment

`oci streaming admin stream list --compartment-id <compartment_OCID>`

For example:

```
oci streaming admin stream list --compartment-id ocid1.tenancy.oc1..exampleuniqueID

{
  "data": [
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.stream.oc1.phx.exampleuniqueID",
      "lifecycle-state": "ACTIVE",
      "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
      "name": "example_stream_2",
      "partitions": 1,
      "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
      "time-created": "2020-08-21T21:19:35.707000+00:00"
    },
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.stream.oc1.phx.exampleuniqueID",
      "lifecycle-state": "DELETED",
      "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
      "name": "example_stream_1",
      "partitions": 5,
      "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
      "time-created": "2020-07-16T20:59:32.904000+00:00"
    }
  ]
}
```

By default, getting a list of streams returns up to the first 10 streams in the compartment.

To get a list of streams in a stream pool

`oci streaming admin stream list --stream-pool-id <stream_pool_OCID>`

For example:

```
oci streaming admin stream list --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID
```

Oracle Cloud Infrastructure User Guide 3860
By default, getting a list of streams returns up to the first 10 streams in the stream pool.

To create a stream

You can create a stream in a compartment or a stream pool. The --compartment-id and --stream-pool-id parameters cannot be specified at the same time.

```
oci streaming admin stream create --name <stream_name> --
partitions <number_of_partitions> --compartment-id <compartment_OCID>
```

```
oci streaming admin stream create --name <stream_name> --
partitions <number_of_partitions> --stream-pool-id <stream_pool_OCID>
```

For example:

```
oci streaming admin stream create --name MyStream --partitions 5 --
compartment-id ocid1.tenancy.oc1..exampleuniqueID
```

```
oci streaming admin stream create --name MyStream --partitions 5 --
compartment-id ocid1.tenancy.oc1..exampleuniqueID
```

```json
{
    "data": [
        {
            "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
            "defined-tags": {},
            "freeform-tags": {},
            "id": "ocid1.stream.oc1.phx.exampleuniqueID",
            "lifecycle-state": "ACTIVE",
            "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
            "name": "example_stream_2",
            "partitions": 1,
            "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
            "time-created": "2020-08-21T21:19:35.707000+00:00"
        },
        {
            "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
            "defined-tags": {},
            "freeform-tags": {},
            "id": "ocid1.stream.oc1.phx.exampleuniqueID",
            "lifecycle-state": "DELETED",
            "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
            "name": "example_stream_1",
            "partitions": 5,
            "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
            "time-created": "2020-07-16T20:59:32.904000+00:00"
        }
    ]
}
```
To view stream details

oci streaming admin stream get --stream-id <stream_OCID>

For example:

oci streaming admin stream get --stream-id
ocid1.stream.oc1.phx.exampleuniqueID
{}

"data": {
  "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
  "defined-tags": {},
  "freeform-tags": {},
  "id": "ocid1.stream.oc1.phx.exampleuniqueID",
  "lifecycle-state": "ACTIVE",
  "lifecycle-state-details": null,
  "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
  "name": "MyStream",
  "partitions": 5,
  "retention-in-hours": 24,
  "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
  "time-created": "2020-11-02T19:12:22.385000+00:00"
},
"etag": "0613d634-86ab-4446-973f-268d175313d4-12e9725e-5574-4f6b-995b-7dcc80271666"
}

To delete a stream

Caution:
Stream contents are deleted immediately. You cannot recover a deleted stream.

oci streaming admin stream delete --stream-id <stream_OCID>

For example:

oci streaming admin stream --delete --stream-id
ocid1.stream.oc1.phx.exampleuniqueID
Are you sure you want to delete this resource? [y/N]:

Select y and press Enter. The stream is deleted with no further prompting.

To move a stream to a different stream pool

oci streaming admin stream update --stream-id <stream_OCID> --stream-pool-id <stream_pool_OCID>

For example:

oci streaming admin stream update --stream-id
ocid1.stream.oc1.phx.exampleuniqueID --stream-pool-id
ocid1.streampool.oc1.phx.exampleuniqueID
To move a stream to a different compartment

oci streaming admin stream change-compartment --stream-id <stream_OCID> --compartment-id <compartment_OCID>

For example:

oci streaming admin stream change-compartment --stream-id ocid1.stream.oc1.phx.exampleuniqueID --compartment-id ocid1.tenancy.oc1..exampleuniqueID

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to manage streams:

- CreateStream
- ListStreams
- GetStream
- UpdateStream
Managing Stream Pools

Stream pools are logical groupings for streams. Every stream needs to be a member of a stream pool. If you don't create a stream pool, the Streaming service uses a default pool to contain your streams.

You can use stream pools to:

- Organize streams into groups matching your organizational structure or a specific solution
- Restrict access to a specified virtual cloud network (VCN) inside your tenancy so that streams in the pool are not accessible through the internet
- Specify whether the data in the pool's streams should be encrypted using your own Vault encryption key or an Oracle-managed key

There is no limit to the number of stream pools you can create.

**Note:**
Stream names must be unique within a stream pool.

Stream Pools and Apache Kafka

Stream pools serve as the root of a virtual Apache Kafka cluster when you use Kafka with Streaming. All streams within the pool share the same Kafka configuration, encryption, and access control settings. Every action on that virtual cluster is scoped to that stream pool.

You can configure the stream pool to automatically create streams, or Kafka topics, and call `KafkaAdminClient::createTopic` to create a stream or topic in that stream pool.

For more information, see Using Streaming with Apache Kafka on page 3880.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

To set up a private endpoint, you must have access to a VCN with a private subnet where DNS resolution is enabled. For general information about policies and permissions to do this, see IAM Policies for Networking on page 2832. Specifically, you need use permissions for a VNIC, a network security group, if you specify one, and a subnet. For example:

```plaintext
allow user group ServiceWriters to use vnics in compartment ABC
allow user group ServiceWriters to use network-security-groups in compartment ABC
allow user group ServiceWriters to use subnets in compartment XYZ
```

To use your own encryption key, you must let the Streaming service use a Vault key to encrypt data in streams in this stream pool. For example:

```plaintext
allow service streaming to use keys in compartment ABC where target.key.id = 'key OCID>'
```
Streaming Service Overview

The preceding policy also requires a companion policy to let Streaming use a key on behalf of a user group to create a stream pool that uses the key for cryptographic purposes. For example:

```
allow user group StreamWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 3895.

Using the Console

To create a stream pool

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Stream Pools on the left side of the screen.

A list of existing stream pools is displayed.
3. Click Create Stream Pool to display the Create Stream Pool page.
4. Enter a name for the stream pool in the Stream Pool Name text box. Avoid entering confidential information.
5. Select a compartment from the Resource Compartment drop-down list.
6. In the Configure Stream Pool panel:
   a. Select Endpoint Type: Click Public Endpoint or Private Endpoint, depending on whether you want to restrict traffic to streams in this stream pool to a private endpoint that does not require traffic to traverse the internet. To create a private endpoint, you need access to a virtual cloud network (VCN) with a private subnet. Select a VCN with a private subnet where DNS resolution is also enabled, and then select the subnet. Optionally, if you want to assign a specific private IP address, you must choose one that belongs to the subnet's CIDR. By default, the Networking service assigns a random private IP address on your behalf and applies no security rules to the stream pool. For more information about VCNs and subnets, see VCNs and Subnets on page 2821.
   b. Configure Encryption Settings: By default, Encrypt using Oracle-managed keys is selected. If you want to encrypt the data in the streams in this stream pool using your own Vault encryption key, click Encrypt using customer-managed keys. To use the Vault service for your encryption needs, you need access to a vault and key and you need to allow the Streaming service to use the key.
      1. Vault: Choose the vault that contains the master encryption key you want to use from the drop-down list.
      2. Master Encryption Key: Choose the master encryption key you want to use from the drop-down list.

   For more information, see Stream Security on page 3858. For more information about encryption with a Vault key that you manage, see Overview of Vault on page 3952 and Managing Keys on page 3962.
7. If you would like to add tags or intend to use Kafka with this stream pool, click Show Advanced Options.
8. Add Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
9. To use the stream pool with Kafka, select the Auto Create Topics checkbox and configure your stream settings:
   a. Add a number of hours for the stream's retention period in Default Retention Period (hours) text box.
   b. Specify the Default Number of Partitions for the stream.
   c. Select the View Kafka settings after the stream pool is created checkbox to display the Kafka Connection settings for the stream pool when it is created.
10. Click Create.

To edit a stream pool

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Stream Pools on the left side of the screen.

A list of existing stream pools is displayed.
3. Click the stream pool you want to edit to bring up the stream pool details page.
4. Click Edit Settings.
5. Click Edit Settings or Cancel when finished.

**To delete a stream pool**
1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Stream Pools on the left side of the screen.
   A list of existing stream pools is displayed.
3. You can delete a stream pool in two ways:
   a. Click the the Actions icon (three dots) on the right side of the stream pool you want to delete and select Delete Stream Pool.
   b. Click the stream pool you want to delete. The stream pool details screen displays. Click Delete.
4. Confirm when prompted.

**To change or remove the master encryption key assigned to an existing stream pool**
1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click Stream Pools.
3. Click a stream pool to display the stream details page.
4. In Stream Pool Information, next to Encryption Key, do one of the following:
   • To stop using an Oracle-managed key in favor of a Vault master encryption key that you manage, click Assign, select a vault and encryption key you have access to, and then click Assign.
   • To select a different Vault master encryption key that you manage, click Update, select a vault and encryption key you have access to, and then click Update.
   • Click Unassign to remove the assigned Vault master encryption key and let Oracle manage the encryption key, and then click Unassign again to confirm the removal of the existing key assignment.

**To move a stream pool to a different compartment**
1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Stream Pools on the left side of the screen.
   A list of existing stream pools is displayed.
3. You can move a stream pool in two ways:
   a. Click the the Actions icon (three dots) on the right side of the stream pool you want to move and select Move Resource.
   b. Click the stream pool you want to move. The stream pool details screen displays. Click Move Resource.
4. In the Move Resource to a Different Compartment dialog box, choose the destination compartment from the drop-down list.
5. Click Move Resource.

**Using the Command Line Interface (CLI)**
For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**
The examples in this section use the full syntax for all parameters, for example --compartment-id. For some parameters, there are shortened versions that you can use instead, like -c. See the CLI online help for instances of a shortened parameter associated with a command.
To get a list of stream pools

oci streaming admin stream-pool list --compartment-id <compartment_OCID>

For example:

oci streaming admin stream-pool list --compartment-id ocid1.tenancy.oc1..exampleuniqueID
{
  "data": [
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
      "is-private": false,
      "lifecycle-state": "ACTIVE",
      "name": "MyStreamPool",
      "time-created": "2020-10-09T22:21:16.931000+00:00"
    },
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
      "is-private": true,
      "lifecycle-state": "ACTIVE",
      "name": "example-stream-pool-02",
      "time-created": "2020-04-03T07:00:56.196000+00:00"
    },
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleCompartmentOCID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.streampool.oc1.phx.exampleStreamPoolOCID",
      "is-private": false,
      "lifecycle-state": "ACTIVE",
      "name": "example-stream-pool-01",
      "time-created": "2020-04-03T05:28:26.025000+00:00"
    }
  ]
}

By default, getting a list of streams returns up to the first 10 streams in the compartment.

To create a stream pool

oci streaming admin stream-pool create --name <stream_pool_name> --compartment-id <compartment_OCID>

For example:

oci streaming admin stream-pool create --name MyStreamPool --compartment-id ocid1.tenancy.oc1..exampleuniqueID
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "custom-encryption-key": {
      "key-state": "NONE",
      "kms-key-id": null
    }
  }
}
Tip:

Provide input for --custom-encryption-key-details, --private-endpoint-details, and --kafka-settings as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

To view stream pool details

oci streaming admin stream-pool get --stream-pool-id <stream_pool_OCID>

For example:

oci streaming admin stream-pool get --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID

{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "custom-encryption-key": {
      "key-state": "NONE",
      "kms-key-id": null
    },
    "defined-tags": {},
    "endpoint-fqdn": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "freeform-tags": {},
    "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "is-private": false,
    "kafka-settings": {
      "auto-create-topics-enable": false,
      "bootstrap-servers": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com:9092",
      "log-retention-hours": 24,
      "num-partitions": 1
    },
    "lifecycle-state": "ACTIVE",
    "lifecycle-state-details": null,
    "name": "MyStreamPool",
    "private-endpoint-settings": {
      "nsg-ids": null,
      "private-endpoint-ip": null,
      "subnet-id": null
    },
    "time-created": "2020-11-02T23:01:59.429000+00:00"
  },
  "etag": "\"b0066564-4bf4-4e27-9255-9055e69a7808-03668273-b0d5-4b8b-9370-74522c29eb56\""
}
To update a stream pool

```bash
oci streaming admin stream-pool update --stream-pool-id <stream_pool_OCID>
```

For example:

```bash
oci streaming admin stream-pool update --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID --name MyUpdatedStreamPool
```

Tip:

Provide input for `--custom-encryption-key-details`, `--private-endpoint-details`, and `--kafka-settings` as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.
To delete a stream pool

Caution:
The stream pool and all streams within the pool are deleted immediately. You cannot recover a deleted stream pool.

`oci streaming admin stream-pool delete --stream-pool-id <stream_pool_OCID>`

For example:

`oci streaming admin stream-pool delete --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID
Are you sure you want to delete this resource? [y/N]:`

Select y and press Enter. The stream pool is deleted with no further prompting.

To move a stream pool to a different compartment

`oci streaming admin stream-pool change-compartment --stream-pool-id <stream_pool_OCID> --compartment-id <target_compartment_OCID>`

For example:

`oci streaming admin stream-pool change-compartment --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID --compartment-id ocid1.compartment.oc1..exampleuniqueID
{
  "etag": "\"b9abe5ea-d473-4451-8cf4-9b058fa9b435-a670293bd0d9-4fff-9c54-4a862418e353\""
}

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to manage stream pools:

- CreateStreamPool
- ListStreamPools
- GetStreamPool
- UpdateStreamPool
- DeleteStreamPool
- ChangeStreamPoolCompartment

Publishing Messages

Once a stream is created and active, you can publish messages.

While you can use the Console to publish test messages to a stream after you create it, you need to use PutMessages to populate your stream, or, if you take advantage of the Streaming service's compatibility with Apache Kafka, your Kafka producer can handle message creation.

Messages

Messages are published to a single partition in a stream. If there is more than one partition in the stream, the decision of which partition to publish the message to depends on whether your producers are using the Streaming API and PutMessages, or taking advantage of Streaming's Kafka compatibility and using the Kafka API.
If your producers are using the Streaming API, partitioning is handled server-side by the Streaming service. If your producers are using the Kafka API, partitioning is handled client-side by Kafka.

**Server-side partitioning**
The partition where a message is published is calculated using the message's key. If the key is null, the partition is calculated using a random 16-byte value. You cannot specify which partition a key uses.

Passing a null key puts the message in a random partition. If a user publishes the same message twice, it could go to different partitions, since a completely new key is generated. Do not expect all messages with a null key to go to the same partition. If you want to ensure that messages with the same value go to the same partition, you should use the same key for those messages.

**Handling large messages**
If your messages are larger than the 1 MB limit, you can either use chunking or send the message by using Oracle Cloud Infrastructure Object Storage.

- **Chunking**: You can split large payloads into multiple, smaller chunks that the Streaming service can accept. The chunks are stored in the service in the same way that ordinary (non-chunked) messages are stored. The only difference is that the consumer must keep the chunks and combine them into the message when all the chunks have been collected. The chunks in the partition can be interwoven with ordinary messages.

- **Object Storage**: A large payload is placed in Object Storage and only the pointer to that data is transferred. The receiver recognizes this type of pointer payload, transparently reads the data from Object Storage, and provides it to the end user.

**Batching and Throttling**
We recommend batching messages to avoid throttling and enable better throughput.

The size of a batch of messages shouldn't exceed 1 MB. If this limit is exceeded, the throttling mechanism is triggered. The throttling mechanism for PutMessages is activated when data write rates exceed 1 MB per second per partition. There is no limitation on the number of writes to a stream, as long as you are under the 1 MB per second per partition throughput.

See [Limits on Streaming Resources](#) on page 3856 for more information.

**Required IAM Policy**
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in [Let streaming users manage streams](#) on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. If you want to dig deeper into writing policies for the Streaming service, see [Details for the Streaming Service](#) in the IAM policy reference and [Accessing Streaming Resources Across Tenancies](#) on page 3895.

**Using the Console**

**To publish a message**
1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. In the list of available streams, click on the stream that you want to publish to.
3. Click **Produce Test Message**.
4. Type the message in the **Data** text box.
5. Click **Produce**.
Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To publish a message

```shell
oci streaming stream message put --stream-id <stream_id> --messages <JSON_messages> --endpoint <messages_endpoint>
```

**Tip:**

Provide input for `--messages` as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

For example, `file.txt` contains the properly formatted JSON. Its values are Base64-encoded:

```json
[
  {
    "key": "a2V5MjQ==",
    "value": "dmFsdWUx"
  },
  {
    "key": "a2V5Mjg==",
    "value": "dmFsdWUy"
  }
]
```

The `--messages` parameter takes the file as its value:

```shell
```

```json
{
  "data": {
    "entries": [
      {
        "error": null,
        "error-message": null,
        "offset": 0,
        "partition": "0",
        "timestamp": "2020-11-03T21:35:03.837000+00:00"
      },
      {
        "error": null,
        "error-message": null,
        "offset": 1,
        "partition": "0",
        "timestamp": "2020-11-03T21:35:03.837000+00:00"
      }
    ],
    "failures": 0
  }
}
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use the following API operations to produce messages:

- PutMessages

Consuming Messages

Consuming messages from a stream requires you to:

- Create a cursor.
- Use the cursor to read messages.
- Use the returned cursor to continue reading messages.

You can use an individual consumer to read messages from one or more streams, or use consumer groups to read messages from a stream.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

You can create a policy that gives a tenant stream-pull access to consume data from a stream in another tenant. See Accessing Streaming Resources Across Tenancies on page 3895 and Details for the Streaming Service if you want to dig deeper into writing policies for the Streaming service.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Using Individual Consumers

If you choose to use individual consumers to consume messages from your streams instead of using consumer groups, you can't take advantage of many of the benefits of Streaming, such as service-managed coordination, horizontal scaling, and offset management. Your applications will need to handle these scenarios, and many more, programmatically.

For these reasons, we recommend using consumer groups in a production environment, but it may be useful to use individual consumers for testing or proof-of-concept applications.

Using Cursors

A cursor is a pointer to a location in a stream. The location could be a specific offset or time in a partition.

Before you start to consume messages, you need to indicate the point from which you want to start consumption. You can do this by creating a cursor using the CreateCursor API.

There are five supported cursor types:

- TRIM_HORIZON - Start consuming from the oldest available message in the stream. Create a cursor at the TRIM_HORIZON to consume all messages in a stream.
- AT_OFFSET - Start consuming at a specified offset. The offset must be greater than or equal to the offset of the oldest message and less than or equal to the latest published offset.
- AFTER_OFFSET - Start consuming after the given offset. This cursor has the same restrictions as the AT_OFFSET cursor.
- AT_TIME - Start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- LATEST - Start consuming messages that were published after you created the cursor.

When you create a cursor for an individual consumer, you need to specify the partition in the stream that the cursor should use. If your stream has more than one partition with messages, you need to create multiple cursors to read them.
Once you've created a cursor, you can start to consume messages using GetMessages.

As long as you keep consuming messages, there is no need to re-create a cursor, so cursors should be created outside of your loops to get messages.

**Getting Messages**

Once you've created a cursor, call GetMessages and specify that cursor to start consuming messages. The service responds with your messages and the opc-next-cursor header value that you should use in your next GetMessages call. The returned cursor is never null, but it expires in five minutes. If you stop consuming messages for longer than five minutes, you will need to re-create a cursor.

If you have more than one consumer reading from the same partition, they will receive the same messages. Your application should decide how to process messages.

If there are no more unread messages in the partition, Streaming returns a list of empty messages.

GetMessages batch sizes are based on the average message size published to the stream. By default, the service returns as many messages as possible. You can use the limit parameter to specify any value up to 10,000, but consider your average message size to avoid exceeding throughput on the stream.

**Falling behind**

To determine if your consumer is falling behind (you're producing faster than you're consuming), you can use the timestamp of the message. If the consumer is falling behind, consider spawning additional consumers to take over some of the partitions from the first consumer. There's no way to recover if you're falling behind on a single partition.

Consider the following options:

- Create a new stream with more partitions.
- Use consumer groups.
- If the issue is caused by a hotspot, change the message key strategy.
- Reduce message processing time, or handle requests in parallel.

If you want to know how many messages are left to consume in a given partition, use a cursor of type LATEST, get the offset of the next published message, and make the delta with the offset that you are currently consuming.

**Managing Offsets**

Offsets indicate the location of a message within a partition. If your consumer restarts or you need to recover from a failure, you can use the offset to restart reading from the stream.

**Tip:**

Consumer groups can manage offset commits automatically.

When you use individual consumers, your consumer application must manage processed offsets. The consumer is responsible for storing which offsets it reached or stopped at, for each partition. When your consumer restarts, read the offset of the last message that you processed, and then create a cursor of type AFTER_OFFSET and specify the offset that you just got. We don't provide any guidance for storing the offset of the last message that you processed. You may use any method, such as another stream, a file on your machine, or Object Storage.

**Note:**

Message offsets aren't dense. Offsets are monotonically increasing numbers. They do not decrease, and sometimes they increase by more than one. For example, if you publish two messages to the same partition, the first message could have an offset of 42 and the second message could have an offset of 45 (offsets 43 and 44 being non-existent).

**Using the Console**

You cannot use the console to consume messages, but you can use it to show recent messages on a stream.
Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create a cursor

```shell
oci streaming stream cursor create-cursor --stream-id <stream_OCID> --partition <partition> --type <cursor_type> --endpoint <messages_endpoint>
```

For example:

```shell
oci streaming stream cursor create-cursor --stream-id ocid1.stream.oc1.phx.exampleuniqueID --partition 0 --type TRIM_HORIZON --endpoint https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com
{
    "data": {
        "value": "examplecursorvalue"
    }
}
```

To get messages

```shell
oci streaming stream message get --stream-id <stream_OCID> --cursor <cursor> --endpoint <messages_endpoint>
```

Your first request to get messages should use the value returned when you created a cursor. Each subsequent request should use the opc-next-cursor value returned in the previous response.

For example:

```shell
{
    "data": [
        {
            "key": "a2V5MQ==",
            "offset": 0,
            "partition": "0",
            "stream": "MyStream",
            "timestamp": "2020-11-03T21:52:58.470000+00:00",
            "value": "dmFsdWUx"
        },
        {
            "key": "a2V5Mg==",
            "offset": 1,
            "partition": "0",
            "stream": "MyStream",
            "timestamp": "2020-11-03T21:52:58.470000+00:00",
            "value": "dmFsdWUy"
        },
        {
            "key": "a2V5MQ==",
            "offset": 2,
            "partition": "0",
            "stream": "MyStream",
            "timestamp": "2020-11-03T22:00:48.305000+00:00",
            "value": "dmFsdWUx"
        },
        {
            "key": "a2V5Mg==",
```
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to consume messages when using a single consumer:

- CreateCursor
- GetMessages

Using Consumer Groups

Consumers can be configured to consume messages as part of a group. In a production environment with multiple partitions, using a consumer group is our recommended method of consuming Streaming messages.

Each stream partition is assigned to a member of a consumer group. An individual member of a consumer group is called an instance. Each instance in a consumer group receives messages from one or more partitions, unless there are more instances than partitions. Instances in excess of the partition count for the stream do not receive messages.

Consumer groups handle the coordination that is required for multiple consumers to share the consumption of a stream. A consumer group automatically:

- Assigns one or more partitions to an instance
- Tracks the messages received by the group and manages commits
- Requests the proper partition(s) and offset(s) on behalf of each instance
- Balances the group as instances join or leave

Up to 50 consumer groups can read from a single stream. Each consumer group receives all of the messages in the stream at least once.

Consumer groups are ephemeral. They disappear when they're not used for the retention period of the stream.

Creating a Consumer Group

A consumer group is created on the first CreateGroupCursor request. Group cursors define a group name/instance name pair. When you create your group cursor, you should provide the ID of the stream, a group name, an instance name, and one of the following supported cursor types:

- TRIM_HORIZON - The group will start consuming from the oldest available message in the stream.
- AT_TIME - The group will start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- LATEST - The group will start consuming messages that were published after you created the cursor.

Group cursor types are ignored on CreateGroupCursor calls that include the name of an existing group. That group's committed offsets are used instead of the provided cursor type.

Streaming uses the instance name to identify members of the group when managing offsets. Use unique instance names for each instance of the consumer group.

If you want the Streaming service to handle committing offsets, you should leave the group cursor's commitOnGet value set to true. We recommend using this method to reduce application complexity since your application does not have to handle commits.
**Consuming as a Group**

After your instances join the consumer group, they can read messages from the stream using `GetMessages`. Each call to `GetMessages` returns the cursor to use in the next `GetMessages` call as the `opc-next-cursor` header value. The returned cursor is never null, but it expires in five minutes. As long as you keep consuming, you should never have to re-create a cursor.

When Streaming receives a request for messages from an instance, the service:

- Checks to see whether a group rebalance is necessary
- **Commits the offset(s)** from that instance's previous request, if any
- Responds with the messages defined by the request's cursor

`GetMessages` batch sizes are based on the average message size published to that stream. By default, the service returns as many messages as possible. You can use the `limit` parameter to specify any value up to 10,000, but consider your average message size to avoid exceeding throughput on the stream or timeouts.

If there are no more unread messages in the partition, Streaming returns a list of empty messages.

Because consumer groups remove instances that have stopped consuming messages for more than 30 seconds, you should request fewer messages to avoid timeouts, or extend the timeout using `ConsumerHeartbeat`.

A partition cannot be assigned to multiple instances within the same consumer group. If you have more instances than partitions, the unassigned instances can send `GetMessages` requests, but they won't receive any messages. They remain otherwise idle until the consumer group needs to replace an instance, such as when an existing member of the group does not act within the timeout period.

If you need to manually update the group's position, you can use `UpdateGroup` to reset the location of all consumers in the group to the specified location in the stream.

**Offsets and Commits**

Offsets indicate the location of a message within a partition. If a consumer restarts or you need to recover from a failure, you can use the offset to restart reading from the stream.

When you use a consumer group, Streaming handles offsets automatically. The default behavior of `commitOnGet=true` means that offsets from the previous request are committed. For example:

**For consumer A:**

- A calls `GetMessages` and receives messages from an arbitrary partition, with offsets of 1–100.
- A processes all 100 messages successfully.
- A processes 15 messages, and then goes offline unexpectedly (for more than 30 seconds).

A new consumer **B**:

- B calls `GetMessages`, and the Streaming service uses the latest committed offset and returns messages with offsets 101–200.
- B continues the message loop.

In this example, a portion (15) of the messages were processed at least once, which means that they could have been processed more than once, but no data is lost.

Streaming provides "at-least-once" semantics for consumer groups. Consider when offsets are committed in a message loop. If a consumer goes offline before committing a batch of messages, that batch might be given to another consumer. When a partition is given to another consumer, the consumer uses the latest committed offset to start consumption. The consumer doesn't get messages before the committed offset. We recommend that consumer applications take care of duplicates.

**Note:**

Message offsets aren't dense. Offsets are monotonically increasing numbers. They do not decrease, and sometimes they increase by more than one. For
Streaming Service Overview

If you want to override the default offset behavior and implement a custom offset commit mechanism, set `commitOnGet` to `false` when creating the group cursor. You can use `ConsumerCommit` to commit messages without reading more messages. ConsumerCommit returns a cursor for you to use in your next request.

Caution:
Writing custom commit logic is complicated and full of race conditions and considerations. Many cases exist in which some internal state is changed, and the client is required to handle the situation.

Balancing and Rebalancing
Streaming considers the number of partitions in the stream and the number of instances in the consumer group when assessing balance. Group balancing is automatic. Each consumer is assigned to one or more partitions based on the following calculation:

\[
\left( \frac{n_{\text{Partitions}}}{n_{\text{Consumers}}} \right) \pm 1
\]

For example, if there are eight partitions in the stream and four consumers in the group, each consumer is assigned to two partitions. If there are 10 partitions in the stream and four consumers in the group, two consumers are assigned to two partitions, and two consumers are assigned to three partitions.

As instances join or leave a consumer group and requests are made for messages, partition assignments are reassessed. If the stream has at least one partition more than the number of current instances in the group, and a new instance joins, partitions are reassigned to all instances, including the new one. If an instance in the group stops consuming messages for more than 30 seconds, or fails to send a `ConsumerHeartbeat` within 30 seconds, that instance is removed from the consumer group and its partition is reassigned, if possible, to another instance.

These events are called `rebalancing`. The instances in the group are not aware of the rebalancing process, but the group has coordinated to own a mutually exclusive set of partitions in the stream.

At the end of a successful rebalance operation for a consumer group, every partition within the stream is owned by an instance within the group.

In this way, you can `scale the number of instances up to the number of the partitions` until each instance is consuming messages from only one partition. This configuration maximizes your stream's available throughput. After that point, any new instance joining the group remains in an idle state without being assigned to any partition.

Using the Console
You cannot use the console to consume messages, but you can use it to show recent messages on a stream.

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create a group cursor

```
oci streaming stream cursor create-group-cursor --stream-id <stream_OCID> --group-name <consumer_group_name> --type <cursor_type> --endpoint <messages_endpoint>
```

For example:

```
oci streaming stream cursor create-group-cursor --stream-id ocid1.stream.oc1.phx.exampleuniqueID --group-name MyConsumerGroup --type TRIM_HORIZON --endpoint https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com
```
**Streaming Service Overview**

```json
{
  "data": {
    "value": "examplegroupcursorvalue"
  }
}
```

**To get messages**

```bash
oci streaming stream message get --stream-id <stream_OCID> --cursor <cursor> --endpoint <messages_endpoint>
```

Your first request to get messages should use the value returned when you created a cursor. Each subsequent request should use the `opc-next-cursor` value returned in the previous response.

For example:

```bash
{
  "data": [
    {
      "key": "a2V5MQ==",
      "offset": 0,
      "partition": "0",
      "stream": "MyStream",
      "timestamp": "2020-11-03T21:52:58.470000+00:00",
      "value": "dmFsdWUx"
    },
    {
      "key": "a2V5Mg==",
      "offset": 1,
      "partition": "0",
      "stream": "MyStream",
      "timestamp": "2020-11-03T21:52:58.470000+00:00",
      "value": "dmFsdWUy"
    },
    {
      "key": "a2V5MQ==",
      "offset": 2,
      "partition": "0",
      "stream": "MyStream",
      "timestamp": "2020-11-03T22:00:48.305000+00:00",
      "value": "dmFsdWUx"
    },
    {
      "key": "a2V5Mg==",
      "offset": 3,
      "partition": "0",
      "stream": "MyStream",
      "timestamp": "2020-11-03T22:00:48.305000+00:00",
      "value": "dmFsdWUy"
    }
  ],
  "opc-next-cursor": "examplenextcursorvalue"
}
```

**To send a heartbeat**

```bash
oci streaming stream group heartbeat --stream-id <stream_OCID> --cursor <cursor> --endpoint <messages_endpoint>
```

Oracle Cloud Infrastructure User Guide 3879
Your first heartbeat request should use the value returned when you created a group cursor. Each subsequent request should use the value returned in the previous response.

For example:

```
oci streaming stream group heartbeat --stream-id ocid1.stream.oc1.phx.exampleuniqueID --cursor examplecursorvalue --endpoint https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com
{
  "data": {
    "value": "examplenextcursorvalue"
  }
}
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to consume messages with consumer groups:

- CreateGroupCursor
- GetMessages
- ConsumerHeartbeat
- UpdateGroup

Using Streaming with Apache Kafka

Oracle Cloud Infrastructure Streaming lets users of Apache Kafka offload the setup, maintenance, and infrastructure management that hosting your own Zookeeper and Kafka cluster requires.

Streaming is compatible with most Kafka APIs, allowing you to use applications written for Kafka to send messages to and receive messages from the Streaming service without having to rewrite your code. See Using Kafka APIs on page 3881 for more information.

Streaming can also utilize the Kafka Connect ecosystem to interface directly with external sources like databases, object stores, or any microservice on the Oracle Cloud. Kafka connectors can easily and automatically create, publish to, and deliver topics while taking advantage of the Streaming service’s high throughput and durability. See Using Kafka Connect on page 3883 for more information.

Use cases for Streaming and Kafka include:

- Move data from Streaming to Autonomous Data Warehouse via the JDBC Connector to perform advanced analytics and visualization.
- Use the Oracle GoldenGate connector for Big Data to build an event-driven application.
- Move data from Streaming to Oracle Object Storage via the HDFS/S3 Connector for long term storage, or to run Hadoop/Spark jobs.

Kafka API Support

Streaming is fully upstream compatible with the latest versions of Kafka APIs. Streaming supports the following Kafka APIs:

- Producer (v0.7.0 and later)
- Consumer (v0.7.0 and later)
- Connect (v0.9.0.0 and later)
- Admin (v0.10.1.0 and later)
- Group Management (v0.7.0 and later)

The following Kafka APIs and features are not yet implemented in the Streaming service:

- Kafka Streams
Streaming Service Overview

- Compaction
- Transactions
- Dynamic Partition Addition
- Idempotent production

Kafka Clients
While many Kafka clients are available, we recommend the those that have been fully tested and certified to work with the Streaming service.

Streaming supports all versions of these Kafka clients:
- librdkafka
- apache-kafka-java
- confluent-kafka-python

Requirements and Limitations

Unique Stream Names
If you have streams with the same names in a compartment, you can't use Kafka with Streaming until you delete the duplicated streams, unless the streams are in different stream pools. Two streams with the same name can exist in the same compartment only if the streams are in different stream pools.

Duplicate stream names otherwise manifest through an "authentication failed" error. If you do not want to delete your streams, contact the Streaming team so we can rename your streams without data loss.

Load Balancing Connection Recycling
Because the Kafka protocol uses long-lived TCP connections, the Streaming Kafka compatibility layer implements a load balancing mechanism to periodically balance connections between front-end nodes. This mechanism periodically closes connections to force new ones. Most Kafka SDKs handle these disconnections automatically when consuming, but producing to Streaming using the Kafka API might raise disconnection errors. Disconnections can be mitigated by adding retries to your requests. Retries are part of the Kafka SDK and are automatically enabled, and you can explicitly configure their behavior.

Using Kafka APIs
This topic describes how to configure Apache Kafka for API compatibility with Oracle Cloud Infrastructure Streaming. When your producers use Kafka APIs to interact with Streaming the decision of which partition to publish a unique message to is handled client-side by Kafka.

Please refer to Kafka API Support on page 3880 for additional information.

Endpoints
For bootstrap servers, use your region endpoint on port 9092. For example:

```
streaming.us-phoenix-1.oci.oraclecloud.com:9092
```

Authentication
Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. You can generate tokens in the Console user details page. See Working with Auth Tokens on page 2456 for more information.

Tip:
Create a dedicated group/user and grant that group the permission to manage streams in the appropriate compartment or tenancy. The policy in Let streaming users manage streams on page 2154 lets the specified group do
everything with streaming and related Streaming service resources. You then can generate an auth token for the user you created and use it in your Kafka client configuration.

Your username must be in the following format:

```
tenancyName/username/streamPoolId
```

**Tip:**

If you are using the Java SDK, you can also use instance principal authorization.

## Kafka Configuration

Set the following properties for your Kafka client.

### For the Java SDK

**Recommended settings for Java SDK:**

```java
Properties properties = new Properties();
properties.put("bootstrap.servers", "streaming.{region}.oci.oraclecloud.com:9092");
properties.put("security.protocol", "SASL_SSL");
properties.put("sasl.mechanism", "PLAIN");
properties.put("sasl.jaas.config",
"org.apache.kafka.common.security.plain.PlainLoginModule required username="{tenancyName}/#{username}/#{streamPoolId}" password="{authToken}";"
);
```

**Recommended settings for Java SDK producers:**

```java
properties.put("retries", 5); // retries on transient errors and load balancing disconnection
properties.put("max.request.size", 1024 * 1024); // limit request size to 1MB
```

**Recommended settings for Java SDK consumers:**

```java
properties.put("max.partition.fetch.bytes", 1024 * 1024); // limit request size to 1MB per partition
```

### For the Librdkafka SDK

**Recommended settings for Librdkafka SDK:**

```python
'metadata.broker.list': 'streaming.{region}.oci.oraclecloud.com:9092',
'security.protocol': 'SASL_SSL',
'sasl.mechanisms': 'PLAIN',
'sasl.username': '{tenancyName}/#{username}/#{streamPoolId}',
'sasl.password': '{authToken}'
```

**Recommended settings for Librdkafka SDK producers:**

```python
'message.send.max.retries': 5 // retries on transient errors and load balancing disconnection
'max.request.size': 1024 * 1024 // limit request size to 1 MB
```
Recommended settings for Librdkafka SDK consumers:

```java
'max.partition.fetch.bytes': 1024 * 1024 // limit request size to 1 MB per partition
```

**Instance Principal Authorization for the Java SDK**

If you are using the Java SDK, you can authorize an instance to interact with Streaming instead of using auth tokens.

To configure the Java SDK for instance principal authorization:

1. Verify that you have a valid Oracle Cloud Infrastructure (OCI) SDK and CLI configuration file.
2. Import the Oracle Cloud Infrastructure SDK for Java into your project. See [Getting Started with the SDK for Java](#) for more information.
3. Add the following Oracle Cloud Infrastructure SDK for Java dependency:

   ```xml
   <dependency>
     <groupId>com.oracle.oci.sdk</groupId>
     <artifactId>oci-java-sdk-addons-sasl</artifactId>
     <optional>false</optional>
     <version>1.13.1</version> <!-- that's the minimum version to use -->
   </dependency>
   ```

4. Modify the `sasl.mechanism` property of your Kafka client configuration:

   ```java
   properties.put("sasl.mechanism",
   OciMechanism.OCI_RSA_SHA256.mechanismName());
   ```

5. Modify the `sasl.jaas.config` property of your Kafka client configuration using one of the following options:

   ```java
   properties.put("sasl.jaas.config",
   "com.oracle.bmc.auth.sasl.InstancePrincipalsLoginModule required intent=
   \"streamPoolId:<streamPoolId>\";");
   ```

   ```java
   properties.put("sasl.jaas.config",
   "com.oracle.bmc.auth.sasl.UserPrincipalsLoginModule required
   config="<pathToConfig>" profile="<profile>" intent=
   \"streamPoolId:<streamPoolId>\";");
   ```

   - If `config` is not specified, the default config path is used (`~/.oci/config`).
   - If `profile` is not specified, the default profile is used (DEFAULT).

**For More Information**

- Apache Kafka documentation
- Blog post: Oracle Streaming Service Producer and Consumer

**Using Kafka Connect**

To use your Kafka connectors with Oracle Cloud Infrastructure Streaming, create a [Kafka Connect configuration](#) using the Console or the command line interface (CLI). The [Streaming API](#) calls these configurations **harnesses**.

**Note:**

Kafka Connect configurations created in a given compartment work only for streams in the same compartment.

You can use multiple Kafka connectors with the same Kafka Connect configuration. In cases that require producing or consuming streams in separate compartments, or where more capacity is required to avoid hitting throttle limits on
the Kafka Connect configuration (for example: too many connectors, or connectors with too many workers), you can create more Kafka Connector configurations.

For more information on managing Kafka Connect configurations using the Console and Streaming API, see Managing Kafka Connect Configurations on page 3885.

**Kafka Connectors**

Streaming's Kafka Connect compatibility means that you can take advantage of the many existing first- and third-party connectors to move data from your sources to your targets.

### Kafka connectors for Oracle products:

- Oracle Cloud Infrastructure Object Storage (Using Kafka Connect for S3)
  - Kafka Connect Amazon S3 source connector, for producers
  - Kafka Connect Amazon S3 sink connector, for consumers
- Oracle Integration Cloud
- Oracle Database (Using Kafka Connect JDBC)
- Oracle GoldenGate

For a complete list of third-party Kafka source and sink connectors, refer to the official Confluent Kafka hub.

**Kafka Connect Topics**

The Streaming service automatically creates the three topics (config, offset, and status) that are required to use Kafka Connect when you create the Kafka Connect configuration. These topics contain the OCID of the Kafka Connect configuration in their names.

Place these topic names in the `connect-distributed.properties` file of the Kafka connector that you want to use with Streaming.

For example:

```bash
# Relevant Kafka Connect setting
config.storage.topic:<connect_configuration_OCID>-config
offset.storage.topic:<connect_configuration_OCID>-offset
status.storage.topic:<connect_configuration_OCID>-status
```

**Note:**

These three compacted topics are meant to be used by Kafka Connect and Streaming to store configuration and state management data, and should not be used to store your data. To ensure that the Kafka Connect configuration topics are being used for their intended purpose by the connectors, there are hard throttle limits of 50 kb/s and 50 rps in place for these topics.

**Bootstrap Server**

Set the bootstrap server in your Kafka connector properties file to the endpoint for Streaming on port 9092. For example:

```bash
streaming.us-phoenix-1.oci.oraclecloud.com:9092
```

**Note:**

For a list of endpoints for Streaming, see the Streaming section in API Reference and Endpoints.
Authentication

Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. You can generate tokens in the Console user details page. See Working with Auth Tokens on page 2456 for more information.

Tip:

It’s a good idea to create a dedicated group/user and grant that group the permission to manage streams in the appropriate compartment or tenancy. You then can generate an auth token for the user you created and use it in your Kafka client configuration.

Example Kafka Connector Properties File

The following shows an example Kafka connector `connect-distributed.properties` file:

```properties
bootstrap.servers=<streaming_endpoint>:9092
sasl.mechanism=PLAIN
security.protocol=SASL_PLAINTEXT
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
producer.sasl.mechanism=PLAIN
producer.security.protocol=SASL_PLAINTEXT
producer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
consumer.sasl.mechanism=PLAIN
consumer.security.protocol=SASL_PLAINTEXT
consumer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
config.storage.topic:<connect_configuration_OCID>-config
offset.storage.topic:<connect_configuration_OCID>-offset
status.storage.topic:<connect_configuration_OCID>-status
```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

For More Information

- Official Kafka Connect documentation
- Blog post: Oracle Streaming Service with Kafka Connect

Managing Kafka Connect Configurations

This topic describes how to work with Kafka Connect configurations. The Streaming API calls these configurations harnesses.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

To allow a group to manage Kafka Connect configurations, you need to create the correct policy in your tenancy. For example:

```plaintext
allow group KafkaAdmins to manage connect-harnesses in tenancy
```

For administrators: The policy in Let streaming users manage streams on page 2154 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 3895.

**Using the Console**

To create a Kafka Connect Configuration

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. Click Create Kafka Connect Configuration to display the Create Kafka Connect Configuration page.
4. Select a compartment in the Compartment drop-down list.
5. Enter a name for the configuration in the Kafka Connect Configuration Name text box. Avoid entering confidential information.
6. **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click Create Kafka Connect Configuration.
8. The details page for the new Kafka Connect configuration has a read-only text box labeled Kafka Connect Storage Topics.
   a. Click Copy to copy the connector configuration so you can paste it into the connect-distributed.properties file for your Kafka connector. For more information, see the official Kafka Connect documentation.

To delete a Kafka Connect Configuration

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. You can delete a Kafka Connect configuration in two ways:
   a. Click the the Actions icon (three dots) on the right side of the configuration you want to delete and select Delete Kafka Connect Configuration.
   b. Click the configuration you want to delete. The Kafka Connect Configuration Details page displays. Click Delete.
4. Confirm when prompted.

To move a Kafka Connect Configuration to a different compartment

1. Open the navigation menu. Under Solutions and Platform, click Analytics, and then click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. You can move a Kafka Connect configuration in two ways:
   a. Click the the Actions icon (three dots) on the right side of the configuration you want to move and select **Move Resource**.
   b. Click the configuration you want to move. The Kafka Connect Configuration Details screen displays. Click **Move Resource**.
4. In the **Move Resource to a Different Compartment** dialog box, choose the destination compartment from the drop-down list.
5. Click **Move Resource**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 4192. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**
The examples in this section use the full syntax for all parameters, for example `--compartment-id`. For some parameters, there are shortened versions that you can use instead, like `-c`. See the CLI online help for instances of a shortened parameter associated with a command.

To get a list of Kafka Connect configurations

```
oci streaming admin connect-harness list --compartment-id <compartment_OCID>
```

For example:

```
oci streaming admin connect-harness list --compartment-id exampleuniqueID
{
    "data": [
    {
        "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
        "defined-tags": {},
        "freeform-tags": {},
        "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
        "lifecycle-state": "ACTIVE",
        "name": "MyKafkaConnectConfig",
        "time-created": "2020-08-31T17:26:09.640000+00:00"
    }
    ]
}
```

By default, getting a list of Kafka Connect configurations returns up to the first 10 configurations in the compartment.

To create a Kafka Connect configuration

```
oci streaming admin connect-harness create --name <kafka_connect_configuration_name> --compartment-id <compartment_OCID>
```

For example:

```
oci streaming admin connect-harness create --name MyKafkaConnectConfig --compartment-id exampleuniqueID
{
    "data": {
        "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
        "defined-tags": {},
        "freeform-tags": {},
        "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
        "lifecycle-state": "CREATING",
    }
}
```
Streaming Service Overview

To view Kafka Connect configuration details

oci streaming admin connect-harness get --connect-harness-id <kafka_connect_configuration_OCID>

For example:

oci streaming admin connect-harness get --connect-harness-id exampleuniqueID

To update a Kafka Connect configuration

oci streaming admin connect-harness update --connect-harness-id <kafka_connect_configuration_OCID> --defined-tags <JSON_tags>

For example:

oci streaming admin connect-harness update --connect-harness-id exampleuniqueid --defined-tags "{"tagNamespace": {"tagKey1": "tagValue1","tagKey2": "tagValue2"}}"

WARNING: Updates to freeform-tags and defined-tags will replace any existing values. Are you sure you want to continue? [y/N]: y

Select y and press Enter. The Kafka Connect configuration is updated:
To delete a Kafka Connect configuration

```plaintext
Caution:
Kafka Connect configurations are deleted immediately. You cannot recover a deleted configuration.
```

```plaintext
oci streaming admin connect-harness delete --connect-harness-id <kafka_connect_configuration_OCID>
```

For example:

```plaintext
oci streaming admin connect-harness delete --connect-harness-id ocid1.connectharness.oc1.phx.exampleuniqueID
Are you sure you want to delete this resource? [y/N]:
```

Select y and press Enter. The Kafka Connect configuration is deleted with no further prompting.

To move a Kafka Connect configuration to a different compartment

```plaintext
oci streaming admin connect-harness change-compartment --connect-harness-id <kafka_connect_configuration_OCID> --compartment-id <target_compartment_OCID>
```

For example:

```plaintext
oci streaming admin connect-harness change-compartment --connect-harness-id ocid1.connectharness.oc1.phx.exampleuniqueID --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following API operations to manage Kafka Connector configurations:

- `CreateConnectHarness`
- `ListConnectHarnesses`
- `GetConnectHarness`
- `UpdateConnectHarness`
- `DeleteConnectHarness`
- `ChangeConnectHarnessCompartment`

### Using Oracle Cloud Infrastructure SDKs with Streaming

Oracle Cloud Infrastructure OCI provides SDKs so that you can interact with Streaming without having to create a framework. The OCI SDKs let you manage streams, stream pools, and Kafka Connect configurations, and publish and consume messages. Refer to the Streaming Service Overview on page 3852 for key concepts and additional information.
Streaming Service Overview

This topic includes examples that use the OCI SDK for Java on page 4225, but basic Streaming usage examples are included with all our SDKs:

- OCI SDK for Python examples
- OCI SDK for TypeScript and JavaScript examples
- OCI SDK for .NET examples
- OCI SDK for Go examples

For more information about using the OCI SDKs, see the SDK Guides.

Streaming Clients

The SDKs encapsulate the Streaming service in two clients: the StreamAdminClient and the StreamClient.

StreamAdminClient

The StreamAdminClient incorporates the control plane operations of Streaming. You can use it to create, delete, update, modify, and list streams.

To instantiate the StreamAdminClient object:

```java
StreamAdminClient adminClient = new StreamAdminClient([authProvider]);
adminClient.setEndpoint("<streaming_endpoint>"); // You cannot use the setRegion method
```

StreamClient

The StreamClient is used to publish and consume messages.

To instantiate a StreamClient object:

```java
// First you have to get the stream you want to consume from/publish to. You can either make a CreateStream, GetStream, or ListStream call. They all return a "messagesEndpoint" as part of a Stream object. That endpoint needs to be used when creating the StreamClient object.
GetStreamRequest getStreamRequest = GetStreamRequest.builder().streamId(streamId).build();
Stream stream = adminClient.getStream(getStreamRequest).getStream();
StreamClient streamClient = new StreamClient([authProvider]);
streamClient.setEndpoint(stream.getMessagesEndpoint());
```

Managing Streams

Creating streams

To create a stream, use the createStream method of StreamAdminClient.

Creating a stream is an asynchronous operation. You can check on the completion of the create operation by checking that the lifecycleStateDetails property of your new stream is either Active or Failed. See Managing Streams on page 3856 for more information.

The following is an example showing how to create a stream:

```java
// No error handling
CreateStreamDetails createStreamDetails = CreateStreamDetails.builder()
    .partitions(5) // number of partitions you want in your stream
    .name("myStream") // the name of the stream - only used in the console
    .compartmentId(tenancy) // the compartment id you want your stream to live in
    .build();
```
// You can also add tags to the createStreamDetails object.
CreateStreamRequest createStreamRequest =
    CreateStreamRequest.builder()
    .createStreamDetails(createStreamDetails)
    .build();

Stream stream = adminClient.createStream(createStreamRequest).getStream();
while (stream.getLifecycleState() != Stream.LifecycleState.Active &&
    stream.getLifecycleState() != Stream.LifecycleState.Failed) {
    GetStreamRequest getStreamRequest =
        GetStreamRequest.builder().streamId(stream.getId()).build();
    stream = adminClient.getStream(getStreamRequest).getStream();
}

// Handle stream Failure

Listing streams
Use the listStreams method to return a list of streams for a given compartment.
You can filter the returned list by OCID, life cycle state, and name.
The results can be sorted in ascending or descending order by name or creation time.
The results are passed back in a paginated list. A token is passed back with each page of results; pass this
token back to the getOpcNextPage method to retrieve the next page of results. A null token returned from
getOpcNextPage indicates that no more results are available.
For example:

// No error handling
ListStreamsRequest listStreamsRequest =
    ListStreamsRequest.builder()
    .compartmentId(tenancy)
    .build();
// You can filter by OCID (exact match only) [builder].id(streamId) -> This
// will return 0..1 item
// You can filter by name (exact match only) [builder].name(name) -> This
// will return 0..n items
// You can order the result per TimeCreated or Name [builder].sortBy(SortBy.
// [TimeCreated|Name])
// You can change the ordering [builder].sortOrder(SortOrder.[Asc|Desc])
// You can filter by lifecycleState [builder].lifecycleState(lifecycleState)
String page;
do {
    ListStreamsResponse listStreamsResponse =
        adminClient.listStreams(listStreamsRequest);
    List<StreamSummary> streams = listStreamsResponse.getItems();
    // Do something with the streams
    page = listStreamsResponse.getOpcNextPage();
} while (page != null);

Retrieving stream details
To get details about a stream, use the getStream method and then examine the properties of the stream. For
example:

// No error handling
GetStreamRequest getStreamRequest =
    GetStreamRequest.builder()
    .streamId(streamId)
Streaming Service Overview

```
.build();
Stream stream = adminClient.getStream(getStreamRequest).getStream();
```

### Deleting streams

To delete a stream, use the `deleteStream` method API of the `StreamAdminClient`. Deleting a stream is an asynchronous operation; the stream state changes to `Deleted` once the delete operation is finished. During the deletion process, the stream can't be used for consuming or producing messages.

The following example shows how to use the `deleteStream` method to delete a stream:

```
// No error handling
DeleteStreamRequest deleteStreamRequest =
    DeleteStreamRequest.builder()
    .streamId(stream.getId())
    .build();
adminClient.deleteStream(deleteStreamRequest);
```

### Managing Kafka Connect Configurations

In order to use Kafka Connect with Streaming, you need a Kafka Connect configuration, or Kafka Connect harness. You can retrieve the OCID for a harness when you create a new harness or use an existing one. For more information, see Using Kafka Connect on page 3883.

#### Creating a Kafka Connect harness

The following code example shows how to create a Kafka Connect harness:

```
CreateConnectHarnessDetails createConnectHarnessDetails =
    CreateConnectHarnessDetails.builder()
    .compartmentId(compartment) //compartment where you want to create connect harness
    .name("myConnectHarness") //connect harness name
    .build();
CreateConnectHarnessRequest connectHarnessRequest =
    CreateConnectHarnessRequest.builder()
    .createConnectHarnessDetails(createConnectHarnessDetails)
    .build();
CreateConnectHarnessResponse createConnectHarnessResponse =
    streamAdminClient.createConnectHarness(connectHarnessRequest);
ConnectHarness connectHarness =
    createConnectHarnessResponse.getConnectHarness();
while (connectHarness.getLifecycleState() !=
    ConnectHarness.LifecycleState.Active &&
    connectHarness.getLifecycleState() != ConnectHarness.LifecycleState.Failed) {
    GetConnectHarnessRequest getConnectHarnessRequest =
        GetConnectHarnessRequest.builder().connectHarnessId(connectHarness.getId()).build();
    connectHarness =
        streamAdminClient.getConnectHarness(getConnectHarnessRequest).getConnectHarness();
}
```
Streaming Service Overview

Listing Kafka Connect harnesses

The following code example shows how to list Kafka Connect harnesses:

```java
ListConnectHarnessesRequest listConnectHarnessesRequest =
    ListConnectHarnessesRequest.builder()
    .compartmentId(compartment) // compartment id to list all the connect harnesses.
    .lifecycleState(ConnectHarnessSummary.LifecycleState.Active)
    .build();

ListConnectHarnessesResponse listConnectHarnessesResponse =
    streamAdminClient.listConnectHarnesses(listConnectHarnessesRequest);
List<ConnectHarnessSummary> items = listConnectHarnessesResponse.getItems();
```

Publishing Messages

Once a stream is created and active, you can publish messages using the `streamClient.putMessages` method. See Publishing Messages on page 3870 for more information about publishing.

The following code example shows how to publish a message:

```java
// No error handling
List<PutMessagesDetailsEntry> messages = new ArrayList<>();

for (int i = 0; i < 40; i++) {
    byte[] key = "<myKey>".getBytes(Charsets.UTF_8); // In this case, all messages will go on the same partition since the key is the same.
    byte[] value = UUID.randomUUID().toString().getBytes(Charsets.UTF_8);
    messages.add(new PutMessagesDetailsEntry(key, value));
}

PutMessagesDetails putMessagesDetails =
    PutMessagesDetails.builder()
    .messages(messages)
    .build();

PutMessagesRequest putMessagesRequest =
    PutMessagesRequest.builder()
    .putMessagesDetails(putMessagesDetails)
    .build();

PutMessagesResult putMessagesResult =
    streamClient.putMessages(putMessagesRequest).getPutMessagesResult();
// It's not because the call didn't fail that the messages were successfully published!
int failures = putMessagesResult.getFailures();
// If failures is > 0, it means we have a partial-success call.
List<PutMessagesResultEntry> entries = putMessagesResult.getEntries();
// entries is a list of the same size as the list of messages you sent.
// It is guaranteed that the order of the messages is the same as when you sent them.
// Each entry contains either "offset/partition/timestamp" if the message was successfully published
// or "error/errorMessage" if it failed.
if (failures != 0) {
    entries.forEach(entry -> {
        if (StringUtils.isNotEmpty(entry.getError())) {
            // That particular message failed to get published.
            // It could be a throttle error and in that case the error would be "429" and errorMessage would contain a meaningful message.
            // Or it could be an internal error and the error would be "500".
```

Oracle Cloud Infrastructure User Guide 3893
Streaming Service Overview

Consuming Messages

Consuming messages requires the use of a cursor, which is a pointer to an offset into a partition. First you must create a cursor, then you must use the cursor to get messages. For more information, see Using Cursors on page 3873 and Getting Messages on page 3874.

Cursors

This example creates a TRIM_HORIZON cursor, which starts consuming starting from the oldest available message:

```java
// No error handling
CreateCursorDetails createCursorDetails =
    CreateCursorDetails.builder()
    .type(Type.TrimHorizon)
    .partition("0")
    .build();
// If using AT_OFFSET or AFTER_OFFSET you need to specify the offset
    [builder].offset(offset);
// If using AT_TIME you need to specify the time [builder].time(new Date(XXX))
CreateCursorRequest createCursorRequest =
    CreateCursorRequest.builder()
    .createCursorDetails(createCursorDetails)
    .build();
String cursor =
    streamClient.createCursor(createCursorRequest).getCursor().getValue();
// Cursor will then be used to get messages from the stream.
```

GetMessages

Once you’ve created a cursor, you can start to consume messages using the GetMessages method. Each call to GetMessages returns the cursor to use in the next GetMessages call.

Here’s an example of using a cursor to retrieve messages:

```java
// No error handling (there is a high chance of getting a throttling error using a tight loop)
while (true) { // or your own exit condition
    GetMessagesRequest getMessagesRequest =
        GetMessagesRequest.builder()
        .cursor(cursor)
        .build();

    GetMessagesResponse getMessagesResponse =
        streamClient.getMessages(getMessagesRequest);

    // This could be empty, but we will always return an updated cursor
    getMessagesResponse.getItems().forEach(message -> {
        // Process the message
    });

    cursor = getMessagesResponse.getOpcNextCursor();
```
Consuming Messages as a Group

Consumers can be configured to consume messages as part of a group. Stream partitions are distributed among members of a consumer group so that messages from any single partition are only sent to a single consumer. Group consumption is accomplished using the same cursor mechanism as with single consumers, but using a different kind of cursor.

For more information, see Using Consumer Groups on page 3876.

To create a consumer group, create a group cursor, providing a group, instance name, and cursor type. Group cursors support the following cursor types:

- **TRIM_HORIZON**: The group will start consuming from the oldest available message in the stream.
- **AT_TIME**: The group will start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- **LATEST**: The group will start consuming messages that were published after you created the cursor.

Consumer groups are created on the first request to create a cursor. For example:

```java
CreateGroupCursorRequest groupRequest = CreateGroupCursorRequest.builder()
    .streamId(streamId)
    .createGroupCursorDetails(CreateGroupCursorDetails.builder()
        .groupName(groupName)
        .instanceName(instanceName)
        .type(CreateGroupCursorDetails.Type.TrimHorizon)
        .commitOnGet(true)
        .build())
    .build());

CreateGroupCursorResponse groupCursorResponse = streamClient.createGroupCursor(groupRequest);
String groupCursor = groupCursorResponse.getCursor().getValue();
// this groupCursor can be used in the same message loop a described above;
subsequent getMessages calls return an updated groupCursor.
```

Once you've created a group cursor, you can start to consume messages using GetMessages.

Accessing Streaming Resources Across Tenancies

This topic describes how to write policies that let your tenancy access Streaming resources in other tenancies.

If you're new to policies, see Getting Started with Policies on page 2135 and refer to Details for the Streaming Service on page 2343.

Cross-Tenancy Policies

Your organization might want to share Streaming resources with another organization that has its own tenancy. It could be another business unit in your company, a customer of your company, a company that provides services to your company, and so on. In cases like these, you need cross-tenancy policies in addition to the required user and service policies described previously.

**Endorse, Admit, and Define statements**

To access and share resources, the administrators of both tenancies need to create special policy statements that explicitly state the resources that can be accessed and shared. These special statements use the words Define, Endorse, and Admit.

Here's an overview of the special verbs used in cross-tenancy statements:

- **Endorse**: States the general set of abilities that a group in your own tenancy can perform in other tenancies. The Endorse statement always belongs in the tenancy with the group of users crossing the boundaries into the other tenancy to work with that tenancy's resources. In the examples, we refer to this tenancy as the source.

- **Admit**: States the kind of ability in your own tenancy that you want to grant a group from the other tenancy. The Admit statement belongs in the tenancy who is granting "admittance" to the tenancy.
Streaming Service Overview

identifies the group of users that requires resource access from the source tenancy and identified with a corresponding ENDORSE statement. In the examples, we refer to this tenancy as the destination.

- **Define**: Assigns an alias to a tenancy OCID for ENDORSE and ADMIT policy statements. A Define statement is also required in the destination tenancy to assign an alias to the source IAM group OCID for ADMIT statements.

Define statements must be included in the same policy entity as the endorse or the admit statement.

The ENDORSE and ADMIT statements work together, but they reside in separate policies, one in each tenancy. Without a corresponding statement that specifies access, a particular ENDORSE or ADMIT statement grants no access. **Agreement is required from both tenancies.**

**Source policies**
The source administrator creates policy statements that endorse a source IAM group allowed to manage resources in the destination tenancy.

Here is an example of a broad policy statement that endorses the IAM group StreamingAdmins group to do anything with all Streaming resources in any tenancy:

```plaintext
ENDORSE group StreamingAdmins to manage streams in any-tenancy
```

To write a policy that reduces the scope of tenancy access, the destination administrator must provide the destination tenancy OCID. Here is an example of policy statements that endorse the IAM group StreamingAdmins group to manage Streaming resources in the DestinationTenancy only:

```plaintext
Define tenancy DestinationTenancy as ocid1.tenancy.oc1..<unique_ID>
ENDORSE group StreamingAdmins to manage streams in tenancy DestinationTenancy
```

**Destination policies**
The destination administrator creates policy statements that:

- Define the source tenancy and IAM group that is allowed to access resources in your tenancy. The source administrator must provide this information.
- Admit those defined sources to access Streaming resources that you want to allow access to in your tenancy.

Here is an example of policy statements that endorse the IAM group StreamingAdmins in the source tenancy to do anything with all Streaming resources in your tenancy:

```plaintext
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StreamingAdmins as ocid1.group.oc1..<unique_ID>
ADMIT group StreamingAdmins of tenancy SourceTenancy to manage streams in tenancy
```

Here is an example of policy statements that endorse the IAM group StreamingAdmins in the source tenancy to manage Streaming resources only the SharedStreams compartment:

```plaintext
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StreamingAdmins as ocid1.group.oc1..<unique_ID>
ADMIT group StreamingAdmins of tenancy SourceTenancy to manage streams in compartment SharedStreams
```

**Streaming Metrics**

You can monitor the health and performance of your streams by using metrics and alarms. For more information, see Monitoring Overview on page 2660.

This topic describes the metrics emitted by the Streaming service using the metric namespace **oci_streaming**.
Overview of Streaming Metrics

The Streaming service provides metrics showing how the service is performing. These metrics are automatically available.

You can use these metrics to:

- Understand the produce/consume latency for a real-time application.
- Calculate and validate the price of service usage.
- Monitor changes in throughput over time.
- Check the time that the last message was consumed.
To view a default set of metrics charts in the Console, navigate to the Service Metrics page and then select the `oci_streaming` metric namespace.

**Available Metrics**

The following tables describe the available Streaming metrics.
You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

**REGION**
- The *REGION* where the stream resides.

**RESOURCEID**
- The *OCID* of the stream.

### Producers

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>

</tr>
<tr>
<td>GetMessagesFailure.Count</td>
<td>Get Messages Failure/sec</td>
<td>count</td>
<td>Total failed getMessage requests per stream measured over time.</td>
<td></td>
</tr>
</tbody>
</table>

**Stream Health**

A healthy stream is a stream that is active: messages are received and consumed successfully.

 Writes to the service are durable. If you can produce to your stream, and if you get a successful response, then the stream is healthy.

 After data is ingested, it is accessible to consumers for the configured retention period. If GetMessages API calls return elevated levels of internal server errors, the service isn't healthy.

 A healthy stream also has healthy metrics:

- **Put Messages Latency** is low.
- **Put Messages Total Throughput** is close to 1 MB per second per partition.
- **Put Messages Throttled Records** is close to 0.
- **Put Messages Failure** is close to 0.
- **Get Messages Latency** is low.
- **Get Messages Total Throughput** is close to 2 MB per second per partition.
- **Get Messages Throttled Requests** is close to 0.
- **Get Messages Failure** is close to 0.

**Suggested Alarms**

**Producers**

For producers, consider setting alarms on the following metrics:

- **Put Messages Latency**: An increase in latency means that the messages are taking longer to publish, which could indicate network issues.
Streaming Service Overview

- **Put Messages Total Throughput:**
  - An increase in total throughput could indicate that the 1 MB per second per partition limit will be reached, and that event will trigger the throttling mechanism.
  - A decrease could mean that the client producer is having an issue or is about to stop.
- **Put Messages Throttled Records:** It's important to get notified when messages are throttled.
- **Put Messages Failure:** It's important to get notified if put messages start failing.

**Consumers**

For consumers, consider setting similar alarms based on the following metrics:

- Get Messages Latency
- Get Messages Total Throughput
- Get Messages Throttled Requests
- Get Messages Failure

**Using the Console**

**To view default producer metrics**

1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click a stream to view its details.
3. Under **Resources**, click **Produce Monitoring Charts**.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view default consumer metrics**

1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click a stream to view its details.
3. Under **Resources**, click **Consume Monitoring Charts**.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

**Troubleshooting Streaming**

This topic covers various issues related to Oracle Cloud Infrastructure Streaming and how you can address them. Details about common API errors that all services return are detailed in **API Errors** on page 4372.

**Troubleshooting Access and Permissions**

**Request returns a "Processing exception while communicating" message and a -1 error**

When you use the Streaming client to send a request, you might see the following error message:

```
Caused by: com.oracle.bmc.model.BmcException: (-1, null, false) Processing exception while communicating to:
```
This error is related to the client. The Streaming service doesn't send it, which means that the request never made it to the service.

**Request returns a NotAuthorizedOrNotFound message and a 404 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
com.oracle.bmc.model.BmcException: (404, NotAuthorizedOrNotFound,false)
Unknown stream ocid1.stream.oc1.phx.exampleuniqueID.
(opc-request-id: <opc_request_id>)
```

A 404 error usually means that the needed resource isn't found or that you don't have access to it. An example is when the stream-push policy is missing, or the stream has been deleted or is not accessible. Ensure that all the permissions are correctly set.

**Request returns a "Not Found" message and a 404 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
redirected: false, status: 404, ok: false, statusText: "Not Found", headers: Headers, bodyUsed: false }
```

This error indicates a permission-related issue. Ensure that all the permissions are correctly set.

**Request returns a "The following tag namespaces/keys are not authorized or not found" message**

This error suggests that there is a tag on the stream that your user is not authorized to use. Remove the tag or authorize the user. See Resource Tags on page 211 for more information.

**Request returns a "bad handshake" message and a 104 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
SSLLError(SSLError("bad handshake: SysCallError(104, 'ECONNRESET'.))
```

This error typically means that your system doesn't have the CA that the certificates were signed by. You may need to install the ca-certificates package on your host or pull the CA certificate from the target endpoint and import it into your system trust store by using `update-ca-trust` command.

**Troubleshooting Limits and Throttling**

Limits on Streaming Resources on page 3856 describes the service and resource limits that might result in the following scenarios.
Partial failures
Streaming supports partial failures caused by throttling, per partition. When a partial failure occurs, the service returns a \texttt{200} status code and indicates the failure in the response payload.

If an entire request is throttled, Streaming returns a \texttt{429} status code.

Request returns a "Too many requests message" and a 429 error
When you send a request to Streaming, you might see an error message that includes the following:

\begin{verbatim}
(429, Too many requests)
\end{verbatim}

This error is caused by the throttling mechanism in the service. It indicates that too many requests per second per partition are being received.

If this error occurs on the producer side, ensure that the total data write rate of 1 MB per second per partition is not exceeded by:

- Lowering the amount of requests per second.
- Decreasing message size by batching.

If this error occurs on the consumer side, ensure that:

- The cursor uses \texttt{commitOnGet(true)}.
- You reduce the number of requests, keeping in mind that the maximum data read rate is 5 GET requests per second per partition per consumer group.
- The \texttt{limit} is set for each GET request.

Request returns a "Request size is limited to 1 MiB" message and a 400 error
When you send a request to Streaming, you might see an error message similar to the following:

\begin{verbatim}
Exception in thread "main" com.oracle.bmc.model.BmcException: (400, InvalidParameter, false) Request size is limited to 1 MiB. (opc-request-id: \texttt{<opc_request_id>})
at com.oracle.bmc.http.internal.ResponseHelper.throwIfNotSuccessful(ResponseHelper.java:129)
at com.oracle.bmc.streaming.internal.http.PutMessagesConverter$1.apply(PutMessagesConverter.java:54)
at com.oracle.bmc.streaming.StreamClient.putMessages(StreamClient.java:466)
\end{verbatim}

This error occurs because the \texttt{PutMessages} call sent to the service is too large. The size must be less than or equal to 1 MB.

Stream creation fails with a "You exceed the number of allowed partitions" message
This error occurs when you try to create more partitions than your tenancy is allowed. You can request an increase.
Troubleshooting Production and Consumption

Messages do not appear in the Console after publishing them to a stream

You must click the Refresh button to show the first 100 messages. See Using the Console to show recent messages for more information.

Because streams using private endpoints are not accessible from the internet, their messages do not display in the Console.

Consumers receive a "The cursor is outside the retention period and is now invalid" message and a 400 error

When requesting messages from a stream, a consumer might see an error message like the following:

```
(400, InvalidParameter, false) The cursor is outside the retention period and is now invalid
```

This error means that the offsets stored for one or more of your partitions has fallen behind the trim horizon. Some data loss has occurred, and the data that was produced to the stream is no longer available for consumption. Data that is outside the retention period can't be recovered. At this point, the administrator must decide the best course of action, given the use case.

This error can happen if you are not committing offsets regularly, or if your consumer falls behind constantly. For more information, see Getting Messages on page 3874.

A manual call to the UpdateGroup method is required to reset the cursor for the instances within a consumer group.

Consumers receive a "Trying to commit unreserved partition" message and a 400 error

When requesting messages from a stream, a consumer that is part of a consumer group might see an error message like the following:

```
(400, InvalidParameter, false) Trying to commit unreserved partition
```

This error means that the consumer tried to commit an offset for a partition that was not reserved for that particular consumer. This error can happen when the consumer appears to have timed out, partitions are rebalanced to another consumer, and then the consumer tries to commit offsets. The default timeout is 30 seconds for a consumer. Timeouts for a consumer can be extended by sending a heartbeat. See Consuming as a Group on page 3877 for more information.

This error can also occur when pipelining (commitOnGet=false) and no commits occurred for a significant amount of time (more than 30 seconds).

Request fails with an "Unable to parse JSON body" message and a 400 error

When you send a request to Streaming, you might see an error message similar to the following:

```
(400, Unable to parse JSON body)
```

This error generally means that the JSON body contains an entry in an invalid format.

Ruby SDK requests fail with an "Unable to parse JSON body" message and a 400 error

When you send a request to Streaming using the Ruby SDK, you might see an error message similar to the following:

```
Unable to parse JSON body, 'status': 400, 'code': 'InvalidParameter'
```
The Ruby SDK doesn't do any encoding. You must use `Base64` to encode the strings that are sent in the key and value fields. For example:

```ruby
msgs << OCI::Streaming::Models::PutMessagesDetailsEntry.new(key: Base64.strict_encode64(k), value: Base64.strict_encode64(record.to_json))
if msgs.length > 0
  res = @oss_client.put_messages(@stream_ocid,
    OCI::Streaming::Models::PutMessagesDetails.new(messages: msgs))
end
```

### Troubleshooting Streaming and Kafka

**Kafka Connect configuration creation fails**

When you try to create a Kafka Connect configuration, you might see an error message like the following:

```
You are not authorized to create Kafka Connect Configurations
```

To create a Kafka Connect configuration, you need to create the correct IAM policy in your tenancy. For example:

```
Allow group xyz to manage connect-harnesses in tenancy
```

See [Managing Kafka Connect Configurations](#) on page 3885 for more information.
Tagging

This chapter explains how to use tags to add metadata to your resources.

Tagging Overview

Oracle Cloud Infrastructure Tagging allows you to add metadata to resources, which enables you to define keys and values and associate them with resources. You can use the tags to organize and list resources based on your business needs.

Caution:

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

How Tagging Works

The Tagging service provides two ways for you to add tags to resources. Each approach offers a different type of tag for you to work with:

- Defined tags - tag administrators manage resource metadata.
- Free-form tags - unmanaged metadata applied to resources by users.

One approach involves a tag administrator creating and managing all the tags that users apply to resources. Use IAM policy to select tag administrators, who can create tags. Grant all others in the tenancy only the ability to apply tags. The benefit to this approach is that you can create and manage the keys and values used to tag resources. You can then avoid typos that weaken automation based on tags and provide better reporting based on tags.

The other approach is to allow users to add tags to resources. Each tag is edited or applied at the resource by you or a user creating or modifying a resource. You can use both types of tags throughout your tenancy.

Most of the Tagging features require defined tags. "Tag" is used generically to refer to defined tags. To create metadata that you can trust to manage resources and collect data, use defined tags. With defined tags, the following scenarios become possible:

- Create default tags that are applied to all resources in compartments. See Managing Tag Defaults on page 3927.
- Specify that users must apply tags to resources to successfully create resources in compartments.
- If you make a typo using defined tags, correct it by editing or even deleting the tag. When you delete a defined tag, Oracle removes the key and any value for that tag from all resources. See Deleting Tag Key Definitions and Namespaces on page 3917.
- Associate a list of predefined values for a defined tag. See Using Predefined Values on page 3924.
- Use system variables to generate values for defined tags or tag defaults automatically. See Using Tag Variables on page 3926.
- Track costs based on tags. Use of defined tags is recommended for this use case.
- Set budgets using cost-tracking tags to be alerted when your spending reaches specified levels. See Using Cost-Tracking Tags on page 3923.
Tagging Concepts

Here's a list of the basic tagging concepts:

**TAG NAMESPACE**

You can think of a tag namespace as a container for your tag keys. It consists of a name and zero or more tag key definitions. Tag namespaces are not case sensitive and must be unique across the tenancy. The namespace is also a natural grouping to which administrators can apply policy. One policy on the tag namespace applies to all the tag definitions contained within that namespace.

**TAG KEY**

The name you use to refer to the tag. Tag keys are case insensitive. For example, "mytagkey" duplicates "MyTagKey". You must create tag keys for defined tags in a namespace. Each tag key must be unique within a namespace.

**TAG VALUE TYPE**

The tag value type specifies the data type allowed for the value. Currently two data types are supported: string and a list of strings.

**KEY DEFINITION**

A key definition defines the schema of a tag and includes a namespace, tag key, and tag value type.

**TAG VALUE**

The tag value is the value that the user applying the tag adds to the tag key. Tag values support two data types: strings and lists of strings. You can define a list of values for the user to select from when you define the tag key, or you can allow the user to enter any value when the tag is applied to the resource. If you select a string tag value when you create the key, the user can leave the value blank when they apply the key.

In the example:

```
Operations.CostCenter="42"
```

Operations is the namespace, CostCenter is the tag key, and 42 is the tag value.

**TAG (OR DEFINED TAG)**

A tag is the instance of a key definition that is applied to a resource. It consists of a namespace, a key, and a value. "Tag" is used generically to refer to defined tags.

**FREE-FORM TAG**

A basic metadata association that consists of a key and a value only. Free-form tags have limited functionality. See Understanding Free-form Tags on page 3922.

**COST TRACKING**

Cost tracking is a feature available with defined tags. This feature is being deprecated and is currently only relevant for use with Budgets. To understand when you need to designate a tag as a cost-tracking Tag, see Using Cost-Tracking Tags on page 3923.

**TAG DEFAULT**

Tag defaults let you specify tags that are applied automatically to all resources in a specific compartment at the time of creation, regardless of the permissions of the user who creates the resource. See Managing Tag Defaults on page 3927.

**RETIRE**

You can retire a tag key definition or a tag namespace. Retired tag namespaces and key definitions can no longer be applied to resources. However, retired tags are not removed from the resources to which they have already been applied. You can still specify retired tags when searching, filtering, reporting, and so on.
Tagging

REACTIVATE

You can reactivate a tag namespace or tag key definition that has been retired to reinstate its usage in your tenancy.

TAG VARIABLE

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Tag Variables on page 3926.

PREDEFINED VALUES

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Predefined Values on page 3924.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators: Use the following topics to find example of IAM policy for Tagging:

- Required Permissions for Working with Defined Tags on page 3915
- Required Permissions for Working with Tag Defaults on page 3928
- Required Permissions for Working with Free-form Tags on page 3922

Region Availability

Tagging is currently available in all regions.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Limits on Tags

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

- Tags per tenancy: unlimited
- Tags per resource: 10 free-form tags and 64 defined tags
- Tags enabled for cost-tracking: 10 per tenancy (includes both active and retired tags)
- Total tag data size: 5 K (JSON). The total tag data size includes all tag data for a single resource (all applied tags and tag values). Sizing is per UTF-8.
Tagging

- Number of pre-defined values for a tag key: 100 per list

<table>
<thead>

Tip:
Watch a video to introduce you to the concepts and features of tagging: Introduction to Tagging.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing tag namespaces and tags. For more policy samples specific to working with tags and tag namespaces, see Required Permissions for Working with Defined Tags on page 3915.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

Overview of Tags and Tag Namespaces

Defined tags provide more features and control than free-form tags. Before you create a defined tag key, you first set up a tag namespace for it. You can think of the tag namespace as a container for a set of tag keys. When you create the tag key definition, you must choose the type of value (which also determines how the user applying the tag adds the value):

- You can leave it empty so that a user can fill in the value.
- You can create a list of values so that the user must choose from those values.

To apply a defined tag to a resource, a user first selects the tag namespace, then the tag key within the namespace, and then they can assign the value. If the tag key contains a blank value, the user can type in a value or leave it blank. If the tag key contains a list, the user must select a value from the list.
Defined tags support policy to allow you to control who can apply your defined tags. The tag namespace is the entity to which you can apply policy. Administrators can control which groups of users are allowed to use each namespace.

The following diagrams illustrate defined tags. Two tag namespaces are set up: Operations and HumanResources. The tag keys are defined in the namespaces. Within each namespace, the tag keys must be unique, but a tag key name can be repeated across namespaces. In the example, both namespaces include a key named "Environment."

The first instance is tagged with two tags from the Operations tag namespace, indicating that it belongs to the Operations production environment and the Operations project "Alpha". The second instance is tagged with tags from both the HumanResources tag namespace and the Operations tag namespace, indicating that it belongs to the HumanResources "Production" environment, the HumanResources cost center "42", and also the Operations project "Beta".

**Working with Defined Tags**

You must set up the tag namespace and tag keys in your tenancy before users can apply a defined tag to a resource. As part of the set up process, you must also grant permissions to the user groups that needs to use the namespace.

**Note:**

Tag namespaces and tag key definitions beginning with "oci" and "orcl" are reserved for internal use.

Features of defined tags include:

- Consist of a tag namespace, a key, and a value.
• The tag namespace and tag key definition must be set up in your tenancy before users can apply a defined tag to a resource.
• You can create the tag key with either a tag value type of string (for the user to add a value or leave blank) or a list of values (from which the user must choose).
• When applying a defined tag, users select from the list of tag keys.
• Users can apply a defined tag during resource creation or to an existing resource.
• Defined tag keys are case insensitive.
• Defined tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.
• You can use tag variables.
• You can create a list of predefined variables to associate with a tag key. Users that apply the tag to a resource must select a value from the list you create.

**Required Permissions for Working with Defined Tags**

To apply, update, or remove defined tags for a resource, a user must be granted permissions on the resource and permissions to use the tag namespace.

Users must be granted `use` access on the `tag namespace` to apply, update, or remove a defined tag for a resource.

Some example policies for tag namespaces:

To allow a group to simply view the tag namespaces in the tenancy (or in a compartment) requires `inspect` access:

```
Allow group GroupA to inspect tag-namespaces in tenancy
```

**Important:**

To apply tags to a resource when using the Console, a user must have permissions to `inspect tag-namespaces in tenancy`. If the user does not have this permission, the list of tag namespaces cannot be presented to the user in the dialog menu.

To allow a group to read the tag definitions contained in tag namespaces requires `read` access:

```
Allow group GroupA to read tag-namespaces in tenancy
```

To allow a group to apply, update, or remove a defined tag for a resource requires the `use` access on the tag namespace:

```
Allow group GroupA to use tag-namespaces in tenancy
```

To allow usage of a specific tag namespace or namespaces, use a `where` clause with the `target.tag-namespace.name` variable. For example:

```
Allow group GroupA to use tag-namespaces in tenancy where target.tag-namespace.name='Operations'
```

or to specify multiple tag namespaces:

```
Allow group GroupA to use tag-namespaces in tenancy where any {target.tag-namespace.name='Operations', target.tag-namespace.name='HumanResources'}
```

To manage tag namespaces and the tag definitions in them, requires `manage` access:

```
Allow group GroupA to manage tag-namespaces in tenancy
```

In addition to the permissions to work with the tag namespace, to apply or remove defined tags on a resource you must have the update permission for the resource. For many resources, the update permission is granted with the `use`
Tagging

verb. For example, users who can use instances in CompartmentA can also apply, update, or remove defined tags for instances in CompartmentA.

Some resources don't include the update permission with the use verb. To allow a group to apply, update, or remove defined tags for these resources without granting the full permissions of manage, you can add a policy statement to grant only the `<RESOURCE>_UPDATE` permission from the manage verb. For example, to allow a group NetworkUsers to work with defined tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA
Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_UPDATE'
```

The inspect permission for a resource grants permissions to view defined tags for that resource. For example, users who can inspect instances can also view any defined tags applied to the instance.

For information about resource permissions, see Policy Reference on page 2167.

**Example Scenario**

Your company has an Operations department. Within the Operations department are several cost centers. You want to be able to tag resources that belong to the Operations department with the appropriate cost center.

1. Create a tag namespace definition called Operations.
2. In the Operations namespace, create a tag key definition called CostCenter.

Alice already belongs to the group InstanceLaunchers. Alice can manage instances in CompartmentA. You want Alice and other members of the InstanceLaunchers group to be able to apply the Operations.CostCenter tag to instances in CompartmentA.

To grant the InstanceLaunchers group access to the Operations tag namespace (and only the Operations tag namespace), add the following statements to the InstanceLaunchers policy:

```
Allow group InstanceLaunchers to use tag-namespaces in compartment CompartmentA where target.tag-namespace.name='Operations'
```

Alice can now apply the Operations.CostCenter tag to resources in CompartmentA.

**Retiring Key Definitions and Namespace Definitions**

You can retire a tag key definition or a tag namespace definition.

When you retire a tag key definition, you can no longer apply it to resources. However, the tag is not removed from the resources that it was applied to. The tag still exists as metadata on those resources and you can still call the retired tag in operations (such as listing, sorting, or reporting).

**Important:**

Retiring a tag stops cost tracking for the tag, but if you do not disable the cost-tracking option on the tag key definition, the retired tag continues to count against your maximum of 10 cost-tracking tags for your tenancy. Disable cost tracking before you retire the tag key definition. To disable cost-tracking after a tag is retired, you must reactivate the tag key definition. You can't update tag key definitions that are in the retired state.

**Reactivating Tag Key Definitions and Namespace Definitions**

You can reactivate retired tag key definitions and tag namespace definitions.

- When you reactivate a tag key, it is again available for you to apply to resources.
• When you reactivate a tag namespace, you can create new tag key definitions in that namespace. However, if you want to use any of the tag key definitions that were retired with the namespace, you must explicitly reactivate each tag key definition.

Moving Tag Namespaces to a Different Compartment

You can move a tag namespace to a different compartment. The tag namespace can be active or retired when you move it. When you move the tag namespace, all its tag key definitions are moved along with it.

This functionality is useful if you need to reorganize your compartment hierarchy, or if you need to delete a compartment that contains a retired tag namespace. Remember that you can't delete a compartment that contains resources. A retired tag namespace, even though it is retired, is still an existing resource. Moving the retired tag namespace to a different compartment can enable you to delete its original containing compartment.

To move a tag namespace, you must be allowed to manage tag-namespaces in both compartments.

See the procedure To move a tag namespace to a different compartment on page 3918.

Deleting Tag Key Definitions and Namespaces

You can delete tag key definitions and tag namespaces.

When you delete a tag key definition, you begin a process that removes the tag from all resources in your tenancy. These things happen immediately:

• If the tag was a cost-tracking tag, it no longer counts against your 10 cost-tracking tags limit, whether you first disabled it or not.
• If the tag was used with dynamic groups, none of the rules that contain the tag will be evaluated against the tag.

The delete action is asynchronous and initiates a work request. Once you start the delete operation, the state of the tag changes to deleting, and tag removal from resources begins. This process can take up to 48 hours depending on the number of resources that were tagged as well as the regions in which those resources reside. When all tags are removed, the state changes to deleted. You cannot restore a deleted tag. After the tag state changes to Deleted, you can use the same tag name again.

To delete a tag key definition, you must first retire it. To delete a tag namespace, you must first retire the tag namespace. When you retire a tag namespace that contains tag key definitions, all the tag keys in the namespace are retired, allowing you to delete the tag namespace.

Using the Console

Managing Tag Namespaces

To create a tag namespace

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.

   A list of the tag namespaces in your current compartment is displayed.

2. Click Create Namespace Definition.

3. Enter the following:

   • **Create in Compartment**: The compartment in which you want to create the namespace definition.
   • **Namespace Definition Name**: A unique name for this set of tags. The name must be unique within your tenancy. Tag namespace is case insensitive. You cannot change this value later. Avoid entering confidential information.
   • **Description**: A friendly description. You can change this value later if you want to.

4. Click Create Namespace Definition.
To update a tag namespace's description

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your tenancy is displayed.
2. Click the tag namespace you want to update.
   The namespace's details are displayed. The description is displayed under the namespace's name.
3. Click the pencil next to the description.
4. Edit the description and save it. Avoid entering confidential information.

To retire a tag namespace

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to retire.
   The namespace's details are displayed.
3. Click Retire Tag Namespace.
4. Confirm when prompted.

To reactivate a tag namespace

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to reactivate.
   The namespace's details are displayed.
3. Click Reactivate Tag Namespace.
4. Confirm when prompted.

To move a tag namespace to a different compartment

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to move.
   The namespace's details are displayed.
3. Click Move Tag Namespace.
4. Select the Target Compartment that you want to move the tag namespace to.
5. Click Move Tag Namespace.

To delete a tag namespace

To delete a tag namespace, you must first retire it.

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that you want to delete.
   The namespace's details are displayed.
3. Click **Delete Tag Namespace**.

   **Tip:**

   If the **Delete Tag Namespace** option is unavailable, first retire your tag namespace.

4. Confirm when prompted.

### Managing Key Definitions

#### To create a key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace you want to add the tag key definition to.

   A list of the tag key definitions that belong to the namespace is displayed.

3. Click **Create Tag Key Definition**.

4. Enter the following:

   - **Tag Key:** Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   - **Description:** Enter a friendly description.
   - **Cost-tracking:** Select the check box to enable this tag for cost tracking. You have a limit of 10 Using Cost-Tracking Tags on page 3923 in your tenancy.

5. Under **Tag Value Type**, choose one of the following:

   - **Static Value:** Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values:** Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.

6. Click **Create Tag Key Definition**.

#### To update a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to update.

   A list of the tag key definitions is displayed.

3. Click the tag key definition you want to update.

   The key definition's details are displayed.

4. Click **Edit Tag Key Definition**.

   The edit dialog appears.

   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.

   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.

   You have a limit of 10 Using Cost-Tracking Tags on page 3923 in your tenancy.

5. Make your changes and save it.
To retire a tag key definition

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to retire.

   A list of the tag key definitions is displayed.

3. Select the tag key definition you want to retire. To retire multiple tag key definitions at the same time, select all of the tag key definitions that you want to retire.

   **Important:**

   If the tag is a cost-tracking tag, disable the cost-tracking flag. If you don't disable cost-tracking, this tag will still count against your tenancy maximum of 10 cost-tracking tags, even after it is retired. For more information, see Using Cost-Tracking Tags on page 3923.

4. Click Retire.

5. Confirm when prompted.

To reactivate a tag key definition

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to reactivate.

   A list of the tag key definitions is displayed.

3. Select the tag key definition you want to reactivate. To reactivate multiple tag key definitions at the same time, select all of the tag key definitions that you want to reactivate.

4. Click Reactivate.

5. Confirm when prompted.

To delete a tag key definition

To delete a tag key definition, you must first retire it.

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to delete.

   A list of the tag key definitions is displayed.

3. Select the retired tag key definition you want to delete. To delete multiple tag key definitions at the same time, select all of the tag key definitions that you want to delete. You can delete up to five tag key definitions at the same time.

4. Click Delete.

   **Tip:**

   If the Delete option is unavailable, first retire your tag key definition.
5. Confirm when prompted.
   After you confirm, the state changes to Deleting. Track the progress of the operation using the work request.

**To track the progress of the delete operation**

a. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.

b. Click the tag namespace that includes the tag key definition you deleted.
   A list of the tag key definitions is displayed.

c. Click **Work Requests**.
   The work requests for deleted tag definitions are displayed.

**To monitor a work request for a deleted tag**

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you deleted.
   A list of the tag key definitions is displayed.

3. Click **Work Requests**.
   The work requests for deleted tag definitions are displayed.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage tag namespaces:

- **GetTagNamespace**
- **ListTagNamespaces**
- **CreateTagNamespace**
- **UpdateTagNamespace** - Use to retire or reactivate a tag namespace.
- **CascadeDeleteTagNamespace** - Use to delete a tag namespace and all of its tag key definitions. You must first retire the tag namespace.
- **DeleteTagNamespace** - Use to delete the tag namespace. You must first delete all of the tag key definitions contained in the tag namespace.
- **ChangeTagNamespaceCompartment**

Use these API operations to manage tag key definitions:

- **GetTag** - gets the tag key definition
- **ListTags** - lists tag key definitions
- **ListCostTrackingTags** - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)
- **CreateTag** - creates a tag key definition
- **UpdateTag** - updates the tag key definition (use this operation to retire or reactivate a tag key)
- **DeleteTag** - deletes the tag key definition
- **BulkDeleteTags** - deletes multiple tag key definitions within a tag namespace

Use these API operations to manage work requests spawned by the DeleteTag operation:

- **ListTaggingWorkRequests**
- **ListTaggingWorkRequestErrors**
- **ListTaggingWorkRequestLogs**
Tagging

- GetTaggingWorkRequest

**Understanding Free-form Tags**

Oracle Cloud Infrastructure supports two kinds of tags: free-form tags and defined tags. This topic describes free-form tags.

Because free-form tags are limited in functionality, Oracle recommends that you only use them to try out the tagging feature in your system when you are first getting started with tagging. For more information about the features and limitations of free-form tags, see Working with Free-form Tags on page 3922.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for free-form tags. For more policy samples specific to working with free-form tags, see Required Permissions for Working with Free-form Tags on page 3922.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

**Overview of Free-form Tags**

Free-form tags consist of a key and a value, for example:

Environment: Production

where "Environment" is the key and "Production" is the value.

You can apply multiple free-form tags to a single resource, up to the limit.

**Working with Free-form Tags**

Free-form tags consist of a key-value pair and have limited features. To experience the full feature set of tagging, use defined tags.

Features of free-form tags include:

- Consist of a key and a value. Free-form tags do not belong to a namespace.
- You can apply free-form tags during resource creation or to an existing resource.
- Free-form tag keys are case sensitive. For example, "Project" and "project" are distinct keys.
- Free-form tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.

Limitations of free-form tags include:

- When applying a free-form tag, you can't see a list of existing free-form tags, so you don't know what tags and values have already been used.
- You can't see a list of existing free-form tags in your tenancy.
- You can't use free-form tags to control access to resources. That is, you can't include free-form tags in IAM policies.
- You can't use tag variables in free-form tags.
- You can't use predefined values in free-form tags.

**Required Permissions for Working with Free-form Tags**

To apply, update, or remove free-form tags for a resource, you must have the update permission on the resource. For many resources, the update permission is granted with the use verb. For example, users who can use instances in CompartmentA can also apply, update, or remove free-form tags for instances in CompartmentA.
Tagging

Some resources do not include the update permission with the use verb. To allow a group to apply, update, or remove free-form tags for these resources without granting the full permissions of manage, you can add a policy statement to grant only the `<RESOURCE>_UPDATE` permission from the manage verb. For example, to allow a group NetworkUsers to work with free-from tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA
Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_UPDATE'
```

The inspect verb for a resource grants permissions to view free-form tags for that resource. Therefore, users who can inspect instances in CompartmentA can also view any free-form tags applied to the instance.

For information about resource permissions, see Policy Reference on page 2167.

Using Cost-Tracking Tags

Cost-tracking tags are only relevant when you set budgets.

- You can only use a cost-tracking tag with defined tags.
- You cannot specify free-form tags as cost-tracking tags.
- You do not have to designate a tag as cost-tracking, in order for it to be exposed in Cost Analysis or Cost and Usage Reports.

Required IAM Policy

Cost tracking is a feature of defined tags. To allow users to work with cost tracking, use the same IAM policy for working with tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags on page 3915.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

Working with Cost-Tracking Tags

Suppose you have a defined tag key definition called Finance.CostCenter. You enable this tag key definition for cost tracking. You apply the tag with a value of "W1" (Finance.CostCenter="W1") to some resources, and you apply the tag with a value of "C2" (Finance.CostCenter="C2") to other resources. These tags enables the following scenario:

- Create one budget for resources tagged "Finance.CostCenter=W1" and a second budget for resources tagged "Finance.CostCenter=C2". If spending surpasses a certain amount or is forecast to exceed a particular threshold, you can set up alerts that notify you.

Limits on Cost-Tracking Tags

- You can have a maximum of 10 tag key definitions enabled for cost-tracking in your tenancy at a time. For example, you could enable the Project tag key as a cost-tracking tag and have 75 different departments, but it only takes up 1 tag.

Using the Console

You can enable cost-tracking when you create a tag key definition, or you can update an existing tag key definition to enable cost tracking.

To create a key definition

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click **Create Tag Key Definition**.
4. Enter the following:
   - **Tag Key**: Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   - **Description**: Enter a friendly description.
   - **Cost-tracking**: Select the check box to enable this tag for cost tracking. You have a limit of 10 **Using Cost-Tracking Tags** on page 3923 in your tenancy.
5. Under **Tag Value Type**, choose one of the following:
   - **Static Value**: Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values**: Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.
6. Click **Create Tag Key Definition**.

**To update a tag key definition**

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click **Edit Tag Key Definition**.
   The edit dialog appears.
   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.
   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.
   You have a limit of 10 **Using Cost-Tracking Tags** on page 3923 in your tenancy.
5. Make your changes and save it.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.
- **ListCostTrackingTags** - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)

**Using Predefined Values**

You can create a list of values and associate that list with a tag key definition. When users then apply the tag to a resource, they must select a value from the list of predefined values. Use lists of predefined values to impose limits on the values that users can apply to tags.
You can use predefined values with defined tags and default tags. You cannot create lists of predefined values for free-form tags.
**Tagging**

**Required IAM Policy**

Predefined values are a feature of defined tags. To allow users to work with predefined values, use the same IAM policy for working with tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags on page 3915.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

**Working with Predefined Values**

You can update existing tags to use predefined values.

Every list of predefined values that you create must contain at least one value. Lists can't contain duplicate values or blank entries. With predefined values, users applying tags can't set the value of a tag to `null`. For more information, see Using the Console on page 3925.

**Predefined Values and Default Tags**

You can use predefined values and default tags to impose limits on the values that users can apply to tags.

Here's how it works:

1. You define a list of predefined values for a tag key.
2. You create a default tag that uses the key with the list of predefined values and requires that users who create resources in the compartment add the value to the tag.
3. Oracle prompts all users creating resources in the compartment to enter a tag value. Because the tag key contains a predefined list that you created, the value the user applies is a value that you trust.

These features help to ensure that new resources contain the values you expect. For more information, see Managing Tag Defaults on page 3927.

**Using the Console**

**To create a key definition**

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tag Namespaces.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace you want to add the tag key definition to.

   A list of the tag key definitions that belong to the namespace is displayed.

3. Click Create Tag Key Definition.

4. Enter the following:
   - **Tag Key**: Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   - **Description**: Enter a friendly description.
   - **Cost-tracking**: Select the check box to enable this tag for cost tracking. You have a limit of 10 Using Cost-Tracking Tags on page 3923 in your tenancy.

5. Under Tag Value Type, choose one of the following:
   - **Static Value**: Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values**: Specifies that the user must apply a value from a list you create. When you select this option, the Values box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.

6. Click Create Tag Key Definition.
To update a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to update.

   A list of the tag key definitions is displayed.

3. Click the tag key definition you want to update.

   The key definition's details are displayed.

4. Click **Edit Tag Key Definition**.

   The edit dialog appears.

   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.

   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.

   You have a limit of 10 **Using Cost-Tracking Tags** on page 3923 in your tenancy.

5. Make your changes and save it.

Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

- **CreateTag** - creates a tag key definition
- **UpdateTag** - updates the tag key definition (use this operation to retire or reactivate a tag key)

Using Tag Variables

You can use a variable to set the value of a defined tag. When you add the tag to a resource, the variable resolves to the data it represents. You can use tag variables in defined tags and default tags. You cannot use tag variables in free-form tags.

Required IAM Policy

Tag variables are a feature of defined tags. To allow users to work with tag variables, use the same IAM policy for working with tag namespaces and tags. For more information, see **Required Permissions for Working with Defined Tags** on page 3915.

If you're new to policies, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see **Details for IAM** on page 2280.

Working with Tag Variables

Consider the following example:

```plaintext
Operations.CostCenter="${iam.principal.name} at ${oci.datetime}"
```

Operations is the namespace, CostCenter is the tag key, and the tag value contains two tag variables `${iam.principal.name}` and `${oci.datetime}`. When you add this tag to a resource, the variables resolve to your user name (the name of the principal that applied the tag) and a time date stamp for when you added the tag.

```
user_name at 2019-06-18T18:00:57.604Z
```

The variable is replaced with data at the time that you apply the tag. If you later edit the tag, the variable is gone and only the data remains. You can edit the tag value in all the ways you would edit any other tag value.
To create a tag variable, you must use a specific format.

```
${<variable>}
```

Type a dollar sign followed by open and close curly brackets. The tag variable goes between the curly brackets. You can use tag variables with other tag variables and with string values.

**Supported Tag Variables**

The following tag variables are supported.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${iam.principal.name}</code></td>
<td>The name of the principal that tagged the resource.</td>
</tr>
<tr>
<td><code>${iam.principal.type}</code></td>
<td>The type of principal that tagged the resource.</td>
</tr>
<tr>
<td><code>${oci.datetime}</code></td>
<td>The date and time that the tag was created.</td>
</tr>
</tbody>
</table>

**Managing Tag Defaults**

This topic describes how to you can specify tags to be automatically applied to resources at creation time.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing tag defaults and tag namespaces. For specific policy information for this feature, see [Required Permissions for Working with Tag Defaults](#) on page 3928.

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. If you want to dig deeper into writing policies for tagging or other IAM components, see [Details for IAM](#) on page 2280.

**Overview of Tag Defaults**

Tag defaults let you specify tags that are applied automatically to all resources at the time of creation in a specific compartment. This feature allows you to ensure that appropriate tags are applied at resource creation without requiring the user creating the resource to have access to the tag namespaces. Consider the following example:

Alice is a finance administrator and has access to the restricted tag namespace Finance. Alice can set up a tag default to apply the Finance.CostCenter tag with a value of W1234 to all resources. Eli can create resources but does not have access to the Finance tag namespace. When Eli creates a resource, the Finance.CostCenter tag is automatically applied with a value of W1234. Eli cannot change this tag, and Alice is confident that it is always applied correctly and not changed by the users who create or edit resources.

Tag defaults allow tenancy administrators to create secure permissions boundaries between users concerned with governance and users who need to create and administer resources.

**Where to Manage Tag Defaults**

Tag defaults are defined for a specific compartment. In the Console, you manage tag defaults on the Compartment Details page.
Required Permissions for Working with Tag Defaults

To create or edit a tag default for a compartment, you must be granted the following combination of permissions:

- manage tag-defaults access on the compartment where you are adding the tag default
- use tag-namespaces access on the compartment where the tag namespace resides
- inspect tag-namespaces access on the tenancy

For the full mapping of permissions to API operations, see Details for IAM on page 2280.

For example, assume you created a set of tag namespaces in CompartmentA. To give a group named TagAdmins access to add tag defaults to CompartmentA, write a policy with the following statements:

```
Allow group TagAdmins to manage tag-defaults in compartment CompartmentA
Allow group TagAdmins to use tag-namespaces in compartment CompartmentA
Allow group TagAdmins to inspect tag-namespaces in tenancy
```

Now assume you also want to allow TagAdmins to create tag defaults in CompartmentA using tag namespaces that reside in CompartmentZ. Add a statement to allow TagAdmins to use tag namespaces in CompartmentZ:

```
Allow group TagAdmins to use tag-namespaces in compartment CompartmentZ
```

Now when TagAdmins create tag defaults in CompartmentC, they can use tag namespaces that reside in either CompartmentA or CompartmentZ.

Working with Tag Defaults

You can only use tag defaults with defined tags. Free-form tags are not supported for tag defaults.

You can define up to 5 tag defaults per compartment.

After a tag default is created in a compartment:

- The default tag is applied to any new resources created in that compartment.
- Previously existing resources in the compartment are not tagged retro-actively.
- If you change the default value of the tag default, existing occurrences are not updated.

Deleting Tag Defaults

- If you delete the tag default from the compartment, existing occurrences of the tag are not removed from resources.
Tagging

- When you delete a tag key definition, existing tag defaults based on that tag key definition are not removed from the compartment. Until you delete the tag default in the compartment, the tag default continues to count against your limit of 5 tag defaults per compartment.

**Required Tag Values**

For tag defaults, you must include a tag value, but you have a choice about how the value is applied.

- Default value
- User-applied value

If you use a default value, then you must create it. This value is applied to all resources.

If you specify that a user-applied value is required, then the user creating the resource must enter the value for the tag at the time of resource creation. Users cannot create resources without entering a value for the tag.

| Tip: |
| You can use predefined values and user-applied values to ensure that users only apply a value that you trust. See Using Predefined Values on page 3924. |

**Tag Inheritance**

The default tag is applied to all resources created in the compartment, including child compartments and the resources created in the child compartments.

Example:

- In CompartmentA, you create a tag default, TagA.
  
  Resources (and compartments) created in CompartmentA are automatically tagged with TagA.
  
  - In the subcompartment, CompartmentB, you create tag default, TagB.
    
    Resources and compartments created in CompartmentB are automatically tagged with TagA and TagB.
    
    - In the sub-subcompartment, CompartmentC, you create tag default TagC.
      
      Resources created in CompartmentC are automatically tagged with TagA, TagB, and TagC.

This example is illustrated in the following graphic:
Overriding Tag Defaults

Tag defaults can be overridden at the time of resource creation by users who have the appropriate permissions to both create the resource and to use the tag namespace.

Example: CompartmentA has a tag default defined to apply CostCenter.Operations="42". Pradeep belongs to a group that grants him permissions to create instances in CompartmentA and also to use tag namespaces in CompartmentA. He creates an instance in CompartmentA, and in the Create Instance dialog, he applies the tag CostCenter.Operations="50". Because he has the appropriate permissions, when the instance is created, the tag default is overridden, and the instance is tagged with CostCenter.Operations="50".

After a resource is created and tagged, users with the appropriate permissions to both update the resource and to use the tag namespace can modify the default tags that were applied at resource creation.

Tag Defaults and Retired Tags

Retired tags can't be applied to new resources. Therefore, if the tag namespace or tag key specified in a tag default is retired, when new resources are created, the retired tag is not applied. As a best practice, you should delete the tag default that specifies the retired tag.

Tag Defaults and Tag Variables

You can use tag variables in tag defaults. Tag variables dynamically resolve at resource creation time. For example, you enter a tag variable for principal name as the tag default in a particular compartment.

Operations.CostCenter="${iam.principal.name}" 

Davis and Garcia each create buckets in that compartment. The buckets that Davis creates include default tags that contain his name as the value, while the buckets that Garcia creates have his name.

Operations.CostCenter="Davis"
Operations.CostCenter="Garcia"

Meanwhile, the tag default still contains the original variables. See Using Tag Variables on page 3926.
Limits on Tag Defaults

A maximum of 5 tag defaults can be defined per compartment.

Note:

When you delete a tag key definition, existing tag defaults based on that tag key definition are not removed from the compartment. Until you delete the tag default in the compartment, the tag default continues to count against your limit of 5 tag defaults per compartment.

See Limits on Tags on page 3908 for more limits on tags.

Using the Console

To create a tag default

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
   
   A list of the compartments that you have access to displays.
2. In the list, click the name of the compartment to which you want to add a tag default.
3. On the compartment details page, click Tag Defaults.
   
   The list of existing tag defaults displays.
4. Click Create Tag Default.
5. Enter the following (all fields are required):
   
   • Tag Namespace: Select the tag namespace for the tag default.
   • Tag Key: Select the tag key.
6. Specify the type of value you want this tag to have:
   
   • Default Value: Enter the value you want this tag to have.
   • User-applied Value: Users that create resources must enter the value as resources are created.
7. Click Create Tag Default.

To update the default value of a tag default

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
   
   A list of the compartments that you have access to displays.
2. In this list, click the name of the compartment that has the tag default that you want to update.
3. On the compartment details page, click Tag Defaults.
   
   The list of existing tag defaults displays.
4. Find the tag default you want to update. Go to the the Actions icon (three dots) and click Edit.
5. Specify the type of value you want this tag to have:
   
   • Default Value: Enter the value you want this tag to have.
   • User-applied Value: Users that create resources must enter the value as resources are created.
6. Click Save Changes.

To delete a tag default

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
   
   A list of the compartments that you have access to displays.
2. In the list, click the name of the compartment that has the tag default that you want to delete.
3. On the compartment details page, click Tag Defaults.
   
   The list of existing tag defaults displays.
4. Find the tag default that you want to delete. Go to the the Actions icon (three dots) and click Delete.
5. Confirm when prompted.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage tag defaults:

- GetTagDefault
- ListTagDefaults
- CreateTagDefault
- UpdateTagDefault
- DeleteTagDefault

Understanding Automatic Tag Defaults

Use tag defaults to manage resources in your tenancy, including tracking costs by principal name and the date resources are created. In tenancies created after December 17, 2019, two tag defaults are automatically added to the root compartment. These tag defaults apply tags to all resources with the following values:

- Name of the principal that created the resource
- Date the resource was created

Overview of Automatic Tag Defaults

The tag defaults Oracle automatically adds come from a tag namespace called Oracle-Tags, which includes two tag key definitions:

- CreatedBy (Cost-tracking tag)
- CreatedOn

Oracle uses these tags to define two tag defaults in the root compartment of your tenancy. When users create resources in your tenancy, each tag is added to the resource automatically. The values for these tags contain the name of the principal that created the resource and the date and time the resource was created. For more information, see Using Tag Variables on page 3926.

Required IAM Policy

Automatic tag defaults are two tag defaults, automatically created in the root compartment. To allow users to work with these tag defaults, use the same IAM policy for working with tag defaults. For more information, see Required Permissions for Working with Defined Tags on page 3915.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

Working with Automatic Tag Defaults

You can use the cost-tracking tag feature to check usage and set budgets or to filter resources by date. You can remove and update tags automatically applied to resources as you would any other tag. For more information, see Using Cost-Tracking Tags on page 3923 and Resource Tags on page 211.

If you no longer want these tags applied to resources automatically, you can remove the tag defaults that Oracle created. Although Oracle created the tag defaults, they are ordinary tag defaults that you can manage as you would any other. For more information, see Managing Tag Defaults on page 3927.

Using Tags to Manage Access

This topic describes how you can use tags in policy to scope access based on tags applied to either the requestor or the target of an authorization call.

About Tag-Based Access Control

Using conditions and a set of tag variables, you can write policy to scope access based on the tags that have been applied to a resource. Access can be controlled based on a tag that exists on the requesting resource (group, dynamic
Tagging

group, or compartment) or on the target of the request (resource or compartment). Tag-based access control provides additional flexibility to your policies by allowing you to define access policies with tags that span compartments, groups, and resources.

**Caution:**

If your organization chooses to create policies that use tags to manage access, then ensure that you have appropriate controls in place to govern who can apply tags. Also, after policies are in place, keep in mind that applying tags to a group, user, or resource has the potential to confer access to resources.

**Before you create a policy** that specifies a tag on either a target or a requestor, ensure that you are aware of:

- all the potential requestors (users, groups, dynamic groups) that carry the tag
- all the resources that carry the tag

**Before you apply a tag to a resource,** ensure that you are aware of any policies in place that include the tag and could impact who has access to the resource.

**Managing Access Using Tags Applied to the Requesting Resource**

You can control access based on the value of a tag applied to:

- a group (of users) requesting access
- a dynamic group (of instances) requesting access
- a compartment that a resource in a dynamic group resides in

By using tags in your policy statements to scope access, you can define access for multiple groups through a single policy statement. You can also confer access and revoke access for groups by applying or removing tags, without changing the original policies.

The basic syntax for each variable is shown in the following table. Note that the syntax is the same for group and dynamic group, but each is presented in a different row. See Supported Operators on page 3936 for more usage examples.

<table>
<thead>
<tr>
<th>Tag Applied to Requestor</th>
<th>Variable Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>request.principal.group.tag.&lt;tagNamespace&gt;.&lt;tagKeyDefinition&gt;=&lt;value&gt;</td>
<td>The tags applied to the groups that the user belongs to are evaluated for a match.</td>
</tr>
</tbody>
</table>

Sample policy for user group:

```
allow any-user to manage instances in compartment HR where request.principal.group.tag.Operations.Project='Prod'
```

Any user who belongs to a group that has been tagged with Operations.Project='Prod' can manage instances in the HR compartment.
Tagging

<table>
<thead>
<tr>
<th>Tag Applied to Requestor</th>
<th>Variable Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dynamic group</td>
<td>request.principal.group.tag.&lt;value&gt;'</td>
<td>The tags applied to the dynamic groups that the instance belongs to are evaluated for a match.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>compartment</td>
<td>request.principal.compartment.tag.&lt;value&gt;'</td>
<td>The tags applied to the compartment that the requesting resource belongs to are evaluated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

Users reside in the root compartment of your tenancy, so tags must be applied to the root compartment for those policy statements to work.

**Managing Access Using Tags Applied to the Target Resource**

You can control access based on the value of a tag applied to:

- a resource
- a compartment that the target resource resides in

The basic syntax for these variables is shown in the following table. See Supported Operators on page 3936 for more usage examples.
Tagged

<table>
<thead>
<tr>
<th>Tag Applied to Target</th>
<th>Variable Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resource</td>
<td>target.resource.tag.{tagNamespace}.{tagKeyDefinition}='{tagKeyDefinition}='value'</td>
<td>The tag applied to the target resource of the request is evaluated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>There are limitations to the permissions that can be granted in this type of policy. See the following sections in this topic for details.</td>
</tr>
<tr>
<td>compartment</td>
<td>target.resource.compartment.tag.{tagNamespace}.{tagKeyDefinition}='{tagKeyDefinition}='value'</td>
<td>The tag applied to the target compartment of the request is evaluated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See <a href="#">Compartment Hierarchies</a> on page 3938 for details on how access is granted in nested compartments.</td>
</tr>
</tbody>
</table>

### Permissions to List a Resource Must Be Granted Separately

Policies that scope access based on the tag applied to the target resource can't allow the permissions that enable you to return a list of resources. Therefore, permissions to allow listing a resource must be granted through an additional policy statement. This means that if you have defined a policy like:

```
allow group GroupA to manage all-resources in compartment Operations where
target.resource.tag.Operations.Project= 'Prod'
```

GroupA will not be able to list any of the resources that they are otherwise allowed to manage. Members of GroupA would not be able to use the Console to interact with these resources and users would need to know the OCID of the resource they are attempting to manage, which makes using the SDK and CLI cumbersome, also.

To allow GroupA to list those resources, you need to add another policy statement like:

```
allow group GroupA to inspect all-resources in compartment Operations
```

This approach improves the tag-based policy because it allows users to use the Console more easily (by allowing them to see the resource they want to manage), but still limits the permissions to only inspect. The members of GroupA cannot take any action on those resources unless they are tagged appropriately. Keep in mind when using tag-based access control that the added flexibility requires this additional potential expansion of access.

Another approach you can use to avoid this limitation is to tag the compartments that contains the resources you want to grant access to. An example policy looks like this:

```
allow group GroupA to manage all-resources in tenancy where
target.resource.compartment.tag.Operations.Project= 'Prod'
```

This policy allows the members of GroupA to manage all resources in the tenancy that are in compartments that are tagged with the Operations.Project='Prod' tag.

### Policies that Require a Tag on the Target Resource Can't Grant Create Permissions

When you write a policy to scope access based on the value of a tag on the resource, keep in mind that the policy cannot grant create permissions. A request to create an instance would fail because the target resource has not been created yet and therefore does not have the appropriate tag to be evaluated. So a policy like:

```
allow group GroupA to manage all-resources in compartment Operations where
target.resource.tag.Operations.Project= 'Prod'
```

would fail because the target resource has not been created yet and therefore does not have the appropriate tag to be evaluated.
allow group GroupA to manage instances in compartment Operations where
target.resource.tag.Operations.Project='Prod'

allows the members of GroupA to use and delete instances that are tagged with Operations.Project='Prod', but they
cannot create instances.

Supported Operators

Your policy using these tag variables can include these operators and match types:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>String</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag='sample'</td>
<td>Evaluates to true if any of the groups that the requestor belongs to is tagged with the matching value &quot;sample&quot; for MyTagNamespace.MyTag. (The value is case insensitive.)</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag=/*sample/</td>
<td>Evaluates to true if any of the values of MyTagNamespace.MyTag ends with &quot;sample&quot;. (Simple case insensitive pattern match.)</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.mytagnamespace.mytag = target.resource.tag.mytagnamespace.mytag</td>
<td>Evaluates to true when the specified resource mytagnamespace.mytag has a value that matches the specified target mytagnamespace.tag.</td>
</tr>
<tr>
<td>!=</td>
<td>String</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag!='sample'</td>
<td>Evaluates to true if none of the string values of the policy variable equals &quot;sample&quot;. (Simple case insensitive string comparison.)</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag=/!*sample/</td>
<td>Evaluates to true if none of the values of MyTagNamespace.MyTag ends with &quot;sample&quot;. (Simple case insensitive pattern match.)</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.mytagnamespace.mytag != target.resource.tag.mytagnamespace.mytag</td>
<td>Evaluates to true if neither side is a subset of the other.</td>
</tr>
</tbody>
</table>
### In / Not In

<table>
<thead>
<tr>
<th>Operator</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>String</td>
<td><code>request.principal.group.tag.MyTagNamespace.MyTag in ('sample', 'sample1')</code></td>
<td>The clause evaluates to true if any of the values of <code>MyTagNamespace.MyTag</code> for any group of the current requesting principal either equals to &quot;sample&quot; or &quot;sample1&quot;.</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td><code>request.principal.group.tag.MyTagNamespace.MyTag in (/*sample/, /sample1*/)</code></td>
<td>The clause evaluates to true if any of the values of <code>MyTagNamespace.MyTag</code> for any group of the current requesting principal either ends with &quot;sample&quot; or starts with &quot;sample1&quot;.</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td><code>request.principal.group.tag.MyTagNamespace.MyTag in (target.resource.tag.mytagnamespace.mytag, 'sample')</code></td>
<td>The clause evaluates to true if any of the following conditions are met: 1. Either <code>request.principal.group.tag.MyTagNamespace.MyTag</code> or <code>target.resource.tag.mytagnamespace.mytag</code> is a subset of the other. 2. Any string values of <code>request.principal.group.tag.MyTagNamespace.MyTag</code> equals &quot;sample&quot;.</td>
</tr>
<tr>
<td>not in</td>
<td>String</td>
<td><code>request.principal.group.tag.MyTagNamespace.MyTag not in ('sample', 'sample1')</code></td>
<td>The clause evaluates to true if none of the values of <code>MyTagNamespace.MyTag</code> for any group of the current requesting principal equals to &quot;sample&quot; or &quot;sample1&quot;.</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td><code>request.principal.group.tag.MyTagNamespace.MyTag not in (/*sample/, /sample1*/)</code></td>
<td>The clause evaluates to true if none of the values of <code>MyTagNamespace.MyTag</code> for any group of the current requesting principal ends with &quot;sample&quot; or starts with &quot;sample1&quot;.</td>
</tr>
<tr>
<td>Operator</td>
<td>Type</td>
<td>Example</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------</td>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag not in (target.resource.tag.mytagnamespace.mytag, 'sample')</td>
<td>The clause evaluates to true if all of the following conditions are met: 1. Neither request.principal.group.tag.MyTagNamespace.MyTag nor target.resource.tag.mytagnamespace.mytag is a subset of the other. 2. None of the string values of request.principal.group.tag.MyTagNamespace.MyTag equals &quot;sample&quot;.</td>
</tr>
</tbody>
</table>

**Support for Wildcards**

You can use the * character to match all occurrences of `{tagNamespace}.{tagKeyDefinition}` regardless of the value. In the policy, you can place * in single quotes '*' or between backslashes /*/. For example,

allow group GroupA to use all-resources in compartment HR where target.resource.tag.HR.Project= '*'

In this example, GroupA can use all resources in the compartment HR that are tagged with the tag namespace and tag key: HR.Project with any value.

**Limitations on Characters in Tag Namespaces and Tag Key Definitions Used in Policy Variables**

Tag namespaces and tag key definitions support a broader set of characters than are allowed in policy variables. Therefore, to use tag namespaces and tag key definitions in variables, ensure that they only include the characters also supported by policy variables. Supported characters are:

a-z, A-Z, 0-9, _, @, -, :

If your tag namespaces or tag keys have characters other than these, you cannot use them in policy variables. Tag namespaces and tag keys cannot be renamed, so you will have to create new tag namespaces and tag key definitions.

**Considerations for Case**

When working with tags in policies, be aware that tag values are case insensitive. For example:

request.principal.group.tag.MyTagNamespace.MyTag='sample'

is the same as

request.principal.group.tag.MyTagNamespace.MyTag='Sample'

**Compartment Hierarchies**

When you write a condition to allow access based on the tag applied to a target compartment, remember that this policy also allows access to all compartments nested inside the tagged compartment. All subcompartments in the tagged compartment are resources in the tagged compartment, and therefore the policy grants access.

For example, in this scenario:
Tagging

The policy:

```plaintext
allow group GroupA to use all-resources in tenancy where
    target.resource.compartment.Operations.Project='ProjectA'
```

allows GroupA to use all the resources in CompartmentA, CompartmentA1, and CompartmentA1.1, even though the tag is applied to CompartmentA only.

**Supported Services**

All Oracle Cloud Infrastructure services support the `request.principal.compartment`, `request.principal.group`, and `target.resource.compartment.tag` policy variables.

Not all services support the `target.resource.tag` policy variable. The following table lists the **supported services**. If the service is not listed in the table, it is not supported at this time.

Some services have limitations. See the appropriate link in the table.

<table>
<thead>
<tr>
<th>Services Supported</th>
<th>More Information</th>

</tbody>
</table>

**Limitations and Additional Policies Needed for Specific Target.Resource.Tag Scenarios**

For some services, not all permissions or resource types are supported. When a permission is not supported, that means that even if the resource is tagged and the permission is included in the verb granting access, that permission is not allowed and authorization fails for the operation governed by the permission. For example, the Block Volume service resource `volume-backups`, does not support tag-based access control for the `VOLUME_BACKUP_COPY` permission. Therefore, this policy:

```sql
allow group TestGroup to manage volume-backups in compartment Compartment1
where target.resource.tag.TagNS.TagKey = 'test'
```

does not allow members of the group TestGroup to perform the `CopyVolumeBackup` operation. To grant that permission to TestGroup, you would need to add another policy statement to cover it.

In addition, some operational scenarios require authorization to access multiple resources. When scoping access to tags that are applied to the target resource, you must include a separate policy for each resource involved in the operation. Also, because of the limitations for listing resources and other service-specific permissions, additional policies (not scoped by tag) are required.

**API Gateway Service Limitations**

In addition to the expected tag-based access control policy for API Gateway resources, you’ll need policy allowing manage permissions for `api-workrequests`.

Here is an example policy with the additional permissions:

```sql
allow group TestGroup to manage api-workrequests in compartment Compartment1
```
Tagging

**Big Data Service Limitations**

In addition to the expected tag-based access control policy for Big Data resources, you’ll need policy allowing manage permissions for `cluster-work-requests`.

Here is an example policy with the additional permissions:

```
allow group TestGroup to manage cluster-work-requests in compartment Compartment1
```

**Block Volume Service Limitations**

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type with Limitations</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Volume</td>
<td>backup-policy-assignments</td>
<td>BACKUP_POLICY_ASSIGNMENT_DELETE</td>
</tr>
<tr>
<td></td>
<td>volume-backups</td>
<td>VOLUME_BACKUP_COPY</td>
</tr>
</tbody>
</table>

Scenarios requiring additional policy:

**Attach a block volume to a compute instance:**

To attach a block volume to a compute instance, in addition to the tag-based access control policy to allow the `use` verb on volumes and instances, you’ll need some additional permissions.

For example:

```
allow group TestGroup to use volumes in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to use instances in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

These two policies allow members of TestGroup to use volumes and instances in Compartment1, when the resources have the appropriate tag. To allow members to attach a block volume to an instance, you’ll also need policies that allow the permissions shown in the following statements:

```
allow group TestGroup to read instances in compartment Compartment1
allow group TestGroup to manage volume-attachments in compartment Compartment1 where any {request.permission='VOLUME_ATTACHMENT_CREATE', request.permission='VOLUME_ATTACHMENT_DELETE'}
```

**Compute Service Limitations**

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute</td>
<td>instance-console-connection</td>
<td>INSTANCE_CONSOLE_CONNECTION_DELETE</td>
</tr>
<tr>
<td></td>
<td>instances</td>
<td>INSTANCE_POWER_ACTIONS</td>
</tr>
</tbody>
</table>

Scenarios requiring additional policy:

**Attach compute instance to subnet:**
To manage a compute instance’s subnet attachment, in addition to the expected tag-based access control policy for instances and subnets, shown here:

allow group TestGroup to use subnets in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to manage instances in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'

You’ll need additional permissions on vnics:

allow group TestGroup to use vnics in compartment Compartment1 where ANY{request.permission='VNIC_ATTACH', request.permission='VNIC_CREATE'}

Delete a VNIC from a compute instance:

To delete a VNIC from a compute instance, in addition to the expected tag-based access control policy for instances and subnets shown here:

allow group TestGroup to manage instances in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to use subnets in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'

You’ll need policy allowing you permissions on vnics:

allow group TestGroup to use vnics in compartment Compartment1 where ANY{request.permission='VNIC_DELETE', request.permission='VNIC_DETACH'}

### Compute Management Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Management</td>
<td>instance-pools</td>
<td>All permissions</td>
<td>The instance-pools resource type is not supported.</td>
</tr>
<tr>
<td></td>
<td>auto-scaling-configurations</td>
<td>AUTO_SCALING_CONFIGURATION_UPDATE</td>
<td></td>
</tr>
</tbody>
</table>

### Content and Experience Limitations

In addition to the expected tag-based access control policy for Content and Experience resources, you’ll need policy allowing manage permissions for oce-work-requests.

Here is an example policy with the additional permissions:

allow group TestGroup to manage oce-requests in compartment Compartment1

### Database Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>all</td>
<td>DATABASE_DELETE</td>
<td></td>
</tr>
</tbody>
</table>

Update Tags for ExaData Infrastructure:
Tagging

Not supported at this time using tag-based access control policies.

Scenarios requiring additional policy:

**Delete a DB-System:**

To delete or update a DB-System, in addition to the expected tag-based access control policy for db-systems, shown here:

allow group TestGroup to manage db-systems in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'

You’ll need policy allowing you permissions for db-backups, db-homes, vnics, subnets and databases. Here is an example policy showing the additional permissions:

allow group TestGroup to manage db-backups in compartment Compartment1 where ANY {request.permission='DB_BACKUP_DELETE', request.permission='DB_BACKUP_INSPECT'}
allow group TestGroup to manage db-homes in compartment Compartment1 where request.permission='DB_HOME_DELETE'
allow group TestGroup to manage vnics in compartment Compartment1 where ANY {request.permission='VNIC_DELETE', request.permission='VNIC_DETACH'}
allow group TestGroup to manage subnets in compartment Compartment1 where request.permission='SUBNET_DETACH'
allow group TestGroup to manage databases in compartment compartment1

**Move a DB-system to another compartment:**

To move a DB-System to another compartment, in addition to the expected tag-based access control policy for db-systems shown here:

allow group TestGroup to manage db-systems in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'

You’ll need policy allowing you permissions for databases, db-homes, and db-backups. Here is an example policy with the additional permissions:

allow group TestGroup to use databases in compartment Compartment1 where request.permission='DATABASE_UPDATE'
allow group TestGroup to manage db-backups in compartment Compartment1 where request.permission='DB_BACKUP_INSPECT'
allow group TestGroup to manage db-homes in compartment Compartment1 where request.permission='DB_HOME_UPDATE'

**Database delete for Exadata DB-System:**

To delete a database resource for an Exadata DB-System, you’ll need the expected tag-based access control policy for db-systems and databases shown here:

allow group TestGroup to manage db-systems in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to manage databases in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'

You’ll also need permissions for db-homes and db-backups. Here is an example policy with the additional permissions:

allow group TestGroup to manage db-homes in compartment Compartment1 where request.permission='DB_HOME_UPDATE'
allow group TestGroup to manage db-backups in compartment Compartment1 where ANY {request.permission='DB_BACKUP_DELETE', request.permission='DB_BACKUP_INSPECT'}

Delete Database:
Deleting a database for a baremetal or virtual machine DB system is not supported using tag-based policies on the target resource.

Database backup create:
To create a database backup, you'll need the expected tag-based access control policy for databases:

```
allow group TestGroup to manage databases in compartment Compartment1 where target.resource.tag.TagNS.TagKey= 'test'
```

You'll also need permissions for db-backups. Here is an example policy with the additional permissions:

```
allow group TestGroup to manage db-backups in compartment Compartment1 where request.permission='DB_BACKUP_CREATE'
```

Database restore:
To restore a database backup, you'll need the expected tag-based access control policy for databases:

```
allow group TestGroup to manage databases in compartment Compartment1 where target.resource.tag.TagNS.TagKey= 'test'
```

You'll also need permissions for backups, like the one shown here:

```
allow group TestGroup to manage db-backups in compartment Compartment1 where ANY {request.permission='DB_BACKUP_INSPECT', request.permission='DB_BACKUP_CONTENT_READ'}
```

Create Data Guard association:
Creating a Data Guard association is not supported using tag-based policies on the target resource.

Data Catalog Service Limitations
In addition to the expected tag-based access control policy for Data Catalog resources, you'll need the following additional policies for data-catalog-family:

```
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'GetWorkRequest'
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'ListWorkRequestErrors'
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'listworkrequestlogs'
```

Data Science Service Limitations
In addition to the expected tag-based access control policy for Data Science resources, you’ll need policy allowing manage permissions for data-science-work-requests.

Here is an example policy with the additional permissions:

```
allow group TestGroup to manage data-science-work-requests in compartment Compartment1
```
### Digital Assistant Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digital Assistant</td>
<td>oda-design</td>
<td>All permissions</td>
</tr>
<tr>
<td></td>
<td>oda-insights</td>
<td>All permissions</td>
</tr>
</tbody>
</table>

In addition to the expected tag-based access control policy for the Oracle Digital Assistant resources, you'll need the following additional policies for `oda-instances`:

```plaintext
allow group TestGroup to inspect oda-instances in compartment Compartment1
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'GetWorkRequest'
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'ListWorkRequestErrors'
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'listworkrequestlogs'
```

### Load Balancing Service Limitations

Scenarios requiring additional policy:

#### Update Load Balancer:

To perform any update to load balancers, in addition to the expected tag-based access control policy for `load-balancers`:

```plaintext
allow group TestGroup to manage load-balancers in compartment Compartment1
   where target.resource.tag.TagNS.TagKey= 'test'
```

You’ll need policy that allows the GetWorkRequest API operation. Here is an example policy with the additional permission:

```plaintext
allow group TestGroup to read load-balancers in compartment Compartment1
   where request.operation = 'GetWorkRequest'
   network-security-group
```

#### Delete Load Balancer:

To delete a load balancer, in addition to the expected tag-based access control policy for `load-balancers`, `subnets`, and `network-security-group`:

```plaintext
allow group TestGroup to manage load-balancers in compartment Compartment1
   where target.resource.tag.TagNS.TagKey= 'test'
allow group TestGroup to use subnets in compartment Compartment1 where
   target.resource.tag.TagNS.TagKey= 'test'
allow group TestGroup to use network-security-group in compartment
   Compartment1 where target.resource.tag.TagNS.TagKey= 'test'
```

You’ll need these additional permissions for `vnics`:

```plaintext
allow group TestGroup to use vnics in compartment Compartment1 where ANY
   {request.permission = 'VNIC_DETACH', request.permission = 'VNIC_DELETE',
    request.permission='VNIC_DISASSOCIATE_NETWORK_SECURITY_GROUP'}
```
Networking Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Networking</td>
<td>private-ips</td>
<td>PRIVATE_IP_UPDATE, PRIVATE_IP_DELETE, VNIC_UNASSIGN, SUBNET_DETACH</td>
<td></td>
</tr>
<tr>
<td></td>
<td>route-tables</td>
<td>UPDATE (INTERNET_GATEWAY_DETACH)</td>
<td>Removing a route rule is not supported.</td>
</tr>
<tr>
<td></td>
<td>vnics</td>
<td>VNIC_UPDATE, VNIC_DELETE</td>
<td></td>
</tr>
</tbody>
</table>

Attach service gateway or NAT gateway to a route table:

Attaching a service gateway or a NAT gateway to a route table is not supported using tag-based policies on the target resource.

Scenarios requiring additional policy:

**Attach DRG to VCN:**

To attach DRG to VCN, in addition to the following expected tag-based access control policy for `virtual-network-family` and `vcns`:

```plaintext
allow group TestGroup to use virtual-network-family in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

You’ll need policy allowing you manage permissions for `drgs`. Here is an example policy with the additional permissions:

```plaintext
allow group TestGroup to manage drgs in compartment Compartment1
```

NoSQL Database Cloud Service Limitations

Supported resources are: `nosql-tables`, `nosql-rows`, and `nosql-indexes`.

In addition to the expected tag-based access control policy for the NoSQL Database Cloud resources, you’ll need these additional policies:

```plaintext
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequests'
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequestErrors'
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequestLogs'
```

Note that the preceding policies are required to navigate the NoSQL Database Cloud resources in the Console.
### Tagging

#### Object Storage Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Storage</td>
<td>objects</td>
<td>All permissions related to accessing objects</td>
<td>Objects are not taggable.</td>
</tr>
</tbody>
</table>

#### Public DNS Limitations

In addition to the expected tag-based access control policy for dns resources, you’ll need policy allowing you manage permissions for dns-records. Here is an example policy with the additional permissions:

```
allow group TestGroup to manage dns-records in compartment Compartment1
```

#### Tagging Namespace Limitations

Policy that grants a user access to a tag namespace based on a tag on the namespace does not allow the user to create or delete tag key definitions in that tag namespace.

For example, the policy:

```
allow group TestGroup to manage tag-namespaces in compartment Compartment1 where target.resource.tag.TagNS.TagKey='test'
```

does not allow the users in TestGroup to create or delete tag key definitions in the tag namespaces tagged with TagNS.TagKey='test'.

#### WAF Limitations

In addition to the expected tag-based access control policy for the WAF resources, you’ll need policy allowing you manage permissions for waas-work-request. Here is an example policy with the additional permissions:

```
allow group TestGroup to manage waas-work-request in compartment Compartment1
```

#### Illustrated Examples

- Illustrated Examples on page 3947
- Example Using Tags Applied to a Target Resource on page 3949

#### Example Using Tags Applied to a Group

Following is an example that demonstrates how you can use tags applied to user groups to manage access to resources in a compartment.

Assume you have three compartments: ProjectA, ProjectB, and ProjectC

For each compartment, there is an admin group set up: A-Admins, B-Admins, and C-Admins.
Each admin group has full access over their compartment through the following policies:

- allow group A-Admins to manage all-resources in compartment ProjectA
- allow group B-Admins to manage all-resources in compartment ProjectB
- allow group C-Admins to manage all-resources in compartment ProjectC

Your organization has set up the following tag namespace and key to tag each group by its role:

- EmployeeGroup.Role

Some values for this tag are 'Admin', 'Developer', 'Test-Engineer'.

All your admin groups are tagged with EmployeeGroup.Role='Admin'

Now you want to set up a Test compartment for members of the three projects to share. You want to give Admin access to all three of your existing admin groups. To accomplish this, you can write a policy like:

allow any-group to manage all-resources in compartment Test where request.principal.group.tag.EmployeeGroup.Role='Admin'
Tagging

With this policy, all of your existing admin groups with the tag will have access to the Test compartment. Also, any new or existing groups that you tag with EmployeeGroup.Role='Admin' in the future will have access to the Test compartment without having to update the policy statements.

**Example Using Tags Applied to a Target Resource**

In this example, each of your organization's project compartments contains two child compartments: Test and Prod. You want to give your test engineers access to the test compartments across all three projects. To accomplish this, you create a tag:

`ResourceGroup.Role='Test'`

and apply this to the Test compartments in each of your project compartments.

You can then use a policy like:
allow group Testers to use all-resources in tenancy where
target.resource.compartment.tag.ResourceGroup.Role='Test'
to allow your group Testers to access the resources across all three test compartments.

Frequently Asked Questions About Tagging

This topic provides answers to frequently asked questions (FAQ) about Tagging.

What is the difference between free-form tags and defined tags?
Free-form tags are simple (string) key and (string) value pairs that can be set on a resource. Free-form tags cannot be used for applying policies or for authentication, and these tags are not included in metering data. Any user can create and apply free-form tags.

Tag administrators create defined tags for the tenancy, and users can apply these tags to resources. Most of the Tagging features require defined tags. For example, tag rules and policies only reference defined tags. For more information, see How Tagging Works.

How do I decide which kind of tag to use?
Most of the Tagging features require defined tags. Because free-form tags are limited in functionality, Oracle recommends that you only use them to try out the tagging feature in your system when you are first getting started with tagging. For more information, see Tagging Overview.

Are there any tools to help users migrate from free-form tags to defined tags?
Not currently.

Who creates defined tags?
Tag administrators create and manage defined tags, and users apply these tags to resources. Use IAM policy to select tag administrators who can create tags. Grant all other users in the tenancy only the ability to apply tags. For more information, see Working with Defined Tags.

What is the difference between a tag namespace, tag key, and key definition?
See Tagging Concepts.

Can I use Tagging with resources that do not have an OCID?
No. Tagging is only supported with resources that have OCIDs.

What are the allowed characters for tag namespaces and keys?
The allowed characters are printable ASCII, except U+0020 space (" "), and U+002E full stop ("."). Namespace and key names cannot be empty.
Avoid entering confidential information.

Can I use an OCID to name my tag namespace?
No. OCIDs do not follow the required format for tag namespaces.

Do I need to provide a value for compartmentId when making API requests?
No. Because namespaces are unique under tenants, you do not need to provide the compartmentId value. All API requests automatically come with tenancy information.
Can I change the name of my tag namespace?
No. You can retire your tag namespace, but you cannot change its name.

Can I change the name of my tag key definition?
No. You can retire your tag key definition, but you cannot change its name.

What is the base URL of the Tagging service?
Tagging is part of the Identity service. The Tagging service has two parts:

• Handling the creation and management of new tag namespaces and tag key definitions. For these operations, use the Identity Service base URL.
• Applying tags to specific resources by including the tag namespace, key, and value information in requests sent to each supporting service.

When I try to delete a tag key definition, why do I get the error "Can't enable definition <tag definition> in retired namespace <namespace name>"?
You cannot delete a tag key definition in a retired namespace. Reactivate the tag namespace and then retire the tag. For more information, see Managing Tags and Tag Namespaces.
Chapter 39

Vault

This chapter explains how to create vaults, encryption keys, and secrets, and how to manage and use them.

Overview of Vault

Oracle Cloud Infrastructure Vault is a managed service that lets you centrally manage the encryption keys that protect your data and the secret credentials that you use to securely access resources. Vaults securely store master encryption keys and secrets that you might otherwise store in configuration files or in code. Specifically, depending on the protection mode, keys are either stored on the server or they are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification.

The key encryption algorithms that the Vault service supports includes the Advanced Encryption Standard (AES), the Rivest-Shamir-Adleman (RSA) algorithm, and the elliptic curve digital signature algorithm (ECDSA). You can create and use AES symmetric keys and RSA asymmetric keys for encryption and decryption. You can also use RSA or ECDSA asymmetric keys for signing digital messages.

You can use the Vault service to create and manage the following resources:

- Vaults
- Keys
- Secrets

You can use the Vault service to exercise the following lifecycle management features for vaults, master encryption keys, and secrets, helping you to control these resources and access to them:

- Create vaults
- Create or import cryptographic material as master encryption keys
- Create secrets to store secret credentials
- Enable or disable master encryption keys for use in cryptographic operations
- Rotate keys to generate new cryptographic material
- Export key or vault metadata to a backup that you can restore and use again later
- Update secrets with new secret contents
- Specify which secret version is currently in use through promotion
- Configure rules to govern the management and use of secrets
- Tag vaults, master encryption keys, or secrets to add metadata to resources
- Delete vaults, keys, or secrets when they're no longer needed

Regarding the use of master encryption keys, you can do the following:

- Use keys for encryption and decryption of data while at rest or in transit
- Use keys to sign messages and verify signed messages
Assign keys to supported Oracle Cloud Infrastructure resources, including, but not limited to, buckets and file systems

Generate data encryption keys

The following services integrate with the Vault service to support the use of customer-managed keys to encrypt data in their respective, specified resources:

- Oracle Cloud Infrastructure Block Volume: block and boot volumes
- Oracle Cloud Infrastructure Container Engine for Kubernetes: Kubernetes secrets at rest in the etcd key-value store (when creating new clusters only)
- Oracle Cloud Infrastructure Database: Autonomous Container Databases on dedicated Autonomous Exadata Infrastructure and Exadata Databases (without Oracle Data Guard enabled)
- Oracle Cloud Infrastructure File Storage: file systems
- Oracle Cloud Infrastructure Object Storage: buckets
- Oracle Cloud Infrastructure Streaming: stream pools

In addition, integration with Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who and what services can access which keys and secrets and what they can do with those resources. Oracle Cloud Infrastructure Audit integration gives you a way to monitor key and secret usage. Audit tracks administrative actions on vaults, keys, and secrets.

Key and Secret Management Concepts

The following concepts are key to understanding the Vault service.

VAULTS

Vaults are logical entities where the Vault service creates and durably stores keys and secrets. The type of vault you have determines features and functionality such as degrees of storage isolation, access to management and encryption, scalability, and the ability to back up. The type of vault you have also affects pricing. You cannot change a vault's type after you create the vault.

The Vault service offers different vault types to accommodate your organization's needs and budget. All vault types ensure the security and integrity of the encryption keys and secrets that vaults store. A virtual private vault is an isolated partition on a hardware security module (HSM). Vaults otherwise share partitions on the HSM with other vaults.

Virtual private vaults include 1000 key versions by default. If you don't require the greater degree of isolation or the ability to back up the vault, you don't need a virtual private vault. Without a virtual private vault, you can manage costs by paying for key versions individually, as you need them. (Key versions count toward your key limit and costs. A key always contains at least one active key version. Similarly, a secret always has at least one secret version. However, limits on secrets apply to the tenancy, rather than a vault.)

The Vault service designates vaults as an Oracle Cloud Infrastructure resource.

KEYS

Keys are logical entities that represent one or more key versions, each of which contains cryptographic material. A key's cryptographic material is generated for a specific algorithm that lets you use the key for encryption or in digital signing. When used for encryption, a key or key pair encrypts and decrypts data, protecting the data where the data is stored or while the data is in transit. With an AES symmetric key, the same key encrypts and decrypts data. With an RSA asymmetric key, the public key encrypts data and the private key decrypts data.

You can use AES keys in encryption and decryption, but not in digital signing. RSA keys, however, can be used not only to encrypt and decrypt data, but also to digitally sign data and verify the authenticity of signed data. You can use ECDSA keys in digital signing, but not to encrypt or decrypt data.

When processed as part of an encryption algorithm, a key specifies how to transform plaintext into ciphertext during encryption and how to transform ciphertext into plaintext during decryption. When processed as part of a signing algorithm, together, the private key of an asymmetric key and a message produce a digital signature that accompanies the message in transit. When processed as part of a signature verifying algorithm
by the recipient of the signed message, the message, signature, and the public key of the same asymmetric key confirm or deny the authenticity and integrity of the message.

Conceptually, the Vault service recognizes three types of encryption keys: master encryption keys, wrapping keys, and data encryption keys.

The encryption algorithms that the Vault service supports for master encryption keys include AES, RSA, and ECDSA. You can create AES, RSA, or ECDSA master encryption keys by using the Console, CLI, or API. When you create a master encryption key, the Vault service can either generate the key material internally or you can import the key material from an external source. (Support for importing key material depends on the encryption algorithm of the key material.) When you create master encryption keys, you create them in a vault, but where a key is stored and processed depends on its protection mode.

Master encryption keys can have one of two protection modes: HSM or software. A master encryption key protected by an HSM is stored on an HSM and cannot be exported from the HSM. All cryptographic operations involving the key also happen on the HSM. Meanwhile, a master encryption key protected by software is stored on a server and, therefore, can be exported from the server to perform cryptographic operations on the client instead of on the server. While at rest, the software-protected key is encrypted by a root key on the HSM. For a software-protected key, any processing related to the key happens on the server. A key’s protection mode affects pricing and cannot be changed after you create the key.

After you create your first symmetric master encryption key, you can then use the API to generate data encryption keys that the Vault service returns to you. Some services can also use a symmetric master encryption key to generate their own data encryption keys.

A type of encryption key that comes included with each vault by default is a wrapping key. A wrapping key is a 4096-bit asymmetric encryption key based on the RSA algorithm. The public and private key pair do not count against your service limits. They also do not incur service costs. You use the public key as the key encryption key when you need to wrap key material for import into the Vault service. You cannot create, delete, or rotate wrapping keys.

The Vault service recognizes master encryption keys as an Oracle Cloud Infrastructure resource.

KEY VERSIONS

Each master encryption key is automatically assigned a key version. When you rotate a key, the Vault service generates a new key version. The Vault service can generate the key material for the new key version or you can import your own key material.

Periodically rotating keys limits the amount of data encrypted or signed by one key version. If a key is ever compromised, key rotation thus reduces the risk. A key’s unique, Oracle-assigned identifier, called an Oracle Cloud ID (OCID), remains the same across rotations, but the key version lets the Vault service seamlessly rotate keys to meet any compliance requirements you might have.

Although you can’t use an older key version for encryption after you rotate a key, the key version remains available to decrypt any data that it previously encrypted. If you rotate an asymmetric key, the public key can no longer be used to encrypt data, but the private key remains available to decrypt data previously encrypted by the public key. When you rotate an asymmetric key used in digital signing, you can no longer use the private key version to sign data, but the public key version remains available to verify the digital signature of data previously signed by the older private key version.

For symmetric keys, you do not need to track which key version was used to encrypt what data because the key’s ciphertext contains the information that the service needs for decryption purposes. Through rotations of asymmetric keys, however, you must track which key version was used to encrypt or sign what data. With asymmetric keys, the key’s ciphertext does not contain the information that the service requires for decryption or verification.

With AES symmetric keys, each key version counts as one key version when calculating service limits usage. However, with RSA and ECDSA asymmetric keys, each key version counts as two when calculating usage against service limits because an asymmetric key has both a public key and private key. (Asymmetric keys are also known as key pairs.)

HARDWARE SECURITY MODULES

When you create an AES symmetric master encryption key with the protection mode set to HSM, the Vault service stores the key version within a hardware security module (HSM) to provide a layer of
physical security. (When you create a secret, secret versions are base64-encoded and encrypted by a master encryption key, but are not stored within the HSM.) Any given key version or secret version, after it’s created, is replicated within the service infrastructure as a measure of protection against hardware failures. Key versions of HSM-protected keys are not otherwise stored anywhere else and cannot be exported from an HSM.

When you create an RSA or ECDSA asymmetric master encryption key with the protection mode set to HSM, the Vault service stores the private key within an HSM and does not allow its export from the HSM. However, you can download the public key.

The Vault service uses HSMs that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. This certification means that the HSM hardware is tamper-evident, has physical safeguards for tamper-resistance, requires identity-based authentication, and deletes keys from the device when it detects tampering.

ENVELOPE ENCRYPTION

The data encryption key used to encrypt your data is, itself, encrypted with a master encryption key. This concept is known as envelope encryption. Oracle Cloud Infrastructure services do not have access to the plaintext data without interacting with the Vault service and without access to the master encryption key that is protected by Oracle Cloud Infrastructure Identity and Access Management (IAM). For decryption purposes, integrated services like Object Storage, Block Volume, and File Storage store only the encrypted form of the data encryption key.

SECRETS

Secrets are credentials such as passwords, certificates, SSH keys, or authentication tokens that you use with Oracle Cloud Infrastructure services. Storing secrets in a vault provides greater security than you might achieve storing them elsewhere, such as in code or configuration files. You can retrieve secrets from the Vault service when you need them to access resources or other services.

You can create secrets by using the Console, CLI, or API. Secret contents for a secret are imported to the service from an external source. The Vault service stores secrets in vaults.

The Vault service supports secrets as an Oracle Cloud Infrastructure resource.

SECRET VERSIONS

Each secret is automatically assigned a secret version. When you rotate secret, you provide new secret contents to the Vault service to generate a new secret version. Periodically rotating secret contents reduces the impact in case a secret is exposed. A secret’s unique, Oracle-assigned identifier, called an Oracle Cloud ID (OCID), remains the same across rotations, but the secret version lets the Vault service rotate secret contents to meet any rules or compliance requirements you might have. Although you can’t use an older secret version’s contents after you rotate it if you have a rule configured preventing secret reuse, the secret version remains available and is marked with a rotation state other than "current". For more information about secret versions and their rotation states, see Secret Versions and Rotation States on page 4018.

SECRET BUNDLES

A secret bundle consists of the secret contents, properties of the secret and secret version (such as version number or rotation state), and user-provided contextual metadata for the secret. When you rotate a secret, you create a new secret version, which also includes a new secret bundle version.

Regions and Availability Domains

The Vault service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Unlike some Oracle Cloud Infrastructure services, however, the Vault service does not have one regional endpoint for all API operations. The service has one regional endpoint for the provisioning service that handles create, update, and list operations for vaults. For create, update, and list operations for keys, service endpoints are distributed across multiple independent clusters. Service endpoints for secrets are distributed further still across different independent clusters.
Because the Vault service has public endpoints, you can directly use data encryption keys generated by the service for cryptographic operations in your applications. However, if you want to use master encryption keys with a service that has integrated with Vault, you can do so only when the service and the vault that holds the key both exist within the same region. Different endpoints exist for key management operations, key cryptographic operations, secret management operations, and secret retrieval operations. For more information, see Oracle Cloud Infrastructure API Documentation.

The Vault service maintains copies of encryption keys and secrets across all availability domains within a region. This replication makes it possible for the Vault service to produce keys or secrets upon request, even when an availability domain is unavailable.

Private Access to Vault

The Vault service supports private access from Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as the instances that your encrypted volumes are attached to) access public Oracle Cloud Infrastructure services such as the Vault service without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway on page 3256.

Resource Identifiers

The Vault service supports vaults, keys, and secrets as Oracle Cloud Infrastructure resources. Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You will be prompted to enter your cloud tenant, your user name, and your password.

For general information about using the API, see REST APIs on page 4368.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Vault Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

For instructions to view your usage level against the tenancy's resource limits, see Viewing Your Service Limits, Quotas, and Usage on page 216. You can also get each individual vault's usage against key limits by viewing key and key version counts in the vault details.
Managing Vaults

This topic describes how to create and manage vaults. For information specifically about backing up and restoring vaults, see Backing Up Vaults and Keys on page 4003. For information about what you can do with keys, see Managing Keys on page 3962. For information about what you can do with secrets, see Managing Secrets on page 4007.

The Vault service lets you create vaults in your tenancy as containers for encryption keys and secrets. If needed, a virtual private vault provides you with a dedicated partition in a hardware security module (HSM), offering a level of storage isolation for encryption keys that’s effectively equivalent to a virtual independent HSM.

Vault management tasks include the following:

• Creating a vault
• Viewing vault configuration details
• Updating the vault name
• Managing vault tags
• Deleting a vault
• Moving a vault to a new compartment

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Moving Resources to a Different Compartment

You can move vaults from one compartment to another. After you move a vault to a new compartment, inherent policies apply immediately and affect access to the vault. Moving a vault doesn't affect access to any keys or secrets that the vault contains. You can move a key or secret from one compartment to another independently of moving the vault it's associated with. For more information, see Managing Compartments on page 2431.

Using the Console

To view vault configuration details

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault you want to view.
3. From the list of vaults in the compartment, click the name of the vault.
4. The console displays the following information:

- **Compartment**: The unique, Oracle-assigned ID of the compartment that contains the vault.
- **OCID**: The unique, Oracle-assigned ID of the vault.
- **Created**: The date and time when you initially created the vault.
- **HSM Key Version Usage**: The number of all key versions across all HSM-protected master encryption keys that the vault contains. A master encryption key comprises one or more key versions, up to the limit allowed by service limits.
- **Software Key Version Usage**: The number of all key versions across all software-protected master encryption keys that the vault contains. This can include one or more key versions for each master encryption key, up to the limit allowed by service limits.
- **Virtual Private**: Whether or not the vault is a virtual private vault.
- **Management Endpoint**: The service endpoint for CreateKey, CreateKeyVersion, EnableKey, DisableKey, UpdateKey, ListKeys, ListKeyVersions, GetKey, GetKeyVersion, ImportKey and ImportKeyVersion operations.
- **Cryptographic Endpoint**: The service endpoint for Encrypt, Decrypt, and GenerateDataEncryptionKey operations.
- **Wrapping Key**: The public RSA wrapping key for the vault.

To create a new vault

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create the vault.
3. Click **Create Vault**.
4. In the **Create Vault** dialog box, click **Name**, and then enter a display name for the vault. Avoid entering confidential information.
5. Optionally, make the vault a virtual private vault by selecting the **Make it a virtual private vault** check box. For more information about vault types, see [Key and Secret Management Concepts](#) on page 3953.

   **Note:**
   You cannot change the vault type after the vault is created.

6. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. When you are finished, click **Create**.

To change a vault name

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to rename.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Edit Name**.
5. In the **Edit Vault Name** dialog box, click **Name**, and then enter a new display name for the vault. Avoid entering confidential information.
6. When you are finished, click **Save**.

To manage a vault’s tags

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault for which you want to manage tags.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click the **Tags** tab to view or editing existing tags. Or, click **Add Tag(s)** to add new ones.

**To delete a vault**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to delete.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Delete**.
5. To confirm that you want to delete the vault, type the name of the vault, and then choose the date and time you want the vault to be deleted.
6. When you are finished, click **Delete Vault**.

**To cancel the deletion of a vault**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that’s in a pending deletion state.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Cancel Deletion**.
5. To confirm that you want to cancel deletion of the vault, click **Cancel Deletion**.

**To move a vault to a different compartment**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **Table Scope**, in the **Compartment** list, choose the compartment that contains the vault that you want to move.
3. Find the vault in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en_us/oci/1.1.4.0.0/compute/plug_oci/index.html). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](https://docs.oracle.com/en_us/oci/1.1.4.0.0/compute/plug_oci/index.html).

**To view vault configuration details**

Open a command prompt and run `oci kms management vault get` to view the configuration details for a vault:

```sh
oci kms management vault get --vault-id <target_vault_id>
```

For example:

```sh
oci kms management vault get --vault-id ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq
```

**To create a new vault**

Open a command prompt and run `oci kms management vault create` to create a new vault:
Note:
You cannot change the vault type after the vault is created.

oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type <vault_type>

For example:

oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgzm2zzum45ibploogtabk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE

Avoid entering confidential information.

**To create a new vault with resource tags**

Open a command prompt and run `oci kms management vault create` with one or both of the `--defined-tags` and `--freeform-tags` options to create a new vault with resource tags:

Note:
You cannot change the vault type after the vault is created.

oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type <vault_type> --defined-tags <JSON_formatted_defined_tag> --freeform-tags <JSON_formatted_freeform_tag>

For example, on a MacOS or Linux machine:

oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgzm2zzum45ibploogtabk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-tags '{"Department": "Finance"}"

Or, for example, on a Windows machine:

oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgzm2zzum45ibploogtabk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-tags '{"Department": "Finance"}"

Avoid entering confidential information.

**To change a vault name**

Open a command prompt and run `oci kms management vault update` to change a vault's name:

oci kms management vault update --vault-id <target_vault_id>

For example:

oci kms management vault update --vault-id ocid1.vault.region1.sea.exampleaaacu2.exampleexravte5wgrxn2jua3olmeausn5fauxsuebuwu5my5 --display-name new-vault-name
Avoid entering confidential information.

**To delete a vault**

Open a command prompt and run `oci kms management vault schedule-deletion` to delete a vault:

```
oci kms management vault schedule-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault schedule-deletion --vault-id ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3
```

When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted.

**To cancel the deletion of a vault**

Open a command prompt and run `oci kms management vault cancel-deletion` to cancel the pending deletion of a vault:

```
oci kms management vault cancel-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault cancel-deletion --vault-id ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3
```

**To move a vault to a different compartment**

Open a command prompt and run `oci kms management vault change-compartment` to move a vault from one compartment to another within the same tenancy:

```
oci kms management vault change-compartment --vault-id <target_vault_id> --compartment-id <new_compartment_id>
```

For example:

```
oci kms management vault change-compartment --vault-id ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqmgczzum45ibploogtqabw3zz
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage vaults:

- CancelVaultDeletion
- CreateVault
- GetVault
- ListVaults
- ScheduleVaultDeletion
- UpdateVault
Managing Keys

This topic describes what you can do with keys and key versions to manage their creation and usage. For information specifically about creating keys with your own key material, see Importing Keys and Key Versions on page 3986. For information about assigning keys to protect supported resources, see Assigning Keys on page 3971. For information about how you can use keys in cryptographic operations, see Using Keys on page 3971. For information about backing up and restoring keys, see Backing Up Vaults and Keys on page 4003. For information about what you can do with vaults where you store keys, see Managing Vaults on page 3957. For information about keys more generally, see Key and Secret Management Concepts on page 3953.

In the context of this topic, management of keys includes the ability to do the following:

- Create keys
- View key details
- View a list of keys
- View a list of key versions for a specific key
- Update a key name
- Manage a key's tags
- Enable keys for use in cryptographic operations
- Rotate keys to generate new cryptographic material
- Disable keys to prevent their usage in cryptographic operations
- Delete keys to permanently prevent their usage in cryptographic operations or assignment to resources
- Move a key to a new compartment

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring the traffic associated with your master encryption keys, see Vault Metrics on page 4020.

Moving Resources to a Different Compartment

You can move keys from one compartment to another. After you move a key to a new compartment, inherent policies apply immediately and affect access to the key and key versions. Moving a key doesn't affect access to the vault that
a key is associated with. Similarly, you can move a vault from one compartment to another independently of moving any of its keys. For more information, see Managing Compartments on page 2431.

**Using the Console**

**To create a new master encryption key**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create the key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create the key.
   - Create a new vault for the key by following the instructions in **To create a new vault**, and then click the name of the vault.
4. Click **Master Encryption Keys**, and then click **Create Key**.
5. In the **Create Key** dialog box, choose a compartment from the **Create in Compartment** list. (Keys can exist outside the compartment the vault is in.)
6. Click **Protection Mode**, and then do one of the following:
   - To create a master encryption key that is stored and processed on a hardware security module (HSM), choose **HSM**.
   - To create a master encryption key that is stored and processed on a server, choose **Software**.
   
   You cannot change a key's protection mode after you create it. For more information about keys, including information about key protection modes, see Key and Secret Management Concepts on page 3953.
7. Click **Name**, and then enter a name to identify the key. Avoid entering confidential information.
8. Click **Key Shape: Algorithm**, and then choose from one of the following algorithms:
   - **AES**. Advanced Encryption Standard (AES) keys are symmetric keys that you can use to encrypt data at rest.
   - **RSA**. Rivest-Shamir-Adleman (RSA) keys are asymmetric keys, also known as key pairs consisting of a public key and a private key, that you can use to encrypt data in transit, to sign data, and to verify the integrity of signed data.
   - **ECDSA**. Elliptic curve cryptography digital signature algorithm (ECDSA) keys are asymmetric keys that you can use to sign data and to verify the integrity of signed data.
9. Depending on what you chose in the previous step, either click **Key Shape: Length** or **Key Shape: Curve ID**, and then choose the key length, in bits, for AES and RSA keys, or specify the curve ID for ECDSA keys. For AES keys, the Vault service supports keys that are exactly 128 bits, 192 bits, or 256 bits in length. For RSA keys, the service supports keys that are 2048 bits, 3072 bits, or 4096 bits. With ECDSA keys, you can create keys that have an elliptic curve ID of NIST_P256, NIST_P384, or NIST_P521.
10. Optionally, to apply tags, click **Show Advanced Options**.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
11. When you are finished, click **Create Key**.

**To view key details**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, and then click the name of the key for which you want to see configuration details. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)
5. The console displays the following information:
   • **OCID**: The unique, Oracle-assigned ID of the key.
   • **Created**: The date and time when you initially created the key.
   • **Compartment**: The unique, Oracle-assigned ID of the compartment that contains the key.
   • **Protection Mode**: Where the key is stored and processed, whether on a hardware security module (HSM) or on a server (software).
   • **Vault**: The unique, Oracle-assigned ID of the vault that contains the key.
   • **Key Version**: The unique, Oracle-assigned ID of the key version.
   • **Algorithm**: The encryption algorithm used by the key.
   • **Length**: The number of bits in the key length (for AES keys and RSA keys).
   • **Curve ID**: The curve ID of the key (for ECDSA keys).

**To view a list of keys**
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the keys you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. To see a list of keys in this vault, click Master Encryption Keys. You can see keys in other compartments by changing the list scope.

**To view a list of key versions**
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, click the name of the key for which you want to see a list of key versions, and then click Versions. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)

**To change the name of a key**
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you want to rename.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to rename, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Edit Name.
6. In the Edit Key Name dialog box, click Name, and then enter a new name. Avoid entering confidential information.
7. When you are finished, click Update.

**To manage a key's tags**
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key for which you want to manage tags.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to manage, and then click the key name. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)
5. On the Key Details page, click the Tags tab to view or edit existing tags. Or, click Add Tags to add new ones.

**To enable a key**
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to enable.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to enable, and then select the check box next to the key name. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Enable**.

### To rotate a master encryption key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rotate.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to rotate, and then select the check box next to the key name. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Rotate Key**. (You can only rotate keys in an enabled state.)
6. In the **Confirm** dialog box, click **Rotate Key**.

Cryptographic operations involving objects that were encrypted with the previous version of this key will continue to use the older key version. You can re-encrypt those objects with the current key version if you prefer.

### To disable a key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to disable.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to disable, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Disable**.

### To delete a key

**Caution:**

When you set a key to the Pending Deletion state, anything encrypted by that key immediately becomes inaccessible. This includes secrets. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to delete, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Delete Key**.
6. Confirm that you want to delete the key by clicking the box and then typing the key name.
7. Schedule when you want the Vault service to delete the key. By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days.
8. When you're ready, click **Delete Key**. If needed, you can restore use of the key and access to encrypted resources and data by canceling the scheduled deletion.
To cancel the deletion of a key

Tip:
You can only cancel the deletion of a key that's in a Pending Deletion state.

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that has the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys. Locate the key you want to delete, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Cancel Deletion.
6. Confirm that you want to cancel the key's deletion by clicking Cancel Deletion. Access to the key and any resources or data encrypted by the key are restored when key returns to an enabled state.

To move a key to a different compartment

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under Scope, in the Compartment list, choose the compartment that contains the vault that has the master encryption key that you want to move.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys. Find the key in the list, click the the Actions icon (three dots), and then click Move Resource. (If needed, first change the list scope to the compartment that contains the key.)
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. If there are alarms monitoring the key, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 2737 for more information.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Tip:
Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 3957.

To create a new key

Open a command prompt and run oci kms management key create to create a new key:

```
oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --key-shape <key_encryption_information> --endpoint <control_plane_url>
```

For example, on a MacOS or Linux machine:

```
oci kms management key create --compartment-id ocidl.compartment.oc1...example1example25qrlpo4agcmothkbgmmuz2zzum45ibploogtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```
Or, for example, on a Windows machine:

```bash
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length ":"16"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Avoid entering confidential information.

By default, the service creates a master encryption key protected by an HSM. If you prefer to create a master encryption key protected by software, specify the protection mode with `--protection-mode`. For example, on a Windows machine:

```bash
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --protection-mode SOFTWARE --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

### To create a new key with resource tags

Open a command prompt and run `oci kms management key create` with one or both of the `--defined-tags` and `--freeform-tags` options to create a new key with resource tags:

```bash
oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --key-shape <JSON_formatted_key_encryption_information> --defined-tags <JSON_formatted_defined_tag> --freeform-tags <JSON_formatted_freeform_tag> --endpoint <control_plane_url>
```

For example, on a MacOS or Linux machine:

```bash
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --defined-tags '{"Operations": {"CostCenter":"42"}}' --freeform-tags '{"Department":"Finance"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Or, for example, on a Windows machine:

```bash
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-tags '{"Department": "Finance"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Avoid entering confidential information.

### To view a key's details

Open a command prompt and run `oci kms management key get` to view a specific key's details:

```bash
oci kms management key get --key-id <key_OCID> --endpoint <control_plane_url>
```
For example:

```shell
to change the name of a key

oci kms management key update --key-id ocid1.key.region1.sea.exampleaaacu2.example.com --display-name key-A --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Avoid entering confidential information.
To enable a key

Open a command prompt and run `oci kms management key enable` to enable a key:

```
oci kms management key enable --key-id <target_key_id> --
endpoint <control_plane_url>
```

For example:

```
oci kms management key enable --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleexamplemtspuqmo45cvblugmizcoeu2nfc6b3zfaux21mqz2
--endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To rotate a key

Open a command prompt and run `oci kms management key rotate` to rotate a key:

```
oci kms management key rotate --key-id <target_key_id> --
endpoint <control_plane_url>
```

For example:

```
oci kms management key rotate --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleexamplemtspuqmo45cvblugmizcoeu2nfc6b3zfaux21mqz2
--endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Cryptographic operations involving objects that were encrypted with the previous version of this key will continue to use the older key version. You can re-encrypt those objects with the current key version if you prefer.

To disable a key

Open a command prompt and run `oci kms management key disable` to disable a key:

```
oci kms management key disable --key-id <target_key_id> --
endpoint <control_plane_url>
```

For example:

```
oci kms management key disable --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleexamplemtspuqmo45cvblugmizcoeu2nfc6b3zfaux21mqz2
--endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To delete a key

**Caution:**
When you set a key to the Pending Deletion state, anything encrypted by that key immediately becomes inaccessible. This includes secrets. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.
Open a command prompt and run `oci kms management key schedule-deletion` to schedule a key's deletion:

```
oci kms management key schedule-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key schedule-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmg22mlvkq9 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days. For example:

```
oci kms management key schedule-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmg22mlvkq9 --time-of-deletion 2019-06-30T10:00:00Z --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To cancel the deletion of a key**

**Tip:**

You can only cancel the deletion of a key that's in a Pending Deletion state.

Open a command prompt and run `oci kms management key cancel-deletion` to cancel a key's scheduled deletion:

```
oci kms management key cancel-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key cancel-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmg22mlvkq9 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To move a key to a different compartment**

Open a command prompt and run `oci kms management key change-compartment` to move a master encryption key from one compartment to another within the same tenancy:

```
oci kms management key change-compartment --key-id <target_key_id> --compartment-id <new_compartment_id>
```

For example:

```
oci kms management key change-compartment --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmg22mlvkq9 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqmmuz2zzum45ibploqtabwk3zz
```
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage keys:

- CreateKey
- DisableKey
- EnableKey
- GetKey
- UpdateKey
- CreateKeyVersion
- GetKeyVersion
- ListKeys
- ListKeyVersions
- CancelKeyDeletion
- ScheduleKeyDeletion
- ChangeKeyCompartment

Assigning Keys

This topic describes how to assign keys to supported resources and how to remove those key assignments when no longer needed.

Instead of using an encryption key that Oracle manages, you can assign master encryption keys that you manage to block or boot volumes, databases, file systems, buckets, and stream pools. Block Volume, Database, File Storage, Object Storage, and Streaming use the keys to decrypt the data encryption keys that protect the data that is stored by each respective service. By default, these services rely on Oracle-managed master encryption keys for cryptographic operations. When you remove a Vault master encryption key assignment from a resource, the service returns to using an Oracle-managed key for cryptography.

You can also assign master encryption keys to clusters that you create using Container Engine for Kubernetes to encrypt Kubernetes secrets at rest in the etcd key-value store.

For information about managing the creation and usage of master encryption keys and key versions, see Managing Keys on page 3962. For information specifically about creating keys with your own key material, see Importing Keys and Key Versions on page 3986. For information about how you can use keys in cryptographic operations, see Using Keys on page 3998. For information about what you can do with vaults where you store keys, see Managing Vaults on page 3957.

Required IAM Policy

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2152 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2153 in Common Policies on page 2142. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1306 in Creating and Managing Exadata Databases on page 1306.</td>
</tr>
</tbody>
</table>
To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see *Let security admins manage vaults, keys, and secrets* on page 2151. For more information about permissions or if you need to write more restrictive policies, see *Details for the Vault Service* on page 2347.

If you're new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142.

**Using the Console**

**To assign a key to a new Object Storage bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a bucket that's encrypted with a Vault service master encryption key.
3. Click **Create Bucket**, and then follow the instructions in To create a bucket on page 3401 in *Managing Buckets* on page 3398.

**To assign a key to an existing Object Storage bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the bucket that you want to encrypt with a Vault service master encryption key.
3. From the list of buckets, click the bucket name.
4. Do one of the following:
   - If the bucket already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the bucket does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click **Assign** or **Update**, as appropriate.

**To assign a key to a new Block Volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a block volume that's encrypted with a Vault service master encryption key.
3. Click **Create Block Volume**, and then follow the instructions in *Creating a Volume*.

**To assign a key to an existing Block Volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the block volume that you want to encrypt with a Vault service master encryption key.
3. From the list of volumes, click the volume name.
4. If the volume is currently attached to an instance, click **Detach from Instance**. Follow the instructions in the **Detach Block Volume** dialog box as appropriate, click **Continue Detachment** and then click **OK**.
5. Then, do one of the following:
   - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Assign** or **Update**, as appropriate.

**To assign a key to a new file system**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a file system that's encrypted with a Vault service master encryption key.
3. Click **Create File System**, and then follow the instructions in **Creating File Systems** on page 1948.

**To create a Compute instance with an encrypted boot volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create an instance with a boot volume that's encrypted with a Vault service master encryption key.
3. Click **Create Instance**, and then follow the instructions in **Launching an Instance**.

**To assign a key to an existing boot volume**

**Note:**

To assign a key to an existing boot volume, you must first detach the boot volume from any instance. However, you can only detach a boot volume from an instance when the instance is stopped. For more information, see **Detaching a Boot Volume** on page 623 and **Stopping and Starting an Instance** on page 779.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume that you want to encrypt with a Vault service master encryption key.
3. From the list of volumes, click the volume name.
4. Do one of the following:
   - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click **Assign** or **Update**, as appropriate.

**To create a Kubernetes cluster with encrypted secrets in the etcd key-value store**

**Note:**

These instructions assume you have already followed the steps in **Encrypting Kubernetes Secrets at Rest in Etcd** on page 900 and created:

- a dynamic group including all clusters in the compartment
- a suitable policy to give the dynamic group access to the master encryption key in Vault

1. Open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a Kubernetes cluster that has Kubernetes secrets encrypted with a Vault service master encryption key.
3. Click **Create Cluster**, follow the instructions under **Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings** on page 873 in **Creating a Kubernetes Cluster** on page 871, and select the **Encrypt Using Customer-Managed Keys** option.

**To assign a key to a new stream pool**

1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a stream pool that's encrypted with a Vault service master encryption key.
3. Click **Create Stream Pool**, and then follow the instructions in **To create a stream pool** on page 3865 in **Managing Stream Pools** on page 3864.

**To change or remove the master encryption key assigned to an existing stream pool**

1. Open the navigation menu. Under **Solutions and Platform**, click **Analytics**, and then click **Streaming**.
2. Click **Stream Pools**.
3. Click a stream pool to display the stream details page.
4. In **Stream Pool Information**, next to **Encryption Key**, do one of the following:

   - To stop using an Oracle-managed key in favor of a Vault master encryption key that you manage, click **Assign**, select a vault and encryption key you have access to, and then click **Assign**.
   - To select a different Vault master encryption key that you manage, click **Edit**, select a vault and encryption key you have access to, and then click **Update**.
   - Click **Unassign** to remove the assigned Vault master encryption key and let Oracle manage the encryption key, and then click **Unassign** again to confirm the removal of the existing key assignment.

**To remove a key assignment from a bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the bucket from which you want to remove a Vault service key assignment.
3. From the list of buckets, click the bucket name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the bucket.

**To remove a key assignment from a Block Volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the block volume from which you want to remove a Vault service key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

**To remove a key assignment from a boot volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume from which you want to remove a Vault service key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

**To change a key assignment for a file system**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system from which you want to remove or change a Vault service key assignment.
3. From the list of file systems, click the file system name.
4. Next to **Encryption Key**, click **Edit**.
5. If you want to use Oracle-managed keys:
   - In **Encryption Type**, select **Encrypt using Oracle-managed keys**.
6. If you want to assign a different customer-managed key:
   - In **Encryption Type**, select **Encrypt using customer-managed keys**.
   - Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Save Changes**.

**To create an X7 or X8 Exadata DB system**

**Tip:** Oracle recommends using the new **Exadata Cloud Service resource model** when provisioning a new service instance. The new resource model is compatible with all available Exadata shape families (X7, X8, and X8M).
The DB system resource described in this topic will be deprecated after a period where both resource models are supported. If you need to provision a service instance using the DB system resource model, you will be able to switch the instance to the new resource model. See To switch an Exadata DB system to the new Exadata resource model on page 1229 for more information. Customers with existing Exadata DB systems will be notified in advance regarding the deprecation of the DB system resource model.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Click Create DB System.

3. On the Create DB System page, provide the basic information for the DB system:
   - **Select a compartment**: By default, the DB system launches in your current compartment and you can use the network resources in that compartment.
   - **Name your DB system**: A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system. Avoid entering confidential information.
   - **Select an availability domain**: The availability domain in which the DB system resides.
   - **Select a shape type**: The shape type you select sets the default shape and filters the shape options in the next field.

When you select Exadata, you are asked if you would like to use the newer Exadata resource model that replaces the DB system resource with a cloud Exadata infrastructure resource and a cloud VM cluster. These resources are compatible with X7, X8, and X8M hardware generations. Click Continue Creating DB System if you do not want to use the new resource model.

   - **Select a shape**: The shape determines the type of DB system and the resources allocated to the system. To specify a shape other than the default, click Change Shape, and select an available shape from the list. See Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base on page 1351 for available shapes in Oracle Cloud Infrastructure.

   Note that the X8M shape is not available when using the DB system resource model.

   - **Configure the DB system**: Specify the following:
     - **Total node count**: The number of nodes in the DB system. The number depends on the shape you select.
     - **Oracle Database software edition**: The database edition supported by the DB system. Exadata DB systems only support Enterprise Edition - Extreme Performance.
     - **CPU core count**: The number of CPU cores for the DB system. The text below the field indicates the acceptable values for that shape. The core count is evenly divided across the nodes.

You can increase the CPU cores to accommodate increased demand after you launch the DB system.

For an X8 or X7 Exadata DB system, or an Exadata base system, you can specify zero (0) CPU cores when you launch the system. This will provision the system and immediately stop it. See Scaling CPU Cores Within an Exadata Cloud Service Instance on page 1222 for information about CPU core scaling and the impact on billing. Oracle recommends that if you are not provisioning a stopped system (0 cores), that you specify at least 3 cores per node.

   - **Configure storage**: Specify the following:
     - **Cluster Name**: (Optional) A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive. Avoid entering confidential information.
     - **Storage Allocation**: The configuration settings that determine the percentage of storage assigned to DATA, RECO, and optionally, SPARSE disk:
       - **Database Backups on Exadata Storage**: Select this option if you intend to perform database backups to the local Exadata storage within your Exadata DB system environment. If you select this option, more space is allocated to the RECO disk group, which is used to store backups on Exadata storage.
you do not select this option, more space is allocated to the DATA disk group, which enables you to store more information in your databases.

- **Create Sparse Disk Group**: Select this configuration option if you intend to use snapshot functionality within your Exadata DB system environment. If you select this option, the SPARSE disk group is created, which enables you to use Exadata DB system snapshot functionality for PDB sparse cloning. If you do not select this option, the SPARSE disk group is not created and Exadata DB system snapshot functionality will not be available on any database deployments that are created in the environment.

### Important:

Creating a sparse disk group impacts the storage available for the ASM disk groups (DATA and RECO) and you cannot change the storage allocation configuration after you provision your DB system. For information about the percentage of storage that will be assigned to DATA, RECO, and SPARSE disk based on your configuration, see *Storage Configuration* on page 1224. Similar information will display under the options in the Console dialog.

- **Add public SSH keys**: The public key portion of each key pair you want to use for SSH access to the DB system. You can browse or drag and drop .pub files, or paste in individual public keys. To paste multiple keys, click + Another SSH Key, and supply a single key for each entry.

- **Choose a license type**: The type of license you want to use for the DB system. Your choice affects metering for billing.
  - **License Included** means the cost of the cloud service includes a license for the Database service.
  - **Bring Your Own License (BYOL)** means you are an Oracle Database customer with an Unlimited License Agreement or Non-Unlimited License Agreement and want to use your license with Oracle Cloud Infrastructure. This removes the need for separate on-premises licenses and cloud licenses.

4. Specify the network information:

- **Virtual cloud network**: The VCN in which to launch the DB system. Click Change Compartment to select a VCN in a different compartment.

- **Client subnet**: The subnet to which the Exadata DB system should attach. Click Change Compartment to select a subnet in a different compartment.

  Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

- **Backup subnet**: The subnet to use for the backup network, which is typically used to transport backup information to and from Oracle Cloud Infrastructure Object Storage, and for Data Guard replication. Click Change Compartment to select a subnet in a different compartment, if applicable.

  Do not use a subnet that overlaps with 192.168.128.0/20. This restriction applies to both the client subnet and backup subnet.

  If you plan to back up databases to Object Storage, see the network prerequisites in *Managing Exadata Database Backups* on page 1320.

- **Network Security Groups**: Optionally, you can specify one or more network security groups (NSGs) for both the client and backup networks. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your DB system. A maximum of five NSGs can be specified. For more information,
see Network Security Groups on page 2841 and Network Setup for Exadata Cloud Service Instances on page 1232.

Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs.

To use network security groups:

- Check the Use Network Security Groups to Control Client Traffic check box. Note that you must have already selected a VCN to be able to assign NSGs to the client network.
- Specify the NSG to use with the client network. You might need to use more than one NSG. If you're not sure, contact your network administrator.
- To use additional NSGs with the client network, click + Another Network Security Group.
- Check the Use Network Security Groups to Control Backup Traffic check box.
- Specify the NSG to use with the backup network just as described previously for the client subnet.
- Hostname prefix: Your choice of host name for the Exadata DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for an Exadata DB system is 12.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.</td>
</tr>
</tbody>
</table>

- Host domain name: The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

If you plan to store database backups in Object Storage, Oracle recommends that you use a VCN Resolver for DNS name resolution for the client subnet because it automatically resolves the Swift endpoints used for backups.

- Host and domain URL: Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

5. Click Show Advanced Options to specify advanced options for the DB system:

- Disk redundancy: Exadata DB systems support only high redundancy (3-way mirroring).
- Time zone: The default time zone for the DB system is UTC, but you can specify a different time zone. The time zone options are those supported in both the Java.util.TimeZone class and the Oracle Linux operating system. For more information, see DB System Time Zone on page 1575.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you want to set a time zone other than UTC or the browser-detected time zone, and if you do not see the time zone you want, try selecting the Select another time zone option, then selecting &quot;Miscellaneous&quot; in the Region or country list and searching the additional Time zone selections.</td>
</tr>
</tbody>
</table>

- Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. After you completed the network configuration and any advanced options, click Next.
7. Provide information for the initial database:

- **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.

- **Database version:** The version of the initial database created on the DB system when it is launched. After the DB system is active, you can create additional databases on it. You can mix database versions on the DB system.

  **Note:**
  
  If you plan to run Oracle Database 19c on your Exadata DB system, you must specify version 19c when you create the DB system. Earlier database versions are supported on a 19c Exadata DB system and can be created at anytime. Exadata DB systems created with earlier Oracle Database versions will not automatically support Oracle Database 19c. The DB system must be upgraded manually.

- **PDB name:** Not applicable to version 11.2.0.4. The name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).

- **Create administrator credentials:** A database administrator SYS user will be created with the password you supply.
  
  - **Username:** SYS
  - **Password:** Supply the password for this user. The password must meet the following criteria:
    
    A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word “oracle” either in forward or reversed order and regardless of casing.
  - **Confirm password:** Re-enter the SYS password you specified.

- **Select workload type:** Choose the workload type that best suits your application:
  
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.

- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  
  - **Enable automatic backups:** Check the check box to enable automatic incremental backups for this database.
  - **Backup retention period:** *(Optional)* If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  - **Backup scheduling (UTC):** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default
window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Automatic Incremental Backups for more information.

- **Click Show Advanced Options** to specify advanced options for the initial database.

  In the **Management** tab you can specify the following options:

  - **Character set**: The character set for the database. The default is AL32UTF8.
  - **National character set**: The national character set for the database. The default is AL16UTF16.

  In the **Encryption** tab, **Use Oracle-managed keys** is the only selection and cannot be changed during this creation process. You can change encryption management to use encryption keys that you manage after the database is provisioned. See To administer Vault encryption keys on page 1311 for more information.

  In the **Tags** tab, you can add tags to the database. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

8. **Click Create DB System**. The DB system appears in the list with a status of Provisioning. The DB system's icon changes from yellow to green (or red to indicate errors).

After the DB system's icon turns green in the list of DB systems and displays the Available status, you can click the highlighted DB system name to see details about the DB system. Note the IP addresses. You’ll need the private or public IP address, depending on network configuration, to connect to the DB system.

**To create a database in an existing Exadata Cloud Service instance**

**Note:**

If IORM is enabled on the Exadata Cloud Service instance, the default directive will apply to the new database and system performance might be impacted. Oracle recommends that you review the IORM settings and make applicable adjustments to the configuration after the new database is provisioned.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to create the database in:

   - **Cloud VM clusters (new resource model)**: Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems**: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. **Click Create Database**.
5. In the Create Database dialog, enter the following:
   - **Database name**: The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
   - **Database version**: The version of the database. You can mix database versions on the Exadata DB system.
   - **PDB name**: (Optional) For Oracle Database 12c (12.1.0.2) and later, you can specify the name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of eight alphanumeric characters. The only special character permitted is the underscore (_).
   - **Database Home**: The Oracle Database Home for the database. Choose the applicable option:
     - **Select an existing Database Home**: The Database Home display name field allows you to choose the Database Home from the existing homes for the database version you specified. If no Database Home with that version exists, you must create a new one.
     - **Create a new Database Home**: A database home will be created using the database version and the Database Home display name you specified.
   - **Create administrator credentials**: A database administrator SYS user will be created with the password you supply.
     - **Username**: SYS
     - **Password**: Supply the password for this user. The password must meet the following criteria:
       A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
     - **Confirm password**: Re-enter the SYS password you specified.
   - **Select workload type**: Choose the workload type that best suits your application:
     - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
     - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
   - **Configure database backups**: Specify the settings for backing up the database to Object Storage:
     - **Enable automatic backup**: Check the check box to enable automatic incremental backups for this database. If you are creating a database in a security zone compartment, you must enable automatic backups.
     - **Backup retention period**: If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
     - **Backup Scheduling**: If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Automatic Incremental Backups for more information.

6. Click Show Advanced Options to specify advanced options for the database:
   - **Character set**: The character set for the database. The default is AL32UTF8.
   - **National character set**: The national character set for the database. The default is AL16UTF16.
   - If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- If you are creating a database in an Exadata Cloud Service VM cluster, then you can choose to use encryption based on encryption keys that you manage. By default, the database is configured using Oracle-managed encryption keys. To configure the database with encryption based on encryption keys you manage:

  a. Click the Encryption tab.

  b. Select Use customer-managed keys. You must have a valid encryption key in Oracle Cloud Infrastructure Vault service. See Let security admins manage vaults, keys, and secrets on page 2151.

  c. Choose a vault from the Vault in compartment drop-down. You can change the compartment by clicking the CHANGE COMPARTMENT link.

  d. Select an encryption key from the Master encryption key in compartment drop-down. You can change the compartment containing the encryption key you want to use by clicking the CHANGE COMPARTMENT link.

  e. If you want to use an encryption key that you import into your vault, then select Choose the key version and enter the OCID of the key you want to use in the Key version OCID field.

  Note:

  - Oracle only supports AES-256 encryption keys.

  - Oracle supports customer-managed keys on databases after Oracle Database 11g release 2 (11.2.0.4).

  - If you choose to provide an OCID for the valid key version, then ensure that the OCID corresponds to the key version you want to use.

7. Click Create Database.

After database creation is complete, the status changes from Provisioning to Available, and on the database details page for the new database, the Encryption section displays the encryption key name and the encryption key OCID.

Caution:

Do not delete the encryption key from the vault. This causes any database protected by the key to become unavailable.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Tip:

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 3957.

To assign a key to an Object Storage bucket

Open a command prompt and run oci os bucket create to create a bucket that is encrypted with a Vault service master encryption key:

oci os bucket create --name <bucket_name> --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
For example:

```
oci os bucket create --name Bucket-1 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --kms-key-id ocid1.key.region1.sea.exampleaaacu2.exemploexamplem5cvblugmizcoeu2nfc6b3zfaux2lmgz25
--namespace-name example_namespace
```

Avoid entering confidential information.

**To update the key assigned to an Object Storage bucket**

Open a command prompt and run `oci os bucket update` to update the Vault service master encryption key assigned to a bucket:

```
oci os bucket update --name <bucket_name> --namespace-name <your_namespace> --kms-key-id <target_key_id>
```

For example:

```
oci os bucket update --name Bucket-1 --namespace-name example_namespace --kms-key-id ocid1.key.region1.sea.exampleaaacu2.exemploexamplem5cvblugmizcoeu2nfc6b3zfaux2lmgz25
```

**To create a block volume that’s encrypted with a Vault key**

Open a command prompt and run `oci bv volume create` to create a block volume that is encrypted with a Vault service master encryption key:

```
oci bv volume create --display-name <volume_name> --compartment-id <target_compartment_id> --size-in-gbs <volume_size> --availability-domain <target_availability_domain> --kms-key-id <target_key_id>
```

For example:

```
oci bv volume create --display-name EncryptedBlockVolume --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --size-in-gbs 50 --availability-domain AAbC:US-ASHBURN-AD-1 --kms-key-id ocid1.key.region1.sea.exampleaaacu2.exemploexamplem5cvblugmizcoeu2nfc6b3zfaux2lmgz25
```

**Caution:**

Avoid entering confidential information in the volume name.

**To update a key assigned to an existing Block Volume**

**Tip:**

If the volume is currently attached to an instance, you must first detach it. To do so, open a command prompt and run `oci compute volume-attachment detach --volume-attachment-id <target_blockvolume-attachment_id>`. For more information, see Oracle Cloud Infrastructure CLI Command Reference.
Open a command prompt and run `oci bv volume-kms-key update` to assign a new Vault service master encryption key to an existing block volume:

```
oci bv volume-kms-key update --volume-id <target_blockvolume_id> --kms-key-id <new_key_id>
```

For example:

```
oci bv volume-kms-key update --volume-id ocid1.volume.oc1.sea.examplerwzq7bnohn5vf6b7k4zkp54miqfcvg6xsuvkl1gzzw63mfuu6z5fa --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2
```

**To create a boot volume that's encrypted with a Vault key**

Open a command prompt and run `oci bv boot-volume create` to create a boot volume that is encrypted with a Vault service master encryption key:

```
oci bv boot-volume create --display-name <volume_name> --compartment-id <target_compartment_id> --size-in-gbs <volume_size> --availability-domain <target_availability_domain> --kms-key-id <target_key_id>
```

For example:

```
oci bv boot-volume create --display-name EncryptedBlockVolume --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqggmuz2zzum45ibplooqtabwk3zz --size-in-gbs 50 --availability-domain AAbC:US-ASHBURN-AD-1 --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2
```

**Caution:**

Avoid entering confidential information in the volume name.

**To create a Compute instance with a boot volume that's encrypted with a Vault key**

1. First, create the JSON input for configuring the instance and boot volume: Open a command prompt and run `oci compute instance launch --generate-full-command-json-input`.
2. Copy, and then paste the output from the command into a text file for editing. Edit the JSON to provide values appropriate for your tenancy and desired image operating system and instance shape. The following example shows the minimum settings required to create an instance and encrypted boot volume.

```json
{
    "availabilityDomain": "ABcD:US-ASHBURN-AD-1",
    "compartmentId": 
    ocid1.tenancy.oc1..examplea54hlbsuugecvb4g67tnth7ouk4iliqpysfauxctd55uiunrykhq",
    "displayName": "InstanceWithEncryptedBootVolume",
    "metadata": {
    },
    "shape": "VM.Standard1.1",
    "subnetId": 
    ocid1.subnet.oc1.iad.exampleaurihk3x3y12vcvb53uz22zgaoujtcwttbxvfauxdvsjmdfv4dza",
    "sourceDetails": {
        "sourceType": "image",
        "imageId": 
        ocid1.image.oc1.iad.exampleaooekczfwutjxzcvb2gcdgdx4yk6x1s7d5fhtlfauxzpaxdedny4a",
        "kmsKeyId": 
        ocid1.key.oc1.iad.exampleoaaeug.examplera4soq2vescvbjmwredhewtt07r1fauxhume73y7jayx
    }
}
```
Caution:
Avoid entering confidential information in the instance name.

3. Save the file with a "json" file extension.
4. In the command prompt, run `oci compute instance launch --from-json file://<file_path>`, providing the location of the file you saved in the previous step. For example:

   ```bash
   oci compute instance launch --from-json file://c:\temp\compute-boot-volume.json
   ```

To update a key assigned to an existing boot volume

Tip:
If the volume is currently attached to an instance, you must first detach the volume. To do so, you must first stop the instance. To stop an instance, open a command prompt and run `oci compute instance action --instance-id <target_instance_id> --action STOP`. Then, to detach the boot volume, run `oci compute boot-volume-attachment detach --boot-volume-attachment-id <target_bootvolume-attachment_id>`. For more information, see the Oracle Cloud Infrastructure CLI Command Reference.

Open a command prompt and run `oci bv boot-volume-kms-key update` to assign a new Vault service master encryption key to an existing boot volume:

   ```bash
   oci bv boot-volume-kms-key update --boot-volume-id <target_bootvolume_id> --kms-key-id <new_key_id>
   ```

   For example:

   ```bash
   oci bv boot-volume-kms-key update --boot-volume-id ocid1.bootvolume.oc1.sea.exampless6hvjs6j6mwc4gfrhtanon3fsqyviqeh522be6wv7x7abz7pq --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsnuqmoym4rsb1ugmizcoeu2nfc6b3zfaux21mzq2
   ```

To create a Kubernetes cluster with encrypted secrets in the etcd key-value store

Note:
These instructions assume you have already followed the steps in Encrypting Kubernetes Secrets at Rest in Etcd on page 900 and created:

- a dynamic group including all clusters in the compartment
- a suitable policy to give the dynamic group access to the master encryption key in Vault

Open a command prompt and run `oci ce cluster create` to create a cluster where Kubernetes secrets at rest in the etcd data-store are encrypted with a Vault service master encryption key:

   ```bash
   oci ce cluster create --name <cluster_name> --compartment-id <target_compartment_id> --vcn-id <target_vcn_id> --kubernetes-version <kubernetes_version> --kms-key-id <target_key_id>
   ```

   For example:
oci ce cluster create --name EncryptedCluster --compartment-id ocid1.compartment.oc1..example1example25r1p04agcmothkbgqmu2zzum45ibploooqtabwk3zz --vcn-id ocid1.vcn.oc1.iad.exampleexamplesgwertshsdgftyp6c5fplejt3miqvya --kubernetes-version v1.14.8 --kms-key-id ocid1.key.region1.sea.exampleaacu2.examplestpsuqmoy4m5cvblugmixcoeu2nfc6b3zfaux2lmqz2

**Caution:**

Avoid entering confidential information in the cluster name.

**To remove the key assigned to an Object Storage bucket**

Open a command prompt and run `oci os bucket update` to remove the Vault service master encryption key assigned to a bucket:

```
oci os bucket update --name <bucket_name> --namespace-name <your_namespace> --kms-key-id ""
```

For example:

```
oci os bucket update --name Bucket-1 --kms-key-id "" --namespace-name example_namespace
```

**To remove a key assigned to a Block Volume**

Open a command prompt and run `oci bv volume-kms-key delete` to remove the Vault service master encryption key assigned to an existing block volume:

```
oci bv volume-kms-key delete --volume-id <target_blockvolume_id>
```

For example:

```
oci bv volume-kms-key delete --volume-id ocid1.volume.oc1.sea.examplerwzq7bnohn5vf6b7k4zkp54miqfvcvg6xsuvkl1gzzw63mfuu6z5fa
```

**To remove a key assigned to a Block Volume boot volume**

Open a command prompt and run `oci bv boot-volume-kms-key delete` to remove the Vault service master encryption key assigned to an existing boot volume:

```
oci bv boot-volume-kms-key delete --boot-volume-id <target_bootvolume_id>
```

For example:

```
oci bv boot-volume-kms-key delete --boot-volume-id ocid1.bootvolume.oc1.sea.exampleless6hvjs6j6mqwcdv4gfrhtanon3fsqyviqeh522be6wv7x7abz7pq
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to assign keys:

- Container Engine for Kubernetes
  - CreateCluster
Core Services
- LaunchInstance
- CreateBootVolume
- CreateVolume
- UpdateBootVolumeKmsKey
- UpdateVolumeKmsKey
- DeleteBootVolumeKmsKey
- DeleteVolumeKmsKey

File Storage
- CreateFileSystem
- UpdateFileSystem

Object Storage
- CreateBucket
- UpdateBucket

Streaming
- CreateStreamPool
- UpdateStreamPool

Importing Keys and Key Versions

This topic describes how to import key material that you already have. When you create a key or key version, you can import your own key material instead of letting the Vault service generate the key material internally. You might want to "bring your own key" (BYOK) if you need more control over the source of the key material. Or, you might do so if you want to use the same keys that you already use for encryption purposes on-premises or on other clouds.

Imported keys can be AES symmetric keys or RSA asymmetric keys. (The Vault service does not support the import of ECDSA asymmetric keys.) For AES keys, the Vault service supports keys that are exactly 16 bytes (or 128 bits), 24 bytes (or 192 bits), or 32 bytes (or 256 bits) in length. For RSA keys, the service supports keys that are 256 bytes (or 2048 bits), 384 bytes (or 3072 bits), or 512 bytes (or 4096 bits). The key length of the key material itself must match what you specify at the time you create a key or import a key.

Furthermore, before you can import a key, you must wrap the key material by using the public wrapping key provided with each vault. The vault's wrapping key pair make it possible for the HSM to unwrap and store the key securely.

To meet payment card industry (PCI) compliance, you cannot import a key of greater strength than the key that you use to wrap it. Vault wrapping keys are 4096-bit RSA keys. As such, if you want to meet PCI compliance, you cannot import AES keys that are longer than 128 bits.

Also, if you plan to use the command line interface (CLI) to create a new external key or external key version, the key material must also be base64-encoded.

Required IAM Policy

Caution:

Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2152 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2153 in Common Policies on page 2142. Keys associated with databases will not work unless
you authorize a dynamic group that includes all nodes in the DB system to
manage keys in the tenancy. For more information, see Required IAM Policy
on page 1306 in Creating and Managing Exadata Databases on page 1306.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Before You Begin

To bring your own key, you must first generate an AES or RSA key and then transform the key material by wrapping it. The process by which you transform the key material is called Optimal Asymmetric Encryption Padding (OAEP). OAEP is commonly used with the RSA encryption algorithm (RSA-OAEP). The Vault service supports RSA-OAEP with a SHA-256 hash. Applying RSA-OAEP to wrap the plaintext provides an additional layer of protection to the key material by making it possible for only the HSM in possession of the private RSA wrapping key to unwrap the key.

You can either import the key or key version by using the Console or the CLI. If you use the CLI, we’ve included an example script that you can refer to that includes all steps of the import process, including generating key material, wrapping the key material, and importing the key or key version. If you want to use the Console or the CLI to create a key or key version with imported key material, you must separately apply RSA-OAEP first to wrap the key. With the CLI, you must also base64 encode the wrapped key material before you import it.

If you're using MacOS or Linux, you'll need to install the OpenSSL 1.1.1 series to run commands. If you're using Windows, you'll need to install Git Bash for Windows and run commands with that tool.

Using the Console

The following procedures assume that you already generated key material by using the third-party tool of your choice. Once you have the key material, use the Console to get the public wrapping key that you'll need to wrap the key material. Wrap the key material, and then use the Console to import it as a new master encryption key or a new key version for an existing master encryption key.

To get the public RSA wrapping key

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault in which you want to create the new master encryption key or key version.
3. From the list of vaults in the compartment, click the name of the vault.
4. In Vault Information, click Public Wrapping Key, and then click Copy.

Save the copied wrapping key, and then continue to To apply RSA-OAEP to wrap the key material on page 3987.

To apply RSA-OAEP to wrap the key material

Open a command prompt and run the following command to wrap the AES or RSA key material with the public RSA wrapping key associated with the vault. Replace example file names and values as appropriate.

```
openssl pkeyutl -encrypt -in <key_material_to_import> -
inkey <public_RSA_wrapping_key> -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

For example:
After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

### To import the key material as a new external key

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to import key material for a new key.
   - Create a new vault for the key by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Master Encryption Keys, and then click Create Key.
5. In the Create Key dialog box, choose a compartment from the Create in Compartment list. (Keys can exist outside the compartment the vault is in.)
6. Click Protection Mode, and then click HSM. (At this time, you cannot import key material for keys protected by software.)
7. Click Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Click Key Shape: Algorithm, and then choose from one of the following algorithms:
   - AES. Advanced Encryption Standard (AES) keys are symmetric keys that you can use to encrypt data at rest.
   - RSA. Rivest-Shamir-Adleman (RSA) keys are asymmetric keys, also known as key pairs consisting of a public key and a private key, that you can use to encrypt data in transit.
9. Click Key Shape: Length, and then choose the key length, in bits. For AES keys, the Vault service supports keys that are exactly 128 bits, 192 bits, or 256 bits in length. For RSA keys, the service supports keys that are 2048 bits, 3072 bits, or 4096 bits.
10. Select the Import External Key check box.
11. Click Wrapping Algorithm, and then choose one of the following:
   - RSA_OAEP_SHA256. RSA encryption with Optimal Asymmetric Encryption Padding (RSA-OAEP) with a SHA-256 hash. (This option is not supported for importing RSA key material.)
   - RSA_OAEP_AES_SHA256. RSA-OAEP with a SHA-256 with a temporary AES key.
12. Under External Key Data Source, provide the file that contains the wrapped AES or RSA key material.
13. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
14. When you are finished, click Create Key.

### To import the key material as a new external key version

**Note:**

Key versions must match the shape of the key to which they're added.

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you want to rotate.
3. From the list of vaults in the compartment, click the name of the vault.
4. Click Master Encryption Keys, and then click the name of the master encryption key that you want to rotate to a new key version.
5. Under Resources, click Versions, and then, in the list of keys, click Rotate Key. (You can only rotate keys in an enabled state.)
6. In the Confirm dialog box, select the Import External Key Version check box.
7. Under **External Key Data Source**, provide the file that contains the wrapped key material.
8. When you're ready, click **Rotate Key**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Tip:**
Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 3957.

When using the command line to import key material from outside Oracle Cloud Infrastructure, you can either refer to example scripts or you can run CLI commands individually.

**Example Scripts**

Example scripts illustrate how you might fully automate generating the key material, applying RSA-OAEP to wrap the key material, and then creating the new key or key version based on the imported, wrapped key material.

This section includes example scripts for importing AES key material and RSA key material. You cannot import ECDSA key material.

*Script to import AES key material as a new external key*

Automate the import of AES key material as a new key with the following example script.

Open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```bash
#!/usr/bin/env bash

# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to import AES keys
# into the Vault service.
#

set -x

OPENSSL="<path_to_OpenSSL>"

**Individual Commands**
Review the commands in this section if you want to run the CLI commands individually rather than use an example script or if you want to examine the individual steps in the example scripts.

The commands in this section assume that you already generated key material by using the third-party tool of your choice. Once you have the key material, use the CLI to get the public wrapping key that you’ll need to wrap the key material. Wrap the key material by applying RSA-OAEP, and then use the CLI again to import the key material as a new master encryption key or a new key version for an existing master encryption key.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you provide complex input, such as JSON, by providing a file that contains the input, rather than formatting the input in the command line.</td>
</tr>
</tbody>
</table>

**To get the public RSA wrapping key**

Open a command prompt and run `oci kms management wrapping-key get` to get the vault’s public RSA wrapping key:

```
oci kms management wrapping-key get --endpoint <control_plane_URL>
```

For example:

```
oci kms management wrapping-key get --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

After you get the public wrapping key, wrap the AES key material by applying RSA-OAEP.

**To apply RSA-OAEP to wrap the key material**

Open a command prompt and run the following command to wrap the AES or RSA key material with the public RSA wrapping key associated with the vault. Replace example file names and values as appropriate.

```
openssl pkeyutl -encrypt -in <key_material_to_import> -inkey <public_RSA_wrapping_key> -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

For example:

```
openssl pkeyutl -encrypt -in "aes_key.bin" -inkey "publickey.pem" -pubin -out "wrappedkey.bin" -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

**To import the key material as a new external key**

Open a command prompt and run `oci kms management key import` to import the wrapped AES or RSA key material with the public RSA wrapping key associated with the vault:

```
oci kms management key import --wrapped-import-key <wrapped_key_material> --compartment-id <compartment_id> --display-name <key_name> --endpoint <control_plane_URL> --key-shape <key_encryption_information>
```

For example:

```
oci kms management key import --wrapped-import-key file:///wrapped_import_key.json --compartment-id
```
To import the key material as a new external key version

Open a command prompt and run `oci kms management key-version import` to import the wrapped AES or RSA key material as a new key version for an existing key:

```
oci kms management key-version import --key-id <key_OCID> --wrapped-import-key <wrapped_key_material>
```

For example:

```
oci kms management key-version import --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2n6b3zfaux2lmqz245gezevsq --wrapped-import-key file://./wrapped_import_key.json
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to wrap and import keys:

- GetWrappingKey
- ImportKey
- ImportKeyVersion
- ExportKey

Exporting Keys and Key Versions

You can export a software-protected master encryption key or key version if you want to use it to perform cryptographic operations in an application running on a client instead of performing those same operations in the cloud with the Vault service. You can use the key locally, and then discard the key from local memory to protect the key contents. Using an exported key locally improves availability, reliability, and latency.

Required IAM Policy

**Caution:**

Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2152 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2153 in Common Policies on page 2142. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1306 in Creating and Managing Exadata Databases on page 1306.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message

---

Oracle Cloud Infrastructure User Guide 3994
that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Before You Begin**

Exporting a key requires you to generate your own RSA key pair to wrap and unwrap the key material. You can use the third-party tool of your choice to generate the RSA key pair.

You can export the key or key version by using the CLI only. We've included example scripts that you can refer to. The scripts include all steps of the export process, from wrapping the key material to exporting the software-protected key or key version.

If you're using MacOS or Linux, you'll need to install the OpenSSL 1.1.1 series to run commands. (If you plan to use the RSA encryption algorithm that uses a temporary AES key, then you must also patch OpenSSL with a patch that supports it.) If you're using Windows, you'll need to install Git Bash for Windows and run commands with that tool.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Tip:

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 3957.

This section provides example scripts that you can use to fully automate applying RSA-OAEP to wrap the key material, and then exporting the wrapped key or key version. Choose the appropriate example script for the type of RSA key wrap mechanism, whether you want to use the RSA encryption algorithm (with OAEP padding using SHA-256) that includes a temporary AES key or not. Also ensure that you patch OpenSSL if you plan to use the script that uses a temporary AES key.

The example scripts are based on the `oci kms crypto key export` command, which exports a software-protected master encryption key:

```bash
oci kms crypto key export --key-id <key_OCID> --algorithm <encryption_algorithm> --public-key "<public_RSA_wrapping_key>" --endpoint <data_plane_url>
```

To export a software-protected master encryption key by applying RSA-OAEP with a temporary AES key

The following example script invokes the RSA AES key wrap mechanism to generate a temporary AES key that wraps and unwraps the exportable key material. The process by which you transform the temporary AES key is called Optimal Asymmetric Encryption Padding (OAEP). OAEP is commonly used with the RSA encryption algorithm (RSA-OAEP). The Vault service supports RSA-OAEP with a SHA-256 hash.

Applying OAEP with the RSA encryption algorithm (RSA-OAEP) with a SHA-256 hash to wrap the temporary AES key with the provided public RSA wrapping key generates a wrapped temporary AES key. The wrapped temporary
AES key and the wrapped exportable key material are concatenated to produce blob output that jointly represents them and which only the possessor of the private RSA wrapping key can decrypt.

To export a software-protected master encryption key, open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```bash
#!/usr/bin/env bash

# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to export software-protected
# AES key material
# from the Vault service by using the RSA_OAEP_AES_SHA256 algorithm.
#

set -x

OPENSSL="<path_to_OpenSSL>" # Use OpenSSL 1.1.1.
KEY_OCID="<key_OCID>" # The Oracle Cloud Identifier (OCID) of the software-
# protected master encryption key to export.
ENCRYPTION_ALGORITHM="RSA_OAEP_AES_SHA256"
RSA_KEY_SIZE_IN_BYTES="<key_size_in_bytes>" # Specify 256 (for 2048 bits) or
# 512 (for 4096 bits).
VAULT_CRYPTO_ENDPOINT="<vault_data_plane_URL>" # The cryptographic endpoint
# of the vault that contains the software-protected master encryption key.
PUBLIC_KEY_STRING="<public_RSA_wrapping_key_in_PEM_format>" # The content of
# the public key.
PRIVATE_KEY_PATH="<path_to_private_RSA_wrapping_key>" # The location of the
# private key.
SOFTWARE_KEY_PATH="<path_to_output_exported_master_encryption_key>" # The
# location for outputting the software-protected master encryption key.
TEMP_AES_KEY_PATH="<path_to_output_temporary_AES_key>" # The location for
# outputting the temporary AES key.
TEMP_WRAPPED_AES_PATH="<path_to_output_wrapped_temporary_AES_key>" # The
# location for outputting the wrapped temporary AES key.
WRAPPED_SOFTWARE_KEY_PATH="<path_to_output_wrapped_master_encryption_key>"
# The location for outputting the wrapped software-protected master
# encryption key, otherwise known as the wrapped target key.

declare -a hex_array wrapped_temp_aes_key_array wrapped_targetKey_array
wrapped_targetKey_array_length

# Invoke the CLI to export a software-protected master encryption key. (The
# response contains the wrapped data in two parts.
# The first part is a wrapped temporary AES key. The second part is the
# wrapped software-protected master encryption key,
# also known as the wrapped target key.)
wrapped_data=$(oci kms crypto key export --key-id ${KEY_OCID} --algorithm
#${ENCRYPTION_ALGORITHM} --public-key "${PUBLIC_KEY_STRING}" --endpoint
${VAULT_CRYPTO_ENDPOINT} | grep encrypted-key | cut -d: -f2 | sed 's# "(.*
\"),\#1\g"')"

# Decode the encoded wrapped data and convert it to hexadecimal format.
wrapped_data_hex_array=('echo $(wrapped_data) | base64 -d | xxd -p -cl')
wrapped_data_hex_array_length=${#wrapped_data_hex_array[*]}

# Extract the wrapped temporary AES key. (The length of this first portion
of the wrapped data is equal to the length of the private RSA wrapping
key.)
wrapped_temp_aes_key_array=($"$(wrapped_data_hex_array[@]:0:
$RSA_KEY_SIZE_IN_BYTES")")
start_index_target_key=${#wrapped_temp_aes_key_array[*]}
To export a software-protected master encryption key by applying RSA-OAEP without a temporary AES key

The following example script transforms the software-protected master encryption key through a mechanism called Optimal Asymmetric Encryption Padding (OAEP). OAEP is commonly used with the RSA encryption algorithm (RSA-OAEP). The Vault service supports RSA-OAEP with a SHA-256 hash.

The script wraps the software-protected master encryption key with the provided public RSA wrapping key, and then unwraps and exports it with the private RSA wrapping key. Only the possessor of the private RSA wrapping key can decrypt the wrapped master encryption key.

To export a software-protected master encryption key, open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```bash
#!/usr/bin/env bash

# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to export software-protected
# AES key material
# from the Vault service by using the RSA_OAEP_SHA256 algorithm.
#

set -x

OPENSSL="<path_to_OpenSSL>" # Use OpenSSL 1.1.1.
```
# Vault

## Key OCI ID

The Oracle Cloud Identifier (OCID) of the software-protected master encryption key to export:

```
KEY_OCID="<key_OCID>" # The Oracle Cloud Identifier (OCID) of the software-
protected master encryption key to export.
```

## Encryption Algorithm

The cryptographic endpoint of the vault that contains the software-protected master encryption key:

```
ENCRYPTION_ALGORITHM="RSA_OAEP_SHA256"
```

## Vault Crypto Endpoint

The cryptographic endpoint of the vault that contains the software-protected master encryption key:

```
VAULT_CRYPTO_ENDPOINT="<vault_data_plane_URL>" # The cryptographic endpoint
of the vault that contains the software-protected master encryption key.
```

## Public Key String

The content of the public key:

```
PUBLIC_KEY_STRING="<public_RSA_wrapping_key_in_PEM_format>" # The content of
the public key.
```

## Private Key Path

The location of the private key:

```
PRIVATE_KEY_PATH="<path_to_private_RSA_wrapping_key>" # The location of the
private key.
```

## Software Key Path

The location for outputting the software-protected master encryption key:

```
SOFTWARE_KEY_PATH="<path_to_output_exported_key>" # The location for
outputting the software-protected master encryption key.
```

## Wrapped Software Key Path

The location for outputting the decoded, wrapped software-protected master encryption key:

```
WRAPPED_SOFTWARE_KEY_PATH="<path_to_output_decoded_wrapped_target_key>" #
The location for outputting the decoded, wrapped software-protected master
encryption key.
```

# Invoke the CLI to export a software-protected master encryption key.

```
wrapped_data=$(oci kms crypto key export --key-id ${KEY_OCID} --algorithm
${ENCRYPTION_ALGORITHM} --public-key "${PUBLIC_KEY_STRING}" --endpoint
${VAULT_CRYPTO_ENDPOINT} | grep  encrypted-key | cut -d: -f2  | sed 's#
\(.*\),\#\1\g\1'#
```

# Decode the encoded wrapped data.

```
echo ${wrapped_data} | base64 -d > ${WRAPPED_SOFTWARE_KEY_PATH}
```

# Unwrap the wrapped software-protected key material by using the private RSA wrapping key.

```
${OPENSSL} pkeyutl -decrypt -in ${WRAPPED_SOFTWARE_KEY_PATH} -
inkey ${PRIVATE_KEY_PATH} -pkeyopt rsa_padding_mode:oaep -pkeyopt
rsa_oaep_md:sha256 -pkeyopt rsa_mgf1_md:sha256 -out ${SOFTWARE_KEY_PATH}
```

## Using Keys

This topic describes what you can do with keys in terms of cryptographic operations and signing operations. For information about managing keys, see Managing Keys on page 3962. For information about exporting keys, see Exporting Keys and Key Versions on page 3994. For information about managing the vaults in which you store keys, see Managing Vaults on page 3957.

Cryptographic operations include the following:

- Encrypting data
- Decrypting data
- Generating data encryption keys
- Signing data
- Verifying signed data

You can use either the command line interface (CLI) or API to perform cryptographic operations.

## Required IAM Policy

### Caution:

Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2152 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2153 in Common Policies on page 2142. Keys associated with databases will not work unless

Oracle Cloud Infrastructure User Guide 3998
you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1306 in Creating and Managing Exadata Databases on page 1306.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring the traffic associated with your master encryption keys, see Vault Metrics on page 4020.

**Using the Console**

**To view the public key of an asymmetric key**

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where the key exists.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Under Master Encryption Keys, click the name of the key.
5. Under Resources, click Versions.
6. In the list of key versions, find the key for which you want to view the public key, click the Actions menu, and then click View Public Key.
7. Do one of the following:
   - To copy the contents of the public key, click Copy. The contents of the public key are copied to your clipboard.
   - To download the public key, click Download. The file is automatically downloaded to your local computer.
8. When you are finished, click Close.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Tip:**

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 3957.
To encrypt data by using your Vault master encryption key

You can use either AES symmetric keys or RSA asymmetric keys to encrypt or decrypt data. ECDSA keys do not support the cryptography required to encrypt or decrypt data. If you want to encrypt data by using an RSA asymmetric key, then you must also provide the --key-version-id of the key. To decrypt the data, you need to provide the same --key-version-id. The need to track key versions exists because, unlike symmetric keys, an asymmetric key’s ciphertext does not contain the information that the service needs for decryption purposes.

Open a command prompt and run `oci kms crypto encrypt` to encrypt data:

```bash
oci kms crypto encrypt --key-id <key_OCID> --plaintext <base64_string> --endpoint <data_plane_url>
```

For example:

```bash
oci kms crypto encrypt --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

Optionally, you can include the `--associated-data` option to provide an encryption context that might contain useful, but non-secret, information about the encrypted data. That information is associated with the encrypted data such that the data cannot be decrypted without it, providing an extra layer of protection. Associated data must be properly formatted JSON.

If using an RSA asymmetric key, provide the public key.

```bash
oci kms crypto encrypt --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --associated-data '{"CustomerId":"12345", "Custom Data":"custom data"}' --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

To decrypt data by using your Vault master encryption key

You can use AES symmetric keys or RSA asymmetric keys to encrypt or decrypt data. ECDSA keys do not support the cryptography required to encrypt or decrypt data.

Open a command prompt and run `oci kms crypto decrypt` to decrypt data:

```bash
oci kms crypto decrypt --key-id <key_OCID> --ciphertext <base64_string> --endpoint <data_plane_url>
```

For example:

```bash
oci kms crypto decrypt --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --ciphertext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```
If you want to decrypt data previously encrypted by an RSA asymmetric key, then you must also provide the `--key-version-id` of the key that encrypted the data. The need to track key versions exists because, unlike symmetric keys, an asymmetric key's ciphertext does not contain the information that the service needs for decryption purposes. If the data you want to decrypt had an encryption context associated with it at the time of encryption, the same encryption context is required to decrypt the data. For example, the `--associated-data` in the following sample matches what was provided in the preceding sample command for encrypting data.

```bash
oci kms crypto decrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmgz2
--ciphertext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmyIy9HROZSBSYXp5IGRvZy4=
--associated-data '{"CustomerId":"12345", "Custom Data":"custom data"}'
--endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

**To generate a data encryption key from your Vault master encryption key**

**Note:**
You can only use AES symmetric keys to generate data encryption keys. You cannot generate data encryption keys from RSA and ECDSA asymmetric keys.

Open a command prompt and run `oci kms crypto generate-data-encryption-key` to generate a data encryption key that you can then use to encrypt and decrypt data:

```bash
oci kms crypto generate-data-encryption-key --key-id <key_OCID> --key-shape <key_encryption_information> --include-plaintext-key <Boolean_value> --endpoint <data_plane_url>
```

For example:

```bash
oci kms crypto generate-data-encryption-key --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmgz2
--key-shape file://path/to/json/file --include-plaintext-key true
--endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

**To view the public key of an asymmetric key**

Open a command prompt and run `oci kms management key-version get` to view the public key of an asymmetric key:

```bash
oci kms management key-version get --key-id <key_OCID> --key-version-id <keyversion_OCID> --endpoint <control_plane_url>
```

For example:

```bash
oci kms management key-version get --key-id
ocid1.key.region1.sea.exampleaaacu2.exampleesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmgz2
--key-version-id
ocid1.keyversion.region1.sea.example5aacuu.ajmfauxaaa.abuwcljt2lolvy7221paefa53mb12fr
--endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```
To sign data by using your Vault master encryption key

**Note:**
You can only use RSA or ECDSA asymmetric keys to digitally sign data and verify signed data. AES keys do not support the asymmetric cryptography required to sign data or to verify signed data.

Open a command prompt and run `oci kms crypto signed-data sign` to sign a message:

```
oci kms crypto signed-data sign --key-id <key_OCID> --key-version-id <keyversion_OCID> --message <base64_string> --signing-algorithm <key_algorithm> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto signed-data sign --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtspuqmooy4m5cvblugmizcoeu2nfcbf3zaux21mq2fz2 --key-version-id ocid1.keyversion.region1.sea.example5aaccu.uumjmfauxaaa.abuwcljt2lo1vy7221paefaf53mb12f4 --message VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --signing-algorithm SHA_224_RSA_PKCS_PSS --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

To verify signed data by using your Vault master encryption key

**Note:**
You can only use RSA or ECDSA asymmetric keys to digitally sign data and verify signed data. AES keys do not support the asymmetric cryptography required to sign data or to verify signed data.

Open a command prompt and run `oci kms crypto verified-data verify` to verify the integrity of signed data:

```
oci kms crypto verified-data verify --key-id <key_OCID> --key-version-id <keyversion_OCID> --message <base64_string> --signature <base64_string> --signing-algorithm <key_algorithm> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto verified-data verify --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtspuqmooy4m5cvblugmizcoeu2nfcbf3zaux21mq2fz2 --key-version-id ocid1.keyversion.region1.sea.example5aaccu.uumjmfauxaaa.abuwcljt2lo1vy7221paefaf53mb12f4 --message VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --signature VGhpcyBpcyBhIHNpZ25hdHVyZS4= --signing-algorithm SHA_224_RSA_PKCS_PSS --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use the following operations to use keys in cryptographic operations:

- Decrypt
- Encrypt
- GenerateDataEncryptionKey
ExportKey
Sign
Verify

Back up vp vaults and keys

This topic describes how to preserve virtual private vaults and encryption keys. You can create backups of these resources to store in a bucket or offline, outside of Oracle Cloud Infrastructure.

Currently, the only type of vault you can back up is a virtual private vault. Similarly, the only type of encryption key that you can back up is a master encryption key protected by a hardware security module (HSM). You cannot back up master encryption keys protected by software. You also cannot back up secrets.

You might want to back up a vault or encryption key before deleting either if you don't need them now, but think you might need to use the key for decryption later. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. Restoring a key lets you resume using a resource that was previously encrypted by the key.

You might also create a backup of a vault to use in a disaster recovery scenario. You can restore a backup in any region within the realm, making it possible to access encrypted resources even in disaster recovery scenarios where the region of the backed-up resource is no longer available.

Note:

By default, a key backup includes metadata about the vault it's associated with. A vault backup might optionally include key metadata, but you cannot back up secrets, whether independently or as part of a vault backup. You can only back up and restore encryption keys protected by an HSM and virtual private vaults.

For information about creating and managing the use of keys, see Managing Keys on page 3962. For information about what you can do with vaults where you store keys and secrets, see Managing Vaults on page 3957. For information about creating and managing the use of secrets, see Managing Secrets on page 4007.

How it works

Keys are always associated with the vault where you created them. This relationship persists even as the key is backed up and restored. As a result, restoring a key always requires you to already have the vault associated with the key. You also need the vault because the vault hosts the management and cryptographic endpoints against which you manage and use the key. This might mean that you need to first restore the vault, and then restore the key, if both were backed up and subsequently deleted.

You back up a vault or key by exporting identifying information about the vault or key and what it contains. (The service encrypts the backups, and only the service can restore them.) Vault backups can optionally include keys, assuming the vault has keys and the keys are in a supported lifecycle state when you perform the backup. You can only back up active, enabled, or disabled keys. Backups exclude keys that are deleted or in a transitional state (for example, "Creating" or "Pending Deletion"). Key backups always include vault metadata, in addition to key metadata. Having vault metadata makes it possible to restore the key at all. You can only back up active vaults.

You can back up only one vault or one key at a time. (The exception is when you backup keys as part of a vault backup.) When you perform a key backup, the file includes all associated key versions in an enabled state. Backups exclude key versions in a deleted or pending deletion state.

Backup operations require you to specify where to download the backup. Downloads can be stored in a new or existing Object Storage bucket or a temporary URL that's created specifically for pre-authenticated requests. For more information about pre-authenticated requests, see Using Pre-Authenticated Requests on page 3482. Backups must be stored in buckets in the same region, but you can copy the backup to a different region by using Object Storage.

Backup and restore operations generate work requests to help you track their progress.

You restore a vault or key by importing the backup from storage to where you want it, as long as you restore the vault to the same tenancy and compartment where you originally created the backup. The key also can only be restored to
its original tenancy and compartment, which might be a different compartment from the vault. You can, however, restore vaults and keys to a different region if your tenancy spans multiple regions.

You can restore a vault or a key individually. If you included keys in a vault backup, then restoring the vault restores all the keys included in the backup. Restoring a key restores all the key versions included in the backup.

You can restore a vault or key even when the vault or key already exists in the region. Also, at any time, you can take a newer backup of a vault or key if you want to capture changes to the vault, such as a new name or tags, or the keys, such as new key versions. Updating an already restored vault or key reflects those changes. Updates from a backup are always additive. This means that updates can only append new information. For example, any new key versions created in a reference vault are added to its restored key when you update the restored key. But, if you delete a key from a reference vault, and then you update a restored vault from a backup of the reference vault, the update does not result in a corresponding key deletion in the restored vault. Similarly, any keys that you create for a restored vault are independent of any keys associated with the reference vault that you created the backup from. You manage them independently, too.

Most other operations are not allowed while a backup or restore operation is in progress. This prevents you from deleting a key while it's being backed up, for example. Prohibited operations include attempts to perform simultaneous backup or restore operations on the same resource.

To make it easier to reuse any policies that you created to allow management and use of vaults and keys, when you restore a vault and key, they maintain the same unique Oracle Cloud Identifier (OCID) if they're restored to the region where they were originally backed up. When you restore a vault or key to a different region, you must review and update policies to correspond to new OCIDs.

When you restore a vault or key, especially a key with a lot of key versions, tenancy service limits do apply.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2151. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 2347.

Depending on where you want to store backups and retrieve them from, you might also need access to an Object Storage bucket. For administrators: for typical policies that gives access to buckets, see Let users write objects to Object Storage buckets on page 2149 and Let users download objects from Object Storage buckets on page 2149.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Using the Console**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only active virtual private vaults and active, enabled, or disabled keys can be exported to a backup.</td>
</tr>
</tbody>
</table>

To back up a vault

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that you want to back up.
3. From the list of vaults in the compartment, click the name of the vault.
5. Choose a source: export a backup to either an Existing Object Storage Bucket (recommended) or a pre-authenticated Object Storage URL for an object that you can write to.
6. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL for an object.

7. Optionally, to back up only the vault without any keys, select the **Back up vault metadata only** check box.

8. When you are finished, click **Back Up Vault**. (Note the compartment so that you can restore this resource to the right compartment later.)

**To back up a key**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the key that you want to back up.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Click **Master Encryption Keys**, and then click the name of the key that you want to back up. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)
5. On the **Key Details** page, click **Back Up Key**.
6. Choose a source: export a backup to either an **Existing Object Storage Bucket** (recommended) or a pre-authenticated Object Storage URL that you can write to.
7. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL to an object.
8. When you are finished, click **Back Up Key**. (Note the compartment so that you can restore this resource to the right compartment later.)

**To restore a vault**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to restore a vault. The compartment must match the compartment of the reference vault at the time of backup.
3. Click **Restore Vault**.
4. Choose a source. You can import a backup from an **Existing Object Storage Bucket** that you have access to or a pre-authenticated Object Storage URL. You can also **Upload a File** from your computer or a mapped network location.
5. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL. Include the backup name.
   - In **Choose a file**, drag and drop a file or, to browse for a file, click **select one**.
6. When you are finished, click **Restore Vault**.

**To update a vault from a backup**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that you want to update from a backup.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Update Vault from Backup**.
5. Choose a source. You can import a backup from an **Existing Object Storage Bucket** that you have access to or a pre-authenticated Object Storage URL. You can also **Upload a File** from your computer or a mapped network location.
6. Do one of the following, depending on what you chose in the previous step:
   • Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the Backup Name. Avoid entering confidential information.
   • Click Object Storage URL, and then provide a pre-authenticated URL. Include the backup name.
   • In Choose a file, drag and drop a file or, to browse for a file, click select one.
7. When you are finished, click Update Vault.

To restore a key
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment of the vault that contains the key that you want to restore.
3. From the list of vaults in the compartment, click the name of the vault. You must choose the same vault where the key was backed up originally. (If needed, also change the list scope to the compartment where the key was at the time of backup.)
4. Click Master Encryption Keys, and then click Restore Key.
5. Choose a source. You can import a backup from an Existing Object Storage Bucket or a pre-authenticated Object Storage URL that you can write to. You can also Upload a File from your computer or a mapped network location.
6. Do one of the following, depending on what you chose in the previous step:
   • Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the Backup Name. Avoid entering confidential information.
   • Click Object Storage URL, and then provide a pre-authenticated URL to an object.
7. When you are finished, click Restore Key.

To update a key from a backup
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment of the vault that contains the key that you want to update from a backup.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Click Master Encryption Keys, click the key name, and then click Update Key from Backup. (If needed, change the list scope to the compartment of the key, if the key is in a different compartment from the vault.)
5. Choose a source. You can import a backup from an Existing Object Storage Bucket that you have access to or a pre-authenticated Object Storage URL. You can also Upload a File from your computer or a mapped network location.
6. Do one of the following, depending on what you chose in the previous step:
   • Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the Backup Name. Avoid entering confidential information.
   • Click Object Storage URL, and then provide a pre-authenticated URL. Include the backup name.
7. When you are finished, click Update Key.

To view a work request for a backup or restore operation
1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment of the vault (or the vault of the key) that you're interested in.
3. From the list of vaults in the compartment, click the name of the vault, and then click Work Requests.
4. Optionally, click Master Encryption Keys, click the key name, and then click Work Requests. (If needed, change the list scope to the compartment of the key, if the key is in a different compartment from the vault.)
5. For detailed information about the work request, click the work request name.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to back up and restore virtual private vaults and keys:

- BackupVault
- RestoreVaultFromFile
- RestoreVaultFromObjectStore
- RestoreKeyFromFile
- RestoreKeyFromObjectStore

Managing Secrets

**Note:**
Support for secrets is not available in Oracle Cloud Infrastructure US Government Cloud realms.

This topic describes how to manage secrets. Management of secrets includes the ability to do the following:

- Create secrets
- View secret details
- View a list of secrets
- View a list of secret versions for a specific secret
- Update a secret description
- Create a new secret version (by updating secret contents)
- Promote a secret version to current
- Manage a secret's tags
- View a secret's rules
- Add or edit secret rules
- Delete secrets or secret versions to permanently prevent the use of their secret contents
- Move a secret to a new compartment

Before You Begin

Before you begin, we recommend that you first read Rules for Secrets on page 4019 and Secret Versions and Rotation States on page 4018 to better understand the implications of working with rules, secret versions, and secret version rotation states.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators:

- The policy Let security admins manage vaults, keys, and secrets on page 2151 lets the specified group do everything with vaults, keys, and secrets.
- The policy Let security admins manage all secrets in a specific vault in a compartment on page 2153 lets the specified group do everything with secrets in a specific vault.
- The policy Let users read, update, and rotate all secrets on page 2153 lets the specified group read, update, and rotate all secrets in any vault in the tenancy.
- For more information about permissions or if you need to write more restrictive policies for secrets, see Details for the Vault Service on page 2347.
If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

### Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring the traffic associated with your secrets, see Vault Metrics on page 4020.

### Moving Resources to a Different Compartment

You can move secrets from one compartment to another. After you move a secret to a new compartment, inherent policies apply immediately and affect access to the secret and secret versions. Moving a secret doesn't affect access to the vault that a secret is associated with. Similarly, you can move a vault from one compartment to another independently of moving any of its secrets. For more information, see Managing Compartments on page 2431.

### Using the Console

**To create a new secret**

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a secret.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create a secret.
   - Create a new vault for the secret by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Secrets, and then click Create Secret.
5. In the Create Secret dialog box, choose a compartment from the Create in Compartment list. (Secrets can exist outside the compartment the vault is in.)
6. Click Name, and then enter a name to identify the secret. Avoid entering confidential information.
7. Click Description, and then enter a brief description of the secret to help identify it. Avoid entering any confidential information in this field.
8. Choose the master encryption key that you want to use to encrypt the secret contents while they're imported to the vault. (The key must belong to the same vault. The key must also be a symmetric key. You cannot encrypt secrets with asymmetric keys.)
9. Specify the format of the secret contents you're providing by choosing a template type from the Secret Type Template list. (You can provide secret contents in plain-text when you use the Console to create a secret or secret version, but secret contents do need to be base64-encoded before they're sent to the service. The Console automatically encodes plain-text secret contents for you if you choose this format.)
10. Click Secret Contents, and then enter the secret contents. (The maximum allowable size for a secret bundle is 25 KB.)
11. Optionally, you can apply a rule to manage how secrets are used. You can either create a rule regarding the reuse of secret contents across versions of a secret, or you can create a rule specifying when the secret contents expire. For more information about rules, see Rules for Secrets on page 4019.

- **Rule Type.** You can specify a Secret Reuse Rule or a Secret Expiry Rule. At most, you can have one of each. If you already have one rule, but want to add another, click **+ Another Rule.**
- **Reuse rule configuration:** You can either enforce the reuse rule so it applies even to deleted secrets versions, or you can allow reuse of secret contents from deleted secret versions.
- **Expiry rule configuration:** You can set how frequently you want secret contents to expire and what you want to happen when the secret or secret version expires. Expiration of individual secret versions is represented by a period of 1 to 90 days that you can specify with the arrow buttons or entering a number. Expiration of the secret itself is represented by an absolute time and date between 1 to 365 days from the current time and date. Specify this date by using the date picker. You can configure expiry values for both the secret version and secret or just one of the two. (It's possible to clear the secret version expiry interval, but you must delete the entire expiry rule and start over if you want to set an absolute time to expire the secret.)

12. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

13. When you are finished, click **Create Secret.**

### To view secret details

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault.**
2. Under **List Scope,** in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets,** and then click the name of the secret for which you want to see configuration details. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)
5. The console displays the following information:
   - **OCID:** The unique, Oracle-assigned ID of the secret.
   - **Created:** The date and time when you initially created the secret.
   - **Compartment:** The name of the compartment that contains the secret.
   - **Vault:** The name of the vault that contains the secret.

### To view a list of secrets

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault.**
2. Under **List Scope,** in the **Compartment** list, click the name of the compartment that contains the vault that has the secrets you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. To see a list of secrets in this vault, click **Secrets.** You can see secrets in different compartments by changing the list scope.

### To view a list of secret versions

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault.**
2. Under **List Scope,** in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets,** and then click the name of the secret for which you want to see a list of secret versions. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)
5. Under **Secret Version List,** you can see all versions that exist for the selected secret. For more information about secret versions, see Secret Versions and Rotation States on page 4018.

### To update a secret description

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault.**
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret with the description you want to update.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret you want to edit. (If needed, first change the list scope to the compartment that contains the secret.)

5. Click **Edit**.

6. In the **Edit Secret** dialog box, click **Description**, and then enter a new description. Avoid entering any confidential information in this field.

7. When you are finished, click **Save Changes**.

**To update a secret's contents to create a new secret version**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the secret you want to provide with new secret contents.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret with the secret contents you want to update. (If needed, first change the list scope to the compartment that contains the secret.)

5. Click **Create Secret Version**. (You can only create a new secret version for a secret that's not pending deletion.)

6. Specify the format of the secret contents you're providing by choosing a template type from the **Secret Type Template** list. (You can provide secret contents in plain-text when you use the Console to create a secret or secret version, but secret contents do need to be base64-encoded before they're sent to the service. The Console automatically encodes plain-text secret contents for you if you choose this format.)

7. Click **Secret Contents**, and then enter the secret contents. (The maximum allowable size for a secret bundle is 25 KB.)

8. If you don't want to immediately promote the new secret version to current, select the **Set to Pending** check box. Otherwise, this new secret version is automatically promoted as the current version.

9. Click **Create Secret Version**.

**To promote an existing secret version to current**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret that you want to update.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret that you want to update to use a different secret version. (If needed, first change the list scope to the compartment that contains the secret.)

5. Make a different secret version the current secret version by doing one of the following:
   - Click **Edit**, click **Current Version**, and then click the version number you want to promote. When you're ready, click **Save Changes**.
   - Under **Secret Version List**, locate the version number that you want to promote, click the Actions icon (three dots) for that secret version, and then click **Promote to Current**. Confirm the promotion by clicking **Promote to Current**.

**To manage a secret's tags**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to manage tags.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, locate the secret you want to manage, and then click the secret name. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)

5. On the **Secret Details** page, click the **Tags** tab to view or edit existing tags. Or, click **Add Tags** to add new ones.

**To view a secret's rules**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to view configured rules.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret that has rules you want to view. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)

5. On the **Secret Details** page, click **Rules** to view existing rules.

**To edit a secret’s rules**

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to add or edit rules.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)

5. On the **Secret Details** page, click **Rules**, and then click **Add/Edit Rules**.

   • **Rule Type**. You can specify a **Secret Reuse Rule** or a **Secret Expiry Rule**. At most, you can have one of each. If you already have one rule, but want to add another, click **+ Another Rule**.

   • Reuse rule configuration: You can either enforce the reuse rule so it applies even to deleted secrets versions, or you can allow reuse of secret contents from deleted secret versions.

   • Expiry rule configuration: You can set how frequently you want secret contents to expire and what you want to happen when the secret or secret version expires. Expiration of individual secret versions is represented by a period of 1 to 90 days that you can specify with the arrow buttons or entering a number. Expiration of the secret itself is represented by an absolute time and date between 1 to 365 days from the current time and date. Specify this date by using the date picker. You can configure expiry values for both the secret version and secret or just one of the two. (It’s possible to clear the secret version expiry interval, but you must delete the entire expiry rule and start over if you want to set an absolute time to expire the secret.)

6. If you want to delete a rule while you're configuring them, do one of the following:

   • To delete the secret version rule, clear the days configured.

   • To delete the rule altogether, click the X next to the rule.

7. When you're ready, click **Save Changes**.

**To delete a secret**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a secret is pending deletion, resources or services that rely on that secret immediately become inaccessible. The secret also can't be rotated or otherwise updated. When the secret is deleted, its are irreversibly destroyed. If you want to restore the use of a secret before it is permanently deleted, you can cancel its deletion.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you want to delete.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, locate the secret you want to delete, and then click the Actions icon (three dots) for that secret. (If needed, first change the list scope to the compartment that contains the secret.)

5. In the **Actions** menu, click **Delete Secret**.

6. Confirm that you want to delete the secret by clicking the box and then typing the secret name.

7. Schedule when you want Vault to delete the secret. By default, the service schedules secrets for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.

8. When you're ready, click **Delete Secret**. If needed, you can restore use of the secret and access to resources and services that use the contents of that secret by canceling the scheduled deletion and making the secret version current again.
To delete a secret version

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a secret version is pending deletion, resources or services that rely on that secret version immediately become inaccessible. The secret version also can't be rotated or otherwise updated. When the secret version is deleted, its contents are irreversibly destroyed. If you want to restore the use of a secret version before it is permanently deleted, you can cancel its deletion.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that has the secret with the secret version you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click Secrets, and the click the secret name. (If needed, first change the list scope to the compartment that contains the secret.)
5. Under Secret Versions List, locate the secret version, and then click the Actions icon (three dots) for that secret version.
6. In the Actions menu, click Delete Secret Version.
7. Confirm that you want to delete the secret version by clicking the box and then typing the secret version number.
8. Schedule when you want Vault to delete the secret version. By default, the service schedules secret versions for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.
9. When you're ready, click Delete Secret Version. If needed, you can restore use of the secret version and access to resources or services that use the contents of that secret version by canceling the scheduled deletion and making the secret version current again.

To cancel the deletion of a secret

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that has the secret you no longer want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click Secrets, locate the secret for which you want to cancel deletion, and then click the Actions icon (three dots) for that secret. (If needed, first change the list scope to the compartment that contains the secret.)
5. In the Actions menu, click Cancel Deletion.
6. Confirm that you want to cancel the secret's deletion by clicking Cancel Deletion. Access to the secret and any resources or services that used the contents of the secret can be restored after the secret returns to active, current use.

To cancel the deletion of a secret version

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that has the secret with the secret version you no longer want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click Secrets, locate the secret with the secret version for which you want to cancel deletion, and then click the secret name. (If needed, first change the list scope to the compartment that contains the secret.)
5. Under Secret Versions List, locate the secret version, and then click the Actions icon (three dots) for that secret version.
6. In the Actions menu, click Cancel Deletion.
7. Confirm that you want to cancel the secret version's deletion by clicking Cancel Deletion. Access to the secret version and any resources or services that used its contents can be restored after the secret version returns to active, current use.

To move a secret to a different compartment

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Under **Table Scope**, in the **Compartment** list, choose the compartment that contains the vault that has the secret that you want to move.

3. Click **Secrets**. Find the secret in the list, click the the Actions icon (three dots), and then click **Move Resource**. (If needed, first change the list scope to the compartment that contains the secret.)

4. Choose the destination compartment from the list.

5. Click **Move Resource**.

6. If there are alarms monitoring the secret, update the alarms to reference the new compartment. See **To update an alarm after moving a resource** on page 2737 for more information.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**Tip:**

Each region has a unique endpoint for create, update, and list operations for secrets. This endpoint is referred to as the control plane URL or secret management endpoint. Each region also has a unique endpoint for operations related to retrieving secret contents. This endpoint is known as the data plane URL or the secret retrieval endpoint. When using the CLI for secret operations, you must provide the appropriate endpoint for the type of operation. For regional endpoints, see the **API Documentation**.

**To create a new secret**

Open a command prompt and run `oci vault secret create-base64` to create a new secret:

```
oci vault secret create-base64 --compartment-id <target_compartment_id> --secret-name <secret_name> --vault-id <target_vault_id> --description <secret_description_text> --key-id <encryption_key_id> --secret-content-content <base64_encoded_secret_content> --secret-content-name <unique_content_name> --secret-content-stage <secret_version_rotation_state>
```

For example:

```
oci vault secret create-base64 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --secret-name testSecret --vault-id ocid1.vault.oc1.iad.exampleyaaeuk.examplesuxtdqzvrwzk4ouq2mh2234o4oq4ghmt6rrzr9example --description "this is a test secret" --key-id ocid1.key.oc1.iad.exampleyaaeuk.abuwcvbrsvwr2nbvrraqomsmhpc74rlq2vpwyv3byhikd4577rxy7example --secret-content-content bXlwYXNzd29yZA== --secret-content-name testpassword1 --secret-content-stage CURRENT
```

Avoid entering confidential information.

**To view a secret's details**

Open a command prompt and run `oci vault secret get` to view a specific secret's details:

```
oci vault secret get --secret-id <secret_OCID>
```
For example:

```
oci vault secret get --secret-id
oci.vaultsecret.ocl.iad.exampleaz5qacpqahuecvbqzql4qmpbrtd7pprafhvckfik6wuitexample
```

To view a list of secrets

Open a command prompt and run `oci vault secret list` to list secrets in a vault:

```
oci vault secret list --compartment-id <target_compartment_id>
```

For example:

```
oci vault secret list --compartment-id
oci.compartment.ocl.example1.example2.5qrlpo4agcmothkbqgqvmuz2zzum45ibploooqtabwk3zz
```

To view a list of secret versions

Open a command prompt and run `oci vault secret-version list` to view a list of secret versions for a specific secret:

```
oci vault secret-version list --secret-id <secret_OCID>
```

For example:

```
oci vault secret-version list --secret-id
oci.vaultsecret.ocl.iad.exampleaz5qacpqahuecvbqzql4qmpbrtd7pprafhvckfik6wuitexample
```

To update a secret description

Open a command prompt and run `oci vault secret update` to edit a secret's description.

**Caution:**

Avoid entering confidential information in the secret description. Also, you must update the current secret version number, secret contents, and secret rules independently of one another. Lastly, you can only update secrets in an Active lifecycle state.

```
oci vault secret update --secret-id <secret_OCID> --description <secret_description_text>
```

For example:

```
oci vault secret update --secret-id
oci.vaultsecret.ocl.iad.exampleaz5qacpqahuecvbqzql4qmpbrtd7pprafhvckfik6wuitexample
--description "this is a new secret description"
```

To update a secret's contents to create a new secret version

Open a command prompt and run `oci vault secret update-base64` to update a secret's contents to create a new secret version:

```
oci vault secret update-base64 --secret-id <target_secret_id> --secret-content-content <base64_encoded_secret_content>
```
For example:

```bash
oci vault secret update-base64 --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
--secret-content-content bXluZXdwYXNzd29yZA==
```

**To promote an existing secret version to current**

Open a command prompt and run `oci vault secret update` to promote a secret version to current, active use:

```bash
oci vault secret update --secret-id <target_secret_id> --current-version-number <target_secret_version_number>
```

For example:

```bash
oci vault secret update --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
--current-version-number 3
```

**To manage a secret's tags**

Open a command prompt and run `oci vault secret update` to manage a secret's tags:

```bash
oci vault secret update --secret-id <target_secret_id> --defined-tags <defined_tags_in_JSON_format>
```

For example:

```bash
oci vault secret update --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
--defined-tags '{"ProdSecrets" : {"NodePool" : "10"}}'
```

**To view a secret's rules**

Open a command prompt and run `oci vault secret get` to view a secret's configured rules:

```bash
oci vault secret get --secret-id <target_secret_id>
```

For example:

```bash
oci vault secret get --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
```

**To edit a secret's rules**

Open a command prompt and run `oci vault secret update` to edit a secret's configured rules:

```bash
oci vault secret update --secret-id <target_secret_id> --secret-rules <secret_rules_in_JSON_format>
```

For example:

```bash
oci vault secret update --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
```
You can specify a secret reuse rule or a secret expiry rule. At most, you can have one of each rule type.

**To delete a secret**

**Caution:**

When a secret is pending deletion, resources or services that rely on that secret immediately become inaccessible. The secret also can't be rotated or otherwise updated. When the secret is deleted, secret contents are irreversibly destroyed. If you want to restore the use of a secret before it is permanently deleted, you can cancel its deletion.

Open a command prompt and run `oci vault secret schedule-secret-deletion` to schedule a secret's deletion:

```
oci vault secret schedule-secret-deletion --secret-id <target_secret_id> --time-of-deletion <time_in_rfc3339_format>
```

For example:

```
oci vault secret schedule-secret-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample --time-of-deletion 2020-04-30T10:00:00Z
```

By default, the service schedules secrets for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.

**To delete a secret version**

**Caution:**

When a secret version is pending deletion, resources or services that rely on that secret version immediately become inaccessible. The secret version also can't be rotated or otherwise updated. When the secret version is deleted, its contents are irreversibly destroyed. If you want to restore the use of a secret version before it is permanently deleted, you can cancel its deletion.

Open a command prompt and run `oci vault secret-version schedule-deletion` to schedule a secret version's deletion:

```
oci vault secret-version schedule-deletion --secret-id <target_secret_id> --secret-version-number <target_secret_version_number> --time-of-deletion <time_in_rfc3339_format>
```

For example:

```
oci vault secret-version schedule-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample --secret-version-number 1 --time-of-deletion 2020-04-09
```

By default, the service schedules secret versions for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days. In the preceding example, because no time is specified, the time of deletion defaults to midnight Coordinated Universal Time (UTC).
To cancel the deletion of a secret
Open a command prompt and run `oci vault secret cancel-secret-deletion` to cancel the scheduled deletion of a secret:

```
oci vault secret cancel-secret-deletion --secret-id <target_secret_id>
```
For example:

```
oci vault secret cancel-secret-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzql1qmpbrtd7pprafhivcfik6wuiexample
```

To cancel the deletion of a secret version
Open a command prompt and run `oci vault secret-version cancel-deletion` to cancel the scheduled deletion of a secret version:

```
oci vault secret-version cancel-deletion --secret-id <target_secret_id> --secret-version-number <target_secret_version_number>
```
For example:

```
oci vault secret-version cancel-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzql1qmpbrtd7pprafhivcfik6wuiexample --secret-version-number 1
```

To move a secret to a different compartment
Open a command prompt and run `oci vault secret change-compartment` to move a secret to a different compartment:

```
oci vault secret change-compartment --secret-id <target_secret_id> --compartment-id <new_compartment_id>
```
For example:

```
oci vault secret change-compartment --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzql1qmpbrtd7pprafhivcfik6wuiexample --compartment-id ocid1.tenancy.oc1..exampleati4wjo6cvbxq4iusld51sdsnescfyz7lr4r46wfauxuwrwed5b3xea
```

To view the contents and properties of the current secret version
Open a command prompt and run `oci secrets secret-bundle get` to view the contents and properties of the current secret version:

```
oci secrets secret-bundle get --secret-id <target_secret_id> --stage <target_secret_version_rotation_state>
```
For example:

```
oci secrets secret-bundle get --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzql1qmpbrtd7pprafhivcfik6wuiexample --stage CURRENT
```
To view the properties for all versions of a secret

Open a command prompt and run `oci secrets secret-bundle-version list-versions` to view information about each of a secret's secret versions:

```
oci secrets secret-bundle-version list-versions --secret-id <target_secret_id>
```

For example:

```
oci secrets secret-bundle-version list-versions --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Tip:

Each region has a unique endpoint for create, update, and list operations for secrets. This endpoint is referred to as the control plane URL or secret management endpoint. Each region also has a unique endpoint for operations related to retrieving secret contents. This endpoint is known as the data plane URL or the secret retrieval endpoint. For regional endpoints, see the API Documentation.

Use the following operations to manage secrets:

- CreateSecret
- GetSecret
- UpdateSecret
- GetSecretVersion
- ListSecrets
- ListSecretVersions
- ScheduleSecretDeletion
- CancelSecretDeletion
- ScheduleSecretVersionDeletion
- CancelSecretVersionDeletion
- ChangeSecretCompartment

Use the following operations to retrieve secrets:

- GetSecretBundle
- ListSecretBundleVersions

Secret Versions and Rotation States

Note:

Support for secrets is not available in Oracle Cloud Infrastructure US Government Cloud realms.

This topic explains the relationship between secrets, secret versions, and rotation states. It also discusses the impact of service limits on secret versions. Understanding secret versions and rotation states will help you track and manage secret contents to stay in compliance with any limits, rotation or other rules, or regulations. For a basic definition of secret concepts, including secret versions and rotation states, see Key and Secret Management Concepts on page 3953. For information about working with secret versions, see Managing Secrets on page 4007.
Secret Versions

Every secret has at least one secret version. Every time you update the contents of a secret, you create a new secret version. Secret version numbers start at 1 and increment by 1. While every secret has at least one version, you might have multiple versions of a secret at any given time.

In addition to a version number, you can identify a secret version by its version name or rotation state. A secret version's rotation state represents how the secret is being used. Typically, applications need the current version of a secret. Marking a secret version as the 'current' version indicates that it has the secret contents currently used for access to the intended resource. Meaning, if you stored the password to connect to a database as a secret, when you request the current version of that secret, you do so with the knowledge that it's the password that the database currently expects.

Rotation States

Secret versions can have more than one rotation state at a time. Where only one secret version exists, such as when you first create a secret, the secret version is automatically marked as both 'current' and the 'latest'. The 'latest' version of a secret contains the secret contents that were last uploaded to the vault, in case you want to keep track of that.

When you rotate a secret to upload new secret contents, you can mark it as 'pending'. Marking a secret version's rotation state as 'pending' lets you upload the secret contents to the vault without immediately putting them into active use. You can continue using the 'current' secret version until you're ready to promote a pending secret version to 'current' status. This typically happens after you’ve rotated credentials on the target resource or service first. You don’t want to unexpectedly change a secret version. Changing what secret version is current prevents the application that needs it from retrieving the expected secret version from the vault.

For the purposes of rolling back to a previous version easily, such as when you've made a mistake in updating the secret contents or when you've restored a backup of an older resource and need to resume using older secret contents, secret versions can also be marked as 'previous.' A secret version marked as 'previous' was previously a secret version marked as 'current.' To roll back to a previous version, you update the secret to specify the secret version number you want.

As long as a secret version hasn't been deleted, you can update the secret to use that past secret version. When you update the secret, the secret version number you choose gets marked as 'current.' This has the same effect as promoting a secret version to 'current.'

You can only delete secret versions that have been marked as 'deprecated.' A deprecated secret version is one that’s not marked as 'current', 'pending', or 'previous.' This helps to prevent circumstances where you might delete a secret version that you need later (for example, when restoring a database you backed up previously). A secret version that’s marked as anything other than 'deprecated' can be marked as 'current' to return it to active use.

Secret Version Limits

The limits on secret versions applies to both a secret’s versions that are in use and versions that are deprecated, including those that have been scheduled for deletion. For information about limits on the number of versions for a given secret and for secret versions in a tenancy, see Service Limits.

Rules for Secrets

This topic explains how the rules you configure for secrets govern their usage. Configuring rules for secrets can help you meet compliance requirements. For information about how to configure or view rules, see Managing Secrets on page 4007.

When you create a secret, you can configure the following types of rules:
• **Secret Reuse Rule.** This type of rule prevents the reuse of secret contents across different versions of a secret.

• **Secret Expiry Rule.** This type of rule restricts how long the secret contents of a particular secret version can remain in use. This rule can also block the retrieval of secret contents for a secret or secret version past the configured expiration date.

You might want to configure either or both of these secret rules to establish best practices around security. You can improve your security posture by acting on secrets that don’t adhere to the rules or, in the case of expiry rules, are in danger of violating them in due time.

Secrets are protected at rest with the encryption guarantees of a Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification-compliant hardware security module (HSM) that backs the vault where the secret is created and stored. However, while in application memory, a secret could be compromised. Preventing the reuse of secret contents by multiple secret versions serves to limit the scope of affected resources in the event of a security breach involving the stored credentials. When only one resource uses the secret contents of a secret version, that resource is the only one that can be impacted. You can deprecate a secret version and then delete it if you find out you can no longer safely use its secret contents. You can choose whether secret reuse rules apply even to deleted secret versions.

Similarly, configuring an expiry rule to specify a time range for how long a secret version can exist also helps limit the impact of a potential security breach. The longer that a set of credentials are used, the more time an attacker has to try to access or decipher them. Frequently updating a secret with new secret contents helps keep credentials safer from users with malicious intent. Or, it at least makes shorter the period of time during which compromised credentials can unknowingly be used or disseminated. You can configure a secret version to expire after 1 to 90 days, but the secret can also have an absolute expiration date and time ranging from 1 to 365 days after its creation date. You can configure either of these values or both. You can also decide whether the secret contents are blocked past the expiration date.

The timer for a secret’s expiry rule resets according to the configured interval. No mechanism exists to update the secret contents. You must rotate the secret version manually.

**Vault Metrics**

You can monitor the usage of your Vault service master encryption keys and secrets by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

This topic describes the metrics emitted by the Vault service in the `oci_kms_keys` and `oci_secrets` namespace.

Resources: master encryption keys and secrets.

**Overview of the Vault Service Metrics**

Vault service metrics help you measure the success and error count of cryptographic operations on keys and the success and error count of HTTP responses to get, create, and update (getSecretBundle, listSecretBundleVersions, createSecret, and updateSecret) operations during the selected time range. You can use metrics data to diagnose and troubleshoot problems with keys and secrets.

To view a default set of metrics charts in the Console, navigate to the key or secret that you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.

**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
**Available Metrics: oci_kms_keys**

The metrics listed in the following table are automatically available for any master encryption keys that you create. You do not need to enable monitoring on the resource to get these metrics.

Vault service metrics for keys include the following dimensions:

**RESOURCEDISPLAYNAME**

The friendly name of the resource to which the metrics apply.

**RESOURCEID**

The OCID of the resource to which the metrics apply.

**RESPONSECODE**

The HTTP response code to the cryptographic operation to which the metrics apply.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>EncryptResponseCount</td>
<td>Encrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Encrypt calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
</tr>
<tr>
<td>DecryptResponseCount</td>
<td>Decrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Decrypt calls.</td>
<td></td>
</tr>
<tr>
<td>GenerateDataEncryptionKeyResponseCount</td>
<td>GenerateDataEncryptionKey Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for GenerateDataEncryptionKey calls.</td>
<td></td>
</tr>
</tbody>
</table>

**Available Metrics: oci_secrets**

The metrics listed in the following table are automatically available for any secrets that you create. You do not need to enable monitoring on the resource to get these metrics.

Vault service metrics for secrets include the following dimensions:

**DISPLAYNAME**

The friendly name of the resource to which the metrics apply.

**RESOURCEID**

The OCID of the resource to which the metrics apply.

**RESPONSECODE**

The HTTP response code to the operation to which the metrics apply.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetSecretBundle</td>
<td>GetSecretBundle</td>
<td>count</td>
<td>HTTP responses received by the service for GetSecretBundle calls during the selected time range.</td>
<td>displayName, resourceId, responseCode</td>
</tr>
<tr>
<td>ListSecretBundleVersions</td>
<td>ListSecretBundleVersions</td>
<td>count</td>
<td>HTTP responses received by the service for ListSecretBundleVersions calls during the selected time range.</td>
<td></td>
</tr>
<tr>
<td>CreateSecret</td>
<td>CreateSecret</td>
<td>count</td>
<td>HTTP responses received by the service for CreateSecret calls during the selected time range.</td>
<td></td>
</tr>
<tr>
<td>UpdateSecret</td>
<td>UpdateSecret</td>
<td>count</td>
<td>HTTP responses received by the service for UpdateSecret calls during the selected time range.</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

To view default metric charts for a single master encryption key

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Click a vault to view the resources it contains.
3. Click a key name to view its details.
4. Under Resources, click Metrics.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for multiple master encryption keys

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the master encryption keys that you're interested in.
3. For Metric Namespace, select oci_kms_keys.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

**Tip:**

If there are multiple master encryption keys in the compartment, the charts default to show a separate line for each master encryption key. You can instead show a single line aggregated across all master encryption keys in the compartment by selecting the Aggregate Metric Streams check box.
To view default metric charts for a single secret

1. Open the navigation menu. Under the Governance and Administration group, go to Security and click Vault.
2. Click a vault to view the resources it contains.
3. Click Secrets.
4. Click a secret name to view its details.
5. Under Resources, click Metrics.

To view default metric charts for multiple secrets

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the secrets that you're interested in.
3. For Metric Namespace, select oci_secrets.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Tip:

If there are multiple secrets in the compartment, the charts default to show a separate line for each secret. You can instead show a single line aggregated across all secrets in the compartment by selecting the Aggregate Metric Streams check box.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Troubleshooting the Vault Service

This section covers common issues related to the Vault service and how you can address them:

- Creating a Secret Fails Due to Authorization or Resource Not Found on page 4023
- Operation Fails Due to Conflicting Vault State on page 4024

Creating a Secret Fails Due to Authorization or Resource Not Found

There are several reasons why you might receive the following error when creating a secret, "Either you don't have permission to create this resource or the vault where you want to create it doesn't exist."

You might not have the required permissions. You need permissions for the vault where you want to create the secret and for the master encryption key that you want to use to encrypt the secret. If there's no policy that grants you the permissions you need, then an administrator must create one for you or add you to a group that's already named in a policy. If you're an administrator, refer to the following example policy:
- The policy Let security admins manage vaults, keys, and secrets lets the specified group do everything with vaults, keys, and secrets.

To write more restrictive policies, see Details for the Vault Service on page 2347. If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

It's possible that the vault doesn't exist. You can only create a secret in a vault that exists and only when you have permissions to do so.

**Operation Fails Due to Conflicting Vault State**

There are several reasons why an operation might result in the following error, "The state of the vault that contains this resource conflicts with the requested operation."

The vault lifecycle state shows that the vault is in a state that prevents the requested operation from proceeding or succeeding. This includes interstitial lifecycle states (for example, "Creating") or terminal states (for example, "Deleted"). Most operations are blocked when a vault is pending deletion.

The service might not recognize the same vault state as seen by a client application. This can happen, for example, if you recently changed the vault lifecycle state. The Vault service is eventually consistent regarding resource state. So, if this is the issue, you can try again later.
Chapter 40

VMware Solution

This chapter explains how to set up and manage software-defined data centers (SDDCs) in Oracle Cloud Infrastructure.

Oracle Cloud VMware Solution

Oracle Cloud VMware Solution allows you to create and manage VMware enabled software-defined data centers (SDDCs) in Oracle Cloud Infrastructure.

Solution Highlights

An Oracle Cloud VMware Solution gives you full access to the features of a VMware SDDC, along with the following benefits:

• High availability: All VMware components are distributed across different fault domains within the Oracle Cloud Infrastructure region’s availability domains. vSAN converged storage technology replicates data across all of the ESXi hosts in the SDDC.
• Scalability: You can start with 3 ESXi hosts and scale up to 64 hosts in a single SDDC.
• Lift and shift: Migration of on-premises VMware workloads to a Oracle Cloud VMware Solution is seamless.
• Full integration: Because the SDDC resides in a virtual cloud network (VCN), it can be configured to communicate with other Oracle Cloud Infrastructure resources such as Compute instances, DB systems and Autonomous Databases, and so on.
• Manageability: The Oracle Cloud Infrastructure Console provides workflows to facilitate SDDC creation and networking configuration.
• Layer 2 networking: SDDCs are configured with VLANs, which support applications that need layer 2 networking to run in the public cloud.

Note:

Bring your own hypervisor deployment of ESXi on bare metal Compute instances is not supported.

SDDC Details

An Oracle Cloud Infrastructure SDDC base configuration has the following properties:

• From 3 to 64 ESXi hosts on Oracle Cloud Infrastructure bare metal BM.DenseIO2.52 Compute instances
• 156 OPCUs, 2304 GB of physical memory, and 153 TB of NVMe-based raw storage
• A version of VMware software on each ESXi host
• An subnet and VLANs in an Oracle Cloud Infrastructure VCN

Supported Shapes

Currently, the only shape supported for ESXi hosts is a two-socket BM.DenseIO2.52 with two CPUs each running 26 cores. See Dense I/O Shapes on page 657 for more detail.
Oracle Cloud VMware Solution Architecture

The following diagram shows how the various components of the Oracle Cloud VMware Solution SDDC are deployed on Oracle Cloud Infrastructure bare metal Compute instances, and how the solution is integrated into the Oracle Cloud Infrastructure environment.

The diagram shows three ESXi hosts of an SDDC that resides in an Oracle Cloud Infrastructure VCN. The center host shows the installed VMware software components for compute (vSphere), network (NSX-T), and storage (vSAN) support. The NSX overlay manages the flow of traffic between the VMs, and between the VMs and the rest of the resources in the solution. The VCN here includes various gateways that allow connectivity between the SDDC and an on-premises network, the internet, and the Oracle Services Network.

When you provision an SDDC, you can enable HCX Manager (not shown in the diagram). HCX is an application mobility platform that simplifies application migration, workload rebalancing, and business continuity across data centers and clouds. For HCX to function properly in your VMware solution, you must have:

- A FastConnect connection for intersite communication
- A NAT gateway as required by HCX Manager for license activation, updates, and VMware enhanced support

**Note:**

HCX Manager requires connectivity to a VMware SaaS portal provided by a NAT gateway. Read more about VMware's requirements for HCX Manager: Why does HCX Manager require connectivity for activation and updates?

About the VMware Software

Oracle Cloud Infrastructure's VMware software bundle contains vSphere, vSAN, NSX, vCenter, and HCX components to support compute, storage, and network needs for a fully functional VMware environment.

- **vSphere:** vSphere is VMware's virtualization platform for unified management of the SDDC's CPU, storage, and networking infrastructure. Two key components of vSphere are ESXi hypervisor and vCenter Server.
- **NSX-T:** NSX-T Data Center provides the SDDC with its virtual networking and security capabilities. The NSX-T deployment includes NSX Manager unified appliances with NSX-T Local Manager and NSX-T Controller, and NSX-T Edge nodes.
- **vSAN:** Oracle Cloud VMware Solution SDDCs use VMware's vSAN storage technology, which provides a single shared datastore for compute and management workloads (VMs).
- **HCX:** The Hybrid Cloud Extension is an application mobility platform that removes complexity from application and workload migration. HCX is optionally installed as a plug-in when you set up your SDDC.
The following table shows the available versions of the software bundle, along with the version of each component:

<table>
<thead>
<tr>
<th>Software Version</th>
<th>vSphere</th>
<th>vSAN</th>
<th>NSX-T</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.7 update 3</td>
<td>6.7 U3</td>
<td>6.7 U3</td>
<td>2.5.1</td>
</tr>
<tr>
<td>6.5 update 3</td>
<td>6.5 U3</td>
<td>6.5 U3</td>
<td>2.5.1</td>
</tr>
</tbody>
</table>

When you provision the SDDC, you select the version of this software bundle to install on the ESXi hosts. You can change the SDDC’s software version later. When you add ESXi hosts to the SDDC, the version of software installed on new hosts is the version currently associated with the SDDC.

**Note:**

Changes that you make to the SDDC by using the Oracle Cloud Infrastructure Console, API, or CLI are not automatically made in vCenter. For example, if you change the software version or the SSH keys, the change applies only to ESXi hosts that you add to the SDDC. To change these properties for existing hosts, you must make the applicable updates in vCenter manually.

**Working with SDDCs**

You use the Oracle Cloud Infrastructure Console, API, or CLI to provision and manage SDDC resources. You use VMware’s vCenter utility to create and manage workloads in the SDDC.

See the following topics for information and instructions on how to create and manage Oracle Cloud VMware Solution resources:

- Setting Up an Oracle Cloud VMware Solution SDDC on page 4029
- Managing Oracle Cloud VMware Solution SDDCs on page 4035
- Configuring Networking Connectivity for an SDDC on page 4032
- Managing Layer 2 Networking Resources for an SDDC on page 4038

**Additional Documentation Resources**

The following Oracle Cloud VMware Solution solution playbooks and white papers are available:

- Deploy Zerto to protect your VMware SDDC in the cloud against disasters
  Learn how to deploy Zerto to protect your Oracle Cloud VMware SDDC data in the cloud.
- Deploy Veeam to protect your VMware SDDC in the cloud against disasters
  Learn how to deploy Veeam to protect your Oracle Cloud VMware SDDC data in the cloud.
- Deploy Actifio to protect your VMware SDDC in the cloud against disasters
  Learn how you can configure Actifio backup and disaster recovery solution for guest VMs in Oracle Cloud VMware Solution.
- Deploy a highly available SDDC to the cloud
  Shows you how to deploy a VMware SDDC on Oracle Cloud Infrastructure and then integrate it with other Oracle services running on Oracle Cloud.
- Migrate your on-premises VMware workloads to the cloud
  Outlines the process of online, or live, migration of your VMware workloads from an on-premises data center environment to Oracle Cloud VMware Solution.
- Build a hybrid SDDC by extending your on-premises VMware deployment to Oracle Cloud
  Describes how to set up a hybrid VMware SDDC between your on-premises environment and Oracle Cloud Infrastructure by using Oracle Cloud VMware Solution.
• Learn about connecting to Oracle Cloud and VMware resources
  Describes several methods for connecting to your Oracle Cloud and VMware resources, plus their benefits, limitations, and how to get started.

• Implement disaster recovery for an Oracle Cloud VMware Solution SDDC on the cloud
  Describes how Oracle Cloud VMware Solution uses VMware Site Recovery Manager (SRM) to implement an automated, reliable, and flexible disaster recovery solution for your VMware SDDC.

• Deploy a multitier application stack on a VMware SDDC connected to an autonomous database
  Shows a 3-tier application stack in Oracle Cloud Infrastructure with the application tier deployed in a VMware SDDC that's created by using Oracle Cloud VMware Solution.

Setting Up an Oracle Cloud VMware Solution SDDC

This topic includes information and instructions for provisioning a software-defined data center (SDDC) by using the Oracle Cloud Infrastructure Console or the API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Prerequisites

• An existing VCN with an IP address CIDR size of /22 or larger available for running the SDDC.
• We recommend that you set up connectivity between the VCN and your on-premises network before provisioning your SDDC. See Access to Your On-Premises Network on page 3252.
• If you do not plan to use the workflow to create an SDDC, ensure that you configure the SDDC's networking resources with the security rules detailed in Security Rules for Oracle Cloud VMware Solution SDDCs on page 4043. Otherwise, provisioning the SDDC will fail.

If you do not yet have a VCN for your SDDC, you can quickly create one and set up an IPSec VPN between your on-premises network and the VCN by using the VPN Connect workflow. See VPN Connect Quickstart on page 2939 to learn how.

Using the Console

The Create SDDC workflow can create the required networking resources for you (recommended), or you can create them yourself and then select them in the workflow. If you plan to select existing networking resources for your SDDC, ensure that you create them before you start the workflow. The following networking resources are required:

• A provisioning subnet with a route table and a security list - See To create a subnet on page 2825.
• VLANs - See Managing Layer 2 Networking Resources for an SDDC on page 4038.

To create an SDDC

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click Create SDDC.
3. Provide basic information for the SDDC:

   • SDDC Name: A descriptive name for the SDDC. This name must be unique among all SDDCs in the creating, active, or updating state across all compartments in the region. Avoid entering confidential information.

   **Note:**

   Unlike most display names in the Oracle Cloud Infrastructure Console, this name has the following additional requirements because it is used by vCenter to build URLs:
• It must be from 1-16 characters long and must start with a letter
• It can contain only alphanumeric characters and hyphens (-), and hyphens cannot be next to each other
This name is not case sensitive. For example, "test" and "Test" are treated as the same name.

• **SDDC Compartment**: The compartment in which to create the SDDC. All ESXi hosts for this SDDC will be placed in this compartment.

• **Enable HCX**: Select this checkbox to have the workflow install the HCX Manager plugin and integrate it with vCenter in the SDDC. *You cannot install this plugin later.*

• **VMware Software Version**: The version of VMware software to install on the ESXi hosts. While the VMware software bundle includes vSphere, vSAN, NSX, and vCenter components, the version you specify here is the version of vSphere. Compatible versions of the other components are installed with the version of vSphere you select. See *About the VMware Software* on page 4027 for details about the vSAN, NSX, or vCenter component versions installed. You can change this software version after provisioning.

• **Number of ESXi Hosts**: The initial number of ESXi hosts to create. Specify at least 3 and at most 64 hosts.

• **Prefix for ESXi Hosts**: (Optional) You can enter a prefix to use for the names of the ESXi hosts to help identify them. This string has the same criteria as the SDDC name. It must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Avoid entering confidential information.

• **SSH Key**: Provide the public key portion of the SSH key. This key is required for remote connections to the ESXi hosts.

• **Availability Domain**: The availability domain in which to create the SDDC. ESXi hosts in the SDDC are distributed across the fault domains in the availability domain to ensure high availability. The management subnet and VLANs for this SDDC must be in this same availability domain.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see *Resource Tags* on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click *Show Advanced Options*. The tags you specify are applied to all of the resources in the SDDC.

4. After you complete the Basic Information page, click **Next** to advance to the SDDC Networks page.

5. Choose a VCN for the SDDC. The VCN can be in a different compartment than the SDDC and its ESXi hosts.

6. If you enabled HCX in step 3, the selected VCN must have a NAT gateway attached to it.

   • If a NAT gateway already exists for the VCN, the name, compartment, and public IP address information is displayed.

   • If there is no NAT gateway attached to the selected VCN, the workflow creates one for you. Enter a name and select a compartment for the NAT gateway.

7. Select whether the workflow should create the network resources for this SDDC (recommended) or use existing network resources that you specify.

**To have the workflow create the network resources:**

   a. Click **Create New Subnet and VLANs**.

   b. Enter an available CIDR block in your selected VCN for the SDDC management CIDR. The workflow divides this CIDR into eight equal segments to use for the provisioning subnet and the seven required VLANs. If you are enabling HCX, the segment for the vSphere VLAN is further divided into two equal segments, one for
vSphere and the other for HCX. The size must be at least /22 to allow the maximum of 64 ESXi hosts to each have their own IP address.

c. Click **Check Availability** to ensure that CIDR block is available in the selected VCN. The check scans all subnets and VLANs in all compartments of the VCN.

You can show or hide details for the subnet and VLANs the workflow will create. Details include the route table and security list for the subnet, and the route table and NSG for each VLAN.

If you have enabled HCX, an additional route rule is created to allow traffic from the vSphere VLAN to the NAT gateway.

**To use existing network resources:**

a. Click **Select Existing Subnet and VLANs**.

b. Choose the compartment and provisioning subnet for your SDDC's management network. You cannot change the subnet after provisioning.

The CIDR value shown is the private address space for your chosen subnet.

c. Choose the compartment and VLAN for each function of your SDDC's management network.

The VLAN Gateway CIDRs shown are the CIDR blocks from which to derive IP addresses for each VLAN's layer 3 traffic. These CIDR blocks also provide the private IP addresses Oracle uses as attachment objects for public IP addresses when ESXi hosts require internet access.

- **NSX Edge Uplink 1:** Uplink used for communication between the VMware SDDC and Oracle Cloud Infrastructure.
- **NSX Edge Uplink 2:** Reserved for future use to deploy public-facing applications on the VMware SDDC.
- **NSX Edge VTEP:** Used for data plane traffic between the ESXi host and NSX Edge.
- **NSX VTEP:** Used for data plane traffic between ESXi hosts.
- **vMotion:** Used for vMotion (VMware migration tool) management and workload.
- **vSAN:** Used for vSAN (VMware storage) data traffic.
- **vSphere:** Used for management of the SDDC components (ESXi, vCenter, NSX-T, and NSX Edge).

**Note:**

If you checked the **Enable HCX** checkbox, verify that the VLAN selected for **vSphere** contains a route table rule that allows traffic to the NAT gateway. See **Managing Layer 2 Networking Resources for an SDDC** on page 4038 for more information.

- **HCX:** Used for HCX traffic. This VLAN appears only if you checked the **Enable HCX** checkbox.

8. (Optional) Provide an SDDC workload CIDR block for the workflow to create an initial logical segment for your VMs. The value must be /30 or larger and must not overlap with the VCN or the SDDC network CIDRs. Note that you can add network segments for the SDDC in NSX Manager after the SDDC is provisioned.

9. Click **Next** to review the summary of settings for creating the SDDC.

If you need to make changes, click **Edit Basic Information** or **Edit SDDC Networks** to return to a page, and update the settings, as applicable.

10. When you are satisfied with the summary information, click **Create SDDC**.

The page shows the provisioning status of each resource.

When provisioning is complete, the SDDC’s details page includes a username and an initial password that lets you access the vCenter management utility for the SDDC.

**Note:**

The password value displayed in the Oracle Cloud Infrastructure Console is not updated with your current password after you change it.
11. (Optional) You can check the status of provisioning by viewing its work request item from the SDDC's details page, under Resources.

    Provisioning takes approximately two and a half hours to complete.

    If errors occur, you can click Retry Provisioning. Clicking Cancel Provisioning cancels the provisioning process and deletes all resources created for the SDDC.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the CreateSddc API to create a VMware solution.

Use these API operations to create networking infrastructure resources for your VMware solution:

- CreateSubnet
- CreateRouteTable
- CreateSecurityList
- CreateNetworkSecurityGroup
- CreateVlan

What's Next?

After you provisioning your SDDC, you might want to perform some of the following tasks:

- Configure network connectivity between the SDDC and resources in your on-premises network, the Oracle Services Network, the internet throught a NAT gateway, or other resources in the VCN. See Configuring Networking Connectivity for an SDDC on page 4032 for information and instructions.

- Modify resources or properties of your SDDC. For example, add ESXi hosts. See Managing Oracle Cloud VMware Solution SDDCs on page 4035.

- Create VMs in your SDDC or perform other VMware tasks. To do so, you can log into vCenter by using the vSphere Client link from the detail page of the SDDC.

Configuring Networking Connectivity for an SDDC

This topic covers configuring network connectivity for an Software-Defined Data Center (SDDC) by using quick action workflows in the Oracle Cloud Infrastructure Console.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

About the SDDC Workflows

The SDDC quick action workflows make it easy for you to configure connectivity between your SDDC and various network resources within and outside of the VCN. Each workflow determines whether the required networking resources for connectivity already exist, and attempts to create or update them as needed. These networking resources can include gateways, subnets, route tables, rules, and network security groups. To use a workflow successfully, you must have the proper permissions for using and managing the applicable resources. See Details for the Core Services on page 2181 for information about networking resource permissions. Resource creation also relies on your limits and remaining capacity to create more resources.

Configuring Connectivity to Your On-premises Network

The workflow for configuring connectivity between your SDDC and an on-premises network does the following:
VMware Solution

- Determines whether the VCN has an attached dynamic routing gateway (DRG), and if not, helps you create one.
- Adds the route table, rules, or network security groups needed to enable routing between the DRG and the SDDC’s NSX Edge Uplink 1 VLAN.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

**Note:**

- In the workflow, you are prompted for the CIDR of the on-premises network. If you do not know this value, check with the on-premises network engineer or administrator before you begin. This CIDR value cannot be the same as the SDDC workload CIDR, and cannot overlap with the VCN’s CIDR.
- The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.

**To configure connectivity between the SDDC and your on-premises network**

1. On the Details page of the SDDC, click **Configure connectivity to your on-premises network**.
2. Use the Networking wizard to set up the DRG, if needed. After the DRG setup is complete, you can continue with the workflow.
3. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
4. Enter the CIDR of the on-premises network.
5. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink 1 VLAN and the DRG.

   If you choose to disallow an update, your SDDC might not have connectivity to your on-premises network. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.

6. When you are satisfied with the configuration settings, click **Apply Configuration**.

   The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

**Configuring Connectivity to the Oracle Services Network**

The workflow for configuring connectivity between your SDDC and the Oracle Services Network does the following:

- Determines whether the VCN has a service gateway, and if not, helps you create one.
- Adds the route table, rules, or network security groups needed to enable routing between the SDDC’s NSX Edge Uplink 1 VLAN and the service gateway.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

**Note:**

The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.
To configure connectivity between the SDDC and Oracle Services Network

1. On the Details page of the SDDC, click **Configure connectivity to Oracle Services Network**.
2. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
3. Click **Next**.
4. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink1 VLAN and the service gateway.

   If you choose to disallow an update, your SDDC might not have connectivity to Oracle Services Network. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.

5. When you are satisfied with the configuration settings, click **Apply Configuration**.

   The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

Configuring Connectivity to the Internet Through a NAT Gateway

The workflow for configuring connectivity between your SDDC and the internet through a NAT gateway does the following:

- Determines whether the VCN has a NAT gateway, and if not, helps you create one.
- Adds a default route rule to the SDDC's NSX Edge Uplink1 VLAN's route table to send traffic to the internet through the NAT gateway.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

**Note:**

The workflow adds a required route rule to the VLAN's route table. If you have reached your route rule limits, you are prompted to check your existing rules and delete one to free up capacity.

To configure connectivity to the internet through a NAT gateway

1. On the Details page of the SDDC, click **Configure connectivity to the internet through NAT gateway**.
2. Review the details of the planned updates to your networking resources.

   If you choose to disallow an update, your SDDC might not have internet connectivity through the NAT gateway. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.

3. When you are satisfied with the configuration settings, click **Apply Configuration**.

   The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.
Configuring Connectivity to Other Resources in the VCN

The workflow for configuring connectivity between your SDDC and other resources in the VCN does the following:

- Allows you to select subnets in the VCN that contain resources you want your SDDC to connect to. If the VCN has no subnets, you can use the Networking Wizard from the workflow to create them.
- Adds the route table, rules, or network security groups needed to enable routing between the SDDC's NSX Edge Uplink 1 VLAN and the resources in the selected subnets.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

**Note:**
The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.

To configure connectivity between the SDDC and other resources in the VCN

1. On the Details page of the SDDC, click **Configure connectivity to VCN resources**.
2. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
3. Click **Select Subnets**.
4. Check the check boxes of the subnets that contain resources your SDDC needs to connect to. You filter and sort the list to help you find the subnets you're interested in.
5. Click **Save Selection**.
6. Click **Next**.
7. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink1 VLAN and the selected subnets.
   
   If you choose to disallow an update, your SDDC might not have connectivity to the resources in a subnet. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.
   
   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.
8. When you are satisfied with the configuration settings, click **Apply Configuration**.

   The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

Managing Oracle Cloud VMware Solution SDDCs

This topic describes how to manage your Oracle Cloud VMware solution software-defined data center (SDDC) resources by using the Oracle Cloud Infrastructure Console or API. SDDC resources include SDDCs and ESXi hosts. To create and manage VMs on the ESXi hosts, you use VMware's vCenter utility.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which **compartments** you should work in.
Using the Console

The procedures that follow include steps for managing SDDCs and ESXi hosts.

To update basic properties of an SDDC

You can modify basic properties of the SDDC, including the name, the VMware software version, and the SSH keys.

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. Click Edit SDDC.
4. Make the applicable changes:
   - **SDDC Name**: Enter a new name for SDDC. This name must be unique among all SDDCs in the creating, active, or updating state across all compartments in the region. Avoid entering confidential information.
     
     **Note:**
     Unlike most display names in the Oracle Cloud Infrastructure Console, this name has the following additional requirements because it is used by vCenter to build URLs:
     - It must be from 1-16 characters long and must start with a letter
     - It can contain only alphanumeric characters and hyphens (-), and hyphens cannot be next to each other
     This name is not case sensitive. For example, "test" and "Test" are treated as the same name.
   - **VMware Software Version**: Select the version of VMware software to install on new ESXi hosts. While the VMware software bundle includes vSphere, vSAN, NSX, and vCenter components, the new version you specify here is the vSphere version only. The update does not impact the versions of the vSAN, NSX, or vCenter components.
   - **SSH Key**: Provide the public key portion of the SSH key. This key is required for remote connections to the ESXi hosts.

5. (Recommended) Click the vSphere Client link to go to vCenter, and make the appropriate updates for the SDDC properties you changed in the Console. You can do this task now or after you save your changes.
6. Click Save Changes.

To add an ESXi host to an SDDC

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. Click Create ESXi Host.
4. (Optional) Enter a name for the new host that helps to identify it later. The name must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Hyphens cannot be next to each other. Avoid entering confidential information.
5. (Optional) Show the ESXi host details to view or modify the following host properties:
   - VMware software version
   - SSH key
   - VLANs
6. When you are satisfied with the properties for this host, click Create ESXi Host.
To rename an ESXi host

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. In the list of ESXi hosts, click the Actions icon (three dots) for the host you want to rename, and then click Rename.
4. Enter the new name for the host. The name must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Hyphens must not be next to each other. Ensure that the name is unique within the SDDC. Avoid entering confidential information.
5. Click Rename.

To remove ESXi hosts from an SDDC

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. In the list of ESXi hosts, click the Actions icon (three dots) for the host you want to remove, and then click Terminate ESXi Host.

To change VLANs the SDDC uses

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. Under Resources, click SDDC Networks.
4. On the VLANs tab, click Change VLANs.
5. Make the applicable changes. See VLANs Required for an SDDC on page 4038 for information about VLANs.

Note:

Changes that you make to the SDDC's VLAN assignments by using the Oracle Cloud Infrastructure Console, API, or CLI are not automatically made in vCenter. You must make these updates in vCenter manually.

6. Click Save Changes.

To move an SDDC to a different compartment

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. Click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To terminate an SDDC

SDDC termination automatically removes the SDDC's associated instances and boot volumes. With a failed SDDC, you can opt to also delete all of its associated networking resources. These resources include the subnet and its route table and security list, and the VLANs and their route tables and NSGs. A networking resource cannot be deleted if that resource is used by another SDDC or networking resource. A networking resource in use will remain after the SDDC is terminated.

1. Open the navigation menu. Under Solutions and Platform, click VMware Solution.
2. Click the name of the SDDC to view details about it.
3. Click Terminate.

   Termination removes the SDDC and its associated resources. Terminated resources cannot be restored.

4. Follow the prompt to confirm termination, and click Terminate All.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use these API operations to manage VMware solution resources:

- ListSddcs
- GetSddc
- UpdateSddc
- ChangeSddcCompartment
- DeleteSddc
- ListEsxiHosts
- GetEsxiHost
- CreateEsxiHost
- UpdateEsxiHost
- DeleteEsxiHost

Managing Layer 2 Networking Resources for an SDDC

This topic describes how to manage layer 2 networking resources for a software-defined data center (SDDC) by using the Oracle Cloud Infrastructure Console or the API.

About SDDC Layer 2 Networking Resources

An Oracle Cloud Infrastructure SDDC requires a management subnet and layer 2 networking resources. The layer 2 networking resources include seven VLANs and their configured external access objects.

When you provision an SDDC by using the Oracle Cloud Infrastructure Console's Create SDDC workflow, you can have the workflow create these required networking resources for you. We recommend that you select this option. If you prefer, you can create them yourself before you start the Create SDDC workflow, and then select the existing subnet and VLANs you created for this purpose. If you create the SDDC using an existing subnet and VLANs, Oracle recommends that you create a size /22 CIDR network segment in your VCN for the SDDC’s networking resources. The documentation and the console refer to this segment as the “SDDC CIDR.” Divide this SDDC CIDR into eight segments of size /25 to use for the subnet and the seven required VLANs indicated in this topic. In addition, you must configure the security rules for these networking resources as detailed in Security Rules for Oracle Cloud VMware Solution SDDCs on page 4043. Otherwise, provisioning the SDDC will fail.

Note:
You can update VCN, VLAN, and subnet CIDR block information after creation. Ensure that any changes you make to the VCN after the SDDC is provisioned follow the preceding requirements.

For more information about editing your VCN, see VCNs and Subnets on page 2821.

VLANs Required for an SDDC

An SDDC requires VLANs for the following functions:

- **NSX Edge Uplink 1:** Uplink used for communication between the VMware SDDC and Oracle Cloud Infrastructure.
- **NSX Edge Uplink 2:** Reserved for future use to deploy public-facing applications on the VMware SDDC.
- **NSX Edge VTEP:** Used for data plane traffic between the ESXi host and NSX Edge.
- **NSX VTEP:** Used for data plane traffic between ESXi hosts.
- **vMotion:** Used for vMotion (VMware migration tool) management and workload.
- **vSAN:** Used for vSAN (VMware storage) data traffic.
- **vSphere:** Used for management of the SDDC components (ESXi, vCenter, NSX-T, and NSX Edge).
• **HCX: (Optional)** Used for HCX traffic. Create this VLAN if you plan to enable HCX when you provision the SDDC.

**Note:**

If you allow the Create SDDC workflow to create the VLANs, the workflow divides the SDDC management CIDR you specify into eight equal segments to use for the provisioning subnet and the seven required VLANs. If you enable HCX, the workflow further divides the vSphere segment into two equal parts, one for the vSphere VLAN and the other for the HCX VLAN. You can follow this model if you choose to create your VLANs manually.

HCX also requires that the vSphere VLAN has a route table rule that allows traffic to a NAT gateway attached to the VCN. See Route Tables on page 2921 for more information.

These VLANs must all be in the same VCN and availability domain you specify when you create the SDDC, but they can be in different compartments.

**External Access to VLAN Resources**

You can enable external access to an SDDC's ESXi hosts by creating a private IP object for the VLAN that can be used as a route target. Additionally, you can enable internet access to hosts in the VLAN by assigning a public IP address to the VLAN's private IP address object. When you configure external access, you have the option to indicate that it be accessible as a route target only and, as such, have no associated public IP address. See To add external access to a VLAN on page 4040 for the steps to configure external access.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

**Using the Console**

Use the procedures that follow to create and manage VLANs and external access objects for your SDDCs.

**To create a VLAN for an SDDC**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.
3. Click the VCN in which you plan to provision your SDDC.
4. Under Resources, click VLANs.
5. Click Create VLAN.
6. Enter the following:

- **Name:** (Optional) A descriptive name for the VLAN. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.

- **Create in Compartment:** The compartment for the VLAN.

- **Availability Domain:** Select the availability domain you plan select when you provision the SDDC. The ESXi hosts must be in the same availability domain as the SDDC's VLANs.

- **IEEE 802.1Q VLAN Tag:** (Optional) The VLAN uses this unique value to identify a broadcast domain for layer 2 traffic. Enter a number from 1 to 4094. If you don't enter a value, Oracle assigns one. You cannot change this value later.

- **VLAN Gateway CIDR:** This CIDR provides IP addresses used by the VLAN for external layer 3 communication and routing. This CIDR block also provides the private IP addresses Oracle uses as attachment objects for public IP addresses when instances require access to internet hosts. You can't change this value later.

  - **Note:**
    This CIDR must be within the VCN's CIDR and cannot overlap with the CIDRs of the other subnets and VLANs in the VCN.

- **Route Table:** The route table contains rules that specify the next hop for traffic from the VLAN to external destinations.

- **Network Security Groups:** Select the NSGs with the security rules to apply to all VNICs in this VLAN. You can select up to 5 NSGs for a VLAN.

  You manage NSG membership for VNICs in a VLAN at the VLAN level. You cannot add or remove individual VNICs in a VLAN from an NSG.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. If you don't see the tagging option, click **Show Advanced Options**.

7. Click **Create VLAN**.

The new VLAN displays in the list of VLANs for the VCN in the selected compartment.

8. Repeat steps 5 through 7 for each VLAN you need for your SDDC. See **VLANs Required for an SDDC** on page 4038.

**To add external access to a VLAN**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.

2. Click the VCN that contains the VLAN you want to modify.

   If you do not see the VCN listed, ensure that you have the correct compartment selected.

3. Under **Resources**, click **VLANs**.

4. Click the name of the VLAN to view details about it.

5. Click **Add External Access**.
6. Specify the type of external access to configure.

**Route Target Only**: Select this option to assign a private IP address only for use as a route target for traffic that needs to reach the VMware overlay. The IP address must be within VLAN gateway CIDR block. If you do not specify a name or a private IP address, or both, Oracle generates the needed values for you.

**Public Access**: Select this option to also provide a public IP address for internet access to the resources such as VNICs and VMs in the VLAN. The public IP address must be attached to a private IP address to enable internet access.

- **Private IP Address**: (Optional) Specify a name and/or a private IP address within the VLAN gateway CIDR block. If you do not specify these values, Oracle generates them for you. Note that as with the route target only option, this private IP address can also be used as a route target for non-internet traffic.
- **Reserved Public IP Address**: (For public access only) Choose whether to specify an existing reserved public IP address or have a new one created for this external access.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click Show Advanced Options.

7. Click Add External Access.

**To modify external access to a VLAN**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN that contains the VLAN you want to modify.
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under Resources, click VLANs.
4. Click the name of the VLAN to view details about it.
5. In the External Access list, select the external access you want to modify, click the Actions icon (three dots), and then click the Edit.

   The settings you can modify depend on the external access type. Consider the following:

   - You can change the external access type from route target only to public access, or the other way around.

     If you change the type from public access to route target only, the private IP address will no longer have an associated reserved IP address. Therefore, any host that uses the private IP address will not be accessible from the internet.

     If you change the type from route target only to public access, you'll need to attach a reserved public IP address to it to enable access from the internet. You can select an existing public IP address or have a new one created for this purpose.

     For both route target only and public access types, you can rename the private IP address but you cannot change the IP address value itself.

     For a public access type, you can rename the reserved public IP address but you cannot change the IP address value itself.

6. When you are done making your updates, click Save Changes.

**To remove external access to a VLAN**

<table>
<thead>
<tr>
<th><strong>Important:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>If an existing route rule targets the private IP address associated with the external access you are removing, the route rule will drop traffic to that private IP address.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN that contains the VLAN you want to modify.
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. In the External Access list, select the external access you want to remove, and click **Remove**.
6. Click **Remove** to complete the action.

**To move a VLAN to a different compartment**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to move.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Move Resource**.
6. Choose the destination compartment from the list.
7. Click **Move Resource**.

**To modify basic properties of a VLAN**
You can rename a VLAN, or change its route table or network security groups.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to modify.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Edit**.
6. Change the applicable settings:
   
   - **VLAN Name**: Use a descriptive name that helps to identify the VLAN. The name doesn't have to be unique. Avoid entering confidential information.
   - **Route Table**: The route table provides mapping for traffic from the VLAN to external destinations.
     
     (To select a route table in a different compartment, click Change Compartment, and select the compartment the target route table is in.)
   - **Network Security Groups**: Select the NSGs with the security rules to apply to all VNICs in this VLAN. You can select up to 5 NSGs for a VLAN.
7. When you are done making changes, click **Save Changes**.

**To modify the network security groups of a VLAN**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to modify.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Next to **Network Security Groups**, click **Edit**.
6. Make the applicable changes to the list of security groups. The VLAN can be associated with up to 5 security groups.
7. Click **Save Changes**.

**To delete a VLAN**

**Note:**

You cannot delete a VLAN if it has any external access resources. You must first remove all external access. See **To remove external access to a VLAN** on page 4041.
1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to delete.
   - If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Delete**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to create and manage layer 2 networking resources for an Oracle Cloud VMware solution SDDC:

- GetVlan
- ListVlans
- CreateVlan
- UpdateVlan
- ChangeVlanCompartment
- DeleteVlan

For a list of API operations to create and manage networking resources used by the VLANs in an SDDC, see the following topics:

- Route tables
- NSGs
- Private IPs

**Security Rules for Oracle Cloud VMware Solution SDDCs**

This topic details the security rules the Console's Create SDDC workflow configures for the new SDDC's subnet and VLANs. The rules are based on the requirements set by VMware.

**Important:**

If you do not use the workflow to create an SDDC, ensure that you configure the SDDC's networking resources with these security rules. Otherwise, provisioning the SDDC will fail.

**Provisioning Subnet**

The security lists for the provisioning subnet have the following stateful ingress security rules:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Source</th>
<th>Protocol</th>
<th>Source Port</th>
<th>Destination Port</th>
<th>Description</th>
</tr>

Chapter 41

Web Application Firewall

This chapter explains how to make your endpoints more secure by monitoring and filtering out potentially malicious traffic.

Overview of the Web Application Firewall Service

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based, Payment Card Industry (PCI) compliant, global security service that protects applications from malicious and unwanted internet traffic. WAF can protect any internet facing endpoint, providing consistent rule enforcement across a customer's applications.

WAF provides you with the ability to create and manage rules for internet threats including Cross-Site Scripting (XSS), SQL Injection and other OWASP-defined vulnerabilities. Unwanted bots can be mitigated while tactically allowed desirable bots to enter. Access rules can limit based on geography or the signature of the request.

The global Security Operations Center (SOC) will continually monitor the internet threat landscape acting as an extension of your IT infrastructure.

Web Application Firewall Service Components

WEB APPLICATION FIREWALL POLICY

WAF policies encompass the overall configuration of your WAF service, including origin management, protection rule settings, and bot detection features.

ORIGIN

Your web application's origin host server. An origin must be defined in your WAF policy in order to set up protection rules or other features.

PROTECTION RULES

Protection rules can be configured to either allow, block, or log network requests when they meet the specified criteria of a protection rule. The WAF will observe traffic to your web application over time and suggest new rules to apply. To view a list of available WAF rules, see Supported Protection Rules.

BOT MANAGEMENT

The WAF service includes several features that allow you to detect and either block or allow identified bot traffic to your web applications. Bot management features include: JavaScript Challenge, CAPTCHA Challenge, and GoodBot whitelists. For more information, see Bot Management.

Ways to Access the WAF Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface), command line interface (CLI), or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.
**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Note About The API**

The WAF service is powered by the Oracle Cloud Infrastructure Web Application Acceleration and Security (WAAS) API. All WAF related calls must be made using the WAAS API. To create a WAF configuration using the API, you must first create a WAAS policy with a defined origin and domain using the API. For the purposes of access control, you must provide the OCID of the compartment where you want the service to reside. For information about access control and compartments, see Overview of the IAM Service.

**WAF Service Capabilities and Limits**

The WAF service is limited to 50 policies per tenant. See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

The WAF service allows a total run time of 20 minutes for upload and download processes through the WAF.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be given access in a policy for waas-policy. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

**Policy examples:**

- To allow a specific user group to manage policies in the WAF:

  ```
  Allow group <GroupName> to manage waas-policy in compartment <CompartmentName>
  ```

- To allow a specific user group to read waas-work-request in compartment <CompartmentName>:

  ```
  Allow group <GroupName> to read waas-work-request in compartment <CompartmentName>
  ```

- To allow a specific user group to manage certificates in the WAF:

  ```
  Allow group <GroupName> to manage waas-certificate in compartment <CompartmentName>
  ```

- To allow a specific user group view policies in the WAF:

  ```
  Allow group <GroupName> to read waas-policy in tenancy <TenancyName>
  ```

If you’re new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service on page 2353.
Moving WAF Policies to a Different Compartment

You can move WAF policies from one compartment to another. After you move a WAF policy to the new compartment, inherent policies apply immediately and affect access to the WAF policies through the Console, SDK or CLI. For more information, see Managing Compartments on page 2431.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about available WAF service metrics and how to view them, see WAF Metrics on page 4170.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Getting Started with WAF

If you're new to Oracle Cloud Infrastructure WAF, this topic gives guidance on how to proceed.

Before You Begin

To begin using the WAF service, you must have the following available if you plan to run your site on HTTPS/443:

- Public certificate for the fully qualified domain name (FQDN) of the application.
- Corresponding private key for the site.
- IP address of the LBaaS or other public facing endpoint of application.
- Ability to update DNS records for the domain.
- WAF only supports traffic on ports 80/443. Make sure your application is not running on other ports.

Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges.

CIDR Ranges

- 129.146.12.128/25
- 129.146.13.128/25
- 129.146.14.128/25
- 129.213.0.128/25
- 129.213.2.128/25
- 129.213.4.128/25
- 130.35.0.0/20
- 130.35.112.0/22
- 130.35.116.0/25
- 130.35.120.0/21
- 130.35.128.0/20
- 130.35.144.0/20
- 130.35.16.0/20
- 130.35.176.0/20
- 130.35.192.0/19
- 130.35.224.0/22
- 130.35.232.0/21
- 130.35.240.0/20
- 130.35.48.0/20
- 130.35.64.0/19
- 130.35.96.0/20
- 132.145.0.128/25
- 132.145.2.128/25
- 132.145.4.128/25
- 134.70.16.0/22
- 134.70.24.0/21
- 134.70.32.0/22
- 134.70.56.0/21
- 134.70.64.0/22
- 134.70.72.0/22
- 134.70.76.0/22
- 134.70.8.0/21
- 134.70.80.0/22
- 134.70.84.0/22
- 134.70.88.0/22
- 134.70.92.0/22
- 134.70.96.0/22
- 138.1.0.0/20
- 138.1.104.0/22
- 138.1.128.0/19
- 138.1.16.0/20
- 138.1.160.0/19
- 138.1.192.0/20
- 138.1.208.0/20
- 138.1.224.0/19
- 138.1.32.0/21
- 138.1.40.0/21
- 138.1.48.0/21
- 138.1.64.0/20
- 138.1.80.0/20
- 138.1.96.0/21
- 140.204.0.128/25
- 140.204.12.128/25
- 140.204.16.128/25
- 140.204.20.128/25
- 140.204.24.128/25
- 140.204.4.128/25
- 140.204.8.128/25
- 140.91.10.0/23
- 140.91.12.0/22
- 140.91.22.0/23
- 140.91.24.0/22
Create a Policy to Route Traffic Through the WAF

To begin, create a policy to route traffic through the WAF without rules enabled. Creating a policy without rules enabled ensures that there are no regressions by having a reverse proxy in front of the application.

To create a policy

1. Select the region and compartment where the policy should be maintained (there is no constraint around the WAF co-existing with Load Balancing or other application resources in Oracle Cloud Infrastructure.)
2. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.

3. Click Create WAF Policy.

4. In the Create WAF Policy dialog box, enter the following:
   - **Name**: A unique name for the policy. Avoid entering confidential information.
   - **Domains**:
     - **Primary Domain**: The fully qualified domain name (FQDN) of the application where the policy will be applied.
     - **Additional Domains**: (Optional) Subdomains where the policy will be applied.

   **Note**: Wildcard domains are accepted, however, only as additional domains and only through the API and CLI.

   - **WAF Origin**: The host or IP address of the public internet facing application that is being protected by the application.
     - **Origin Name**: A unique name for the origin.
     - **URI**: Enter the public facing endpoint (IPv4 or FQDN) of the application.
     - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
     - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
     - **Headers**: (Optional)
       - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
       - **Header Value**: Specifies the data requested by the header.
     - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create WAF Policy. The WAF Policy overview appears. Expect the policy to become active within 15 minutes of creation.

**Update Origin Keep Alive Timeout**

WAF requires that your origin’s (load balancer or web server) keep alive timeouts are maintained for 301 seconds or more as our upstream timeout value is 300 seconds. During this period of time, the connections will be safely maintained while TCP is optimized. This is due to the network multiplexing methodology our nodes use to maintain connectivity with your origin.

**Update DNS to Enable WAF**

In this step, you update the CNAME for your zone to route requests from internet clients to WAF. Use the following instructions to make this DNS change in the Console. If your DNS setup resides with another provider, refer to their documentation for instructions.

**To update the CNAME for your zone**

1. In the Policy Information tab of the WAF Policy overview, select the CNAME Target.
2. Copy the CNAME target to your clipboard.
3. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
4. Click the Zone Name of the primary domain where you want to update the record. Zone details and a list of records appear.
5. Select the check box for the CNAME record and select Edit from the Actions drop-down menu.
6. In the Edit Record dialog box, update the Target field with the CNAME Target from your clipboard.
7. Click Submit.
8. Click **Publish Changes**.
9. In the confirmation dialog box, click **Publish Changes**.

**Upload Your Certificate and Key**

This step assumes that your site runs on HTTPS/443.

**To upload your certificate and key**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of your WAF Policy. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **General Settings**.
5. Click **Edit**.
6. In the **Edit Settings** dialog box, enter the following:
   
   - **Enable HTTPS Support**: Click this check box to enable all communications between the browser and web app to be encrypted.
   
   - **Certificate Source**: Choose one of the following methods:
     
     - **Choose Certificate**: Select an existing certificate from the drop down menu. Click **Change Compartment** to select a certificate from another compartment.
     
     - **Upload or Paste Certificate and Private Key**
       
       - Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Intermediate_Base64_encoded_certificate>
-----END CERTIFICATE-----
```

- **Private Key**: Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

```
-----BEGIN PRIVATE KEY-----
<Base64_encoded_private_key>
```
• **Self Signed Certificate:** Enable this field when using a self-signed certificate to show an SSL warning in the browser.

• **HTTP to HTTPS Redirect:** When enabled, all HTTP traffic is automatically redirected to HTTPS.

• **TLS Protocols Support:** Select a TLS protocol from the drop down list.

  **Caution:**

  TLS versions 1 and 1.1 have been deprecated and cannot be used in policy configurations. If you use these versions, a validation error might occur. Use versions 1.2 or 1.3 instead.

• **Enable SNI:** Server Name Indication (SNI) is an extension of the TLS protocol, which allows multiple secure hostnames to be served from a single IP address.

• **Advanced Options**
  - **Enable Response Buffering:** Enable or disable buffering of the response from the origin.
  - **Cache Control Respected:** Enable or disable automatic content caching based on the response cache-control header.
  - **Behind CDN:** Enable this to allow the collection of IP addresses from the client request if WAF is connected to a CDN.

7. Click **Save Changes**. Updates to your WAF policy appear in the list to be published in Unpublished Changes.

8. In the WAF Policy overview, under **Unpublished Changes**, click **View**.

9. In the Unpublished Changes list, click the drop down arrow beside an unpublished change to review the change.

10. Click **Publish All**.

11. In the Publish Changes dialog box, click **Publish All**.

---

**Test Your Application**

In this step, you ensure that requests are being routed to the WAF and that your application continues to function normally with a reverse proxy in the topology.

**To test your application**

1. Open a browser.

2. Enter the FQDN of the website protected by WAF.

3. Test the functionality of the application.

4. Inspect HTTP Response Headers to see if traffic is flowing through WAF. Some HTTP Response Headers to look for are:

   - **X-Cdn: Served-By-Zenedge**
   - **Server: ZENEDGE**

5. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.

6. Click the name of your WAF Policy. The WAF Policy overview appears.

  **Note:**

  You may experience a one-minute delay on logs aggregated and available through the console.

8. Copy the IP address and User-Agent value of your requests to your clipboard. You can use this information when you enable WAF to passively detect for access rules.
Enable WAF to Passively Detect Rules

In this step, you enable WAF to detect protection rules without blocking requests. Enabling WAF to passively detect rules helps you visualize the traffic that may pose a threat to your site and help you tune the WAF to exclude false positives.

To enable WAF to detect protection rules

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Use the Protection Rules table to locate the rules you want to detect.
5. Enter the Rule IDs you located from the table into the Rule ID filter. For this example, enter 941140 (Cross-Site Scripting) in the Rule ID filter.
6. Select Detect from the Actions drop down menu for the protection rules you filtered.

To enable WAF to detect access rules

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure access rules for. The WAF Policy overview appears.
3. Click Access Control.
4. Click Add Access Rule.
5. In the Add Access Rule dialog box, enter the following:
   a. Name: DetectRequestsFromMySpecificBrowser
   b. Rule Action: Select Detect Only.
   c. Conditions: Select IP Address is from the drop down and enter the IP address you copied to your clipboard while testing your application in the IP Address field.
   d. Click +Additional Condition.
   e. Condition: Select User Agent is from the drop down and enter the agent value you copied to your clipboard while testing your application in the User Agent Header field.

   Note:
   Both the IP Address and the User Agent in the preceding example must match for the rule to be triggered. If a different User Agent is used to test your application, the request will not be detected.

6. Click Add Access Rule.
7. Click Unpublished Changes.
8. Click Publish All.

Test the Rules

When the policy is active, you can test that your rules are detected by WAF.

To initiate requests

1. Use the same browser you used when you tested your application to do the following:
   a. Request the FQDN of your application.
   b. Request the FQDN of your application with the following query parameter appended: ?id=<script>alert("TEST");</script>.
2. Use a different browser on the same machine and repeat the preceding requests. All requests should go through the application.

To verify that WAF is detecting requests

To verify that WAF is detecting requests identified as a risk:
1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click **Logs**. Logs for the WAF policy appear.
4. Select the **Detect** check box from the **Actions** filter.
5. Verify that there are two entries for the protection rule triggered by the Cross-Site Scripting request and one entry for detecting the User Agent and IP Address.

View Recommendations

To view protection rule recommendations

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to view protection rule recommendations for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab. This list is generated based on the traffic the WAF detects flowing through the WAF. If nothing appears in this list, keep testing the FQDN of your application and check back later.
5. Select the protection rules with a **Detect** recommended action and then click **Accept Recommendations**.

**Tip:**

You can use the **Recommended Action** filter to locate a recommendation by **Detect**.

Enable WAF to Actively Block Requests

After you verify that requests are being detected, you can start blocking the undesired traffic.

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Enter rule ID **941140** in the **Rule ID** filter.
5. (Optional) To search for rules with a Detect action, select the **Detect** check box from the **Rule Action** filter.
6. Select **Block** from the **Actions** drop down menu for rule ID **941140** and any other protection rules you filtered.
7. Under WAF Policy, click **Unpublished Changes**.
8. Click **Publish All**.
9. In the Publish Changes dialog box, click **Publish All**.
10. Test the rules again by initiating requests. You should get 403 Forbidden errors when testing with the JavaScript on the URL.

Managing WAF Policies

The Oracle Cloud Infrastructure WAF service enables you to create a WAF policy and origin.

Order of Processing

The order in which rules and handlers are processed is:

1. IP Whitelists/Blocklists/Good Bot Whitelists
2. Access Rules
3. JavaScript Challenge
4. Device Fingerprinting Challenge (available in the API)
5. Human Interaction Challenge (available in the API)
6. Captcha Challenge
7. Protection Rules
8. Rate Limiting (available in the API)

**Using the Console**

**Create and Manage WAF Policies**

**To create a WAF policy**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click Create WAF Policy.
3. In the Create WAF Policy dialog box, enter the following:
   - **Name**: Optional. A unique name for the policy. Avoid entering confidential information.
   - **Domains**:
     - **Primary Domain**: The fully qualified domain name (FQDN) of the application where the policy will be applied.
     - **Additional Domains**: (Optional) Subdomains where the policy will be applied.
   - **WAF Origin**: The host or IP address of the public internet facing application that is being protected by the application.
     - **Origin Name**: A unique name for the origin. Avoid entering confidential information.
     - **URI**: The IPv4 address or fully qualified domain name (FQDN) of the origin. The URI can be a full URI, not just a host/IP.
     - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
     - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
   - **Header(s)**: (Optional)
     - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
     - **Header Value**: Specifies the data requested by the header.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

   **Note:**
   You can add multiple origins to your WAF policy and load balance them accordingly using the origins and originGroups field of the UpdateWaasPolicy operation in the WAAS API.

4. Click Create WAF Policy. The WAF Policy overview appears. You can access Origin Management, Access Control, WAF, Bot Management, Alerts, and any unpublished changes. While the policy is being created, no changes can be made until the process has completed. Expect the policy to become active within 15 minutes of creation.

   A CNAME target is generated for each policy. The CNAME target is a hyphenated version of your FQDN within the Oracle Cloud Infrastructure domain (for example, myapp-mydomain-com.oraclecloud.net).

5. In your DNS zone, update the CNAME record entry with the value of the CNAME target that is generated. This enables traffic to be routed through the WAF before the application. This value is presented soon after you publish your policy the first time on the main page of the policy.

**To update a WAF policy**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to update. The WAF Policy overview appears.

   | Tip: |
   | You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order. |

3. Click Edit.
4. In the Edit WAF Policy dialog box, make the needed changes and then click Save Changes.

**To delete a WAF policy**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Select the check box for the policy you want to delete.

   | Tip: |
   | You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order. |

3. Click Delete.
4. In the confirmation dialog box, click Delete.

   The status of the policy changes from Active to Deleting. Deleted policies are maintained for a short time before they are unavailable in the Console.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click Unpublished Changes.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click Publish All.
4. In the Publish Changes dialog box, click Publish All.

**To manage tags for a WAF policy**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to view. The WAF Policy overview appears.
3. Click the Tags tab to view or edit existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 211.

**To move a WAF policy to a different compartment**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. In the Scope section, select a compartment.
3. Find the WAF policy in the list, click the the Actions icon (three dots), and then click Move Resource to a Different Compartment.
4. Choose the destination compartment from the list.
5. Click Move Resource.

**Using the CLI**

Open a command prompt and run the following command to get the details of a WAAS policy:

```
oci waas waas-policy get --waas-policy-id <policy_ocid>
```
This can be useful in retrieving the necessary information when opening a ticket with Oracle Cloud Infrastructure support. For more information about how to access and use the CLI, see Command Line Interface (CLI).

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy
- DeleteWaasPolicy
- ChangeWaasPolicyCompartment

Origin Management

An origin is an endpoint (typically an IP address) of the application protected by the WAF. An origin can be an Oracle Cloud Infrastructure load balancer public IP address which can be used for high availability to an origin. When you create a WAF policy, you define a default origin and optional HTTP headers. An origin must be defined in your WAF policy in order to set up protection rules or other features. The details for the origin can be modified later in the Settings of the WAF policy. In the Origin Settings you can modify or set up HTTP headers for outbound traffic from the WAF to the origin server. These name value pairs are then available to the application.

Origin Groups

Multiple origins can be defined for a WAF policy using Origin Groups. When at least two origins are configured, load balancing is enabled. You can group together multiple origins in an origin group. An origin group can include origin servers and their weights. The weight of each origin in the origin group determines the priority when load balancing across origins in this group. Origins with higher weights receive larger proportions of client requests. You can use origin groups to specify the default origin that will be used in your WAF policy.

Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges.

CIDR Ranges

- 129.146.12.128/25
- 129.146.13.128/25
- 129.146.14.128/25
- 129.213.0.128/25
- 129.213.2.128/25
- 129.213.4.128/25
- 130.35.0.0/20
- 130.35.112.0/22
- 130.35.116.0/25
- 130.35.120.0/21
- 130.35.128.0/20
- 130.35.144.0/20
- 130.35.16.0/20
- 130.35.176.0/20
- 130.35.192.0/19
- 130.35.224.0/22

- 140.91.28.0/23
- 140.91.30.0/23
- 140.91.32.0/23
- 140.91.34.0/23
- 140.91.36.0/23
- 140.91.38.0/23
Using the Console  
To add an origin or origin group

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to add an origin to. The WAF Policy overview appears.
3. Click Settings.
4. Click Origin Groups. If there is more than one origin for the WAF policy, the origins and its group appear.
5. Click Edit. If there is only one origin defined for the WAF policy, the origin belongs to a default origin group.
6. Optionally, you can edit the name of the existing default group or add an additional group to group together multiple origins. You can use origin groups to specify the default origin that will be used in your WAF policy.
7. Click + Additional Origin below the origin group where you want to add an origin.
8. Enter the following:
   - **Name**: A unique name for the origin. Avoid entering confidential information.
   - **Default Origin**
     - **Name**: A unique name for the origin.
     - **URI**: The IPv4 address or FQDN of the origin.
     - **HTTP Port**: The HTTP port on the origin that the web application listens on. The default port is 443.
     - **HTTPS Port**: The HTTPS port on the origin that the web application listens on. The default port is 80.
     - **Weight**: The weight of the origin within the group is used for load balancing purposes. Origins with higher weights will receive larger proportions of client requests.

9. Click **Save Changes**.

   The changes must be published before they take affect. See To publish changes on page 4069.

**To edit an origin**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy where you want to edit the origin. The WAF Policy overview appears.
3. Click **Settings**.
4. Click the **Origin Settings** tab.
5. Click **Edit**.
6. In Origin Management Settings, make the necessary changes:
   - **Enable Health Checks**: Optional. Click the check box to enable Health Checks, then enter the following:
     - **Request and URL**: The type of request and the specific path to visit on the origin when performing the check.
     - **Host Header**: The value of the host header in the HTTP health check request. If this field is left blank, the policy domain will be used instead.
     - **User Agent**: The value of the user agent header in the HTTP health check request.
     - **Expected Response Code Group**: The HTTP response codes that signify the health state.
     - **Check Interval (seconds)**: Interval (in seconds) between health checks to the origin.
     - **Response Timeout (seconds)**: Enter the time to wait for a reply before marking the health check as failed.
     - **Healthy Threshold (number of times)**: Number of successful health checks after which the origin server is marked up.
     - **Unhealthy Threshold (number of times)**: Number of failed health checks after which the origin server is marked down.
     - **Enable Response Text Checking**: Enable to check for predefined text in addition to the response code.
     - **Expected Response Text**: Optional. Health checks will search for the given text in a case-sensitive manner within the response body and will fail if the text is not found.
   - **Load Balancing Method**:
     - **Note**: Load balancing is only enabled when at least two origins have been defined. To define additional origins, see To add an origin or origin group on page 4066.

Select one of the following methods:
   - **IP_HASH**: All of the incoming requests from the same client IP address should go to the same content origination server. IP_HASH load balancing method uses origin weights when choosing which origin should be hashed assigned to initially.
   - **ROUND_ROBIN**: Forwards requests sequentially to the available origin servers. The first request is to the first origin server, the second request is to the next origin server, and so on. After it sends a request to the last origin server, it starts again with the first origin server. When using weights on origins, Weighted
Round Robin assigns more requests to origins with a greater weight. Over a period of time, origins will receive a number of requests in proportion to their weight.

- **STICKY_COOKIE**: Adds a session cookie to the first response from the origin server and identifies the server that sent the response. The client's next request contains the cookie value, and nginx routes the request to the origin server that responded to the first request. STICKY_COOKIE load balancing method falls back to Round Robin for the first request.

- **Enable Origin Compression**: Enable or disable GZIP compression of origin responses.
- **Custom Headers**: Optional. Enter the custom HTTP headers to set or override in requests to origin servers.

7. Click Save Changes.

**To edit an origin group**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to edit the origin for. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **Origin Groups**. If there is more than one origin for the WAF policy, the origins and its group appear.
5. Click **Edit**. If there is only one origin defined for the WAF policy, the origin belongs to a default origin group.
6. Edit the name of the existing default group or add an additional group to group together multiple origins. You can use origin groups to specify the default origin that will be used in your WAF policy.
7. Click Save Changes.

The changes must be published before they take effect. See To publish changes on page 4069.

**To edit the load balancing method for origins**

Note:

Load balancing is only enabled when at least two origins have been defined. To define additional origins, see To add an origin or origin group on page 4066.

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy where you want to edit the origin. The WAF Policy overview appears.
3. Click **Settings**.
4. Click the **Origin Settings** tab.
5. Click **Edit**.
6. In Origin Management Settings, select one of the following options:
   - **IP_HASH**: All of the incoming requests from the same client IP address should go to the same content origination server. IP_HASH load balancing method uses origin weights when choosing which origin should the hash be assigned to initially.
   - **ROUND_ROBIN**: Forwards requests sequentially to the available origin servers. The first request is to the first origin server, the second request is to the next origin server, and so on. After it sends a request to the last origin server, it starts again with the first origin server. When using weights on origins, Weighted Round Robin assigns more requests to origins with a greater weight. Over a period of time, origins will receive a number of requests in proportion to their weight.
   - **STICKY_COOKIE**: Adds a session cookie to the first response from the origin server and identifies the server that sent the response. The client's next request contains the cookie value, and nginx routes the request to the origin server that responded to the first request. STICKY_COOKIE load balancing method falls back to Round Robin for the first request.
7. **Enable Origin Compression**: Optional. Enable or disable GZIP compression of origin responses.
8. **Custom Headers**: Optional. Enter the custom HTTP headers to set or override in requests to origin servers.
9. Click Save Changes.
To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy  To remove an origin from the policy using the API, use the UpdateWaasPolicy method and leave the origin field empty upon update.

Example

Each origin has a unique name (key). The name of the origin to be used by the WAF must be referenced in the wafConfig portion of the settings. For example, if you have the following origins in your configuration:

```json
{
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "lifecycleState":"ACTIVE",
   "displayName":"myWAFprotectedApp",
   "origins":{
      "primaryorigin":{
         "httpPort":80,
         "httpsPort":443,
         "uri":"67.205.161.231",
         "customHeaders":[
            
            
         ],
      },
      "secondaryorigin":{
         "httpPort":80,
         "httpsPort":443,
         "uri":"54.175.154.7",
         "customHeaders":{
            
            
         }
      }
   }
}
```

Then within the wafConfig, the origin in use would be referenced by name. In this example, the WAF is actively using secondaryorigin.

```
"wafConfig":{
```
"deviceFingerprintChallenge":{
    "isEnabled":false
},
"origin":"secondaryorigin",
"whitelists":[]
],

Example

Using the API, you can define multiple origins for the WaasPolicy.origins field, however, only one of those defined origins can be used in the WaasPolicy.wafConfig.origin field. The following example shows multiple origins defined for the WaasPolicy.origins field, however, only one of these defined origins is used in the WaasPolicy.wafConfig.origin field, as only one origin can be active for a policy.

"origins": {
    "origin1": {
        "uri": "6.6.6.6",
        "httpPort": 80
    },
    "origin2": {
        "uri": "1.1.1.2",
        "httpPort": 80
    }
},
"wafConfig": {
    "origin": "origin1"
}

Example

The following is an example of origin groups being used to specify the weight of each origin:

{
    "originGroup1": {
        "origins": [
            {
                "origin": "origin1",
                "weight": 2
            },
            {
                "origin": "origin2",
                "weight": 1
            }
        ]
    },
    "originGroup2": {
        "origins": [
            {
                "origin": "origin3",
                "weight": 1
            },
            {
                "origin": "origin4",
                "weight": 1
            }
        ]
    }
}
Bot Management

Bot Management enables you to mitigate undesired bot traffic from your site using CAPTCHA and JavaScript detection tools, while enabling known published bot providers to bypass these controls.

Non-human traffic makes up most of the traffic to sites. Bot Manager is designed to detect and block, or otherwise direct, non-human traffic that may interfere with site operations. The Bot Manager features mitigate bots that conduct content and price scraping, vulnerability scanning, comment spam, brute force attacks, and application-layer DDoS attacks. You can also allowlist good bots.

Caution:

When you enable Bot Management, you incur a higher rate on requests to the WAF.

JavaScript Challenge

JavaScript Challenge validates that the client can accept JavaScript with a binary decision. JavaScript Challenge is generally the first level of bot mitigation, but not sufficient with more advanced bot tools, which require more advanced challenges. Additional functionality, like detecting Network Address Translation (NAT) traffic, can mitigate the risk of blocking legitimate user traffic from users behind a shared IP address.

The Action Threshold parameter defines the number of requests that fail the challenge before the action is taken. The requests that fail under this threshold are not logged. For example, if you set the JavaScript challenge action to Block and the Action Threshold to 10, and a client that doesn't accept JavaScript makes 11 requests within the Action Expire Time, the first 10 requests will be allowed through to origin (assuming there are no other rules) and logs will show one Block entry action taken for the JavaScript Challenge.

Human Interaction Challenge

Human Interaction Challenge is an advanced countermeasure that looks for natural human interactions such as mouse movements, time on site, and page scrolling to identify bots. When an EDGE server receives requests from a client, instead of instantly reporting with the requested content, the human interaction challenge checks various event listeners in the user's browser to determine if there is a human user making a request.

Device Fingerprint Challenge

The device fingerprint challenge generates hashed signatures of both virtual and real browsers to identify and block malicious bots.

CAPTCHA Challenge

If a specific URL should be accessed only by a human, you can control it with CAPTCHA protection. You can customize the comments for the CAPTCHA Challenge for each URL. Bots are kept from accessing protected web application functionality using CAPTCHA images designed to be out of reach of computer vision and OCR technologies.

Good Bot Whitelist

Good Bots provides the list of bots managed by known providers, such as Baidu or Google. You can allow the access from a specific good bot, or block the bot if they serve no business purpose. Allowed good bots from this section are allowlisted.

Allowlisted bots are flagged with a Bypass action in the WAF policy Logs. You can select the Bypass check box from the Action filter in Logs to search for the traffic allowed from these rules. Logged good bot events are categorized as a Threat Intelligence Leads log type, however, they are not a threat when the action taken is to Bypass.

The list of good bots on this menu are managed and continuously updated. Additional good bots can be added as a new access control rule in Access Control.
Using the Console
To configure JavaScript Challenge settings

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click Edit JavaScript Challenge.
5. In the JavaScript Challenge dialog box, select the Enable JavaScript Challenge check box.
6. In the JavaScript Challenge Action section, choose one of the following methods:
   • Detect Only: Select this option if you want to be alerted for every matched request.
   • Block: Select this option to block requests by returning a response code, error page, or CAPTCHA.
     • Block Action: Select the action that will be taken when a matching request is blocked.
     • Show CAPTCHA
       • CAPTCHA Title: Enter the text for the CAPTCHA page title.
       • CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
       • CAPTCHA Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
       • CAPTCHA submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
   • Set Response Code: Select a status code to return in response to blocked requests.
   • Show Error Page
     • Block Error Page Message: Defines the error or error code.
     • Block Error Page Description: Provides more details about the error, including the cause and further instructions.
     • Block Error Page Code: The error code that is displayed with the error.
7. Enter the following information:
   • Enable Conditions: When enabled, conditions must match for a set action to be taken. See Access Control on page 4149 for more information about conditions and rules.
   • Action Threshold (number of requests): Specify the number of failed requests before taking action. Due to the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   • Action Expire Time (seconds): Enter the number of seconds between challenges to the same IP address. Due to client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3600 seconds for apps with desktop users only.
   • Follow Redirects: When enabled, redirect responses from the origin will also be challenged.
   • Enable NAT Support: When enabled, the user is identified not only by the IP address but also by a unique additional hash, which prevents blocking visitors with shared IP addresses. It is recommended that this NAT support is disabled for high-load apps (200+RPS).
8. Click Save Changes.

To edit JavaScript Challenge settings

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to edit JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click Edit JavaScript Challenge.
5. In the Edit JavaScript Challenge dialog box, make the needed changes.
6. Click Save.

To configure Human Interaction Challenge settings
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Human Interaction Challenge tab.
5. Click Edit Human Interaction Challenge.
6. In the Edit Human Interaction Challenge dialog box, select the Enable Human Interaction Challenge check box.
7. In the Human Interaction Action section, choose one of the following methods:
   - Detect Only: Select this option if you want to be alerted for every matched request.
   - Block: Select this option to block requests by returning a response code, error page, or CAPTCHA.
     - Block Action: Select the action that will be taken when a matching request is blocked.
     - Show CAPTCHA
       - CAPTCHA Title: Enter the text for the CAPTCHA page title.
       - CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
       - CAPTCHA Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
       - CAPTCHA submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
     - Set Response Code: Select a status code to return in response to blocked requests.
     - Show Error Page
       - Block Error Page Message: Defines the error or error code.
       - Block Error Page Description: Provides more details about the error, including the cause and further instructions.
       - Block Error Page Code: The error code that is displayed with the error.
8. Enter the following information:
   - Action Threshold (number of requests): Specify the number of failed requests before taking action. Due to the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - Threshold Expiry Period (seconds): The number of seconds before the threshold expires.
   - Action Expire Time (seconds): Enter the number of seconds between challenges to the same IP address. Due to client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3600 seconds for apps with desktop users only.
   - Interaction Threshold (number of interactions): Number of interactions before the threshold expires.
   - Recording Period (seconds): The period of time to record the user's events.
   - NAT Support: When enabled, the user is identified not only by the IP address but also by an unique additional hash, which prevents blocking visitors with shared IP addresses. It's recommended to disable the support for the high-load apps (200+ RPS).
9. Click Save Changes.

The Human Interaction Challenge is added to the list of changes to be published.

To edit Human Interaction Challenge settings
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure Human Interaction Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Human Interaction Challenge tab.
5. Click Edit Human Interaction Challenge.
6. Update the Human Interaction Challenge and then click Save Changes.

To configure Device Fingerprint Challenge settings
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure Device Fingerprint Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Device Fingerprint Challenge tab.
5. Click Edit Device Fingerprint Challenge.
6. In the Device Fingerprint Challenge dialog box, select the Enable Device Fingerprint Challenge check box.
7. In the Device Fingerprint Action section, choose one of the following methods:
   • Detect Only: Select this option if you want to be alerted for every matched request.
   • Block: Select this option to block requests by returning a response code, error page, or CAPTCHA.
     • Block Action: Select the action that will be taken when a matching request is blocked.
       • Show CAPTCHA
         • CAPTCHA Title: Enter the text for the CAPTCHA page title.
         • CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
         • CAPTCHA Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
         • CAPTCHA submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
       • Set Response Code: Select a status code to return in response to blocked requests.
       • Show Error Page
         • Block Error Page Message: Defines the error or error code.
         • Block Error Page Description: Provides more details about the error, including the cause and further instructions.
         • Block Error Page Code: The error code that is displayed with the error.
8. Enter the following information:
   • Action Threshold (number of requests): Specify the number of failed requests before taking action. Due to the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   • Threshold Expiry Period (seconds): The number of seconds before the threshold expires.
   • Action Expire Time (seconds): Enter the number of seconds between challenges to the same IP address. Due to client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3600 seconds for apps with desktop users only.
   • Max Address Count (IP addresses): The maximum number of IP addresses that are added to the list before the specified action is taken.
   • Max Address Count Expiration (seconds): The number of seconds an IP address is kept in the list before it is removed.
9. Click Save Changes.
To edit Device Fingerprint Challenge settings

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Device Fingerprint Challenge tab.
5. Click Edit Device Fingerprint Challenge.
6. Update the Device Fingerprint Challenge and then click Save Changes.

To add a CAPTCHA Challenge

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to edit CAPTCHA challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Click Add CAPTCHA Challenge.
6. In the Add CAPTCHA Challenge dialog box, enter the following information:
   - CAPTCHA Title: Enter the text for the CAPTCHA page title.
   - CAPTCHA URL Path: Enter the URL path challenged by CAPTCHA.
   - Session Duration: Enter the number of seconds after which the CAPTCHA challenge cannot be resubmitted to the same user.
   - CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
   - Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
   - Incorrect CAPTCHA Text: Enter the text that will appear when incorrect text is entered (for example, "The CAPTCHA was incorrect. Please try again.").
   - Submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
7. Click Preview CAPTCHA to preview the CAPTCHA challenge in a new tab.
8. Click Add.

To edit a CAPTCHA Challenge

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to edit CAPTCHA Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Select the check box for the CAPTCHA you want to edit.
6. Select Edit from the Actions drop down menu.
7. Update the CAPTCHA Challenge and then click Save.

To delete a CAPTCHA Challenge

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to delete CAPTCHA Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Select the check box for the CAPTCHA Challenge you want to delete.
6. Click **Delete**.
7. In the Confirm dialog box, click **Delete**.

**To manage the Good Bot Whitelist**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to configure Bot Management for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Good Bot Whitelist** tab.
5. Select each bot you want to designate as a good bot.

The designated good bots are added to the list of changes to be published.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Using the CLI**

You can use the CLI to enable rate limiting, device fingerprinting, and human interaction challenges.

**To enable rate limiting**

Open a command prompt and run the following command to enable rate limiting:

```
oci waas address-rate-limiting update-waf --is-enabled true --allowed-rate-per-address 1 --max-delayed-count-per-address 2 --waas-policy-id <policy_ocid>
```

This default rate limit setting will allow one request per second before starting to delay. It will delay for two requests until the traffic falls within the threshold boundaries. It will use the default error response code of 503.

**To enable device fingerprinting to detect**

Open a command prompt and run the following command to enable device fingerprinting to detect:

```
oci waas device-fingerprint-challenge update --is-enabled true --action DETECT --failure-threshold 2 --action-expiration-in-seconds 240 --failure-threshold-expiration-in-seCONDS 600 --max-address-count 2 --max-address-count-expiration-in-seconds 255 --waas-policy-id <policy_ocid>
```
To enable the human interaction challenge to detect

Open a command prompt and run the following command to enable the human interaction challenge to detect:

```
oci waas human-interaction-challenge update --is-enabled true --waas-policy-id <policy_ocid>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

WAF Protection Rules

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met. Protection Rule Settings allow you to define the parameters for enforcement any time a protection rule is matched. Recommendations aid in the optimization of your WAF security profile. The Security Operations team proactively monitors all events to provide recommendations about the action of a specific ruleset. See Supported Protection Rules on page 4081 for additional information.

Using the Console

To apply an action to a protection rule

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Rules tab.
5. Find the protection rule you want to apply an action to.

Tip:

You can use the Rule ID or Rule Action filters to locate a protection rule.
6. Click the Actions icon (three dots) and select one of the following options:
   - **Detect**: Matching requests generate an alert and the request is proxied.
   - **Block**: Matching requests are blocked.
   - **Off**: The rule is disabled.
   - **Exclusions**: Exclusions are set to specify the types of request that are to be bypassed by the protection rule(s). If a request matches any of the set exclusions, the protection rule(s) will not be executed for that request.
     a. In the Exclusions dialog box, enter the following criteria:
        - **Exclusion**: Select request cookie values, request cookie names, request parameters, or request parameter names.
        - **Value**: Enter the value for the selected exclusion.
     b. Click **Save Changes**.

The protection rule action is added to the list to be published.

**To edit rule settings**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Settings** tab.
5. Click **Edit Rule Settings**.
6. In the Edit Rule Settings dialog box, enter the following:
   - **Block Action**: The action taken on malicious requests blocked by WAF.
   - **Block Response Code**: Provides information indicating why the request was blocked.
   - **Max Number of Arguments**: The maximum number of arguments allowed in the request. The recommended setting is 255.
   - **Max Length of Argument**: The maximum argument length allowed in the request. The recommended setting is 400.
   - **Max Total Argument Length**: The maximum argument length for all arguments in the request. The recommended setting is 64000.
   - **Recommendations Period**: The period in days to analyze for recommended actions.
   - **Allowed HTTP Methods**: The list of allowed HTTP protocol methods.
7. Click **Save Changes**.

The accepted protection rules are added to the list to be published.

**To accept recommendations**

Recommendations will begin appearing once sufficient traffic has gone through the WAF to profile the right security posture.

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab.
5. Select the protection rules you want to accept.
   - **Tip**: You can use the **Recommended Action** filter to locate a recommendation by **Detect** or **Block**.
6. Click **Accept Recommendations**.

The accepted protection rules are added to the list to be published.
To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Listing and Accepting Protection Rule Recommendations

Use the following operations to get the list of recommended rules:

- ListRecommendations

```json
{
  "name": "SQL authentication bypass attempts",
  "action": "OFF",
  "description": "Detects basic SQL authentication bypass attempts."
}
{
  "modSecurityRuleIds": [
    "950001",
    "959070",
    "959071",
    "959072",
    "950908",
    "959073"
  ],
  "name": "Common SQL Injections"
}
```
"action": "OFF",
"description": "detects common SQL injection attacks",
"exclusions": [],
"key": "950001",
"tags": "SQL Injections, WASCTC, OWASP, A1, PCI, Recommended"
},

Using the key values from the output of the GET call above, you can accept one or more of the recommendations using the following operation passing an array of the keys:

- **AcceptRecommendations**

**Body:**

```json
[
  "981244",
  "950001"
]
```

### Protection Rule Specific Settings

Several protection rule settings are settings for specific protection rules.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Rule ID</th>
<th>Rule Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allowed HTTP Methods</td>
<td>911100</td>
<td>Restrict HTTP Request Methods</td>
</tr>
<tr>
<td>Max Total Argument Length</td>
<td>960341</td>
<td>Total Arguments Limits</td>
</tr>
<tr>
<td>Max Number of Arguments</td>
<td>960335</td>
<td>Number of Arguments Limits</td>
</tr>
<tr>
<td>Max Length of Argument</td>
<td>960208</td>
<td>Values Limits</td>
</tr>
</tbody>
</table>

The term "Arguments" refers to either query parameters or body parameters in a PUT/POST request. For instance, if the Max Number of Arguments is 2 and RuleID 960335 is set to BLOCK, any of the following requests would be blocked:

```text
GET /myapp/path?query=one&query=two&query=three
POST /myapp/path with Body {"arg1":"one","arg2":"two","arg3":"three"}
POST /myapp/path?query=one&query=two with Body {"arg1":"one"}
```

**Max Length of Argument** is the length of either a name or the value of the argument. **Total Argument Length** refers to the sum of the name and value length.

### Exclusions

Sometimes a protection rule can trigger a false positive. You can configure an exception if the request(s) generating the false positive have a particular argument or cookie that can be used to identify that request be excluded from the action normally taken on the rule. Exclusions have to be created through the API. The following exclusion parameters can be used:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQUEST_COOKIES</td>
<td>Cookie Value</td>
</tr>
<tr>
<td>REQUEST_COOKIES_NAMES</td>
<td>Cookie Name (value is irrelevant)</td>
</tr>
</tbody>
</table>
Web Application Firewall

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGXS</td>
<td>Argument (Query Parameter or POST/PUT data)</td>
</tr>
<tr>
<td>ARGXS_NAMES</td>
<td>Query Parameter Name (value is irrelevant)</td>
</tr>
</tbody>
</table>

**Example**

In this example, a block is applied to WAF Rule 911100 (Restrict HTTP Request Methods) with an exception to allow requests with an argument that contains “passthrough”.  

```
PUT / waasPolicies /<policy_ocid>/wafConfig/protectionRules
```

With the body:

```
[
  {
    "key":"911100",
    "action":"BLOCK",
    "exclusions":
    [
      {
        "target":"REQUEST_COOKIES",
        "exclusions":["yourcompany.com", "Wed, 21 Oct 2015 07:28:00 GMT", "12345", "219ffwef9w0f"]
      },
      {
        "target":"REQUEST_COOKIES_NAMES",
        "exclusions":["OAMAuthnCookie", "JSESSIONID", "HCM-PSJSESSIONID"]
      },
      {
        "target":"ARGS",
        "exclusions":["passthrough"]
      }
    ]
  }
]
```

This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

**Supported Protection Rules**

The Oracle Cloud Infrastructure WAF service supports many protection rule types. The following list provides a brief explanation of the purpose of each protection rule type.

**Protection Rules**

<table>
<thead>
<tr>
<th>Rule ID/Key</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>90001</td>
<td>Filter Profanity</td>
<td>Detects profanity used in request headers and body.</td>
</tr>
<tr>
<td>90002</td>
<td>United States Social Security Number Leakage</td>
<td>Detects leakage of US SSN in C3 body and headers.</td>
</tr>
<tr>
<td>90004</td>
<td>Executable file upload attempt</td>
<td>Detects attempts to upload executable files through input forms.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>90005</td>
<td>Brazilian Social Security Number (CPF) Leakage</td>
<td>Detects leakage of Brazilian CPF in response body and headers.</td>
</tr>
<tr>
<td>90006</td>
<td>Credit card leakage in request: GSA SmartPay</td>
<td>Detects GSA SmartPay credit card numbers in user input.</td>
</tr>
<tr>
<td>90007</td>
<td>Credit card leakage in request: MasterCard</td>
<td>Detects MasterCard credit card numbers in user input.</td>
</tr>
<tr>
<td>90008</td>
<td>Credit card leakage in request: Visa</td>
<td>Detects Visa credit card numbers in user input.</td>
</tr>
<tr>
<td>90009</td>
<td>Credit card leakage in request: American Express</td>
<td>Detects American Express credit card numbers in user input.</td>
</tr>
<tr>
<td>90010</td>
<td>Credit card leakage in request: Diners Club</td>
<td>Detects Diners Club credit card numbers in user input.</td>
</tr>
<tr>
<td>90011</td>

<td>Detects enRoute credit card numbers in user input.</td>
</tr>
<tr>
<td>90012</td>
<td>Credit card leakage in request: Discover</td>
<td>Detects Discover credit card numbers in user input.</td>
</tr>
<tr>
<td>90013</td>
<td>Credit card leakage in request: JCB</td>
<td>Detects JCB credit card numbers in user input.</td>
</tr>
<tr>
<td>90014</td>
<td>Credit card leakage in response: GSA SmartPay</td>
<td>Detects GSA SmartPay credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90015</td>
<td>Credit card leakage in response: MasterCard</td>
<td>Detects MasterCard credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90016</td>
<td>Credit card leakage in response: Visa</td>
<td>Detects Visa credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90017</td>
<td>Credit card leakage in response: American Express</td>
<td>Detects American Express credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90018</td>
<td>Credit card leakage in response: Diners Club</td>
<td>Detects Diners Club credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90019</td>
<td>Credit card leakage in response: enRoute</td>
<td>Detects enRoute credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90020</td>
<td>Credit card leakage in response: Discover</td>
<td>Detects Discover credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>90021</td>
<td>Credit card leakage in response: JCB</td>
<td>Detects JCB credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90022</td>
<td>Credit card Track 1 data leakage</td>
<td>Detects credit card track 1 data in the response body.</td>
</tr>
<tr>
<td>90023</td>
<td>Credit card Track 2 data leakage</td>
<td>Detects credit card track 2 data in the response body.</td>
</tr>
<tr>
<td>90024</td>
<td>Credit card PAN leakage</td>
<td>Detects credit card primary account number in the response body.</td>
</tr>
<tr>
<td>90025</td>
<td>visitorTracker_isMob malware detection</td>
<td>Detects and/or blocks visitorTracker_isMob malware.</td>
</tr>
<tr>
<td>120133</td>
<td>Canadian Social Identification Number (SIN) leakage</td>
<td>Detects leakage of Canadian SIN in response body and headers.</td>
</tr>
<tr>
<td>900032</td>
<td>HTTP Parameter Polution (HPP) detection</td>
<td>Rule Detects requests that have multiple arguments with the same name indicative of HPP attack.</td>
</tr>
<tr>
<td>911100</td>
<td>Restrict HTTP Request Methods</td>
<td>Allows only request methods specified by the configurable &quot;Allowed http methods&quot; parameter.</td>
</tr>
<tr>
<td>920021, 920022, 920023</td>
<td>Credit card PAN leakage</td>
<td>Detects credit card primary account number in the response body.</td>
</tr>
<tr>
<td>920100</td>
<td>Invalid HTTP Request Line</td>
<td>Invalid HTTP Request Line.</td>
</tr>
<tr>
<td>920120</td>
<td>File Name Validation</td>
<td>Detects multipart/form-data file name evasion attempts.</td>
</tr>
<tr>
<td>920160</td>
<td>Content-Length Header Validation</td>
<td>Detects if content-length HTTP header is not numeric.</td>
</tr>
<tr>
<td>920170</td>
<td>GET/HEAD Requests Validation</td>
<td>Detects if GET/HEAD requests contain request body by checking for content-length header, since it is not a common practice.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920171</td>
<td>GET/HEAD Requests Validation</td>
<td>Detects if GET/HEAD requests contain request body by checking for Transfer-Encoding header since it is not a common practice.</td>
</tr>
<tr>
<td>920180</td>
<td>Content-Length Header Validation</td>
<td>Detects if content-length and Transfer-Encoding headers are provided with every POST request.</td>
</tr>
<tr>
<td>920190</td>
<td>Range Header Validation</td>
<td>This rule inspects the Range request header to see if it starts with 0.</td>
</tr>
<tr>
<td>920200, 920201</td>
<td>Range Header Validation</td>
<td>Detects range header inconsistencies and invalid formatting.</td>
</tr>
<tr>
<td>920220, 920240</td>
<td>Check URL encodings</td>
<td>There are two different chained rules. We need to separate them as we are inspecting two different variables - REQUEST_URI and REQUEST_BODY. For REQUEST_BODY, we only want to run the @validateUrlEncoding operator if the content-type is application/x-www-form-urlencoded.</td>
</tr>
<tr>
<td>920230</td>
<td>Detect multiple url encoding</td>
<td>Detection of multiple url encodings.</td>
</tr>
<tr>
<td>920260</td>
<td>Disallow use of full-width unicode as decoding evasions may be possible.</td>
<td>This rule looks for full-width encoding by looking for %u followed by 2 'f' characters and then 2 hex characters. It is a vulnerability that affected IIS circa 2007.</td>
</tr>
<tr>
<td>920270</td>
<td>Restrict type of characters sent</td>
<td>This rule uses the @validateByteRange operator to restrict the request payloads.</td>
</tr>
<tr>
<td>920280</td>
<td>Missing/Empty Host Header</td>
<td>Missing/Empty Host Header.</td>
</tr>
<tr>
<td>920300</td>
<td>Missing Accept Header</td>
<td>Detection of missing accept header.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920310, 920311</td>
<td>Empty Accept Header</td>
<td>Checks if an Accept header exists, but has an empty value. Also detects an empty Accept header if there is no user agent.</td>
</tr>
<tr>
<td>920320</td>
<td>Missing User-Agent header</td>
<td>Detection of missing user-agent header.</td>
</tr>
<tr>
<td>920330</td>
<td>Empty User-Agent Header</td>
<td>Detects empty request user-agent header.</td>
</tr>
<tr>
<td>920350</td>
<td>Invalid HTTP Request Line</td>
<td>Invalid HTTP Request Line.</td>
</tr>
<tr>
<td>920360</td>
<td>Limit length of argument names</td>
<td>Detects HTTP requests argument name length exceeding the configurable &quot;Max length of argument name&quot; value.</td>
</tr>
<tr>
<td>920370</td>
<td>Limit argument value length</td>
<td>Detects HTTP requests argument values exceeding the configurable &quot;Max argument value length&quot; parameter.</td>
</tr>
<tr>
<td>920380</td>
<td>Number of Arguments Limits</td>
<td>Detects HTTP requests with number of arguments exceeding the configurable &quot;Max amount of arguments&quot; value.</td>
</tr>
<tr>
<td>920390</td>
<td>Limit arguments total length</td>
<td>Detects HTTP requests argument length exceeding the configurable &quot;Max argument length&quot; parameter.</td>
</tr>
<tr>
<td>920400</td>
<td>Limit file size</td>
<td>Limits the size of a file by checking Content-Length Header for a variable max_file_size.</td>
</tr>
<tr>
<td>920410</td>
<td>Limit combined file size</td>
<td>Limits the size of combined files by checking Content-Length Header for a variable combined_file_sizes.</td>
</tr>
<tr>
<td>920420</td>
<td>Check content-type header</td>
<td>Restrict Content Types by checking the variable allowed_request_content_type.</td>
</tr>
<tr>
<td>920430</td>
<td>Request protocol version</td>
<td>Restrict protocol versions by using the variable allowed_http_versions.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920440</td>
<td>Restriction by file extension</td>
<td>Restrict file extensions using the variable restricted_extensions.</td>
</tr>
<tr>
<td>920450</td>
<td>Restricted HTTP headers</td>
<td>The use of certain headers is restricted. They are listed in the variable restricted_headers.</td>
</tr>
<tr>
<td>920470</td>
<td>Restrict Content Type</td>
<td>Restrict Content Types by checking the content-type header.</td>
</tr>
<tr>
<td>920480</td>
<td>Charset restriction in content-type</td>
<td>Restrict charset in Content Types by checking the variable allowed_request_content_type_charset.</td>
</tr>
<tr>
<td>920500</td>
<td>Detect backup or working files</td>
<td>Detect backup or working files.</td>
</tr>
<tr>
<td>921110</td>
<td>HTTP Request Smuggling</td>
<td>Looks for CR/LF characters in combination with HTTP / WEBDAV.</td>
</tr>
<tr>
<td>921120, 921130</td>
<td>HTTP Response Splitting</td>
<td>Looks for CR/LF characters, may cause problems if the data is returned in a responses header and may be interpreted by an intermediary proxy server and treated as two separate responses.</td>
</tr>
<tr>
<td>921140</td>
<td>HTTP Header Injection</td>
<td>These rules look for Carriage Return (CR) %0d and Linefeed (LF) %0a characters, on their own or in combination with header field names. These characters may cause problems if the data is returned in a responses header and interpreted by the client.</td>
</tr>
<tr>
<td>921150, 921160</td>
<td>Argument Newline Detection</td>
<td>Detect newlines in argument names.</td>
</tr>
<tr>
<td>921151</td>
<td>Newline in GET Args</td>
<td>Detect newlines in GET arguments which may point to HTTP header injection attacks.</td>
</tr>
<tr>
<td>921190</td>
<td>HTTP Splitting</td>
<td>This rule detect \n or \r in the REQUEST FILENAME.</td>
</tr>
<tr>

<td>Session fixation</td>
<td>Session Fixation is an attack technique that forces a user's session ID to an explicit value. Depending on the functionality of the target web site, a number of techniques can be utilized to &quot;fix&quot; the session ID value. These techniques range from Cross-site Scripting exploits to peppering the web site with previously made HTTP requests. After a user's session ID has been fixed, the attacker will wait for that user to login. Once the user does so, the attacker uses the predefined session ID value to assume the same online identity.</td>

**Custom Protection Rules**

The WAF service allows you to define and apply custom protection rules from open source firewall modules to your WAF configurations, such as ModSecurity modules. This topic describes how to format, create, and implement custom protection rules in your WAF policies using the Console and WAAS API. For a list of protection rules already available in the service, see Supported Protection Rules on page 4081.

**Custom Protection Rule Syntax**

All custom protection rules are expressed in ModSecurity Rule Language. For more information about ModSecurity syntax, see Making Rules: The Basic Syntax.

Additionally, each rule must include two placeholder variables that are updated by the WAF service upon publication of the rule.

**id: {{id_1}}** - This field is updated with a unique rule ID generated by the WAF service which identifies a `SecRule`. More than one `SecRule` can be defined in the template field of a `CreateCustomProtectionRule` call. The value of the first `SecRule` must be `id: {{id_1}}` and the `id` field of each subsequent `SecRule` should increase by one, as shown in the example.

**ctl:ruleEngine={{mode}}** - The action to be taken when the criteria of the `SecRule` are met, either OFF, DETECT or BLOCK. This field is updated with the corresponding value of the `action` field of the `CustomProtectionRuleSetting` object when using the `UpdateWafConfig` operation.

**Example of a custom protection rule format:**

```
SecRule REQUEST.Cookies "regex matching SQL injection - part 1/2" "
```
Web Application Firewall

"phase:2,"  
msg:'Detects chained SQL injection attempts 1/2.',  
id: {{id_1}},  
ctl:ruleEngine={{mode}},  
deny"

SecRule REQUEST_COOKIES "regex matching SQL injection - part 2/2"  
"phase:2,"  
msg:'Detects chained SQL injection attempts 2/2.',  
id: {{id_2}},  
ctl:ruleEngine={{mode}},  
deny"

**Actions**

The WAF service can take an action on an HTTP request when the criteria of a custom protection rule are met.

- **DETECT** - Logs the request when the criteria of the custom protection are met.
- **BLOCK** - Blocks the request when the criteria of the custom protection rule are met.
- **OFF** - The custom protection rule is inactive and will take no action.

**Using the Console**

*To create a custom protection rule*

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Custom Protection Rules**.
3. Click **Create WAF Custom Protection Rule**.
4. In the Create a Custom Protection Rule dialog box, enter the following:
   - **Name**: A unique name for the protection rule. Avoid entering confidential information.
   - **Description**: Optional. A description of the custom protection rule.
   - **Template**: Enter the protection rule criteria in ModSecurity Rule Language. Each rule must include two placeholder variables: id: {{id_1}} and ctl:ruleEngine={{mode}}. For more information about ModSecurity syntax, see **Making Rules: The Basic Syntax**.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

*To edit a custom protection rule*

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Custom Protection Rules**.
3. Click the name of the custom protection rule you want to edit.
4. Click **Edit**.
5. Make the necessary changes and then click **Save Changes**.

*To manage tags for a custom protection rule*

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Custom Protection Rules**.
3. Click the name of the custom protection rule you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 211.
To move a custom protection rule to another compartment

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click Custom Protection Rules.
3. Find the protection rule in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To delete a custom protection rule

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click Custom Protection Rules.
3. Select the check box for the protection rule you want to delete.
4. Click Delete.
5. In the confirmation dialog box, click Delete.

To add a custom protection rule to a WAF policy

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Custom Rules tab.
5. Click Add from the Actions drop down menu.
6. In the Add Custom Rule dialog box, select a custom protection rule from the drop down menu. If the custom protection rule exists in another compartment, you can change the compartment where the rule exists.
7. Select one of the following actions to apply to the rule:
   • Detect: Matching requests generate an alert and the request is proxied.
   • Block: Matching requests are blocked.
8. Click Add.

To apply a new action to a custom protection rule in a WAF policy

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy where you want to edit a custom protection rule.
3. Click Protection Rules and then click the Custom Rules tab.
4. Select the check box for the custom rule you want to change the action for.
5. Select the action from the Actions drop down menu.

To delete a custom protection rule from a WAF policy

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy where you want to remove a custom protection rule. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Custom Rules tab.
5. Select the check box for the custom rule you want to delete.
6. Select delete from the Actions drop down menu.

Using the API

Custom protection rules can be created and added to a compartment using the CreateProtectionRule call in the WAAS API. Using ModSecurity Rule Language formatting, populate the template field with the criteria of the rule.
Example:

```json
{
  "compartmentId": "ocid1.compartment.region1..<unique_ID>",
  "description": "The description text for the rule being created",
  "displayName": "Custom Protection Rule Name",
  "template": "SecRule REQUEST_URI /""phase:2, t:none, capture, msg:'Custom (XSS) Attack. Matched Data: %{TX.0} found within %{MATCHED_VAR_NAME}: %{MATCHED_VAR}', id:{{id_1}}, ctl:ruleEngine={{mode}}, tag:'Custom', severity:'2'"
}
```

Adding Custom Protection Rules to a WAF Configuration

Custom protection rules can be added to a WAF configuration using the `UpdateWafConfig` call in the WAAS API. Add the OCID and the desired action to take to the `CustomProtectionRuleSetting` object of the `UpdateWafConfig` schema.

Example:

```json
[
  {
    "action": "BLOCK",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaalxd4jrws4rbbnddz1notu3giuzo53kobj747mbvarttr7vyy7ja",
  },
  {
    "action": "DETECT",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaamx5r72ntmmhwgeaspzpdqcwspuvwsa7xoshny03k"
  }
]
```

To view a list of available custom protection rules in a compartment and their corresponding OCIDs, use the `ListCustomProtectionRules` call in the WAAS API.

Access Control

Access Rules

As a WAF administrator you can define explicit actions for requests that meet various conditions. Conditions use various operations and regular expressions. A rule action can be set to log and allow, detect, block, redirect, bypass, or show a CAPTCHA for all matched requests.

The available conditions for an access rule are shown in the following table:
<table>
<thead>
<tr>
<th>Criteria Type</th>
<th>Criteria</th>
</tr>
</thead>
</table>
| **URL**      | Users shall be able to define one or more criteria based on:  
• URL is  
• URL is not  
• URL starts with  
• URL does not start with  
• URL part ends with  
• URL part does not end with  
• URL part contains  
• URL part does not contain  
• URL regex  
• URL does not match regex  
The URL regex matching uses Perl-compatible regular expressions. |
| **IP Address** | Users shall be able to define one or more criteria based on:  
• IP Address is  
• IP Address is not  
• IP Address in Address List  
• IP Address not in Address List  
These values can be a valid IPv4 address, subset, or CIDR notation for a range. IPv6 is not yet supported. See [To add an IP address list](#) to create a list of IP addresses that can be used in the access rule. |
| **Country/Region** | Users shall be able to define one or more criteria based on:  
• Country/Region is  
• Country/Region is not  
For the API, use a 2-letter country code. |
| **User Agent** | User Agent is a value that identifies the browser client.  
• User Agent is  
• User Agent is not |
| **HTTP Header** | HTTP Request headers can be evaluated as criteria:  
• HTTP Header contains  
The HTTP Header contains value should be entered with colon-delimited `<name>:<value>`.

| **HTTP Method** | HTTP Methods can be evaluated as criteria:  
• HTTP method is  
• HTTP method is not  
Available methods include GET, POST, PUT, DELETE, HEAD, CONNECT, OPTIONS, TRACE, and PATCH. |

**IP Address Whitelists**

You can use the IP Whitelist tab to manage whitelists containing trusted IP addresses that bypass all rules and challenges.
Using the Console

Note:
The WAF uses a first-match algorithm so that once an Access Rule criteria matches, it will stop evaluating future rules. The order of rules matters. Use the API to reorder rules.

To add an access rule
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click Access Control.
4. Click Add Access Rule.
5. In the Add Access Rule dialog box, enter the following:
   - **Name**: A unique name for the access rule. Avoid entering confidential information.
   - **Action**: Determines the response to a request when the rule is matched. Select one of the following options:
     - **Log and Allow**: A log will be created for all matched requests and no further action will be taken.
     - **Detect Only**: A detection alert will be created for all matched requests and no further action will be taken.
     - **Block**: All matched requests will be blocked and a browser page for the selected response code will be returned.
     - **Block Action**: Select the action that will be taken when a matching request is blocked.
     - **Block Response Code**: Select a response code that will be returned when the request has been blocked. The response code provides information indicating why the request was blocked. The default response code is 403 "Forbidden".
   - **Redirect**:
     - **Redirect Status Code**: The status code returned in response to redirect requests.
     - **Redirect URL**: The URL address to redirect the request to.
   - **Bypass**: Select the challenge(s) to bypass. If this section is not specified, all challenges are bypassed.
   - **Show CAPTCHA**: Select this option to show a CAPTCHA for all matched requests and take no further action. Enter the following:
     - **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
     - **CAPTCHA Header**: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
     - **CAPTCHA Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
     - **CAPTCHA submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
   - **Conditions**: Select the condition that must be met before the rule is matched and specify the details of the condition. Additional conditions can be added in this section.
   - **Header Manipulation(s)**:
     - **Action**: Select the action to apply to the request.
     - **Header Name**: Enter the HTTP header name of the request.
     - **Header Value**: Enter the HTTP header value of the request.
6. Click Add Access Rule. The access rule is added to the access rule list.

To edit an access rule
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click Access Control.
4. Select the check box for the access rule you want to update, and then click Edit.
5. In the Edit Access Rule dialog box, make the necessary updates and then click Save.

**To delete an access rule**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click Access Control.
4. Select the check box for the access rule you want to delete and then click Delete.

**To add an IP address list**

You can use an IP address list to group IP addresses and use the list to define the conditions for an access rule. An IP Address List can be used in multiple WAF policies.

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click IP Address Lists.
3. Click Create WAF IP Address List.
4. In the Create WAF IP Address List dialog box, enter the following:
   - **Name:** A user-friendly name for the IP address list. Avoid entering confidential information.
   - **IP Addresses:** Enter IP addresses or CIDR notations.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click Create.

**To edit an IP address list**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click IP Address Lists.
3. Click the name of the IP address list you want to update.
4. Click Edit.
5. In the Edit WAF IP Address List dialog box, update the Name or IP Addresses. Avoid entering confidential information.
6. Click Save Changes.

**To delete an IP address list**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click IP Address Lists.
3. Select the check box for the IP address list you want to delete.
4. Click Delete.
5. In the confirmation dialog box, click Delete.

**To move an IP address list to another compartment**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. In the List Scope section, select a compartment.
3. Click IP Address Lists.
4. Find the IP address list in the list, click the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
**To manage tags for an IP address list**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.  
2. Click **IP Address Lists**.  
3. Click the name of the IP address list you want to manage tags for.  
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 211.

**To add an IP address whitelist in a WAF policy**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.  
2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.  
3. Click **Access Control**.  
4. Select the **IP Whitelist** tab.  
5. Click **Add IP Address Whitelist**.  
6. In the Add IP Address Whitelist dialog box, enter the following:
   - **Whitelist Name**: A name for the IP addresses used in the list.  
   - **IP Addresses**: Select an IP address or enter an IP address and select it to add it. This field supports CIDR notation.  
7. Click **Add IP Address Whitelist**.

The IP Address Whitelist is added to the list of changes to be published.

**To edit an IP address whitelist in a WAF policy**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.  
2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.  
3. Click **Access Control**.  
4. Select the **IP Whitelist** tab.  
5. Select the check box for the IP Address Whitelist name you want to edit.  
6. Click **Edit**.  
7. In the Edit IP Address Whitelist dialog box, make the needed changes.  
8. Click **Save**.  

The IP Address Whitelist change is added to the list of changes to be published.

**To delete an IP address whitelist in a policy**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.  
2. Click the name of the WAF Policy you want to view alerts for. The WAF Policy overview appears.  
3. Click **Access Control**.  
4. Select the **IP Whitelist** tab.  
5. Select the check box for the IP Address Whitelist name you want to delete.  
6. Click **Delete**.  

The deleted IP Address Whitelist is added to the list of changes to be published.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.
1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Address Lists**

Use the following API operations to create and manage address lists that can be applied to access rules:

- CreateAddressList
- ListAddressLists
- GetAddressList
- UpdateAddressList
- DeleteAddressList

**Example**

To create an address list:

```json
POST /addressLists
{
   "addresses": [
      "198.51.100.0",
      "198.51.255.45",
      "198.51.145.55"
   ],
   "compartmentId": "ocid1.compartment.region1...",
   "displayName": "example IP addresses"
}
```

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

**Access Rules**

Use the following operations to get an array of all access rules in the policy:

- UpdateAccessRules
- ListAccessRules
- UpdateWhitelists
- ListWhitelists

**Example**
To create an access rule:

```
PUT /waasPolicies/{waasPolicyId}/wafConfig/accessRules

[
  {
    "name": "DetectRequestsToHealthCheck",
    "criteria": [
      {
        "condition": "URL_IS",
        "value": "/health/check"
      }
    ],
    "action": "DETECT",
  }
]
```

### Caching Rules

Caching rules allow you to selectively cache requested content on Oracle Cloud Infrastructure's edge servers, such as web pages or certain file types.

**Using the Console**

**To create a caching rule**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to add a caching rule. The WAF Policy overview appears.
3. Click Caching Rules.
4. Click Create Caching Rule.
5. In the Create Caching Rule dialog box, enter the following:
   - **Name**: A unique name for the access rule. Avoid entering confidential information.
   - **Caching Rule Action**: Select one of the following options:
     - **Cache**: Cache the requested content when criteria of the rule is met.
     - **Caching Duration**: The duration to cache content for the caching rule.
     - **Time Unit**: The unit of time for the caching duration.
     - **Enable Client Caching**: Select this check box to specify the duration to cache content in the user's browser.
     - **Bypass Cache**: Allow requests to bypass the cache and be directed to the origin when the criteria of the rule is met.
   - **Conditions**: Select the condition and URL address that must match for the action to be taken. At least one condition must match for the set action to be taken.
6. Click Create. The caching rule is added to the Caching Rules list.

**To edit a caching rule**

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF policy you want to edit the Caching Rules for. The WAF policy overview appears.
3. Click Caching Rules.
4. Select the check box for the caching rule you want to update.
5. Select Edit from the Actions drop down menu.
6. In the Edit Caching Rule dialog box, make the necessary updates.
7. Click Save Changes.

To delete a caching rule

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF policy where you want to delete a caching rule. The WAF policy overview appears.
3. Click Caching Rules.
4. Select the check box for the caching rule you want to delete.
5. Select Delete from the Actions drop down menu.
6. In the confirmation dialog box, click Delete.

To purge the cache

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy where you want to purge the cache. The WAF Policy overview appears.
3. Click Caching Rules.
4. Select Purge Cache from the Actions dropdown menu.
5. In the Purge Cache dialog box, select the condition and URL address to purge and click Purge.

Using the API

Use the following API operations to create and manage caching rules that can be applied to your WAF configurations:

- ListCachingRules
- UpdateCachingRules
- PurgeCache

Available Cache Rules Criteria

The criteria of the caching rule determines if the requested content should be cached.

- URL_IS - Matches if the concatenation of requested URL path and query is identical to the contents of the value field. For example, if this rule is set to cache the content of www.example.com/products, only HTTP requests for www.example.com/products will cache.
- URL_STARTS_WITH - Matches if the concatenation of requested URL path and query starts with the contents of the value field. For example, if this rule is set to cache content from www.example.com/products, all HTTP requests requesting URLs starting with www.example.com/products will be cached and subsequent requests will receive content from the cache, including requests for www.example.com/products/new-product and www.example.com/products/old-product.
- URL_PART_ENDS_WITH - Matches if the concatenation of requested URL path and query ends with the contents of the value field. For example, if the rule is set to cache content from URLs that end with /product.jpg, HTTP requests for the URLs www.example.com/products/new-product/product-banner.jpg and www.example.com/products/old-product/product-banner.jpg will be cached and subsequent requests will receive content from the cache.
- URL_PART_CONTAINS - Matches if the concatenation of requested URL path and query contains the contents of the value field. If the rule is set to cache content from URLs that contain /product-banner, HTTP requests for the URLs www.example.com/products/new-product/product-banner/blue.jpg and www.example.com/products/new-product/product-banner/red.jpg will be cached and subsequent requests will receive content from the cache.

Available Cache Rule Actions

A caching rule can be set to take one of two available actions when receiving a request:

- CACHE - Requests matching the criteria of the rule will be cached and subsequent requests will receive content from the cache.
- **BYPASS_CACHE** - Requests matching the criteria of the rule will bypass the cache and be directed to the origin.

### Cache Duration

Content can be cached for a specified period of time on Oracle Cloud Infrastructure's edge servers or cached locally by the client. The duration is set in the `cachingDuration` and `clientCachingDuration` fields, in ISO 8601 extended format.

#### Example of a Caching Rule

```json
[
  {
    "action": "CACHE",
    "cachingDuration": "PT20M",
    "clientCachingDuration": "PT20M",
    "criteria": [
      {
        "condition": "URL_IS",
        "value": "/path/to-cache"
      }
    ],
    "isClientCachingEnabled": true,
    "name": "Caching Rule 1"
  },
  {
    "action": "BYPASS_CACHE",
    "criteria": [
      {
        "condition": "URL_PART_ENDS_WITH",
        "value": "urp-part-not-to-cache"
      }
    ],
    "isClientCachingEnabled": false,
    "name": "Do not cache"
  }
]
```

### Best Practices

The order the caching rules is specified in are important. The rules are processed in the order they are specified in and the first matching rule will be used when processing a request. It is best to add rules that bypass cache to the top of the order and caching rules below any bypass rules.

### Purge Caches

Caches can be purged using the `PurgeCache` operation. Caches can either be selectively purged by specifying the URL path of a resource or all caches can be purged for the WAF by not specifying any resources to pass to the API.

#### Examples

Purge the cache for specified resources:

```json
{
  "resources": [
    "/path/to-purge",
    "/multiple-paths"
  ]
}
```
## Threat Intelligence

WAF has several sources of known IP address threats that are updated daily. The IP address threats are displayed in the following table:

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABUSE\ch</td>
<td>Blocklist of &quot;bad&quot; SSL certificates identified by abuse.ch to be associated with malware or botnet activities.</td>
</tr>
<tr>
<td>Bambenek Consulting</td>
<td>Active and non-sinkholed Command &amp; Control (C&amp;C) IP addresses.</td>
</tr>
<tr>
<td>BlockList.de</td>
<td>Includes IP addresses for hosting phishing sites and other kinds of fraud activities such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>BruteForceBlocker Project</td>
<td>Feed of known IP addresses from blocked SSH brute force attacks.</td>
</tr>
<tr>
<td>Proofpoint ET Labs</td>
<td>IP addresses involved in suspicious and malicious activity.</td>
</tr>
<tr>
<td>Feodo IP Blocklist</td>
<td>IP addresses used as C&amp;C communication channel by the Feodo Trojan.</td>
</tr>
<tr>
<td>Palevo</td>
<td>IP addresses which are being used as botnet C&amp;C for the Palevo crimeware.</td>
</tr>
<tr>
<td>Webroot BotNets</td>
<td>Botnet C&amp;C channels and infected zombie machine controlled by Bot master.</td>
</tr>
<tr>
<td>Webroot Denial of Service</td>
<td>Includes DOS, DDOS, anomalous sync flood, and anomalous traffic detection.</td>
</tr>
<tr>
<td>Webroot Mobile Threats</td>
<td>IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research tea.</td>
</tr>
<tr>
<td>Webroot Phishing</td>
<td>IP addresses hosting phishing sites and other kinds of illicit activities such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>Webroot Proxy</td>
<td>IP addresses providing proxy and def services.</td>
</tr>
<tr>
<td>Webroot Reputation</td>
<td>IP addresses currently known to be infected with malware. This category also includes IP addresses with an average low Webroot Reputation Index score.</td>
</tr>
<tr>
<td>Webroot Scanners</td>
<td>Includes all reconnaissance such as probes, host scan, domain scan and password brute force attacks.</td>
</tr>
<tr>
<td>Webroot Spam Sources</td>
<td>Includes tunneling spam messages through proxy, anomalous SMTP activities, and forum spam activities.</td>
</tr>
<tr>
<td>Webroot Tor Proxy</td>
<td>Includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator’s intended destination.</td>
</tr>
</tbody>
</table>
### Using the CLI

You can use the CLI to enable threat intelligence sources to block.

Open a command prompt and run the following command to list the keys for all of the threat intelligence:

```
oci waas threat-feed list --waas-policy-id <policy_ocid>
```

Then parse the keys to block and add them to the JSON:

```
oci waas threat-feed update --threat-feeds 
'[{"key":"<key_id>"","action":"BLOCK"}]' --waas-policy-id <policy_ocid>
```

For example:

```
oci waas threat-feed update --threat-feeds 
'[{"key":"0998d237-bce8-4612-82c8-a1ca126c0492","action":"BLOCK"}]' --waas-policy-id ocidi.waaspolicy.oc1..aaaaaaaapfa5zrwnns75kru7mrlzkkmcdevp7w55ld3phjxtgl4s2phuepjq
```

### Using the API

Enabling Threat Intelligence can only be performed by using the API at this time.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To return a set of keys for the threat intelligence:

- **ListThreatFeeds**

```json
{
  "8d3f7f1b-673f-4e3a-ba49-08226f385df3": "OFF",
  "0ff7b308-6afe-4b83-91e0-e3ca04afed6e": "OFF",
  "ea5d7c67-1326-43c9-ac31-1df034b9c063": "OFF",
  "87b420ca-5fbb-4ad4-aeba-1b02a9e60b30": "OFF",
  "2168fc70-2d05-466a-9db5-c13c0e32177d": "OFF",
  "7d080a4a-58ce-4370-a02c-f600b3a84e7b": "OFF",
  "a36c7c50-e99e-4b84-9140-5653fc68ce8d": "OFF",
  "5de7bbec-313f-4995-9810-f6f77cfd30c9": "OFF",
  "fd2152cc-14f5-4471-a58b-d94cc8a61444": "OFF",
  "cfac3d33-65d9-4368-93e0-62e906e7a748": "OFF",
  "6eb86368-01ea-4e94-ac1b-49bf0e551443": "OFF",
  "aabb459d-0745-481d-9568-58edad217e1": "OFF",
  "3805ecc2-16d6-428b-a03e-2a0fe77fd46f": "OFF",
  "c3452861-4910-4f3a-9872-22cf92d424eb": "OFF",
  "4cf31deb-11af-460e-a46a-ecc1946a6688": "OFF",
}
```

**Note:**

Do not use the keys in the example below, as keys are unique across each policy.
To set all threats to DETECT:

- UpdateThreatFeeds

With body:

```
[  
  {"action":"DETECT","key":"8d3f7f1b-673f-4e3a-ba49-08226f385df3"},  
  {"action":"DETECT","key":"0ff7b308-9e83-9e0-e3ca0af6e6"},  
  {"action":"DETECT","key":"ea5d7c67-1326-43c9-ac31-1df034b9c063"},  
  {"action":"DETECT","key":"87b420ca-8fbb-4f04-a2a1-1b02aeb9ac3e"},  
  {"action":"DETECT","key":"2168fc70-2d05-466a-9db5-c13c0e32177d"},  
  {"action":"DETECT","key":"7d080a4a-58ce-4370-a02c-f60b3ab84e7b"},  
  {"action":"DETECT","key":"a36c7c50-e99e-4b84-9140-5653fc68ce8d"},  
  {"action":"DETECT","key":"5de7bbcc-313f-4995-9810-f6f77cfd30c9"},  
  {"action":"DETECT","key":"fd2152cc-14f5-4471-a98b-d94cc8a6144"},  
  {"action":"DETECT","key":"cfac3d3-659-4368-930-0290607748"},  
  {"action":"DETECT","key":"6eb86368-01e-4e9-4c1b-49bf0554443"},  
  {"action":"DETECT","key":"aabb450d-075-481d-958f-58edca217e1e"},  
  {"action":"DETECT","key":"3805ecc2-16d2-428b-a03e-20fe77fed46f"},  
  {"action":"DETECT","key":"d9cfe533-550-427d-830ea612f535c1f"},  
  {"action":"DETECT","key":"c3452861-4901-4f3-987-22cf92d242"},  
  {"action":"DETECT","key":"efc31deeb-11af-460-a-4a-ecc1946a6688"},  
  {"action":"DETECT","key":"eff34d63-6235-4081-976-acd39248bd3"},  
  {"action":"DETECT","key":"1d1c94d9-08b-4eb4cad4-fb422e184f"},  
  {"action":"DETECT","key":"687b5ff4-f1b6-4d12-8da3ea90b456a1"},  
  {"action":"DETECT","key":"65cf274d-991-41f8-7adda-6fe60ba2704f"}  
]
```

This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

**Certificates**

To use SSL with your WAF policy, you must add a certificate bundle. The certificate bundle you upload includes the public certificate and the corresponding private key. Self-signed certificates can be used for the internal communication within Oracle Cloud Infrastructure.

**Working with SSL Certificates**

Oracle Cloud Infrastructure accepts third-party and self-signed certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

**Obtaining Third-Party SSL Certificates**

You can purchase an SSL certificate from a trusted Certificate Authority such as Symantec, Thawte, RapidSSL, or GeoTrust. The certificate issuer will provide an SSL certificate that includes a certificate, intermediate certificate, and private key. Use this information, including the intermediate certificate, when adding an SSL certificate to Oracle Cloud Infrastructure.
Web Application Firewall

Converting to PEM format
If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format.

Uploading Certificate Chains
If you have multiple certificates that form a single certification chain, you must include all relevant certificates in one file before you upload them to the system. The following example of a certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Submitting Private Keys
If your private key submission returns an error, the most common reasons are your private key is malformed or the system does not recognize the encryption method used for your key.

Private key consistency
If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```
openssl rsa -check -in <private_key>.pem
```
This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

Decrypting a private key
If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

Using the Console
To create a WAF certificate
1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click Certificates.
3. Click Create WAF Certificate.
4. In the Create WAF Certificate dialog box, enter the following:
   - Name: A unique name for the certificate. Avoid entering confidential information.
   - SSL Certificate: Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```
• **Private Key:** Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

```
-----BEGIN PRIVATE KEY-----
<Base64_encoded_private_key>
-----END PRIVATE KEY-----
```

• **Self Signed Certificate:** Enable this field when using a self-signed certificate to show an SSL warning in the browser.

• **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

**To delete a WAF certificate**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Certificates**.
3. Select the check box for the certificate you want to delete.
4. Click **Delete**.
5. In the confirmation dialog box, click **Delete**.

**To edit the name of a WAF certificate**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Certificates**.
3. Click the name of the certificate you want to edit.
4. Click **Edit**.
5. In the Edit WAF Certificate dialog box, update the **Name** field. Avoid entering confidential information.
6. Click **Save Changes**.

**To manage tags for a WAF certificate**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. Click **Certificates**.
3. Click the name of the WAF certificate you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see Resource Tags on page 211.

**To move a WAF certificate to a different compartment**

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **Web Application Firewall**.
2. In the **List Scope** section, select a compartment.
3. Click **Certificates**.
4. Find the WAF certificate in the list, click the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.
To add a certificate to a WAF policy

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy where you want to view certificate settings. The WAF Policy overview appears.
3. Click Settings.
4. Click General Settings.
5. Click Edit.
6. In the Edit Settings dialog box, enter the following:
   - **Enable HTTPS Support**: Click this check box to enable all communications between the browser and web app to be encrypted.
   - **Certificate Source**: Choose one of the following methods:
     - **Choose Certificate**: Select an existing certificate from the drop down menu. Click Change Compartment to select a certificate from another compartment.
     - **Upload or Paste Certificate and Private Key**: Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:
       
       ```plaintext
       -----BEGIN CERTIFICATE-----
       <Base64_encoded_certificate>
       -----END CERTIFICATE-----
       -----BEGIN CERTIFICATE-----
       <Intermediate_Base64_encoded_certificate>
       -----END CERTIFICATE-----
       
       -----BEGIN PRIVATE KEY-----
       <Base64_encoded_private_key>
       -----END PRIVATE KEY-----
       ```
     - **Self Signed Certificate**: Enable this field when using a self-signed certificate to show an SSL warning in the browser.
     - **HTTP to HTTPS Redirect**: When enabled, all HTTP traffic is automatically redirected to HTTPS.
     - **TLS Protocols Support**: Select a TLS protocol from the drop down list.
       ```plaintext
       Caution:
       TLS versions 1 and 1.1 have been deprecated and cannot be used in policy configurations. If you use these versions, a validation error might occur. Use versions 1.2 or 1.3 instead.
       ```
     - **Enable SNI**: Server Name Indication (SNI) is an extension of the TLS protocol, which allows multiple secure hostnames to be served from a single IP address.
     - **Advanced Options**
       - **Enable Response Buffering**: Enable or disable buffering of the response from the origin.
       - **Cache Control Respected**: Enable or disable automatic content caching based on the response cache-control header.
       - **Behind CDN**: Enable this to allow the collection of IP addresses from the client request if WAF is connected to a CDN.
7. Click Save Changes.
To edit a certificate in a WAF policy

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy where you want to view certificate settings. The WAF Policy overview appears.
3. Click Settings.
4. Click General Settings.
5. Click Edit.
6. In the Edit Settings dialog box, make the necessary updates to the certificate.
7. Click Save Changes.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

- CreateCertificate
- GetCertificate
- DeleteCertificate

Logs

Logs displays log activity and the details of each logged event within a specified time frame. Logs enable you to understand what rules and countermeasures are triggered by requests and are used as a basis to move request handling into block mode. Logs can come from Access Control, Protection Rules, or Bot events.

Note:
If you have concerns over General Data Protection Regulation (GDPR) requirements, Logs can be disabled for the WAF service. You can use My Oracle Support to file a service request to disable Logs.

Using the Console

To view Logs

1. Open the navigation menu. Under Governance and Administration, go to Security and click Web Application Firewall.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click Logs. Logs for the WAF policy appear.
4. To help find a log, you can use the following filter options:
   • To view alerting activity data for a specific time range, enter a **Start Date**, **Start Time**, **End Date**, or **End Time**.
   • To view logs for a URL, enter a **Request URL**.
   • To view logs for a client IP address, select an address from the **Client IP Address** drop-down menu.
   • To view logs for a country, select a country from the **Country Name** drop-down list.
   • To find a type of action, select an **Action** check box.
   • To find a type of log, select a **Log Type** check box from the following options:
     • Access Rules
     • CAPTCHA Challenge
     • JavaScript Challenge
     • Protection Rules
     • Human Interaction Challenge
     • Device Fingerprinting Challenge
     • Threat Intelligence Feeds
     • Address Rate Limiting
     • Access

5. Click the plus sign next to the Alert Type you want to view.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use the **ListWafLogs** API operation to display log activity. You can use filters to help find a log.

**Example**

You can filter logs by the following logType:

- **ACCESS_RULES**
- **CAPTCHA_CHALLENGE**
- **JAVASCRIPT_CHALLENGE**
- **PROTECTION_RULES**
- **HUMAN_INTERACTION_CHALLENGE**
- **DEVICE_FINGERPRINT_CHALLENGE**
- **THREAT_INTELLIGENCE_FEEDS**
- **ADDRESS_RATE_LIMITING**
- **ACCESS**

Logs can be filtered by logType by making the following request:

```
GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?logType=\langle logType \rangle &timeObservedGreaterThanOrEqualTo=\langle timestamp \rangle &timeObservedLessThan=\langle timestamp \rangle &compartmentId=ocid1.compartment.oc1.....
```

For example:

```
GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?logType=PROTECTION_RULES&timeObservedGreaterThanOrEqualTo=2019-10-24T13:00:00+00:00&timeObservedLessThan=2019-10-24T13:47:00+00:00&compartmentId=ocid1.compartment.oc1.
```

The following response output for the filtered logs is returned:

```

"requestUrl": "/?abc=cmd.exe",
"userAgent": "curl/7.54.0"}
Example

Logs can be filtered by clientAddress and time range by making the following request:

GET /20181116/waasPolicies/<unique_ID>/wafLogs?clientAddresss=<IP address>&timeObservedGreaterThanOrEqualTo=<timestamp>&timeObservedLessThan=<timestamp>&compartmentId=<unique_ID>

For example:

GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?clientAddresss=192.0.2.0&timeObservedGreaterThanOrEqualTo=2019-10-24T13:26:47+00:00&timeObservedLessThan=2019-10-24T13:26:56+00:00&compartmentId=ocid1.compartment.oc1..

The following response output for the filtered logs is returned:

```json
[
  {
    "clientAddress": "192.0.2.0",
    "countryName": "Unknown",
    "domain": "example.com",
    "fingerprint": "-",

WAF Metrics

You can monitor the health, capacity, and performance of your WAF policies by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_waf` (the WAF service).

Overview of the WAF Service Metrics

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based global security service that protects applications from malicious and unwanted internet traffic. The WAF service metrics help you measure various levels of traffic encountering your WAF policies, including non-malicious traffic. For more information, see Overview of the Web Application Firewall Service.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

- Permissions are required to allow monitoring, alarm, and notification (ONS) definition for users in a group for all compartments. The following policies must be configured in the root compartment:

```plaintext
Allow group <WAFMonitors> to read metrics in compartment <CompartmentName>

Allow group <WAFMonitors> to manage alarms in compartment <CompartmentName>

Allow group <WAFmonitors> to manage ons-family in compartment <CompartmentName>
```

Available Metrics: oci_waf

The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have the policy properly set up with web traffic passing through it to make the `oci_waf` metric space available in the Metrics Explorer feature. Policies with no web traffic emit no metric data.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Number of Requests</strong></td>
<td></td>
<td>count</td>
<td>The total number of requests serviced by the WAF.</td>
</tr>
<tr>
<td><strong>Traffic</strong></td>
<td></td>
<td>byte</td>
<td>Data egress from the WAF (compressed by default) measured in one minute intervals.</td>
</tr>
<tr>
<td><strong>Bandwidth</strong></td>
<td></td>
<td>B/s</td>
<td>Bandwidth rate calculated by dividing total data egress in a minute by 60.</td>
</tr>
<tr>
<td><strong>NumberOfRequestsDetected</strong></td>
<td></td>
<td>count</td>
<td>The number of requests that triggered a detect (alert) for a WAF policy.</td>
</tr>
</tbody>
</table>

**Available Dimensions**

The following dimensions are available for WAF metrics:
Multiple dimensions can be combined and aggregated to form ad-hoc subset reports of telemetry.

**Using the Console**

WAF service metrics are currently only available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

Any metric/dimension combination can be used as criteria for alarms. Alarms can leverage Oracle Notification Service for alerting through communication mechanisms like email and pagerduty.

**To view WAF metric charts**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. For Metric Namespace, select oci_waf.
3. Select a metric to view from the Metric Name field.
4. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId specified in the metric definition for NumberOfRequests.
5. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.
6. Click Update Chart.

The chart will be updated with the metrics that have been requested. You can hover over the line graphs to see a breakdown of the dimensions for data displayed.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.
Using the API

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

Layer 7 DDoS Mitigation

**Distributed Denial of Service (DDoS) Overview**

A DDoS attack is an often intentional attack that consumes an entity’s resources, usually using a large number of distributed sources. DDoS can be categorized into either Layer 7 or Layer 3/4 (L3/4), as defined by the Open Systems Interconnection (OSI) model. L3/4 DDoS attacks are DDoS attacks that occur at lower levels of the OSI stack than layer 7. Examples of such attacks include UDP, CharGen, and NTP Floods. L3/4 DDoS mitigation is inherently provided by Oracle Cloud Infrastructure.

A layer 7 DDoS attack is a DDoS attack that sends HTTP/S traffic to consume resources and hamper a website’s ability to delivery content or to harm the owner of the site. The Web Application Firewall (WAF) service can protect layer 7 HTTP-based resources from layer 7 DDoS and other web application attack vectors.

Layer 7 DDoS Mitigation Services

Oracle provides a Layer 7 DDoS Mitigation service to help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists are trained members of our Cloud Customer Support team who help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists help onboard you to WAF if you are not already using it. They must be granted access to your account to make changes to the WAF policy on your behalf. A DDoS attack report is generated after mitigation is complete. The report describes the type and parameters of the attack and what actions were taken to mitigate the attack. At the conclusion of the DDoS mitigation effort of a layer 7 DDoS attack, you may seek to receive credits for services that incurred additional Cloud Service fees. Details of this claim is available in the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Requesting Help

It is your responsibility to report an attack through My Oracle Support. You can use monitoring and alarm definitions based on telemetry to receive notifications of thresholds exceeded. For more information about setting up alarms, see Managing Alarms on page 2719. All changes will be audited in the Audit service.

To request help, go to My Oracle Support and select the WAF product and then DDoS. You will be invited to a web conference where you will interact with a DDoS Mitigation Specialist to review the issue. At this time, you can also participate in the WAF on-boarding and tuning process.

Required IAM Service Policy

In order for the Mitigation Specialist to manage rules to block the attack, you must provision an IAM user account with permissions.

To create an account with the correct permissions:

1. Create a user with the email address of the Mitigation Specialist. See Managing Users on page 2414.
2. Create a group named "SOCMember". See Managing Groups on page 2419.
3. Assign the user to the new group.
4. Grant group access to WAF, audit, and metrics in the compartment where the WAF policy resides.

Policy example:

- To allow the SOCMember group to manage WAF:

  ```
  Allow group SOCMember to manage waas-family in compartment <CompartmentName>
  ```
To allow the SOCMember group to read audit events:

Allow group SOCMember to read audit-events in compartment <CompartmentName>

To allow the SOCMember group to read metrics:

Allow group SOCMember to read metrics in compartment <CompartmentName>

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service on page 2353.

The following scripts in the SDK for Python on page 4242 enable you to provision an IAM user account with the correct permissions.

- add_soc_user.py
- add_soc_group_policy.py

**Python script example:**

```bash
code python add_soc_user.py -c ~/.oci/config  -u 'ddos.mitigation.specialist@oracle.com' -g DDoSMitigationGroup -f ~/.oci/ddos_public_key.pem
```

Where:

- `-c` is the tenancy configuration file
- `-u` is the username to be created
- `-g` is the group name to be created
- `-f` is the path to the public certificate to be attached to the user in PEM format

Debug options:

- `-h` shows help
- `-d` turns on debug mode

```bash
code python add_soc_group_policy.py -c ~/.oci/config -g DDoSMitigationGroup -o ocid1.compartment.oc1..<unique_ID>
```

Where:

- `-c` is the tenancy configuration file
- `-g` is the existing group name to be used in IAM policy
- `-o` is the compartment of the WAF policy and where the IAM policy will be created

**DDoS Attack Report**

A DDoS attack report will be sent to you within a few days of the attack. The report contains metrics on the resources consumed by the attack and include all WAF policy changes made during the mitigation effort. This report is used by Oracle Cloud Infrastructure to review what possible service credits are available.

**Price Insurance Program**

You may be eligible for credits due to excessive consumption due to a DDoS attack. Refer to the Oracle PaaS and IaaS Public Cloud Services Pillar documentation for details. Contact your customer success manager for details on how to apply for credits.

**Monitoring**

For future monitoring, you can create an alarm definition in the Monitoring service that will alert you of high activity levels of HTTP traffic that could indicate another layer 7 DDoS attack. For more information, see Managing Alarms
Oracle Cloud Infrastructure automatically scrubs layer 3 and 4 attacks. If you suspect malicious activity that is not being properly remediated, go to My Oracle Support to open a service request to report your concerns.

**HTTP WAF Headers**

HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with X-, are common. The WAF service adds or modifies the following headers when it passes the requests to your servers or the response to the end users.

**X-Client-IP**

Contains the remote user IP address. If the webapp is using a CDN and has the feature "behind cdn" enabled, this IP is taken from one of the configured headers. While forwarding the request to the origin, WAF adds X-Client-IP.

**X-Country-Code**

Contains the geo location country code where the user's IP belongs to. While forwarding the request to the origin, WAF adds X-Country-Code.

**Zen-Host: ZENEDGE**

Identifies that the request was analyzed by a WAF node. While forwarding the request to the origin, WAF adds Zen-Host: ZENEDGE.

**Request-Id**

Identifies the request in the logs. While forwarding the request to the origin, WAF adds Request-Id.

**Connection**

If there is not a defined Connection value previously established (for example, "Upgrade" or "WebSocket"), WAF clears the Connection header by default. This header can be modified based on the available connection pool to "close" or "keep-alive". While forwarding the request to the origin, WAF modifies, adds, or removes Connection.

**Accept-Encoding**

In this header, WAF clears Accept-Encoding with an empty string. This means the header is not passed to the origin side as it comes from the user side. This header can be removed, based on WAF settings on response body inspection and caching. While forwarding the request to the origin, WAF modifies or adds or removes Accept-Encoding.

**X-Cdn: Served-By-Zenedge**

Our platform injects this header to say that we are handling the connection. While forwarding the response to the client, WAF adds X-Cdn: Served-By-Zenedge.

**X-Zen-Fury**

This header identifies the WAF node which processed the request via an encrypted token. While forwarding the response to the client, WAF adds X-Zen-Fury.

**X-Cache-Status**

WAF can act as a cache server. Based on the configuration, WAF can respect Cache-Control headers or cache based on the caching configuration rules. The status of the cache is reported via the X-Cache-Status response header. The value of the header can be one of the standard values: MISS, BYPASS, EXPIRED, STALE, UPDATING, REVALIDATED, or HIT. In addition, for never cache rules, a non-standard NOTCACHED value will be set.
Cache-Control

This header can be modified based on various user caching and Bot Management configurations. While forwarding the response to the client, WAF modifies or adds Cache-Control.
Chapter 42

Developer Tools

This chapter includes general information about using the Oracle Cloud Infrastructure REST API and developer tools.

Developer Resources

This section provides reference documentation and tutorials for building applications that leverage Oracle Cloud Infrastructure.

- Developer Guide on page 4178
- Developer Tutorials

Developer Guide

Welcome to the Oracle Cloud Infrastructure Developer Guide.

This guide is intended to be a one-stop source for anyone interested in developing applications that leverage Oracle Cloud Infrastructure resources.

What's In This Guide

Here's an overview of what's in this guide:

- Introduction and overview (you are here)
- Quick-start walkthroughs that let you try out some of the SDKs using Cloud Shell
- How to setup SSH keys and configure the SDKs
- Working with Cloud Shell
- Working with the Command Line Interface (CLI)
- SDK references
- DevOps Tools and Plug-ins
- Other Tools
- Appendix and API Reference

Overview

Oracle Cloud Infrastructure provides kits, tools, and plug-ins to facilitate the development of apps and simplify the management of infrastructure.

- Cloud Shell Cloud Shell is a free-to-use browser-based terminal accessible from the Oracle Cloud Console that provides access to a Linux shell with pre-authenticated Oracle Cloud Infrastructure CLI and other useful developer tools. You can use the shell to interact with OCI resources, follow labs and tutorials, and quickly run OCI CLI commands.
- Command Line Interface (CLI) on page 4192 The CLI is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend the Console's functionality.
• **Software Development Kits and Command Line Interface** on page 4225 Oracle Cloud Infrastructure provides Software Development Kits (SDKs) to enable the development of apps and custom solutions.

• **Other Tools** on page 4347 These tools can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery. Tools include Terraform Provider used with Resource Manager.

• **Appendix and Reference** on page 4368 This general reference shows how to configure the SDKs and other developer tools to integrate with Oracle Cloud Infrastructure services.

• **REST APIs** on page 4368 This complete reference provides details on the Oracle Cloud Infrastructure REST APIs, including descriptions, syntax, endpoints, errors, and signatures.

**Setup and Prerequisites**

This section covers how to set up the required SSH keys to work with the OCI SDKs and developer toolkits as well as how to configure your SDKs.

What's included:

• **Required Keys and OCIDs** on page 4179

• **SDK and CLI Configuration File** on page 4184

**Required Keys and OCIDs**

Whether you're using an Oracle client (see **Software Development Kits and Command Line Interface** on page 4225) or a client you built yourself, you need to do the following:

1. Create a user in IAM for the person or system who will be calling the API, and put that user in at least one IAM group with any desired permissions. See "Adding Users" in the **Oracle Cloud Infrastructure Getting Started Guide**. You can skip this if the user exists already.

2. Get these items:
   - RSA key pair in **PEM format** (minimum 2048 bits). See **How to Generate an API Signing Key** on page 4180.
   - Fingerprint of the public key. See **How to Get the Key's Fingerprint** on page 4183.
   - Tenancy's OCID and user's OCID. See **Where to Get the Tenancy's OCID and User's OCID** on page 4184.

3. Upload the public key from the key pair in the Console. See **How to Upload the Public Key** on page 4184.

4. If you're using one of the Oracle SDKs or tools, supply the required credentials listed above in either a configuration file or a config object in the code. See **SDK and CLI Configuration File** on page 4184. If you're instead building your own client, see **Request Signatures** on page 4383.

**Important:**

This key pair is **not** the SSH key that you use to access compute instances. See **Security Credentials** on page 179.

Both the private key and public key must be in PEM format (not SSH-RSA format). The public key in PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBiANBgkqhkiG9w0BAQE...
...
-----END PUBLIC KEY-----
```
How to Generate an API Signing Key

Note:
You can use the Console or command line tools available for Linux, Mac OS or Windows to generate an API signing key.

Generating an API Signing Key (Console)

You can use the Console to generate the private/public key pair for you. If you already have a key pair, you can choose to upload the public key. When you use the Console to add the key pair, the Console also generates a configuration file preview snippet for you.

The following procedures work for a regular user or an administrator. Administrators can manage API keys for either another user or themselves.

About the Config File Snippet

When you use the Console to add the API signing key pair, a configuration file preview snippet is generated with the following information:

- **user** - the OCID of the user for whom the key pair is being added.
- **fingerprint** - the fingerprint of the key that was just added.
- **tenancy** - your tenancy's OCID.
- **region** - the currently selected region in the Console.
- **key_file** - the path to your downloaded private key file. You must update this value to the path on your file system where you saved the private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

You can copy this snippet into your config file, to help you get started. If you don't already have a config file, see SDK and CLI Configuration File on page 4184 for details on how to create one. You can also retrieve the config file snippet later for an API signing key whenever you need it. See: To get the config file snippet for an API signing key.

To generate an API signing key pair

**Prerequisite:** Before you generate a key pair, create the .oci directory in your home directory to store the credentials. See SDK and CLI Configuration File on page 4184 for more details.

1. View the user's details:

   - If you're adding an API key for **yourself**:
     
     Open the **Profile** menu and click **User Settings**.
     
     - If you're an administrator adding an API key for **another user**: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select **Generate API Key Pair**.

4. Click **Download Private Key** and save the key to your .oci directory. In most cases, you do not need to download the public key.

   **Note:** If your browser downloads the private key to a different directory, be sure to move it to your .oci directory.

5. Click **Add**.

   The key is added and the **Configuration File Preview** is displayed. The file snippet includes required parameters and values you’ll need to create your configuration file. Copy and paste the configuration file snippet from the text...
box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 4184 for details on how to create one.)

After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

6. Update the permissions on your downloaded private key file so that only you can view it:

a. Go to the .oci directory where you placed the private key file.

b. Use the command chmod go-rwx ~/.oci/<oci_api_keyfile>.pem to set the permissions on the file.

To upload or paste an API key

**Prerequisite:** You have generated a public **RSA key in PEM format (minimum 2048 bits).** The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY-----
```

1. View the user's details:

   - If you're adding an API key for **yourself:**
     
     Open the Profile menu and click User Settings.
   
   - If you're an administrator adding an API key for **another user:** Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select **Choose Public Key File** to upload your file, or **Paste Public Key**, if you prefer to paste it into a text box.

4. Click **Add**.

   The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 4184 for details on how to create one.)

   After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:

   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

**To get the config file snippet for an API signing key**

The following procedure works for a regular user or an administrator.
1. View the user's details:
   - If you're getting an API key config file snippet for yourself:
     Open the **Profile** menu (Profile) and click **User Settings**.
   - If you're an administrator getting an API key config file snippet for another user: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **API Keys**. The list of API key fingerprints is displayed.

3. Click the the Actions icon (three dots) for the fingerprint, and select **View configuration file**.

   The **Configuration File Preview** is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config` file. (If you have not yet created this file, see [SDK and CLI Configuration File](#) on page 4184 for details on how to create one.) After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:
   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

Generating an API Signing Key (Linux and Mac OS X)

Use the following **OpenSSL** commands to generate the key pair in the required PEM format.

1. If you haven't already, create an `.oci` directory to store the credentials:
   ```bash
   mkdir ~/.oci
   ```

2. Generate the private key with one of the following commands.
   - To generate the key, encrypted with a passphrase you provide when prompted:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```
     **Note:** We recommend that you use a passphrase for your key.

   - To generate the key with no passphrase:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Change the file permission to ensure that only you can read the private key file:
   ```bash
   chmod go-rwx ~/.oci/oci_api_key.pem
   ```

4. Generate the public key from your new private key:
   ```bash
   openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
   ```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:
   ```bash
   cat ~/.oci/oci_api_key_public.pem | pbcopy
   ```

   Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).
Generating an API Signing Key (Windows)

If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

**Note:**
Be sure to include the openssl binary in your Windows path. On default installations, the openssl.exe file can be found in `C:\Program Files\Git\mingw64\bin`.

Use the following OpenSSL commands to generate the key pair in the required PEM format.

1. If you haven't already, create a `.oci` directory to store the credentials. For example:

   ```
   mkdir %HOMEDRIVE%%HOMEPATH%\.oci
   ```

2. Generate the private key with one of the following commands:
   - To generate the key that is encrypted with a passphrase you provide when prompted:
     ```
     openssl genrsa -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem -aes128 -passout stdin 2048
     ```
   - To generate the key with no passphrase:
     ```
     openssl genrsa -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem 2048
     ```

3. Generate the public key from your new private key:

   ```
   openssl rsa -pubout -in %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key_public.pem
   ```

4. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later). For example:

   ```
   type \oci\oci_api_key_public.pem
   ```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

**How to Get the Key's Fingerprint**

You can get the key's fingerprint with the following OpenSSL command.

**For Linux and Mac OS X:**

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```  

**For Windows:**

**Note:**
If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.

```
openssl rsa -pubout -outform DER -in \oci\oci_api_key.pem | openssl md5 -c
```  

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef
Where to Get the Tenancy’s OCID and User’s OCID

Both OCIDs are in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator. If you're not familiar with OCIDs, see Resource Identifiers.

Tenancy’s OCID

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the navigation menu, under Governance and Administration, go to Administration and click Tenancy Details.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

User’s OCID

Get the user's OCID in the Console on the page showing the user's details. To get to that page:

- If you're signed in as the user:
  
  Open the Profile menu ( ) and click User Settings.
  
  - If you're an administrator doing this for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Select the user from the list.
  
  The user OCID is shown under User Information. Click Copy to copy it to your clipboard.

How to Upload the Public Key

You can upload the PEM public key in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:

   - If you're signed in as the user:

     Open the Profile menu ( ) and click User Settings.
     
     - If you're an administrator doing this for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Select the user from the list.

3. Click Add Public Key.
4. Paste the contents of the PEM public key in the dialog box and click Add.

Notice that after you've uploaded your first public key, you can also use the UploadApiKey API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

SDK and CLI Configuration File

Oracle Cloud Infrastructure SDKs and CLI require basic configuration information, like user credentials and tenancy OCID. You can provide this information by:

- Using a configuration file
- Declaring a configuration at runtime

Note:

You can use the Console to help generate a configuration file. For more information, see Generating an API Signing Key (Console) on page 4180.

The SDKs fully support both options. Refer to the documentation for each SDK for information about the config object and any exceptions when using a configuration file:
The CLI requires a configuration file, but also allows you to set environment variables to provide certain information. See CLI Environment Variables for more information.

File Name and Location

The default configuration file name and location is `~/.oci/config`.

### Note:

On Windows, you can use PowerShell to create the folder with the following command:

```
mkdir %HOMEDRIVE%%HOMEPATH%\.oci
```

File Explorer does not support creating folder names that start with a period.

File Entries

The following table lists the basic entries that are required for the configuration file, as well as where to get the required information.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the user calling the API. To get the value, see Required Keys and OCIDs on page 4179. Example: ocid1.user.oc1..&lt;unique_ID&gt; (shortened for brevity)</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the public key that was added to this user.</td>
</tr>
<tr>
<td>key_file</td>
<td>Full path and filename of the private key. <strong>Important:</strong> The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 4179. Example (Linux/Mac OS): <code>~/.oci/oci_api_key.pem</code> Example (Windows): <code>%HOMEDRIVE%\%HOMEPATH%\.oci\oci_api_key.pem</code></td>
</tr>
<tr>
<td>pass_phrase</td>
<td>Passphrase used for the key, if it is encrypted.</td>
</tr>
<tr>
<td>tenancy</td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 4179. Example: ocid1.tenancy.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>Entry</td>
<td>Description and Where to Get the Value</td>
</tr>
<tr>
<td>-------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td><strong>region</strong></td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 180. Example: us-ashburn-1</td>
</tr>
</tbody>
</table>

**Custom Values**

Some Oracle Cloud Infrastructure SDKs support defining custom values in the configuration file. Refer to the documentation for each SDK for more information.

**Profiles and Inheritance**

You can create multiple profiles with different values for these entries, then you can specify which profile to load. Some Oracle Cloud Infrastructure SDKs require a DEFAULT profile and support profile inheritance. This means that any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile. Refer to the documentation for each SDK for more information.

**Example Configuration**

The following example (for Linux and Mac OS) shows key values in a configuration file and how to set profiles for a SDK that supports profile inheritance.

```plaintext
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=keys/admin_key.pem
pass_phrase=<your_passphrase>
```

This example is for Windows:

```plaintext
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=%HOMEDRIVE%%HOMEPATH%/oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=keys/admin_key.pem
pass_phrase=<your_passphrase>
```

**SDK Quick Starts with Cloud Shell**

This section includes quick and easy no-setup walk-throughs that demonstrate how to use OCI developer tools and SDKs using Cloud Shell.

- **SDK for Python Cloud Shell Quick Start** on page 4187
- **SDK for Java Cloud Shell Quick Start** on page 4187
- **SDK for .NET Cloud Shell Quick Start** on page 4188
- **SDK for Go Cloud Shell Quick Start** on page 4189
SDK for Python Cloud Shell Quick Start

This section discusses how to quickly get started with the Oracle Cloud Infrastructure SDK for Python using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Run Python:

   ```
   user@cloudshell:oci (us-phoenix-1)$ python3
   Python 3.6.8 (default, Oct 1 2020, 20:32:44)
   [GCC 4.8.5 20150623 (Red Hat 4.8.5-44.0.3)] on linux
   Type "help", "copyright", "credits" or "license" for more information.
   >>>
   ```

4. Run the following code sample to see your current Object Storage namespace:

   ```
   import oci
   object_storage_client =
   oci.object_storage.ObjectStorageClient(oci.config.from_file())
   result = object_storage_client.get_namespace()
   print("Current object storage namespace: {}".format(result.data))
   ```

   This will return output similar to the following:

   ```
   Current object storage namespace: mynamespace
   ```

SDK for Java Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Java using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a working directory and move to it:

   ```
   mkdir java_demo
   cd java_demo
   ```

4. Copy a pre-installed example (also available from github) from the OCI Java SDK examples/ folder to your working directory:

   ```
   cp $OCI_JAVA_SDK_LOCATION/examples/ListDBVersionExample.java .
   ```

5. Compile the example:

   ```
   javac -cp .:$OCI_JAVA_SDK_FULL_JAR_LOCATION:$OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample.java
   ```
6. Run the example:

```
java -cp .:$OCI_JAVA_SDK_FULL_JAR_LOCATION:$OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample $OCI_TENANCY BM.HighIO1.36
```

This will return output similar to the following:

```
SLF4J: Failed to load class "org.slf4j.impl.StaticLoggerBinder".
SLF4J: Defaulting to no-operation (NOP) logger implementation
SLF4J: See http://www.slf4j.org/codes.html#StaticLoggerBinder for further details.

DB Versions Fetched for Shape ocid1.tenancy.oc1..aaaaaaaayexample and compartment ocid: BM.HighIO1.36
[DbVersionSummary(version=11.2.0.4, isLatestForMajorVersion=true, supportsPdb=false, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
DbVersionSummary(version=12.1.0.2, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
DbVersionSummary(version=12.2.0.1, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
DbVersionSummary(version=18.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
DbVersionSummary(version=19.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
DbVersionSummary(version=21.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb])]
```

SDK for .NET Cloud Shell Quick Start

This topic explains how to quickly get started with the Oracle Cloud Infrastructure SDK for .NET using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a working directory and move to it:

```
mkdir DotnetDemo && cd DotnetDemo
```
4. Create a new .NET console application project:

```
dotnet new console
```
5. Add the OCI.DotNetSDK.Objectstorage package to your project.

```
dotnet add package OCI.DotNetSDK.Objectstorage --source /usr/lib/dotnet/NuPkgs/
```

Optionally, you can include the `--source` parameter, which will fall back to retrieving the package from the pre-installed location (`/usr/lib/dotnet/NuPkgs/`) if it cannot be downloaded from nuget.org.

**Note:**
To bypass nuget.org and force usage of the pre-installed .NET SDK, you can use the `nuget.config` provided in step 2a of the instructions here.

6. Add the following code to the `Program.cs` file:

```csharp
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Oci.ObjectstorageService;
using Oci.ObjectstorageService.Requests;
using Oci.ObjectstorageService.Responses;
using Oci.Common.Auth;

namespace DotnetDemo
{
    public class Program
    {
        static void Main(string[] args)
        {
            var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
            var compartmentId = Environment.GetEnvironmentVariable("OCI_TENANCY");
            var objectStorageClient = new ObjectStorageClient(provider);

            Task<GetNamespaceResponse> getNamespaceResponse = objectStorageClient.GetNamespace(new GetNamespaceRequest());
            Console.WriteLine(getNamespaceResponse.Result.Value);
        }
    }
}
```

7. Run the example:

```
dotnet run
```

### SDK for Go Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Go using Cloud Shell. The OCI Go SDK is pre-installed in the Cloud Shell environment and included in your `$GOPATH`.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `main.go` with the following code, which will list the availability domains in your tenancy:

```go
package main

import (  
    "context"  
    "fmt"
)
func main() {
    c, err := identity.NewIdentityClientWithConfigurationProvider(common.DefaultConfigProvider())
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    // The OCID of the tenancy containing the compartment.
    tenancyID, err := common.DefaultConfigProvider().TenancyOCID()
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    request := identity.ListAvailabilityDomainsRequest{
        CompartmentId: &tenancyID,
    }

    r, err := c.ListAvailabilityDomains(context.Background(), request)
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    fmt.Printf("List of available domains: %v", r.Items)
    return
}

4. Run the example:

go run main.go

SDK for TypeScript and JavaScript Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript using Cloud Shell. The OCI SDK for TypeScript and JavaScript SDK is pre-installed globally through npm.

JavaScript Example

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `region_subscriptions_example.js` with the following example code, which lists the subscribed regions for your current tenancy:

```javascript
const identity = require("oci-sdk/node_modules/oci-identity");
const common = require("oci-sdk/node_modules/oci-common");
const provider = new common.ConfigFileAuthenticationDetailsProvider();
const compartmentId = provider.getTenantId() || "";

let identityClient;

async function getSubscriptionRegions(tenancyId) {
    const regions = await identityClient.listRegionSubscriptions({
        tenancyId: tenancyId
    });
```
return regions.items.map(region => {
    return region.regionName;
});
}

(async () => {
    identityClient = await new identity.IdentityClient({
        authenticationDetailsProvider: provider
    });

    const regions = await getSubscriptionRegions(compartmentId);
    console.log("Currently subscribed to the following region(s): ",
    regions)
})();

4. Run the example:

    node region_subscriptions_example.js

**TypeScript Example**

This TypeScript example will list the subscribed regions for the current tenancy.

1. Create an empty project named ts_demo and link the global installation of oci-sdk library using the following commands:

    # create a new project folder and move into it
    mkdir ts_demo
    cd ts_demo

    # initialize a new javascript/typescript project
    npm init --y

    # link the global installation of oci-sdk to the current project
    npm link oci-sdk
    npm link @types/node

2. Create a file named `region_subscriptions_example.ts` inside your ts_demo project with the following code:

    import * as identity from "oci-sdk/node_modules/oci-identity";
    import common = require("oci-sdk/node_modules/oci-common");

    const provider: common.ConfigFileAuthenticationDetailsProvider = new common.ConfigFileAuthenticationDetailsProvider();

    const compartmentId = provider.getTenantId();

    let identityClient: identity.IdentityClient;

    export async function getSubscriptionRegions(tenancyId: string) {
        const listRegionSubscriptionsRequest:
            identity.requests.ListRegionSubscriptionsRequest = {
            tenancyId: tenancyId
        };

        const regions = await identityClient.listRegionSubscriptions(listRegionSubscriptionsRequest);
        return regions.items.map(region => {
            return region.regionName;
        });
    }

    (async () => {
    ...
identityClient = await new identity.IdentityClient({ authenticationDetailsProvider: provider });
const regions = await getSubscriptionRegions(compartmentId);
console.log("Currently subscribed to the following region(s): ", regions);
})();

3. Compile the example:

```bash
# use the TypeScript compiler to compile the example
tsc region_subscriptions_example.ts
```

4. Run the example:

```bash
# run the example using node
node region_subscriptions_example.js
```

SDK for Ruby Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Ruby using Cloud Shell. The OCI SDK for Ruby is installed in the cloud shell environment and automatically added to your GEM_PATH.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `list_users_example.rb` with the following code, which lists the users in your tenancy:

```ruby
require 'oci'
api = OCI::Identity::IdentityClient.new()
response = api.list_users(OCI.config.tenancy)
response.data.each { |user| puts user.name }
```

4. Run the example:

```bash
ruby list_users_example.rb
```

OCI Modules for PowerShell Cloud Shell Quick Start

This topic discusses how to quickly get started with the Oracle Cloud Infrastructure Modules for PowerShell using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. From the Cloud Shell session's command prompt, start the PowerShell environment:

```bash
user@cloudshell:oci (us-phoenix-1)$ pwsh
```
4. Run the following command to list the users in your current tenancy:

```bash
oci iam user list
```

Command Line Interface (CLI)

The CLI is a small-footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend Console functionality.
This CLI and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

The CLI is built on the Oracle Cloud Infrastructure SDK for Python and runs on Mac, Windows, or Linux. The Python code makes calls to Oracle Cloud Infrastructure APIs to provide the functionality implemented for the various services. These are REST APIs that use HTTPS requests and responses. For more information, see About the API.

**Installation:** See Quickstart on page 4195.

**Reference:** For help with a specific command, you can enter `help <command>` on the command line or view the Command Line Reference. This reference is derived from the APIs and help text in the Python source code.

**Requirements**

To install and use the CLI, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This account user can be you, another person, or a system that calls the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of other typical Oracle Cloud Infrastructure policies, see Common Policies.
- A keypair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. See Configuring the CLI.

**Note:**
To use the CLI without a keypair, you can use token-based authentication. For more information, see Token-based Authentication for the CLI on page 4200.

- A supported version of Python on a supported operating system.
- If you require FIPS-compliance, see Using FIPS-validated Libraries on page 4206.

**Supported Python Versions and Operating Systems**

The CLI supports Python versions 3.6 and later running on MacOS, Windows, or a supported Linux distribution:

- Oracle Linux 6.10, Oracle Linux 7.7 and 7.8, and Oracle Linux 8.0
- Oracle Autonomous Linux 7.8
- CentOS 7.0 and CentOS 8.x
- Ubuntu 16.04, Ubuntu 18.04, and Ubuntu 20.04

**Note:**
Newer versions of Python may not be immediately supported. The CLI might work on unlisted operating systems, but we do not test them for compatibility.

If you use the CLI installer and do not have Python on your machine, the installer offers to automatically install Python for you. If you already have Python installed on your machine, you can use the `python --version` command to find out which version is installed.

**Services Supported**

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
• Blockchain Platform
• Budgets
• Cloud Guard
• Compute Instance Agent (Oracle Cloud Agent)
• Container Engine for Kubernetes
• Content and Experience
• Core Services (Networking, Compute, Block Volume)
• Data Catalog
• Data Flow
• Data Integration
• Data Safe
• Data Science
• Data Transfer
• Database
• Database Management
• Digital Assistant
• DNS
• Email Delivery
• Events
• Functions
• File Storage
• Golden Gate
• Health Checks
• IAM
• Integration
• Key Management (for the Vault service)
• Limits
• Load Balancing
• Logging
• Logging Analytics
• Logging Search
• Logging Ingestion
• Management Agent Cloud
• Management Dashboard
• Marketplace
• Monitoring
• MySQL Database
• NoSQL Database Cloud
• Notifications
• Object Storage
• OCI Registry
• Organizations
• Operations Insights
• Optimizer
• OS Management
• Quotas
• Resource Manager
• Search
• Secret Management (for the Vault service)
• Secret Retrieval (for the Vault service)
• Service Connector Hub
• Streaming
• Support Management
• Usage
• VMWare Solution
• Web Application Acceleration and Security
• Work Requests (Compute, Database)

Quickstart
Using the installer script and the setup command is the fastest way to get up and running with the CLI.

Installing the CLI
The installer script automatically installs the CLI and its dependencies, Python and virtualenv. Before running the installer, be sure you meet the Requirements on page 4193.

**Note:**
Oracle Autonomous Linux 7 and Cloud Shell have the CLI pre-installed.

Linux and Unix (Including Oracle Linux 8)
1. Open a terminal.
2. To run the installer script, run the following command.

   ```bash
   ```

   **Note:**
   To run a 'silent' install that accepts all default values with no prompts, use the `--accept-all-defaults` parameter.

Oracle Linux 7
If you're using Oracle Linux 7, you can use yum to install the CLI.

To use yum to install the CLI:

   ```bash
   sudo yum install python36-oci-cli
   ```
The CLI will be installed to the Python site packages:

- /usr/lib/python3.6/site-packages/oci_cli
- /usr/lib/python3.6/site-packages/services

Documentation and examples will be installed in the /usr/share/doc/python36-oci-cli-<version>/ directory.

To uninstall the CLI:

```
sudo yum remove python36-oci-cli
```

**Mac OS X**

You can use Homebrew to install, upgrade, and uninstall the CLI on Mac OS.

To install the CLI on Mac OS X with Homebrew:

```
brew update && brew install oci-cli
```

To upgrade your CLI install on Mac OS X using Homebrew:

```
brew update && brew upgrade oci-cli
```

To uninstall the CLI on Mac OS X using Homebrew:

```
brew uninstall oci-cli
```

**Windows**

1. Open the PowerShell console using the Run as Administrator option.
2. The installer enables auto-complete by installing and running a script. To allow this script to run, you must enable the RemoteSigned execution policy.

   To configure the remote execution policy for PowerShell, run the following command.

   ```
   Set-ExecutionPolicy RemoteSigned
   ```

3. Download the installer script:

   ```
   ```

4. Run the installer script with or without prompts:

   a. To run the installer script with prompts, run the following command:

   ```
   ```

   ...and respond to the Installation Script Prompts on page 4196.

   b. To run the installer script without prompting the user, accepting the default settings, run the following command:

   ```
   install.ps1 -AcceptAllDefaults
   ```

**Installation Script Prompts**

The installation script prompts you for the following information.
• If you do not have a compatible version of Python installed:
  • Windows and Linux: You are prompted to provide a location for installing the binaries and executables. The script will install Python for you.
  • MacOS: You are notified that your version of Python is incompatible. You must upgrade before you can proceed with the installation. The script will not install Python for you.
  • When prompted to upgrade the CLI to the newest version, respond with Y to overwrite an existing installation.
  • When prompted to update your PATH, respond with Y to be able to invoke the CLI without providing the full path to the executable. This will add oci.exe to your PATH.

Setting up the Config File

Before using the CLI, you must create a config file that contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup dialog or manually using a text editor.

Use the Setup Dialog

To have the CLI walk you through the first-time setup process, use the `oci setup config` command. The command prompts you for the information required for the config file and the API public/private keys. The setup dialog generates an API key pair and creates the config file.

For more information about how to find the required information, see:

- Where to Get the Tenancy's OCID and User's OCID on page 4184
- Regions and Availability Domains on page 180

Manual Setup

If you want to set up the API public/private keys yourself and write your own config file, see SDK and Tool Configuration.

Tip:

Use the `oci setup keys` command to generate a key pair to include in the config file.

Next Steps

- For details on starting a session, see Starting a CLI Session on page 4207.
- Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.

Manual Installation

Instead of using the installer script as described in the Quickstart on page 4195, you can manually install the CLI and its dependencies. Before proceeding, be sure you meet the Requirements on page 4193.

Step 1: Installing Python

Python installation instructions vary for each operating system that the CLI supports.

Note:

The CLI supports only the Python versions listed in the CLI Requirements.

Windows

Install a supported version of Python from the Python Windows downloads page. During installation, choose to add Python to the PATH and/or environment variables (depending on the prompt).

Oracle Linux

Some versions of Oracle Linux come with incompatible versions of Python, and might require additional components to install the CLI. Before installing the CLI, run the following commands on a new Oracle Linux image.
Tip:
Oracle Autonomous Linux 7 comes with the CLI pre-installed.

Oracle Linux 7 and Oracle Linux 8

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
./configure --enable-optimizations
sudo make altinstall
```

Oracle Linux 6

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.6.3/Python-3.6.3.tgz
tar xvf Python-3.6.3.tgz
cd Python-3.6*/
./configure --enable-optimizations
sudo make altinstall
```

CentOS

Before you install the CLI, run the following commands on a new CentOS image.

CentOS 7, CentOS 8

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
./configure --enable-optimizations
sudo make altinstall
```

Ubuntu

Before you install the CLI, run the following commands on a new Ubuntu image.

Ubuntu 16, Ubuntu 18, and Ubuntu 20

```
sudo apt update
sudo apt install build-essential zlib1g-dev libncurses5-dev libgdbm-dev
libnss3-dev libssl1-dev libreadline-dev libffi-dev libsqlite3-dev wget
libbz2-dev
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar -xf Python-3.8.3.tgz
cd Python-3.8.3
./configure --enable-optimizations
sudo make altinstall
```

Mac OS X

Mac OS X comes with Python pre-installed.
To install the latest version of Python on Mac OS X, see the official Python documentation.

**Step 2: Creating and Configuring a Virtual Environment**

The venv Python module is a virtual environment builder that lets you create isolated Python environments. We recommend installing the CLI in a virtual environment.

**Installing and Activating your Virtual Environment**

After Python is installed, set up a virtual environment for your operating system using the following steps.

**Windows**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running the following command:
   ```
   python -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:
   ```
   oracle-cli/Scripts/activate
   ```

**Linux and Mac**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running one of the following commands, depending on the version of Python installed:
   ```
   python3.8 -m venv oracle-cli
   ```
   ```
   python3.6 -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:
   ```
   source oracle-cli/bin/activate
   ```

**Step 3: Installing the Command Line Interface**

You can download the CLI from GitHub or install the package from Python Package Index (PyPI).

To install using the GitHub download:

- Download and unzip `oci-cli.zip`.
- Run the following command.
  ```
  pip install oci-cli-*-py2.py3-none-any.whl
  ```

To install using PyPI, run the following command:

```
pip install oci-cli
```

For information on how to start a CLI session, see Starting a CLI Session on page 4207.

**Installing Without a Virtual Environment**

We do not recommend installing the CLI in your system-wide Python and suggest that instead you install the CLI using the installer or virtual environment.

In cases where you are trying to install the CLI in your system-wide Python using the latest pip version, you might encounter conflicts with some `distutils` installed packages. Following is an example error message when this occurs:

```
sudo pip install oci-cli
```
Cannot uninstall 'requests'. It is a distutils installed project and thus we cannot accurately determine which files belong to it which would lead to only a partial uninstall.

Another option is to install the CLI for the user using the following command, although this approach is not supported:

```
pip install --user oci-cli
```

**Token-based Authentication for the CLI**

Token-based authentication for the CLI allows customers to authenticate their session interactively, then use the CLI for a single session without an API signing key. This enables customers using an identity provider that is not SCIM-supported to use a federated user account with the CLI and SDKs.

**Requirements**

The requirements are the same as those listed for the CLI in Requirements on page 4193, except that instead of a SSH keypair, you need a web browser for the authentication process.

**Starting a Token-based CLI Session**

To use token-based authentication for the CLI on a computer with a web browser:

1. In the CLI, run the following command. This will launch a web browser.

   ```
   oci session authenticate
   ```

2. In the browser, enter your user credentials. This authentication information is saved to the .config file.

**Validating a Token**

To verify that a token is valid, run the following command:

```
oci session validate --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

You should receive a message showing the expiration date for the session. If you receive an error, check your profile settings.

**Refreshing a Token**

The default token TTL is set to 1 hour before it expires and can be refreshed within the validity period up to 24 hours. To refresh the token, run the following command:

```
oci session refresh --profile <profile_name>
```

**Starting a Token-based CLI Session without a Browser**

To use token-based authentication for the CLI on a computer without a web browser, you must export a session from a web-enabled computer, then import it to the computer without a web browser.

**Exporting from Source Computer**

On the source computer with the browser:

1. In the CLI, run the following command:

   ```
   oci session authenticate
   ```

2. Enter the user credentials you wish to use on the target computer.
3. To export a zip file, run the following command:

```
oci session export --profile <profile_name> --output-file <output_filename>
```

To verify the export, see Validating a Token on page 4200.

**Importing to Target Computer**

On the target computer without the browser, run the following command in the CLI:

```
oci session import --session-archive <path_to_exported_zip>
```

You can test the import by running the following:

```
oci iam region list --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

It should return a list of regions. Successful execution of this command verifies that the token authentication is working as expected.

**Running Scripts on a Computer without a Browser**

After importing the authentication to the target computer, you can run the CLI and SDKs by using the following settings.

**For CLI**

To run scripts on the CLI, append the following suffix:

```
--config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

**For SDKs**

To run SDKs on the target computer, you must read in the token file, then use it to initialize the SecurityTokenSigner.

After creating a token file as shown in Starting a Token-based CLI Session on page 4200, use the following process.

**Note:**

These code samples demonstrate how to accomplish this using the Oracle Cloud Infrastructure SDK for Python. For other SDKs, follow the same process, but adjust the syntax accordingly.

1. Read the token file from the `security_token_file` parameter of the `.config` file.

```
config = oci.config.from_file(profile_name='TokenDemo')
token_file = config['security_token_file']
token = None
with open(token_file, 'r') as f:
    token = f.read()
```

2. Read the private key specified by the `.config` file.

```
private_key = oci.signer.load_private_key_from_file(config['key_file'])
```

3. Create the initial SDK client which targets the user-specified region.

```
signer = oci.auth.signers.SecurityTokenSigner(token, private_key)
```
4. Make the identity request.

```python
result = client.list_region_subscriptions(config['tenancy'])
```

**Configuring the CLI**

You can use these optional configurations to extend CLI functionality. The CLI supports using a file for CLI-specific configurations. You can:

- Specify a default profile.
- Set default values for command options so you don't have to type them into the command line.
- Define aliases for commands. For example, using "ls" as an alias for list.
- Define aliases for options. For example, using "--ad" as an alias for --availability-domain.
- Define named queries that are passed to the --query option instead of typing a JMESPath expression on the command line.

The CLI also supports the use of environment variables to specify defaults for some options. See **CLI Environment Variables** for more information.

**CLI Configuration File**

The default location and file name for the CLI-specific configuration file is `~/.oci/oci_cli_rc`, but you can use the `OCI_CLI_RC_FILE` environment variable to modify where the CLI looks for a configuration file and its default values upon startup.

You can also explicitly specify a CLI configuration file with the `--cli-rc-file` option or with the legacy `--defaults-file` option. For example:

```bash
# Uses the file from ~/.oci/oci_cli_rc
# or OCI_CLI_RC_FILE environment variable
oci os bucket list

# Uses a custom file
oci os bucket list --cli-rc-file path/to/my/cli/rc/file
```

To set up an `oci_cli_rc` file, run the following command:

```bash
oci setup oci-cli-rc --file path/to/target/file
```

This command creates the file you specify that includes examples of default command aliases, parameter aliases, and named queries.

**Note:**

If you are using Windows, you should use backslash as the directory separator in pathnames, instead of the forward slash.

**Specifying a Default Profile**

Specify a default profile in the `OCI_CLI_SETTINGS` section of the CLI configuration file. The next example shows how to specify a default profile named IAD. The CLI looks for a profile named IAD in your `~/.oci/config` file, or any other file that you specify using the `--config-file` option or the `OCI_CLI_CONFIG_FILE` environment variable.

```ini
[OCI_CLI_SETTINGS]
default_profile=IAD
```

You can also specify a default profile by using the `--profile` option or by setting the `OCI_CLI_PROFILE` environment variable.
If a default profile value has been specified in multiple locations, the order of precedence is:

1. The value specified in the `--profile` option.
2. The value specified in the `OCI_CLI_PROFILE` environment variable.
3. The value specified in the `default_profile` field in the `OCI_CLI_SETTINGS` section of the CLI configuration file.

**Specifying Default Values**

The CLI supports using default values so that you don't have to keep typing every value into the command line. For example, instead of typing in a `--compartment-id` on each launch instance command or having to keep specifying the `--namespace` when using Object Storage commands. You can specify this information in a default values file.

Default values can be applied at different levels, from general to specific:

- Globally, across all the CLI commands.
- To a particular service, such as Compute or Object Storage.
- To a specific group, such as commands related to exporting images.
- To a specific command.

Default values are treated hierarchically, with specific values having a higher order of precedence than general values. For example, if there is a globally defined value for `compartment-id` and a specific `compartment-id` defined for the `compute instance launch` command, the CLI uses the value for the `compute instance launch` instead of the global default.

**Command Value Priority**

If a value is provided on the command line also exists in `--cli-rc-file`, the value from the command line has priority. For a command with options that take multiple values, the values are taken entirely from the command line or from `--cli-rc-file`. The 2 sources aren't merged.

**Defaults Value File Syntax**

The `--cli-rc-file` file can be divided into different sections with one or more keys per section.

**Sections**

In the next example, the file has two sections, with a key in each section. To specify which section to use, you use the `--profile` option in the CLI.

```
[DEFAULT]
compartment-id = ocid1.compartment.oc1..<unique_ID_1>
[ANOTHER_SECTION]
compartment-id = ocid1.compartment.oc1..<unique_ID_2>
```

**Keys**

Keys are named after command line options, but do not use a leading double hyphen (`--`). For example, the key for `--image-id` is `image-id`. You can specify keys for single values, multiple values, and flags.

- **Keys for Single Values.** The next example shows how to specify key values at different levels, and with different scope.

```
[DEFAULT]
# Defines a global default for bucket-name
bucket-name = my-global-default-bucket-name

# Defines a default for bucket-name, which applies to all 'compute' commands
compute.bucket-name = bucket-name-for-image-import-export
```
# Defines a default for bucket-name, which applies to all 'os object' commands (e.g., os object get)

```
os.object.bucket-name = bucket-name-for-object-commands
```

# Defines a default for bucket-name, for the 'os object multipart list' command

```
os.object.multipart.list.bucket-name = bucket-name-for-multipart-list
```

- **Keys for Multiple Values.** Some options, such as `--include` and `--exclude` on the `oci os object bulk-upload` command can be specified more than once. For example:

```
oci os object bulk-upload -ns my-namespace -bn my-bucket --src-dir my-directory --include *.txt --include *.png
```

The next example shows how you would enter the `--include` values in the `--cli-rc-file` file

```
[DEFAULT]
os.object.bulk-upload.include = *.txt
  *.png
```

In the previous example, one value is given for each line and each line must be indented underneath its key. You can use tabs or spaces and the amount of indentation doesn't matter. You can also put a value on the same line as the key, add more values on the following lines, and use a path statement for a value. For example:

```
[DEFAULT]
os.object.bulk-upload.include = *.pdf
  *.txt
  *.png
  my-subfolder/*.tiff
```

- **Keys for Flags.** Some command options are flags, like `--force`, which uses a Boolean value. To set a flag for the `--force` option, use the following command.

```
os.object.delete.force=true
```

### Specifying Command Aliases

Specify named queries in the `OCI_CLI_COMMAND_ALIASES` section of the CLI configuration file. There are two types of aliases, global aliases and command sequence aliases. The following example shows each type of alias.

```
[OCI_CLI_COMMAND_ALIASES]
# This is a global alias that lets you use "ls" instead of "list" for any
# list command in the CLI.
#
ls = list

# Command examples:
# oci os object ls or oci os compute ls

# This is a command sequence alias that lets you use "oci os object rm"
# instead of "oci os object delete".
# <alias> = <dot-separated sequence of groups and sub-groups>.<command or
group to alias>
# rm = os.object.delete
# Command example:
```
If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `-ls` as an alias for `--list`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.ls.compartment-id=ocid1.compartment.oc1..<unique_ID>
```

**Specifying Option Aliases**

Specify option aliases in the `OCI_CLI_PARAM_ALIASES` section of the CLI configuration file. Option aliases are applied globally. The following example shows some aliases for command options.

```
[OCI_CLI_PARAM_ALIASES]
# Option aliases either start with a double hyphen (--) or are a single
# hyphen (-) followed by a # single letter. For example: --example-alias, -e
#
--ad = --availability-domain
--dn = --display-name
--egress-rules = --egress-security-rules
--ingress-rules = --ingress-security-rules
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `-ad` as an alias for `--availability-domain`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.list.ad=xyx:PHX-AD-1
```

**Specifying Named Queries**

If you use the `--query` parameter to filter or manipulate output, you can define named queries instead of using a JMESPath expression on the command line.

Specify named queries in the `OCI_CLI_CANNED_QUERIES` section of the CLI configuration file.

**Examples of Named Queries**

```
[OCI_CLI_CANNED_QUERIES]
# For list results, this gets the ID and display-name of each item in the
# list.
# Note that when the names of attributes have dashes in them they need to
# be surrounded
# with double quotes. This query knows to look for a list because of the
# [*] syntax
get_id_and_display_name_from_list=data[*].{id: id, "display-name": "display-
name"}

get_id_and_display_name_from_single_result=data.{id: id, "display-name":
"display-name"}

# Retrieves a comma separated string, for example:
# ocid1.instance.oc1.phx.xyz....,cli_test_instance_675195,RUNNING
#
get_id_display_name_and.lifecycle_state_from_single_result.as_csv=data.{id,
"display-name", "lifecycle-state"} | join(\',\', @)

# Retrieves comma separated strings from a list of results
get_id_display_name_and_lifecycle_state_from_list_as_csv=data[*].[join(`,`, [id, "display-name", "lifecycle-state"])][[]]

# Filters where the display name contains some text
#
# filter_by_display_name_contains_text=data[?contains("display-name", `your_text_here`)]

# Filters where the display name contains some text and pull out certain attributes(id and time-created)
#
# filter_by_display_name_contains_text_and_get_attributes=data[?contains("display-name", `your_text_here`)].{id: id, timeCreated: "time-created"}

# Get the top 5 results from a list operation
#
# get_top_5_results=data[:5]

# Get the last 2 results from a list operation
#
# get_last_2_results=data[-2:]}

You can reference any of these queries using this syntax: query://<query name>.

For example, to get id and display name from a list, run the following command.

```
oci compute instance list -c $C --query query://get_id_and_display_name_from_list
```

**Enabling Auto-complete**

If you used the CLI installer, you don't have to configure auto-complete because it's enabled automatically.

To enable auto-complete (tab completion) for a manual CLI installation, run the following command.

```
oci setup autocomplete
```

To enable auto-complete on a session by session basis, run the following command.

```
eval "$_OCI_COMPLETE=source oci"
```

**Note:**

**Support for Auto-complete on Windows**

Auto-complete on Windows is only supported if you're using PowerShell. A script runs to enable this feature. However, you must change the PowerShell execution policy to RemoteSigned. To configure this policy, run the following command at the PowerShell command line.

```
Set-ExecutionPolicy RemoteSigned
```

**Using FIPS-validated Libraries**

The CLI can be configured to use FIPS-validated libraries on Linux. The CLI is built on the Oracle Cloud Infrastructure SDK for Python and leverages operating system level cryptographic libraries.
Configuring the Environment

1. Verify the installed version of OpenSSL is FIPS-compliant. Run the following command:

   openssl version

   If "fips" is not part of the version name, you should upgrade OpenSSL to a FIPS-compliant version. You can download the latest versions of OpenSSL at: https://www.openssl.org/source/

2. Determine the location of the FIPS-compliant version of libcrypto:

   ls -l /usr/lib64/libcrypto*

3. Set the environment variable OCI_CLI_FIPS_LIBCRYPTO_FILE to the location of libcrypto:

   export OCI_CLI_FIPS_LIBCRYPTO_FILE=/path/to/libcrypto.x.x.x

   If you do not want to run this command at the start of every session, you can add it to your .bashrc or .bash_profile file.

   You can confirm that the environment variable is set properly with this command:

   set | grep OCI_CLI_FIPS_LIBCRYPTO_FILE

   You can now proceed to the standard installation process outlined in Quickstart on page 4195

Verifying the Configuration

To verify that the CLI is using the library that you specified during Configuring the CLI on page 4202, execute the following commands in Python. Be sure to do so in the same environment that the CLI uses.

   import ssl
   ssl.FIPS_mode()

   This should return 1, indicating that SSL is using the library specified by the OCI_CLI_FIPS_LIBCRYPTO_FILE environment variable.

Using the CLI

This topic describes how to use the CLI to access Oracle Cloud Infrastructure and carry out service-related tasks. This topic assumes that you have configured the CLI and are ready to start using it.

Tip:

Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.

Starting a CLI Session

MacOS, Linux, and Unix

To start a CLI session, run the following commands.

1. Open a terminal.
2. Change the working directory.

   cd myvirtualspaces/virtualenvs/cli-testing/bin

3. Run the activate batch file.

   source activate
To stop using the CLI, run the following command in a terminal.

```
deactivate
```

**Windows**

To start a CLI session, run the following commands.

1. Open the Command Prompt using the **Run as administrator** option.
2. Change the working directory.

```
cd myvirtualspaces/virtualenvs/cli-testing/Scripts
```
3. Run the activate batch file.

```
activate
```

To stop using the CLI, run the following command from the command line.

```
deactivate
```

**Command Line Syntax**

Most commands must specify a service, followed by a resource type and then an action. The basic command line syntax is:

```
oci <service> <type> <action> <options>
```

For example, this syntax is applied as follows:

- **compute** is the `<service>`
- **instance** is the resource `<type>`
- **launch** is the `<action>`, and
- the rest of the command string consists of `<options>`.

The following command to launch an instance shows a typical command line construct.

```
oci compute instance launch --availability-domain "EMIr:PHX-AD-1" --compute.id oci1.compartment.ocl..aaaaaaaaa13gzi jdli eqeyq35nz5zx1i26astxxhgo12pgeyqdr gnx7jhwa
--shape "VM.Standard1.1" --display-name "Instance 1 for sandbox" --image-id
oci1.image.ocl.phx.aaaaaaaaajutj4qjxihp14mboabsa27mrpusygv6gurp47kat5z7vljmq3puq
--subnet-id
oci1.subnet.ocl.phx.aaaaaaaaaypsr25bzjmjyn6xgwcrgxd3dbhiha6lodzus3gafscirbhj5bpa
```

In the previous example, you can provide a friendly name for the instance using the **--display-name** option.

Avoid entering confidential information.

**Basic Examples**

This section provides examples of basic operations using the CLI.

**Note:**

Using Environment Variables for OCIDs

Several of the CLI examples use environment variables for OCIDs, such as:

- `$T` for a tenancy OCID
- `$C` for a compartment OCID
For example:

T=ocid1.tenancy.oc1..aaaaaaaaba3pv6wm2ytdrwrz32uzr4h25vkcr4jqaee5f15p2b2qst
C=ocid1.compartment.oc1..aaaaaaarahifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2

To get a namespace, run the following command.

```
oci os ns get
```

To list compartments, run the following command.

```
oci iam compartment list --tenancy-id $T
```

To get a list of buckets, run the following command.

```
oci os bucket list --namespace mynamespace --compartment-id $C
```

To list users and limit the output, run the following command.

```
oci iam user list --compartment-id $T --limit 5
```

To add a user to a group, run the following command.

```
oci iam group add-user --user-id ocid1.user.oc1..aaabcaaaxkkhhtmghvqqq7rgvzwuj3drwmt1sgz6bfo7y4uc5sprzli377q --group-id ocid1.group.oc1..aaabcaaa66plootq6uwwxhfdw2lsdqtegeb6l4pjsv5eeuenxrauujj35b7b
```

**Getting Help with Commands**

You can get help for any command using `--help`, `-h`, or `-?`. For example:

```
oci --help
```

```
oci os bucket -h
```

```
oci os bucket create -?
```

**Viewing all the CLI Help**

You can view the command line help.

**Determining the Installed Version of the CLI**

To get the installed version of the CLI, run the following command.

```
oci --version
```

**Using Dates and Times in CLI Commands**

The CLI supports the following accepted date formats.

- UTC with milliseconds
  
  Format: `YYYY-MM-DDTHH:mm:ss.sssTZD`, Example: `2017-09-15T20:30:00.123Z`

- UTC without milliseconds
  
  Format: `YYYY-MM-DDTHH:mm:sssTZD`, Example: `2017-09-15T20:30:00Z`
- UTC with minute precision
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T20:30Z

- Timezone with milliseconds
  Format: YYYY-MM-DDTHH:mm:ss.sssTZD, Example: 2017-09-15T12:30:00.456-08:00

- Timezone without milliseconds
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T12:30:00-08:00

- Timezone with offset with minute precision
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T12:35-08:00

- Date Only (This date will be taken as midnight UTC of that day)
  Format: YYYY-MM-DD, Example: 2017-09-15

- Epoch seconds
  Example: 1412195400

**Note:**
In our datetime formats, the T can be replaced with a space.
For example, both "2017-09-15 20:30:00.123Z" and 2017-09-15T20:30:00.123Z are acceptable. (Note that if you do not include the T, you must wrap the value in quotes.) We also support time zones with and without the colon. Both +10:00 and +1000 are acceptable.

**Managing CLI Input and Output**
The CLI provides several options for managing command input and output.

**Passing Complex Input**
Complex input, such as arrays and objects with more than one value, are passed in JSON format and can be provided as a string at the command line, as a file, or as a command line string and as a file.

**MacOS, Linux, or Unix**
The following command shows how to pass two values for the --metadata object.

```
oci os bucket create -ns mynamespace --name mybucket --metadata 
"{"key1":"value1","key2":"value2"}" --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmrsvqyve5g6rcz6cpzqck3ukc5f1drwpp2jojdcypxfga
```

**Windows**
On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

The following command shows how to pass two values for the --metadata object on Windows.

```
oci os bucket create -ns mynamespace --name mybucket --metadata 
"{"key1":"value1","key2":"value2"}" --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmrsvqyve5g6rcz6cpzqck3ukc5f1drwpp2jojdcypxfga
```
Note:

JSON Errors

The error message "Parameter '<PARAMETER NAME>' must be in JSON format." indicates that the value you passed for the parameter with name "PARAMETER NAME" was not valid JSON. This error is typically a result of the JSON string not being escaped correctly.

For more information about using JSON strings, see Advanced JSON Options

Format Output as a Table

By default, all responses to a command are returned in JSON format. For example, a response like the following is returned when you issue the command to get a list of regions.

```json
{
  "data": [
    {
      "key": "FRA",
      "name": "eu-frankfurt-1"
    },
    {
      "key": "IAD",
      "name": "us-ashburn-1"
    },
    {
      "key": "ICN",
      "name": "ap-seoul-1"
    },
    {
      "key": "PHX",
      "name": "us-phoenix-1"
    },
    {
      "key": "LHR",
      "name": "uk-london-1"
    },
    {
      "key": "NRT",
      "name": "ap-tokyo-1"
    },
    {
      "key": "YYZ",
      "name": "ca-toronto-1"
    }
  ]
}
```

In some cases, readability can become an issue, which is easily resolved by formatting a response as a table. To get a response to a command formatted as a table, run the following command.

```
oci iam region list --output table
```

The following sample list of regions is returned as a two column table.

```
+-----+----------------+
| key | name            |
+-----+----------------+
| FRA | eu-frankfurt-1  |
| IAD | us-ashburn-1    |
```

Filter Output

You can filter output using the JMESPath query option for JSON. Filtering is very useful when dealing with large amounts of output. For example, run the following command with the output table option to get a list of images.

```bash
oci compute image list -c
ocid1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7rrrob2u2zbesh3wlafsgthhqtea
--output table
```

The image information is returned in table format, but too much data is returned, which overflows the width of the terminal. In addition, you might not need all the information that's returned.

```
<table>
<thead>
<tr>
<th>base-image-id</th>
<th>compartment-id</th>
<th>create-image-allowed</th>
<th>display-name</th>
<th>id</th>
<th>lifecycle-state</th>
<th>operating-system</th>
<th>operating-system-version</th>
<th>time-created</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle-Linux-7.4-2017.09.29-0</td>
<td>None</td>
<td>None</td>
<td>True</td>
<td>Oracle-Linux-7.4-2017.09.29-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaaa32xpzlbrdnocjtzv2tvxcofjfc55vdcmpxdlbohmtt7encpiana</td>
<td>AVAILABLE</td>
<td>Oracle Linux</td>
<td></td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.08.25-1</td>
<td>None</td>
<td>None</td>
<td>True</td>
<td>Oracle-Linux-7.4-2017.08.25-1</td>
<td>ocid1.image.oc1.phx.aaaaaaaaajan2cd2g65tphibaegiz41bs422rdc73okcu7dt2uya6p5szywsa</td>
<td>AVAILABLE</td>
<td>Oracle Linux</td>
<td></td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.08.25-0</td>
<td>None</td>
<td>None</td>
<td>True</td>
<td>Oracle-Linux-7.4-2017.08.25-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaaa32xpzlbrdnocjtzv2tvxcofjfc55vdcmpxdlbohmtt7encpiana</td>
<td>AVAILABLE</td>
<td>Oracle Linux</td>
<td></td>
</tr>
</tbody>
</table>
```
You can limit the amount of data returned by combining the `--query` option with `--output table` to get the information you want from a command.

To get filtered image information returned in a table format, run the following command.

```bash
oci compute image list -c
ocidl.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7rrob2u2zbesh3wlafsgthhqtea
--output table --query "data [*].{ImageName:"display-name", OCID:id}"
```

The previous command returns the following image information, formatted as a two column table.

<table>
<thead>
<tr>
<th>ImageName</th>
<th>OCID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows-Server-2012-R2-Standard-Edition-VM-2017.04.03-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaa53cliasgqvmutf1wqkafeb0b2y4wjebeci5szc4eus5yy2e2b7ua</td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.09.29-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaa32xpx2brrdrknqctzv2tvxc0fjc55vdcmpxdlbohmtt7encpana</td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.08.25-1</td>
<td>ocid1.image.oc1.phx.aaaaaaaajan2cd2g65tphaiegliz4l6s422rdc73okcu7d2uya6p5szywsa</td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.08.25-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaaabf12bmaygtu4riw3vcuowl15cqwzdqzwmdqneobybcfcn2pgyc6a</td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.07.17-1</td>
<td>ocid1.image.oc1.phx.aaaaaaaa7jvfm572d4ehcgh3iijapvhr525voie133ispumygi3k17mph55ha</td>
</tr>
<tr>
<td>Oracle-Linux-7.3-2017.07.17-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaaa5y6p3riqthxzov7fdngi4tsteganmao54nq3pyxu3hxucuzmoa</td>
</tr>
<tr>

</tr>
</tbody>
</table>
For more information about the JMESPath query language for JSON, see [JMESPath](https://docs.oracle.com/en-us/m-metal/oci/developer_tools/index.html).

**Advanced JSON Options**

You can get the correct JSON format for command options and commands.

- For a command option, use `--generate-param-json-input` and specify the command option that you want to get the JSON for. To generate the JSON for creating or updating a security rule, run the following command.

  ```bash
  oci network security-list create --generate-param-json-input ingress-security-rules
  ```

- For an entire command, use `--generate-full-command-json-input`. To generate the JSON for launching an instance, run the following command.

  ```bash
  oci compute instance launch --generate-full-command-json-input
  ```

**Order of Precedence for JSON Input**

The CLI supports combining arguments on the command line with file input. However, if the same values are provided in a file and on the command line, the command line takes precedence.

**Using a JSON File for Complex Input**

You can pass complex input from a file by referencing it from the command line. For Windows users, this removes the requirement of having to escape JSON text. You provide a path to the file using the `file://` prefix.

**Path Types**

Using `testfile.json` as an example, the following types of paths are supported.

- Relative paths from the same directory, for example: `file://testfile.json` and `file://relative/path/to/testfile.json`
- Absolute paths on Linux, MacOS or Unix, for example: `file:///absolute/path/to/testfile.json`
- Full file paths on Windows, for example: `file://C:\path\to\testfile.json`

**Note:**

File Path Expansions

File path expansions, such as `~` and `./`, are supported. On Windows, the `~` expression expands to your user directory, which is stored in the...
%USERPROFILE% environment variable. Using environment variables in paths is also supported.

**File Locations**

The following file locations are supported.

- Your home directory.
  ```bash
  oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga --metadata file://~/testfile.json
  ```

- The current directory.
  ```bash
  oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga --metadata file://testfile.json
  ```

- The /tmp directory (Linux, Unix, or MacOS).
  ```bash
  oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga --metadata file:///tmp/testfile.json
  ```

- The C:\temp directory (Windows).
  ```bash
  oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga --metadata file://C:\temp\testfile.json
  ```

**Examples of Using a JSON File as Input**

The examples in this section use JSON that's generated for a command option and an entire command. The JSON is saved in a file, edited, and then used as command line input.

**Use File Input for a Command Option**

This end-to-end example shows how to generate the JSON for a security list id option used to create a subnet. The JSON is saved in a file, edited, and then used as command line input.

Response from the Command

```
[
  {
    "icmpOptions": {
      "code": 0,
      "type": 0
    },
    "isStateless": true,
    "protocol": "string",
    "source": "string",
    "tcpOptions": {
      "destinationPortRange": {
        "max": 0,
        "min": 0
      },
      "sourcePortRange": {
        "max": 0,
        "min": 0
      }
    }
  },
  {
    "icmpOptions": {
      "code": 0,
      "type": 0
    },
    "isStateless": true,
    "protocol": "string",
    "source": "string",
    "tcpOptions": {
      "destinationPortRange": {
        "max": 0,
        "min": 0
      },
      "sourcePortRange": {
        "max": 0,
        "min": 0
      }
    }
  }
]`
Response from the Command

{
  "assignPublicIp": true,
  "availabilityDomain": "string",
  "compartmentId": "string",
  "displayName": "string",
  "extendedMetadata": {
    "string1": {
      "string1": "string",
      "string2": "string"
    },
    "string2": {
      "string1": "string",
      "string2": "string"
    }
  },
  "hostnameLabel": "string",
  "imageId": "string",
  "metadata": {
    "string1": {
      "string1": "string",
      "string2": "string"
    },
    "string2": {
      "string1": "string",
      "string2": "string"
    }
  }
}
Use a JSON File as Input for a Security List Option

1. To generate the JSON for the `security-list-ids` option, run the following command.

   ```shell
   oci network subnet create --generate-param-json-input security-list-ids
   ```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   ["string", "string"]
   ```

3. Edit the file and replace the "string" values with values, as shown in the following example.

   ```json
   [
   "ocid1.securitylist.oc1.phx.aaaaaaaaw7c62ybv4676muq5tdrwup3v2maiquhbkbb4sf75tjc5dm64y",
   "ocid1.securitylist.oc1.phx.aaaaaaaa7snx4jh5drwo2h33rwcdeqev6elir555hnrhij2yfnfedsfons5rct
   
   ```

4. Save the file as "security-list.json".

5. To create the subnet using "security-list.json" as input, run the following command.

   ```shell
   oci network subnet create --vcn-id ocid1.vcn.oc1.phx.aaaaaaaa6wmuahgxejkvy7ukyroqdrwlrumt16vyisxxavagiqw2eeet2sa
   --compartment-id ocid1.compartment.oc1..aaaaaaaal3gzijdliedxxhgl2rgndrwyg935n5zxi126astpgeyq7jnhwa
   --availability-domain "EMIr:PHX-AD-1" --display-name TESTSUB --dns-label "testinstances" --cidr-block "10.0.0.0/16" --security-list-ids file://security-list.json
   ```

### Use File Input for an Entire Command

This end-to-end example shows how to generate the JSON to create a virtual cloud network (VCN). The JSON is saved in a file, edited, and then used as command line input.

Use a JSON File as Input to Create a VCN

1. To generate the JSON needed to create a VCN, run the following command.

   ```shell
   oci network vcn create --generate-full-command-json-input
   ```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   {
   "cidrBlock": "string",
   "compartmentId": "string",
   "displayName": "string",
   "dnsLabel": "string"
   }
   ```

### Use File Input for an Entire Command

This end-to-end example shows how to generate the JSON to create a virtual cloud network (VCN). The JSON is saved in a file, edited, and then used as command line input.

Use a JSON File as Input to Create a VCN

1. To generate the JSON needed to create a VCN, run the following command.

   ```shell
   oci network vcn create --generate-full-command-json-input
   ```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   {
   "cidrBlock": "string",
   "compartmentId": "string",
   "displayName": "string",
   "dnsLabel": "string"
   }
   ```
3. Edit the file and replace the "string" values with values, as shown in the following example.

```json
{
   "cidrBlock": "10.0.0.0/16",
   "compartmentId": "ocid1.compartment.oc1..aaaaaaaal3gzijdliedxxhjqol2rggnrdwyyg35nz5zxil26astpgeyq7jnhw",
   "displayName": "TestVCN",
   "dnsLabel": "testdns"
}
```

4. Save the file and name it "create-vcn.json"

5. To create the VCN using "create-vcn.json" as input, run the following command.

```
oci network vcn create --from-json file://create-vcn.json
```

**Advanced Examples**

The following examples show how you can use the CLI to complete complex tasks in Oracle Cloud Infrastructure.

**Working with Object Storage**

You can use the CLI for several object operations with the Object Storage service.

**Uploading and Downloading Files**

Objects can be uploaded from a file or from the command line (STDIN), and can be downloaded to a file or to the command line (STDOUT).

Upload an object:

```
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt --metadata '{"key1":"value1","key2":"value2"}"
```

Upload object contents from the command line (STDIN):

```
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file <---'object content'
```

Download an object:

```
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt
```

Print object contents to the command line (STDOUT):

```
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file -
```

**Bulk Operations in Object Storage**

The CLI supports the following bulk operations in Object Storage:

- Uploading files in a directory and all its subdirectories to a bucket

```
# Upload all the files in a directory.
oci os object bulk-upload -ns mynamespace -bn mybucket --src-dir path/to/upload/directory
```
• Downloading all objects, or all the objects that match a specified prefix, in a bucket

```bash
# Download all the objects.
oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory

# Download all the objects that match the specified prefix.
oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory --prefix myprefix
```

• Deleting all objects, or all the objects that match a specified prefix, in a bucket

```bash
# Delete all the objects.
oci os object bulk-delete -ns mynamespace -bn mybucket

# Delete objects that match the specified prefix.
oci os object bulk-delete -ns mynamespace -bn mybucket --prefix myprefix
```

Bulk operations support several options that let you:

• Overwrite or skip files/objects using `--overwrite` or `--no-overwrite`. (**Note:** If you pass neither of these options you are prompted for confirmation every time there is something to overwrite.)

• Limit delete, upload, or download operations using `--prefix` and/or `--delimiter`

• Preview a bulk deletion with `--dry-run`

To get more information about the commands for bulk operations, run the following help commands:

```bash
# bulk-upload
oci os object bulk-upload -h

# bulk-download
oci os object bulk-download -h

# bulk-delete
oci os object bulk-delete -h
```

**Multipart Operations in Object Storage**

Multipart operations for Object Storage include object uploads and downloads.

**Multipart Uploads**

Large files can be uploaded to Object Storage in multiple parts to speed up the upload. By default, files larger than 128 MiB are uploaded using multipart operations. You can override this default by using the `--no-multipart` option.

You can configure the following options for the `oci os object put` command:

• `--no-multipart` overrides an automatic multipart upload if the object is larger than 128 MiB. The object is uploaded as a single part, regardless of size.

• `--part-size` in MiB, to use in a multipart operation. The default part size is 128 MiB and a part size that you specify must be greater than 10 MiB. If the object is larger than the `--part-size`, it is uploaded in multiple parts.

• `--parallel-upload-count`, to specify the number of parallel operations to perform. You can use this value to balance resources and upload times. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The `--resume-put` command allows you to resume a large file upload in cases where the upload was interrupted.
Multipart Uploads from STDIN

Objects uploaded from STDIN are uploaded in multiple parts. If the object content is smaller than 10 MiB, the upload is only 1 part, and the MultipartUpload API is used for the upload. Specifying --no-multipart when uploading from STDIN will result in an error.

The following example shows the command for a multipart upload if the object is larger than 200 MiB.

```bash
oci os object put -ns my-namespace -bn my-bucket --file path/to/large/file --part-size 200
```

For more information about multipart uploads, see Using Multipart Uploads on page 3477.

Multipart Downloads

Large files can be downloaded from Object Storage in multiple parts to speed up the download.

You can configure the following options for the `oci os object get` command:

- `--multipart-download-threshold` lets you specify the size, in MiB at which an object should be downloaded in multiple parts. This size must be at least 128 MiB.
- `--part-size`, in MiB, to use for a download part. This gives you the flexibility to use more (smaller size) or fewer (larger size) parts as appropriate for your requirements. For example, compute power and network bandwidth. The default minimum part size is 120 MiB.
- `--parallel-download-count` lets you specify how many parts are downloaded at the same time. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The following example shows the command to download any object with a size greater than 500 MiB. The object is downloaded in 128 MiB parts.

```bash
oci os object get -ns my-namespace -bn my-bucket --name my-large-object --multipart-download-threshold 500 --part-size 128
```

Upgrading the CLI

If you installed the CLI manually, use one of the following commands to upgrade the CLI.

- To upgrade a standard installation, run the following command.
  ```bash
  pip install oci-cli --upgrade
  ```
- To upgrade a standard virtualenv installation, run the following command.
  ```bash
  cli-testing/bin/pip install oci-cli --upgrade
  ```

If you installed the CLI using the install script, use the following process to upgrade the CLI:

- Run the install script and specify the same install directory.
- When prompted, reply Y to remove the existing directory.

Upgrading the CLI on Mac OS X with Homebrew

Homebrew offers a convenient way to manage your CLI install on Mac OS.

To upgrade your CLI install using Homebrew:

```bash
brew update && brew upgrade oci-cli
```
Uninstalling the CLI

For Manual Installations
If you manually installed the CLI using pip, run the following command:

```
pip uninstall oci-cli
```

If you manually installed the CLI in a virtual environment, run the following command:

```
<path/to/virtualenv>/bin/pip uninstall oci-cli
```

For Script Installations
If you used the install script and the default installation location, you should delete the following directories.

On Windows:

- %USERPROFILE%/lib/oracle-cli
- %USERPROFILE%/bin/oci
- %USERPROFILE%/bin/oci-cli-scripts

On Mac:

- $HOME/lib/oracle-cli
- $HOME/bin/oci
- $HOME/bin/oci-cli-scripts

If you used the install script, but installed to a custom location, you should delete the directories at that location.

Uninstalling Python

The script also installs Python as a dependency if it was not already installed. In Windows 10, you can uninstall Python in Control Panel or at the command line.

Using Control Panel

To uninstall Python in Control Panel, select Programs and Features. Right-click Python and select Uninstall. For more information, see Repair or remove programs in Windows 10.

Using the Command Line

To uninstall Python at the command line, run the following command:

```
msiexec /x python<version>.msi
```

If you do not have the MSI file, you can also use the package or product code. For more information, see Using the Windows Installer.

Uninstalling the CLI on Mac OS X with Homebrew

To unsinstall the CLI from Mac OS X using Homebrew:

```
brew uninstall oci-cli
```

Troubleshooting the CLI

This topic describes how to resolve issues that you might encounter when installing Python or the CLI, or when using the CLI.
Service Errors

Any operation resulting in a service error causes an error of type "ServiceError" to be returned by the CLI. For information about common service errors that Oracle Cloud Infrastructure returns, see API Errors.

Oracle Linux Permissions Issues

On Oracle Linux 7.3, if you encounter permission issues when running pip install, you might need to use sudo.

oci Command Not Found

If the oci command isn't found, this can be caused by one of the following reasons:

• pip installed the package to a different virtual environment than your active one.
• You switched to a different active virtual environment after you installed the CLI.

To determine where the CLI is installed, run the which pip and which oci commands.

Wheel File Won't Install

If the wheel file won't install, verify that pip is up to date. To update pip, run the pip install -U pip command. Try to install the wheel again.

Windows Issues

If the oci command isn't found, make sure that the oci.exe location is in your path (for example, the Scripts directory in your Python installation).

Contact Information

If you want to contribute ideas, report a bug, get notified about updates, have questions, or want to give feedback, use one of the following links.

Contributions

Got a fix for a bug, or a new feature you'd like to contribute? The CLI is open source and accepting pull requests on GitHub.

Notifications

To be notified when a new version of the CLI is released, subscribe to the Atom feed.

Questions or Feedback

Ways to get in touch:

• GitHub: To file bugs and feature requests only.
• Stack Overflow: Use the oracle-cloud-infrastructure and oci-cli tags in your post.
• Developer Tools section of the Oracle Cloud forums

CLI Environment Variables

The Oracle Cloud Infrastructure CLI supports the use of environment variables to specify default values for some options.

Environment Variables

The following table lists the available environment variables and their corresponding CLI options or ~/.oci/config entries.
<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>CLI option</th>
<th>OCI config entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCI_CLI_PROFILE</td>
<td>--profile</td>
<td>Specified by [DEFAULT]</td>
<td>The profile in the OCI config file to load. This profile will also be used to locate any default parameter values which have been specified in the OCI CLI-specific configuration file.</td>
</tr>
<tr>
<td>OCI_CLI_USER</td>
<td>n/a</td>
<td>user</td>
<td>The OCID of the user calling the API. To get the value, see Required Keys and OCIDs on page 4179. Example: ocid1.user.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>OCI_CLI_REGION</td>
<td>--region</td>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 180. Example: us-ashburn-1</td>
</tr>
<tr>
<td>OCI_CLI_FINGERPRINT</td>
<td>n/a</td>
<td>fingerprint</td>
<td>The fingerprint for the public key that was added to this user. To get the value, see Required Keys and OCIDs on page 4179. Example: 20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34</td>
</tr>
<tr>
<td>OCI_CLI_KEY_FILE</td>
<td>n/a</td>
<td>key_file</td>
<td>The full path and filename of the private key. Important: The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 4179. If you encrypted the key with a passphrase, you must also include the pass_phrase entry in the config file. Example: ~/.oci/oci_api_key.pem</td>
</tr>
<tr>
<td>Environment Variable</td>
<td>CLI option</td>
<td>OCI config entry</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OCI_CLI_TENANCY</td>
<td>n/a</td>
<td>tenancy</td>
<td>The OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 4179. Example: ocid1.tenancy.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>OCI_CLI_ENDPOINT</td>
<td>--endpoint</td>
<td>n/a</td>
<td>The value to use as the service endpoint, including any required API version path. Example: <a href="https://iaas.us-phoenix-1.oracle.com/20160918">https://iaas.us-phoenix-1.oracle.com/20160918</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Note:</strong> The <strong>--region</strong> parameter is the recommended way of targeting different regions. This value can also be set in the OCI CLI-specific configuration file. See Configuring the CLI on page 4202 for more information.</td>
</tr>
<tr>
<td>OCI_CLI_CONFIG_FILE</td>
<td>--config-file</td>
<td>n/a</td>
<td>The path to the OCI config file.</td>
</tr>
<tr>
<td>OCI_CLI_RC_FILE</td>
<td>--cli-rc-file</td>
<td>n/a</td>
<td>The path to the OCI CLI-specific configuration file, containing parameter default values and other configuration information such as command aliases and predefined queries. See Configuring the CLI on page 4202 for more information.</td>
</tr>
<tr>
<td>OCI_CLI_CERT_BUNDLE</td>
<td>--cert-bundle</td>
<td>n/a</td>
<td>The full path to a CA certificate bundle to be used for SSL verification.</td>
</tr>
</tbody>
</table>
Software Development Kits and Command Line Interface

Oracle Cloud Infrastructure provides a number of Software Development Kits (SDKs) and a Command Line Interface (CLI) to facilitate development of custom solutions.

- Software Development Kits (SDKs) Build and deploy apps that integrate with Oracle Cloud Infrastructure services. Each SDK provides the tools you need to develop an app, including code samples and documentation to create, test, and troubleshoot. In addition, if you want to contribute to the development of the SDKs, they are all open source and available on GitHub.
  - SDK for Java
  - SDK for Python
  - SDK for TypeScript and JavaScript
  - SDK for .NET
  - SDK for Go
  - SDK for Ruby
- Command Line Interface (CLI) on page 4192 The CLI provides the same core capabilities as the Oracle Cloud Infrastructure Console and provides additional commands that can extend the Console's functionality. The CLI is convenient for developers or anyone who prefers the command line to a GUI.
- PL/SQL SDK The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write code to manage Oracle Cloud Infrastructure resources. The latest version of the PL/SQL SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

SDK for Java

The Oracle Cloud Infrastructure SDK for Java enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: GitHub or Maven.
Tip:

The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see SDK for Java Cloud Shell Quick Start on page 4187.

Requirements

To use the SDK for Java, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 57. For a list of typical policies you may want to use, see Common Policies on page 2142.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Configuring the SDK on page 4228.
- Java 8
- A TTL value of 60. For more information, see Configuring the SDK on page 4228.

Services Supported

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
- Blockchain Platform
- Budgets
- Cloud Guard
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Data Catalog
- Data Flow
- Data Integration
- Data Science
- Data Safe
- Data Transfer
- Database
- Database Management
- Digital Assistant
- DNS
- Email Delivery
- Events
- File Storage
- Functions
- Golden Gate
- Health Checks
Developer Tools

- IAM
- Integration
- Key Management (for the Vault service)
- Limits
- Load Balancing
- Logging
- Logging Analytics
- Logging Search
- Logging Ingestion
- Management Agent Cloud
- Management Dashboard
- Marketplace
- Monitoring
- MySQL Database
- NoSQL Database Cloud
- Notifications
- Object Storage
- OCI Registry
- Operations Insights
- Optimizer
- Organizations
- OS Management
- Quotas
- Resource Manager
- Roving Edge Infrastructure
- Search
- Secret Management (for the Vault service)
- Service Connector Hub
- Streaming
- Support Management
- Usage
- VMWare Solution
- Web Application Acceleration and Security
- Work Requests (Compute, Database)

Questions or Feedback
- GitHub Issues: To file bugs and feature requests only
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-java-sdk tags in your post
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support
**Getting Started**

This topic describes how to install and configure the Oracle Cloud Infrastructure SDK for Java.

**Tip:**

The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see **SDK for Java Cloud Shell Quick Start** on page 4187.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Java, along with other Oracle development tools.

Downloading the SDK from GitHub

You can download the SDK for Java as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples. For best compatibility and to avoid issues, use the version of the dependencies included in the archive. Some notable issues are:

- Bouncy Castle: The SDK bundles 1.60 (included in this distribution). If you need FIPS compliance, see **Using BC-FIPS Instead of Bouncy Castle** on page 4232.
- Jersey Core and Client: The SDK bundles 2.24.1, which is required to support large object uploads to Object Storage. Older versions will not support uploads greater than ~2.1 GB.
- Jax-RS API: The SDK bundles 2.0.1 of the spec. Older versions will cause issues.

**Note:**

The SDK for Java is bundled with Jersey (included in this distribution), but you can also use your own JAX-RS implementation. For details, see **Using Your Own JAX-RS Implementation** on page 4233.

Downloading the SDK from Maven or JCenter

Maven Central and JCenter.

Installing with yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for Java:

```
sudo yum-config-manager --enable ol7_developer
dsudo yum install java-oci-sdk.x86_64
```

The OCI jar file will be located in: `/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar`, and third-party libraries will be in `/usr/lib64/java-oci-sdk/third-party/lib`.

You can add the following entries to your classpath:

```
/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar:
/usr/lib64/java-oci-sdk/third-party/lib/*
```

For example:

```
javac -cp "/usr/lib64/java-oci-sdk/third-party/lib/*:/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-1.8.2.jar" MyFile.java
```

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.
**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 4184.

Next you need to set up the client to use the credentials. The credentials are abstracted through an AuthenticationDetailsProvider interface. Clients can implement this however you choose. We have included a simple POJO/builder class to help with this task (SimpleAuthenticationDetailsProvider).

- You can load a config with or without a profile:

```java
ConfigFile config = ConfigFileReader.parse("~/.oci/config");
ConfigFile configWithProfile = ConfigFileReader.parse("~/.oci/config", "DEFAULT");
```

- The private key supplier can be created with the file path directly, or using the config file:

```java
Supplier<InputStream> privateKeySupplier = new SimplePrivateKeySupplier("~/oci/oci_api_key.pem");
Supplier<InputStream> privateKeySupplierFromConfigEntry = new SimplePrivateKeySupplier(config.get("key_file"));
```

- To create an auth provider using the builder:

```java
AuthenticationDetailsProvider provider = SimpleAuthenticationDetailsProvider.builder()
    .tenantId("myTenantId")
    .userId("myUserId")
    .fingerprint("myFingerprint")
    .privateKeySupplier(privateKeySupplier)
    .build();
```

- To create an auth provider using the builder with a config file:

```java
AuthenticationDetailsProvider provider = SimpleAuthenticationDetailsProvider.builder()
    .tenantId(config.get("tenancy"))
    .userId(config.get("user"))
    .fingerprint(config.get("fingerprint"))
    .privateKeySupplier(privateKeySupplier)
    .build();
```

- Finally, if you use standard config file keys and the standard config file location, you can simplify this further by using ConfigFileAuthenticationDetailsProvider:

```java
AuthenticationDetailsProvider provider = new ConfigFileAuthenticationDetailsProvider("ADMIN_USER");
```

**Configuring Client-side Options**

Create a client-side configuration through the ClientConfiguration class. If you do not provide your own configuration, the SDK for Java uses a default configuration. To provide your own configuration, use the following:

```java
ClientConfiguration clientConfig = ClientConfiguration.builder()
    .connectionTimeoutMillis(3000)
    .readTimeoutMillis(60000)
    .build();
```

After you have both a credential configuration and the optional client configuration, you can start creating service instances.
Developer Tools

Configuring Custom Options

In the config file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file like so (highlighted in red italics):

```
[DEFAULT]
user=ocid1.user.oc1..aaaaaaat5nvwcna5j6aqzjcmdy5egbb6gt2jvpkanhtgdagf5w3rynjq
key_file=/usr/local/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaba3pv6kcr4jqae5f15p2bcmdyt2j6rx32uzr4h25vqstifsfsdsq

custom_compartment_id=ocid1.compartment.oc1..aaaaaaayzfqeibduyox6iib3olcmdar3ugly4fmame
```

Then you can retrieve the value like so:

```java
ConfigFile config = ConfigFileReader.parse("~/.oci/config");
String compartmentId = config.get("custom_compartment_id");
```

Using the SDK for Java

To use the Oracle Cloud Infrastructure SDK for Java in your project, import the `oci-java-sdk-bom`, followed by your project dependencies. For example:

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.oracle.oci.sdk</groupId>
      <artifactId>oci-java-sdk-bom</artifactId>
      <!-- replace the version below with your required version -->
      <version>1.5.2</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-audit</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-core</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-database</artifactId>
  </dependency>
  <!-- more dependencies if needed -->
</dependencies>
```

Configuration

This topic provides details on compatibility, advanced configurations, and add-ons for the Oracle Cloud Infrastructure SDK for Java.

Security Manager Permissions
If your application needs to run inside the Java Security Manager, you must grant additional permissions by updating a policy file, or by specifying an additional or a different policy file at runtime.

The SDK requires the following permissions:

- **Required by Jersey:**

  ```java
  permission java.lang.RuntimePermission "getClassLoader;"
  permission java.lang.reflect.ReflectPermission "suppressAccessChecks;"
  permission java.lang.RuntimePermission "accessDeclaredMembers;"
  permission java.util.PropertyPermission "+", "read,write;"
  permission java.lang.RuntimePermission "setFactory;"
  ```

- **Required by the SDK to overwrite reserved headers:**

  ```java
  permission java.util.PropertyPermission "sun.net.http.allowRestrictedHeaders", "write;"
  ```

- **Required by the SDK to open socket connections:**

  ```java
  permission java.net.SocketPermission "+", "connect;"
  ```

To include another policy file, in addition to Java Runtime Environment's default policy file, launch the Java Virtual Machine with:

```bash
java -Djava.security.manager -Djava.security.policy=</path/to/other_policy>
```

To replace the default policy file, launch the Java Virtual Machine with:

```bash
java -Djava.security.manager -Djava.security.policy==</path/to/other_policy>
```

**Note:**

Use a single equals sign (=) when supplying an additional policy file. Use a double equals sign (==) only if you wish to replace the default policy file.

### Java Virtual Machine TTL for DNS Name Lookups

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called *time-to-live* (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the `networkaddress.cache.ttl` property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, `-1`, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- **To set TTL globally for all applications using the JVM,** add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

  ```java
  networkaddress.cache.ttl=60
  ```

- **To set TTL only for your application,** set the following in your application's initialization code:

  ```java
  java.security.Security.setProperty("networkaddress.cache.ttl", "60");
  ```

### Apache Connector Add-On

The `oci-java-sdk-addons-apache` is an optional add-on to the SDK for Java that allows for configuring a client connection pool and an HTTP proxy. The add-on leverages the Jersey `ApacheConnectorProvider`
instead of the SDK’s default `HttpUrlConnectorProvider` when making service calls. The add-on can be found in the `bmc-addons` directory of the SDK.

For details on installation and configuration, see the [Readme](#) for the add-on.

**Using BC-FIPS Instead of Bouncy Castle**

If you need FIPS compliance, you must download and use a FIPS-certified version. The SDK supports `bc-fips 1.0.2` and `bcpkix-fips 1.0.3`. You can download them at: [https://www.bouncycastle.org/fips-java/](https://www.bouncycastle.org/fips-java/)

For help installing and configuring Bouncy Castle FIPS, see "BC FIPS Documentation" in the [User Guides](#) and [Security Policy](#) of the Bouncy Castle Documentation.

**Self-Managed Dependencies**

If you are managing dependencies yourself:

1. Remove the non-FIPS Bouncy Castle jar files from the class path:
   
   a. `bcprov-jdk15on-1.60.jar`
   
   b. `bcpkix-jdk15on-1.60.jar`

2. Add the FIPS Bouncy Castle jar files to the class path instead:

   a. `bc-fips-1.0.2.jar`
   
   b. `bcpkix-fips-1.0.3.jar`

**Maven-Managed Dependencies**

If you are using Maven to manage your dependencies:

1. Add the correct versions of `bc-fips` and `bcpkix-fips` to your dependencies:

   ```xml
   <dependencies>
   . . .
   <dependency>
     <groupId>bc-fips</groupId>
     <artifactId>bc-fips</artifactId>
     <version>1.0.2</version>
   </dependency>
   <dependency>
     <groupId>bcpkix-fips</groupId>
     <artifactId>bcpkix-fips</artifactId>
     <version>1.0.3</version>
   </dependency>
   . . .
   </dependencies>
   ```

2. Since you are depending on an `oci-java-sdk*` package, you need to remove the non-FIPS Bouncy Castle dependencies:

   ```xml
   <dependencies>
   . . .
   <dependency>
     <groupId>com.oracle.oci.sdk</groupId>
     <artifactId>oci-java-sdk-common</artifactId>
     <version> . . .</version>
   </dependency>
   <exclusions>
     <exclusion>
       <groupId>org.bouncycastle</groupId>
       <artifactId>bcprov-jdk15on</artifactId>
     </exclusion>
     <exclusion>
       <groupId>org.bouncycastle</groupId>
       <artifactId>bcpkix-jdk15on</artifactId>
     </exclusion>
   </exclusions>
   </dependencies>
   ```
Using Your Own JAX-RS Implementation

The SDK for Java is bundled with Jersey, but you can also use your own JAX-RS implementation.

RESTEasy Client Configurator Add-On

The `oci-java-sdk-addons-resteasy-client-configurator` is provided to demonstrate how to configure an alternate JAX-RS implementation. The add-on can be found in the `bmc-addons` directory of the SDK.

For details on installation and configuration, see the Readme for the add-on.

For code samples that demonstrate how to configure the client, see:

- ResteasyClientExample.java
- ResteasyClientWithObjectStorageExample.java
- InstancePrincipalsAuthenticationDetailsProviderWithResteasyClientExample.java

Using SLF4J for Logging

Logging in the SDK is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following is an example that enables basic logging to standard out. More advanced logging options can be configured by using the log4j binding.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath (e.g., add it to the `/third-party/lib` directory of the SDK download)
3. Add the following VM arg to enable debug level logging (by default, info level is used):
   ```
   -Dorg.slf4j.simpleLogger.defaultLogLevel=debug
   ```

Concepts

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for Java.

Synchronous Calls

To make synchronous calls, create an instance of the synchronous client. The general pattern for synchronous clients is that for a service named Example, there will be an interface named ExampleService, and the synchronous client implementation will be called ExampleServiceClient. Here's an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorage clientWithDefaultClientConfig = new
    ObjectStorageClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorage clientWithExplicitClientConfig = new
    ObjectStorageClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Synchronous calls will block until the response is available. All SDK APIs return a response object (regardless of whether or not the API sends any content back). The response object typically contains at least a request ID that you can use when contacting Oracle support for help on a particular request.

```java
ObjectStorage client = ...;
GetBucketResponse response = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
String requestId = response.getOpcRequestId();
Bucket bucket = response.getBucket();
```
Asynchronous Calls

To make asynchronous calls, create an instance of the asynchronous client. The general pattern for asynchronous clients is that for a service named Example, there will be an interface named ExampleServiceAsync, and the asynchronous client implementation will be called ExampleServiceAsyncClient. Here's an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorageAsync clientWithDefaultClientConfig = new
    ObjectStorageAsyncClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorageAsync clientWithExplicitClientConfig = new
    ObjectStorageAsyncClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Asynchronous calls return immediately. You need to provide an AsyncHandler that will be invoked after the call completes either successfully or unsuccessfully:

```java
ObjectStorageAsync client = ...;
AsyncHandler<GetBucketRequest, GetBucketResponse> handler = new
    AsyncHandler<GetBucketRequest, GetBucketResponse>() {
        @Override
        public void onSuccess(GetBucketRequest request, GetBucketResponse response) {
            String requestId = response.getOpcRequestId();
            Bucket bucket = response.getBucket();
            System.out.println(requestId);
            System.out.println(bucket.getName());
        }
        
        @Override
        public void onError(GetBucketRequest request, Throwable error) { error.printStackTrace(); }
    };

Future<GetBucketResponse> future = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build(),
    handler);
```

Polling with Waiters

The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write into an easy-to-use single method call.

Waiters are obtained through the service client (client.getWaiters()). Both a `Get<Resource>Request` and the desired lifecycle state are passed in to the `waiters.for<Resource>` method. For example:

```java
public static Instance waitForInstanceProvisioningToComplete( ComputeClient computeClient, String instanceId) throws Exception {
    ComputeWaiters waiters = computeClient.getWaiters();
    GetInstanceResponse response = waiters.forInstance(}
GetInstanceRequest.builder().instanceId(instanceId).build(),
  Instance.LifecycleState.Running)
  .execute();
  return response.getInstance();
}

Each `waiters.for<Resource>` method has two versions:

- One version uses the default polling values. For example:

  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState)
  ```

- The other version gives you full control over how long to wait and how much time between polling attempts. For example:

  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState,
  TerminationStrategy, DelayStrategy)
  ```

Threading Model

A client becomes thread-safe when it is initialized. After setting its endpoint, you can safely use a client in multiple threads and concurrently call methods on it.

You can reuse a client on multiple requests, both across concurrent threads or within a single thread. Unless the environment's resources are constrained, you should only close the client immediately before it goes out of scope.

Note:

This guarantee applies only to the default JAX-RS implementation, Jersey. When using an alternate implementation, you must manage thread safety yourself. For more information, see Configuring the SDK on page 4228

Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for Java supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the `UploadManager`, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The `UploadObject` example shows how to use the `UploadManager` to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for Java exposes the `DefaultRequestSigner` class that you can use to create a `RequestSigner` instance for non-standard requests.

The Raw Request example on GitHub shows how to:

- create an authentication provider and request signer
- integrate with an HTTP client (Jersey in this example) to authenticate requests

Setting the Endpoints

Service endpoints can be set in three ways.

- Call `setEndpoint()` on the service instance. This lets you specify a full host name (for example, https://www.example.com).
• Call `setRegion()` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for Java returns an error.
• Pass the region in the configuration file. For more information, see [SDK and CLI Configuration File](#) on page 4184.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

**Forward Compatibility and enums**

If you have conditional logic based on an enum, be sure that your code handles the `UnknownEnumValue` case to ensure forward compatibility. Some response fields are of type enum, but in the future, individual services may return values not covered by existing enums for that field. To address this possibility, every response field of type enum has an additional value named `UnknownEnumValue`. If a service returns a value that is not recognized by your version of the SDK, then the response field will be set to this value.

**New Region Support**

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see [Regions and Availability Domains](#) on page 180.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.register` to register the new region, and then you can set the region by either using the configuration file or by calling the `setRegion` method.

```
Note:

Once a region is registered, the federation endpoint is no longer required while using instance principals. For an example, see [https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java](https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java).
```

**oraclecloud.com Realm**

For regions in the `oraclecloud.com` realm, you can pass new region names just as you would pass ones that are already defined in the `Region` enum for your SDK version.

```
Note:

For the following code samples, be sure to supply the appropriate endpoints for your region.
```

If you are using version 1.2.34 or later of the SDK for Java, you can pass the new region name as a string using one of the following methods:

• To set the region on a previously created client:

```
client.setRegion("ca-toronto-1");
```

• To set a region when building a new client:

```
Identity identityClient = IdentityClient.builder().
.region("ca-toronto-1")
 .build(provider);
```

• You can also pass the region in the configuration file. For more information, see [SDK and CLI Configuration File](#) on page 4184.
Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To specify the endpoint:

```java
AuthenticationDetailsProvider provider =
    new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);

IdentityClient client = IdentityClient.builder()
    .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
    .build(provider);
```

If you are authenticating via instance principals, you can set the endpoint and federationEndpoint via the following process:

```java
InstancePrincipalsAuthenticationDetailsProvider provider =
    InstancePrincipalsAuthenticationDetailsProvider.builder()
    .federationEndpoint("https://auth.ca-toronto-1.oraclecloud.com/v1/x509")
    .build();

IdentityClient identityClient = IdentityClient.builder()
    .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
    .build(provider);
```

Paginated Responses

Some APIs return paginated result sets, so you must check for additional items and if necessary, fetch the next page. You can do so manually or you can use an iterator.

Manually Fetching Pages

The Response objects contain a method to fetch the next page token. If the token is null, there are no more items. If it is not null, you can make an additional request, by setting the token on the Request object, to get the next page of responses.

**Note:**

Some APIs may return a token even if there are no additional results. Be sure to also check whether any items were returned and stop if there are none.

This example shows how to handle page tokens returned by the Object Storage API:

```java
ObjectStorage client = ...;

ListBucketsRequest.Builder builder =
    ListBucketsRequest.builder().namespaceName(namespace);
String nextPageToken = null;
while (nextPageToken != null) {
    builder.page(nextPageToken);
    ListBucketsResponse listResponse = client.listBuckets(builder.build());
    List<Bucket> buckets = listResponse.getItems();
    // handle buckets
    nextPageToken = listResponse.getOpcNextPage();
} while (nextPageToken != null);
```
Using an Iterator

Instead of manually working with page tokens, you can use an iterator. Each service client exposes a `getPaginators()` method that returns a `Paginator` object. This object contains methods to return objects of type `Iterable`. We support two approaches to using `Iterable`:

- **Response Iterator**: You can iterate over the `Response` objects that are returned by the list operation. These are referred to as `ResponseIterators`, and their methods are suffixed with "ResponseIterator," for example, `listUsersResponseIterator`.

  ```java
  Iterable<ListUsersResponse> responseIterator =
      identityClient.getPaginators().listUsersResponseIterator(request);
  for (ListUsersResponse response : responseIterator) {
      for (User user : response.getItems()) {
          System.out.println(user);
      }
  }
  ```

- **Record Iterator**: You can iterate over the resources/records that are listed. These are referred to as `RecordIterator`, and their methods are suffixed with "RecordIterator," for example, `listUsersRecordIterator`.

  ```java
  Iterable<User> recordIterator =
      identityClient.getPaginators().listUsersRecordIterator(request);
  for (User user : recordIterator) {
      System.out.println(user);
  }
  ```

Client-Side Encryption

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the `CreateKey` or `ImportKey` operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

Java Prerequisites

The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171, and 6u16. For those versions and later the policy files are included but not enabled by default.

Current versions of the JDK do not require these policy files. They are provided here for use with older versions of the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.

Examples

The following code example shows how to encrypt a string:

```java
// String encryption example
final byte[] plainText = "Hello World".getBytes();
String masterKeyId = "OCID....";
Map<String, String> context = Collections.singletonMap("Example", "value");
OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
    Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(kmsMasterKey);
```
// Encrypt the data and embed the master key ID in the header
final OciCryptoResult encryptResult =
    ociCrypto.encryptData(kmsMasterKeyProvider, plainText, context);
final byte[] cipherText = encryptResult.getResult();

// Decrypt the data
final OciCryptoResult decryptResult =
    ociCrypto.decryptData(kmsMasterKeyProvider, cipherText);

The following example shows how to encrypt a file stream:

// Create Encryption file stream
FileInputStream in = new FileInputStream(srcFile);
OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
    Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(kmsMasterKey);
OciCryptoInputStream encryptingStream =
    ociCrypto.createEncryptingStream(kmsMasterKeyProvider, in);

// Write the encrypted data to file
FileOutputStream out = new FileOutputStream(srcFile + "_.encrypted");
IOUtils.copy(encryptingStream, out);
encryptingStream.close();
out.close();

// For decryption, no need to pass key info
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(authenticationProvider);
// Create the Decryption file stream.
in = new FileInputStream(srcFile + "_.encrypted");
OciCryptoInputStream decryptingStream =
    ociCrypto.createDecryptingStream(kmsMasterKeyProvider, in);

// Return the plaintext data
out = new FileOutputStream(srcFile + "_.decrypted");
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
out.close();

Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as
the status code or timeout. You can also get the request ID when handling a BmcException by using the
getOpcRequestId method.

This example shows a try-catch block that handles a BmcException and prints the request ID.

ObjectStorage client = ...;
try {
    GetBucketResponse response = client.getBucket(
        GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
    String requestId = response.getOpcRequestId();
    System.out.println(requestId);
} catch (BmcException e) {
    String requestId = e.getOpcRequestId();
    System.out.println(requestId);
    e.printStackTrace();
}
Exceptions in the SDK for Java are runtime exceptions (unchecked), so they do not show up in method signatures. All APIs can throw a BmcException.

**Examples**

**GitHub**

Examples of SDK usage can be found on GitHub, including:

- Example: Synchronous Object Storage
- Example: Asynchronous Object Storage
- Example: Create an instance
- Example: Get an instance's public IP address

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

**SDK Reference**

In addition to the examples found on GitHub, the SDK for Java API reference contains code examples that you can copy and modify to run in your own environment.

**Running Examples**

1. Download the SDK to a directory named oci. See GitHub for the download.
2. Unzip the SDK into the oci directory. For example: tar -xf oci-java-sdk-dist.zip
3. Create your configuration file in your home directory (~/.oci/config). See Configuring the SDK on page 4228.
4. Use javac to compile one of the previous example classes from the examples directory, ex:

   ```bash
   javac -cp lib/oci-java-sdk-full-<version>.jar:third-party/lib/* examples/ObjectStorageSyncExample.java
   ```

5. You should now have a class file in the examples directory. Run the example:

   ```bash
   java -cp examples:lib/oci-java-sdk-full-<version>.jar:third-party/lib/* ObjectStorageSyncExample
   ```

**Third-Party Dependencies and Shading**

The SDK requires a number of third-party dependencies, which are available in the third-party/lib directory. To use the SDK library lib/oci-java-sdk-full-<version>.jar, all of the third-party dependencies in third-party/lib have to be on the class path.

The SDK also includes a second version of the SDK library, shaded/lib/oci-java-sdk-full-shaded-<version>.jar, which contains most of the third-party dependencies already. Only a few more third-party libraries in shaded/third-party/lib have to be on the class path when you use this version of the SDK library.

These two versions of the SDK library are functionally the same, however the second version, shaded/lib/oci-java-sdk-full-shaded-<version>.jar can simplify dealing with different versions of third-party dependencies. This is because all the dependencies that are included in shaded/lib/oci-java-sdk-full-shaded-<version>.jar were shaded, which means they will not interfere with other versions of themselves you may want to include along with this SDK.

To use the shaded version of the SDK, replace the `javac` commands in steps 4 and 5 with the following:

- **Step 4:**

  ```
  ```

- **Step 5:**

  ```
  ```

**Troubleshooting**

This section contains troubleshooting information for the Oracle Cloud Infrastructure SDK for Java.

ObjectStorage client does not close connections when client is closed.

Too many file descriptors are opened up, and it takes too long to close existing ones. An exception may look like this:

```
Caused by: java.io.FileNotFoundException: classes/caspertest.pem (Too many open files)
  at java.io.FileInputStream.open0(Native Method)
  at java.io.FileInputStream.open(FileInputStream.java:195)
  at java.io.FileInputStream.<init>(FileInputStream.java:138)
```

Use one of the following workarounds to fix this issue.

- Make this call before creating a client:
  ```
  System.setProperty("http.keepAlive", "false");
  ```
- Use this command line argument when running Java:
  ```
  -Dhttp.keepAlive=false
  ```

Serialization errors when making requests or handling responses

An `UnrecognizedPropertyException` error when handling a response indicates that the version of the Jackson library does not support a feature that was injected at runtime from another dependency in your application's class path. This happens even if the `FAIL_ON_UNKNOWN_PROPERTIES` deserialization property is set to `false` for the configured `ObjectMapper`.

**Solution:**

Determine which version of Jackson libraries are referenced in your application’s class path and, if necessary, upgrade to version 2.9.5. For a complete list of Jackson libraries that the SDK for Java depends on, please refer to the `pom.xml` file that is hosted on GitHub.

An alternative solution is to use the shaded version of the SDK for Java jar file, which includes a bundled version of the Jackson libraries.

Encryption key size errors

By default, the SDK for Java can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256.

Use one of the following workarounds to fix this issue.

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: [http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html](http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html)
Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the SDK. For information about common service errors returned by OCI, see API Errors.

SDK for Python

The Oracle Cloud Infrastructure SDK for Python enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The SDK for Python is available on GitHub or the Python Package Index (PyPi).

Documentation: Available on docs.cloud.oracle.com and readthedocs.io.

Tip: The SDK for Python is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Python from within Cloud Shell, see SDK for Python Cloud Shell Quick Start on page 4187.

Services Supported

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
- Blockchain Platform
- Budgets
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Cloud Guard
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- Digital Assistant
- DNS
- Email Delivery
- Events
- File Storage
- Functions
- Golden Gate
- Health Checks
Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Python, along with other Oracle development tools.

Installing with yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for Python.

The following example shows how to use yum to install the OCI SDK for Python 3.6:

```bash
sudo yum install python36-oci-sdk.x86_64
```

This example shows how to use yum to install the OCI SDK for Python 2.7:

```bash
sudo yum install python oci-sdk.x86_64
```
Client-Side Encryption

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the CreateKey or ImportKey operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

Examples

The following code example shows how to encrypt a string:

```
import oci

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
data_to_encrypt_bytes = b"This is a secret message"

crypto_result = crypto.encrypt(kms_master_key_provider, data_to_encrypt_bytes)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
print("unencrypted text: {}".format(crypto_result.get_data()))
```

The following example shows how to encrypt a file stream:

```
import oci
import shutil

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
file_to_encrypt = "/file/to/encrypt/message.txt"
output_encrypted_file = "/tmp/message.txt.encrypted"
output_decrypted_file = "/tmp/message.txt.decrypted"

# setup OCI KMS keys
config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id
)
kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

crypto_result = crypto.encrypt(kms_master_key_provider, file_to_encrypt)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
print("unencrypted text: {}".format(crypto_result.get_data()))
```
```python
config=config,
kms_master_keys=[kms_master_key]
)

# encrypt stream example
with open(output_encrypted_file, 'wb') as output_stream,
open(file_to_encrypt, 'rb') as stream_to_encrypt:
    with crypto.create_encryption_stream(
        kms_master_key_provider,
        stream_to_encrypt
    ) as encryption_stream:
        shutil.copyfileobj(encryption_stream, output_stream)

# decrypt stream example
with open(output_decrypted_file, 'wb') as output_stream,
open(output_encrypted_file, 'rb') as stream_to_decrypt:
    with crypto.create_decryption_stream(
        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)
```

**SDK for TypeScript and JavaScript**

The Oracle Cloud Infrastructure SDK for TypeScript and JavaScript enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download**: GitHub or NPM.

**Requirements**

To use the SDK for TypeScript and JavaScript, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 57. For a list of typical policies you may want to use, see Common Policies on page 2142.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Getting Started on page 4247.
Services Supported

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
- Blockchain Platform
- Budgets
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Cloud Guard
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- Digital Assistant
- DNS
- Email Delivery
- Events
- File Storage
- Functions
- Golden Gate
- Health Checks
- IAM
- Integration
- Key Management (for the Vault service)
- Limits
- Load Balancing
- Logging
- Logging Analytics
- Logging Search
- Logging Ingestion
- Management Agent Cloud
- Management Dashboard
- Marketplace
- Monitoring
- MySQL Database
- NoSQL Database Cloud
- Notifications
- Object Storage
- OCI Registry
• Operations Insights
• Optimizer
• Organizations
• OS Management
• Quotas
• Resource Manager
• Roving Edge Infrastructure
• Search
• Secret Management (for the Vault)
• Service Connector Hub
• Streaming
• Support Management
• Usage
• VMWare Solution
• Web Application Acceleration and Security
• Work Requests (Compute, Database)

**Versions Supported**

The SDK for TypeScript and JavaScript currently supports NodeJS version 10.15.3 and TypeScript version 4.1.3.

**NodeJS & Browser Support**

The SDK for TypeScript and JavaScript currently supports NodeJS but does not have browser support.

**Contact Us**

**Contributions**

Got a fix for a bug or a new feature you’d like to contribute? The SDK is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the SDK for TypeScript and JavaScript is released, subscribe to the Atom feed.

**Questions or Feedback**

- GitHub Issues: To file bugs and feature requests only
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-typescript-sdk tags in your post
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

**Getting Started**

This topic describes how to install and configure the SDK for TypeScript and JavaScript.

To use the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript in your project, import any service from `./oci-typescript-sdk/index.ts`. For example:

```typescript
// Container Engine
export import containerengine = require("oci-containerengine");

// Core
export import core = require("oci-core");

// Database
```
export import database = require("oci-database");

Downloading the SDK from GitHub

You can download the SDK for TypeScript and JavaScript as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

Installing with yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for TypeScript and JavaScript:

```
sudo yum install oracle-nodejs-release-el7
sudo yum install --enablerepo=ol7_developer_nodejs10 --enablerepo=ol7_developer oci-typescript-sdk
```

The oci-typescript-sdk yum package will only work for Node version 10.X.X. The oci-sdk package will be installed into the global node_modules folder. To use the oci-sdk package in a project, link the oci-sdk global package to your local project.

For example:

```
# Assuming you are in your project's top level directory
npm link oci-sdk
# You should now see oci-sdk package in your local project's node_modules folder
```

Because the oci-sdk package is globally installed, you must update the import statements for oci-sdk's sub-packages when running the oci-typescript-sdk examples on GitHub.

For example:

```
import * as identity from "oci-identity"; // Change needed
import * as oci from "oci-sdk"; // No change needed

import * as identity from "oci-sdk/node_modules/oci-identity"; // Changed
import * as oci from "oci-sdk"; // No change
```

Using the SDK for TypeScript and JavaScript with NPM

NPM.

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 4184.

The default configuration location is "~/.oci/config" and "DEFAULT" profile is used. You can use ConfigFileAuthenticationDetailsProvider with or without specifying the configuration location and profile name:

```
// TypeScript
import common = require("oci-common");
// Using default configuration
const provider: common.ConfigFileAuthenticationDetailsProvider = new
common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const provider: common.ConfigFileAuthenticationDetailsProvider = new
common.ConfigFileAuthenticationDetailsProvider(
```
const common = require("oci-common");
// Using default configurations
const provider = new common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "/your_config_location";
const configProfile = "your_profile_name";
const provider = new common.ConfigFileAuthenticationDetailsProvider(
    configurationFilePath,
    configProfile
);

Configuring Custom Options

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

```
[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>
```

Then you can retrieve the value:

```
// TypeScript
import common = require("oci-common");
const configurationFilePath = "/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile =
    config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";

// JavaScript
import common = require("oci-common");
const configurationFilePath = "/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile =
    config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";
```

Concepts

This topic explains some of the key concepts for using the SDK for TypeScript and JavaScript.

Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for TypeScript and JavaScript exposes the DefaultRequestSigner class that you can use to create an instance and call signHttpRequest.
The Raw Request example on GitHub shows how to create an instance of DefaultRequestSigner and call signHttpRequest.

Retries

You can configure the SDK for TypeScript and JavaScript to retry SDK operations that fail. The SDK allows you to specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

Delay Strategy

The delayStrategy parameter determines how long to wait between each retry call. There are two options for this parameter:

- **FixedTimeDelayStrategy (seconds)** - Each retry is delayed by a specified number of seconds.
- **ExponentialBackoffStrategy (seconds)** - The delay time for subsequent retry calls increases by an exponential factor of 2 until it reaches the defined maximum delay (in seconds), with a base value of one second.

The default delay strategy is set to ExponentialBackoffDelayStrategy with 30 seconds of delay.

Retry Condition

The retryCondition defines a function with an error argument that returns a boolean indicating whether to retry or not. The operation will be retried if this function returns true.

**Note:**

Retries are not supported for requests that have binary or stream bodies. This includes UploadManager operations. Requests with binary or stream bodies will not be retried.

Termination Strategy

The terminationStrategy parameter defines when to terminate the retry attempts. This parameter supports the following options:

- **MaxTimeTerminationStrategy (seconds)** - Defines total duration in seconds for which the retry attempts.
- **MaxAttemptsTerminationStrategy (attempts)** - Defines the total number of retry attempts.

Retry Examples

**TypeScript**

This example sets the retry configuration at the client level:

```javascript
identityClient.clientConfiguration = {
   retryConfiguration : {
      delayStrategy : new common.FixedTimeDelayStrategy(5),
      terminationStrategy : new common.MaxTimeTerminationStrategy(30),
      retryCondition : (error) => { return error.statusCode >= 500; }
   }
}
```

This example sets the retry configuration at the request level:

```javascript
const request: identity.requests.ListAvailabilityDomainsRequest = {
   compartmentId: tenancyId,
   retryConfiguration : {
      terminationStrategy : new common.MaxAttemptsTerminationStrategy(6),
   }
};
```
JavaScript

This example sets the retry configuration at the client level:

```javascript
identityClient.clientConfiguration = {
  retryConfiguration : {
    delayStrategy : new common.FixedTimeDelayStrategy(5),
    terminationStrategy : new common.MaxTimeTerminationStrategy(30),
    retryCondition : (error) => { return error.statusCode >= 500; }
  }
}
```

This example sets the retry configuration at the request level:

```javascript
const request = {
  compartmentId: tenancyId,
  retryConfiguration : {
    terminationStrategy : new 
    common.MaxAttemptsTerminationStrategy(6),
  }
};
```

Setting Endpoints

Service endpoints can be set in three ways:

- Set `.endpoint = '<YOUR_ENDPOINT>'` on the service instance. This lets you specify a full host name (for example, https://www.example.com).
- Set `.region = '<YOUR_REGION_ID>'` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for TypeScript and JavaScript returns an error. You can refer to the list of regionIds in: ./oci-typescript-sdk/common/lib/region.ts
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for xyz.abc.123.oraclecloud.com is oraclecloud.com.

You must first call Region.register to register the new region, and then you can set the region by either using the configuration file or by set .region = <Your_new_registered_region>.

oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the Region enum for your SDK version.

To set the region:

```javascript
identityClient = await new 
identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.region = 'us-phoenix-1'
```

Other Realms
For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the endpoint:

```javascript
// Instantiate an identity client
identityClient = await new
    identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.endpoint = 'https://<your_endpoint>.com'
```

### Paginated Responses

Sometimes it is better to lazy load a result. In order to retrieve more data from lazy load, you have to continue to make calls to the list operation, passing in the value of the most recent response’s next token. The pagination module allows you:

- Eagerly load all possible results from a list call
- Lazily load results

For an example on how to use these functions, please check [GitHub](https://github.com).

### Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or timeout. You can also get the request ID when handling an exception by looking at the opcRequestId property of the error object.

```javascript
try {
    const response = await identityClient.listAllUsersResponses(listUserReq);
} catch (err) {
    console.log('requestId: ', err.opcRequestId);
}
```

### Logging

The SDK for Typescript and JavaScript enables you to integrate your own logger. Logging in the SDK is done through the Logger interface. This interface is a logging abstraction that allows the use of a user-supplied logging library, such as log4js, bunyan, or winston.

For more information, see the [logging example on GitHub](https://github.com).

To enable logging:

```typescript
// TypeScript
// Download the logger that you want to use with the SDK (like bunyan)
import { LOG } from "oci-sdk";
var bunyan = require("bunyan");

// Set the logger here
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;
```

```javascript
// Javascript
import { LOG } from "oci-sdk";
var bunyan = require("bunyan");

// Set the logger here.
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;
```

**Examples**

[GitHub](https://github.com)
Examples of SDK usage can be found on GitHub, including:

- Example: Create an instance
- Example: Invoke Oracle Function
- Example: Move Compartment

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you’d like to see another example not already covered, file a GitHub issue.

**SDK Reference**

In addition to the examples found on GitHub, the SDK for TypeScript and JavaScript API reference contains code examples that you can copy and modify to run in your own environment.

**Running Examples**

**Note:**
If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

1. git clone the SDK for TypeScript and JavaScript

   ```
git clone https://github.com/oracle/oci-typescript-sdk.git
   ```

2. Change to the directory where you installed the oci-typescript-sdk repository.

3. Run npm install

4. Run npm run build

5. If you do not have typescript globally installed, run:

   ```
   npm install -g typescript@4.1.3.
   ```

**Note:**
We've tested and support TypeScript version 4.1.3 with the OCI SDK for TypeScript and JavaScript. We cannot guarantee full support for other versions of TypeScript.

6. You can optionally install ts-node globally to make it easier to run examples:

   ```
   npm install -g ts-node
   ```

7. Create your configuration file in your home directory. See SDK and CLI Configuration File on page 4184 for more information.

8. Change directory into the TypeScript example folder to run TypeScript examples. For example:

   ```
   cd ./oci-typescript-sdk/examples/typescript/
   ```

9. Run any of the examples.

   For example, if you're running ts-node:

   ```
   ts-node "./identity.ts"
   ```

   If you're not running ts-node:

   ```
   tsc ./identity.ts
   node ./identity.js
   ```
10. Some examples are available in JavaScript. They are located in the `oci-typescript-sdk/examples/javascript` folder. To run the JavaScript equivalent of the above example:

```
node "./identity.js"
```

**SDK for .NET**

The Oracle Cloud Infrastructure SDK for .NET enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** [GitHub](#) or [Nuget](#).

**Requirements**

To use the SDK for .NET, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](page 57). For a list of typical policies you may want to use, see [Common Policies](page 2142).
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see [SDK and CLI Configuration File](page 4184).
- [.NET Standard version 2.0 or higher](#)

**Services Supported**

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
- Blockchain Platform
- Budgets
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Cloud Guard
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- Digital Assistant
- DNS
- Email Delivery

- The Developer Tools section of the Oracle Cloud forums
• My Oracle Support

Getting Started

This topic describes how to install and configure the SDK for .NET.

To use a specific Oracle Cloud Infrastructure service in your project, you can use the dotnet add package command from the root directory of your project workspace that contains the project file. The syntax for the add package command is:

```
dotnet add package <PACKAGE_ID> -v <DESIRED_VERSION>
```

If you do not specify a version number, the `add package` command will install the latest version.

This example installs the latest version of the Core Service package:

```
dotnet add package OCI.DotNetSDK.Core
```

This example installs version 1.0.0 of the Identity Service package:

```
dotnet add package OCI.DotNetSDK.Identity -v 1.0.0
```

**Note:**

To avoid dependency conflicts, you should use the same versions of all OCI .NET SDK Nuget packages within an application.

Downloading the SDK from GitHub

You can download the SDK for .NET as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

Installing the SDK with Yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for .NET.

1. To install the OCI SDK for .NET using yum:

   ```
   sudo yum-config-manager --enable ol7_developer
   sudo yum install oci-dotnet-sdk
   ```

   The OCI Dotnet SDK service packages and its dependencies are located in `/usr/lib/dotnet/NuPkgs/`.

2. So the dotnet CLI can find the installed packages, you must do one of the following:

   a. Create a file named `nuget.config` in the root of your .NET application project and add the following content:

   ```xml
   <?xml version="1.0" encoding="utf-8"?>
   <configuration>
     <packageSources>
       <clear />
       <add key="local" value="/usr/lib/dotnet/NuPkgs" />
     </packageSources>
   </configuration>
   ```

   ...or...

   b. Use the `--source` option with the dotnet CLI commands, passing in the directory `/usr/lib/dotnet/NuPkgs/`. For example:

   ```
   dotnet build --source /usr/lib/dotnet/NuPkgs/
dotnet restore --source /usr/lib/dotnet/NuPkgs/
   ```
Developer Tools

3. To get information about the installed package, run the following command:

```bash
rpm -qi oci-dotnet-sdk
```

4. Add the OCI Service packages to your project using the dotnet command line:

```bash
dotnet add package OCI.DotNetSDK.Common
dotnet add package OCI.DotNetSDK.Audit --version 4.3.0
```

5. You can now import namespaces into your project. For example:

```csharp
using Oci.AuditService;
using Oci.AuditService.Models;
using Oci.Common;
using Oci.Common.Auth;
```

Using the SDK for .NET with Nuget

**Nuget.**

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see [SDK and CLI Configuration File](#) on page 4184.

Next, you need to set up the client to use the credentials. The credentials are abstracted through an `IAuthenticationDetailsProvider` interface that the client needs to implement.

These examples show implementations of `ConfigFileAuthenticationDetailsProvider` and `SimpleAuthenticationDetailsProvider`.

**Using a Standard Configuration**

If you use standard config file keys and the standard config file location, you can use `ConfigFileAuthenticationDetailsProvider`:

```csharp
using Oci.Common.Auth;

// uses DEFAULT profile in default file location: i.e ~/.oci/config
var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
```

**Using a Custom Configuration**

If you are using custom key names in the config file, you can use `SimpleAuthenticationDetailsProvider`.

To load a config with or without a profile:

```csharp
using Oci.Common;

var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);
```
var configWithProfile = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH, "DEFAULT");

Next, create an Auth provider using SimpleAuthenticationDetailsProvider:

using Oci.Common;
using Oci.Common.Auth;

var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);

// The private key supplier can be created with the file path, or using the config file
var provider = new SimpleAuthenticationDetailsProvider {
    TenantId = config.GetValue("tenancy"),
    UserId = config.GetValue("user"),
    Fingerprint = config.GetValue("fingerprint"),
    Region = Region.FromRegionId(config.GetValue("region")),
    PrivateKeySupplier = new FilePrivateKeySupplier(config.GetValue("key_file"),
        config.GetValue("pass_phrase"))
};

Configuring Client-Side Options

Create a client-side configuration through the ClientConfiguration class. If you do not provide your own configuration, the SDK for .NET uses a default configuration.

The following example shows how to provide your own configuration:

var clientConfiguration = new ClientConfiguration {
    ClientUserAgent = "DotNet-SDK-Example",
    RetryConfiguration = new RetryConfiguration {
        MaxAttempts = 5,
        // retries the request if the response status code is in the range [400-499] or [500-599]
        RetryableStatusCodeFamilies = new List<int> { 4, 5 }
    }
};

Configuring Custom Options

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>

Then you can retrieve the value:

using Oci.Common;
var config = ConfigFileReader.parse(ConfigFileReader.DEFAULT_FILE_PATH);
String compartmentId = config.GetValue("customCompartmentId");
Enabling Logging

The OCI SDK for .NET uses the NLog package for logging. NLog is automatically installed with the .NET SDK, so no additional installation is required.

To enable logging in your project:

1. Add an NLog.config file at the project's root directory. You can find an example NLog.config file here
2. Add an ItemGroup section in the project file. For example:

```xml
<ItemGroup>
  <Content Include="PATH TO NLog.config File" />
  <CopyToOutputDirectory>PreserveNewest</CopyToOutputDirectory>
</Content>
```

3. To log from an application, create a Logger and use the Info() method. For example:

```csharp
var logger = NLog.LogManager.GetCurrentClassLogger();
logger.Info("Hello World");
```

**Note:**

Only SDK logging will be captured if you don’t create a logger from an application.

Concepts

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for .NET.

Raw Requests

Raw requests can be useful, and in some cases necessary. Typical use cases include using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, or making a request to a OCI API that is not currently supported in the SDK. The SDK for .NET exposes the OciHttpClientHandler class that you can use to create a client handler which signs the request.

This raw request example on GitHub shows how to use the OciHttpClientHandler.

Setting the Endpoints

Service endpoints can be set in several ways:

- Call `SetEndpoint(<YOUR_ENDPOINT>)` on the service client instance. This lets you specify a full host name (for example, https://www.example.com).
- Call `SetRegion(<YOUR_REGION_ID>)` on the service client instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for .NET returns an error.
- Call `SetRegion(<Region>)` on the service client instance. For example, `SetRegion(Region.US_PHOENIX_1)`.
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 4184.

An example on setting endpoint can be found on GitHub.

Note that a service client instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service client instances.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains on page 180.
A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.Register()` to register the new region, and then you can set the region by either using the configuration file or by calling the `SetRegion` method.

An example on adding a new region can be found on GitHub.

**oraclecloud.com Realm**

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the `Region` enum for your SDK version.

To set the region:

```csharp
using Oci.IdentityService;
var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetRegion("US_NEWYORK_1");
```

**Other Realms**

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the region:

```csharp
using Oci.IdentityService;
var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetEndpoint("https://<your_endpoint>.com");
```

**Uploading Large Objects**

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for .NET supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the `UploadManager`, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The `UploadObject` example shows how to use the `UploadManager` to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

**Paginated Responses**

For large result sets, most OCI calls supported paginated responses. Paginated responses require you to make multiple calls to the list operation, passing in the value of the most recent response's next token. The pagination module allows you to:

- Load all possible results from a list call in one call
- Lazily load results using token-based paginated responses

For an example on how to use these functions, please see GitHub.

**Polling with Waiters**

The SDK offers *waiters* that allow your code to wait until a specific resource reaches a desired state. A waiter can be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write into an easy-to-use single method call.
Waiters are obtained through the service client (client.Waiters). Both a Get<Resource>Request and the desired lifecycle state are passed in to the Waiters.For<Resource> method.

For example:

```csharp
using Oci.CoreService;

public static Instance WaitForInstanceProvisioningToComplete(ComputeClient computeClient, String instanceId)
{
    GetInstanceRequest getInstanceRequest = new GetInstanceRequest
    { InstanceId = instanceId
    );
    GetInstanceResponse getInstanceResponse =
    computeClient.Waiters.ForInstance(getInstanceRequest,
    Instance.LifecycleStateEnum.Running).Execute();
    return getInstanceResponse.Instance;
}
```

Each `waiters.for<Resource>` method has two versions:

One version uses the default polling values. For example:

```csharp
Waiters.ForInstance(getInstanceRequest, Instance.LifecycleStateEnum.Running)
```

The other version gives you full control over how long to wait and how much time between polling attempts. For example:

```csharp
using Oci.Common.Waiters;
WaiterConfiguration waiterConfiguration = new WaiterConfiguration
{
    MaxAttempts = 5,
    GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds
};
Waiters.ForInstance(getInstanceRequest, waiterConfiguration,
Instance.LifecycleStateEnum.Running)
```

Some API requests return work request identifiers to track the progress of the request. Waiters can be used to wait until the work request has reached the desired state.

For example:

```csharp
using Oci.Common.Waiters;
using Oci.ContainerengineService;
using Oci.ContainerengineService.Responses;
using Oci.ContainerengineService.Requests;
CreateClusterResponse clusterResponse = await
    containerEngineClient.CreateCluster(createClusterRequest);
GetWorkRequestResponse workRequestResponse =
    WaitForWorkRequestFinished(containerEngineClient, workRequestId);
private static GetWorkRequestResponse
    WaitForWorkRequestFinished(ContainerEngineClient containerEngineClient,
    string workRequestId)
{
    var waiterConfiguration = new WaiterConfiguration
    {
        MaxAttempts = 5,
        GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds
    };
    GetWorkRequestRequest getWorkRequestRequest = new GetWorkRequestRequest
    {
```
Developer Tools

WorkRequestId = workRequestId
};
return
containerEngineClient.Waiters.ForWorkRequest(getWorkRequestRequest,
waiterConfiguration, WorkRequestStatus.Succeeded).Execute();
}
Further examples on waiters can be found on Github.
Exception Handling
When handling an exception, you can get more information about the HTTP request that caused it, such as the status
code or service code. You can also get the request ID when handling an exception by looking at the opcRequestId
property of the error object.
For example:

try {
var response = await identityClient.ListAllUsersResponses(listUserReq);
} catch (OciException e) {
logger.Info($"requestId: {e.OpcRequestId}");
logger.Info($"StatusCode: {e.StatusCode}");
logger.Info($"ServiceCode: {e.ServiceCode}");
}
Authenticating with Instance Principals
Instance principals is an IAM service feature that enables instances to be authorized actors (or principals) that
can perform actions on service resources. Each compute instance has its own identity, and it authenticates using
the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated,
preventing the need for you to distribute credentials to your hosts and rotate them.
Note:
For more information on instance principals, see Calling Services from an
Instance on page 2410.
While using the .NET SDK on an OCI Instance, you can use
InstancePrincipalsAuthenticationDetailsProvider class as shown in the following example. You
will not need to provide your authentication details when you use this class.
using Oci.Common.Auth;
using Oci.IdentityService;
// Creates an Instance Principal provider that holds authentication details
of the OCI Instance
var instanceProvider = new
InstancePrincipalsAuthenticationDetailsProvider();
// Create a client for the service to enable using its APIs
var client = new IdentityClient(instanceProvider);
A full working example of using instance principals with the OCI .NET SDK can be found on GitHub.
Examples
GitHub
Examples of SDK usage can be found on GitHub, including:
•
•
•

Example: Create an instance
Example: Invoke Oracle Function
Example: Move Compartment

Oracle Cloud Infrastructure User Guide

4262


The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

**SDK Reference**

In addition to the examples found on GitHub, the SDK for .NET API reference contains code examples that you can copy and modify to run in your own environment.

**Running Examples**

1. Use git to clone the OCI SDK for .NET repository:
   
   ```
   git clone https://github.com/oracle/oci-dotnet-sdk.git
   ```

2. Create a configuration file in your home directory (`~/.oci/config`). See SDK and CLI Configuration File on page 4184 for more information.

3. Change directory into the .NET Examples folder. For example:
   
   ```
   cd ./oci-dotnet-sdk/Examples/
   ```

4. All of the examples require the environment variable `OCI_COMPARTMENT_ID` populated with the tenant ID or compartment ID.

5. From the command line, run `dotnet run`. The Audit example runs by default.

6. To run any other example, make sure it has a `Main()` function.

**SDK for Go**

The Oracle Cloud Infrastructure SDK for Go enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** Download the SDK from GitHub.

**Documentation:** The reference documentation is available from Oracle here and at godoc.org.

---

**Tip:**

The SDK for Go is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Go from within Cloud Shell, see SDK for Go Cloud Shell Quick Start on page 4189.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Go, along with other Oracle development tools.

Installing with yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for Go:

```
sudo yum-config-manager --enable ol7_developer
sudo yum install go-oci-sdk.x86_64
```

The OCI Go SDK requires at least Golang version 1.13. To install a recent version of Golang:

```
sudo yum install -y oracle-golang-release-el7.x86_64
sudo yum install golang
```

SDK for Ruby

The Oracle Cloud Infrastructure SDK for Ruby enables you to write code to manage Oracle Cloud Infrastructure resources.

Note:

This project is no longer being actively developed by Oracle. We will continue to address security vulnerabilities for the foreseeable future, and will respond to questions on github, but have no plans to introduce any new functionality, and may not be able to address any non-security related issues. We encourage developers to migrate to other OCI SDKs, and developers may fork the project and enhance it as they desire.

This SDK and sample are dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The SDK for Ruby is available on GitHub or RubyGems.

Documentation: SDK for Ruby documentation.

Installing with yum

If you're using Oracle Linux 7, you can use yum to install the OCI SDK for Ruby.

The following example shows how to use yum to install the OCI SDK for Ruby 2.6:

```
sudo yum-config-manager --enable ol7_developer
```
sudo yum install -y oci-ruby-sdk
source /opt/rh/rh-ruby26/enable
export GEM_PATH="/usr/share/gems:`gem env gempath`"

PL/SQL SDK
The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write PL/SQL code to manage Oracle Cloud Infrastructure resources.

The latest version of the SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

Requirements
To use the PL/SQL SDK, you must have the following:
• An Oracle Cloud Infrastructure account.
• A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 57. For a list of typical policies you may want to use, see Common Policies on page 2142.
• A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key.

Services Supported
• Analytics Cloud
• Announcements
• API Gateway
• Application Migration
• Audit
• Autoscaling (Compute)
Examples

This section contains examples of how to use the PL/SQL SDK.

Working with Object Storage Buckets
The following example shows examples of how to use the PL/SQL SDK to create and delete buckets using the OCI Object Storage service:

```
-- ###################################################################
-- ## Create bucket ##
-- ###################################################################
set serveroutput on
declare
  response_body  dbms_cloud_oci_obs_object_storage_bucket_t;
  response       dbms_cloud_oci_obs_object_storage_create_bucket_response_t;
  bucket_details dbms_cloud_oci_obs_object_storage_create_bucket_details_t;
  json_obj       json_object_t;
  l_keys         json_key_list;
begin
  bucket_details :=
    dbms_cloud_oci_obs_object_storage_create_bucket_details_t();
  bucket_details.name := 'bucketname';
  bucket_details.compartment_id := 'compartment_OCID';
  response := dbms_cloud_oci_obs_object_storage.create_bucket(
    namespace_name => 'namespace-string',
    opc_client_request_id => 'random-request-id',
    create_bucket_details => bucket_details,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');
  response_body := response.response_body;
  -- Response Headers
  dbms_output.put_line('Headers: ' || CHR(10) || '------------');
  json_obj := response.headers;
  l_keys := json_obj.get_keys;
  for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
      json_obj.get(l_keys(i)).to_string);
  end loop;
  -- Response status code
  dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
  dbms_output.put_line(CHR(10));
  -- Response body
  dbms_output.put_line(response_body.namespace);
  dbms_output.put_line(response_body.name);
  dbms_output.put_line(response_body.compartment_id);
  dbms_output.put_line(response_body.metadata.to_string());
  dbms_output.put_line(response_body.created_by);
  dbms_output.put_line(response_body.time_created);
  dbms_output.put_line(response_body.approximate_count);
  dbms_output.put_line(response_body.approximate_size);
  dbms_output.put_line(response_body.etag);
  dbms_output.put_line(response_body.public_access_type);
  dbms_output.put_line(response_body.storage_tier);
  dbms_output.put_line(response_body.freeform_tags.to_string());
  dbms_output.put_line(response_body.defined_tags.to_string());
  dbms_output.put_line(response_body.kms_key_id);
  dbms_output.put_line(response_body.object_lifecycle_policy_etag);
  dbms_output.put_line(response_body.id);
end;
/```
set serveroutput on
declare
response       dbms_cloud_oci_obs_object_storage_delete_bucket_response_t;
json_obj       json_object_t;
l_keys         json_key_list;
begin

response := dbms_cloud_oci_obs_object_storage.delete_bucket(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
        json_obj.get(l_keys(i)).to_string);
end loop;

-- Response status code
dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
dbms_output.put_line(CHR(10));
end;
/

Working with Object Storage Objects

The following example shows how to use the PL/SQL SDK to store and retrieve objects using the OCI Object Storage service:

declare
my_blob_data   blob;
response       dbms_cloud_oci_obs_object_storage_put_object_response_t;
json_obj       json_object_t;
l_keys         json_key_list;
begin

/* Some processing producing BLOB data and populating my_blob_data */
response := dbms_cloud_oci_obs_object_storage.put_object(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    object_name => 'objectname',
    put_object_body => my_blob_data,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
        json_obj.get(l_keys(i)).to_string);
end loop;
-- Response status code
dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
CHR(10) || response.status_code);
dbms_output.put_line(CHR(10));
end;
/

-- #################################
-- ## Get Object      ##
-- #################################
declare
    response       dbms_cloud_oci_obs_object_storage_get_object_response_t;
    response_body  blob;
    json_obj       json_object_t;
    l_keys         json_key_list;
begin
    response := dbms_cloud_oci_obs_object_storage.get_object(
        namespace_name => 'namespace-string',
        bucket_name => 'bucketname',
        object_name => 'objectname',
        credential_name => 'OCI_KEY_CRED',
        region => 'region-identifier');
    response_body := response.response_body;
    -- Response Headers
    dbms_output.put_line('Headers: ' || CHR(10) || '------------');
    json_obj := response.headers;
    l_keys := json_obj.get_keys;
    for i IN 1..l_keys.count loop
        dbms_output.put_line(l_keys(i)||':'||
        json_obj.get(l_keys(i)).to_string);
    end loop;
    -- Response status code
    dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
    dbms_output.put_line(CHR(10));
    -- Response body
    dbms_output.put_line('Contents: ' ||
    UTL_RAW.cast_to_varchar2(response_body));
end;
/

Listing Compartments

The following example shows how to list compartments using the PL/SQL SDK:

-- #################################
-- ## ListCompartments  ##
-- #################################
set serveroutput on
declare
    response_body  dbms_cloud_oci_id_identity_compartment_tbl;
    response       dbms_cloud_oci_id_identity_list_compartments_response_t;

```sql
json_obj       json_object_t;
l_keys         json_key_list;
begin
  response := dbms_cloud oci id identity . list compartments(
      compartment_id  => 'compartment OCID',
      limit           => 2,
      credential_name => 'OCI KEY CRED',
      region          => 'region identifier');

  response_body := response . response_body;

  -- Response Headers
  dbms_output . put_line ('Headers: ' || CHR(10) || '----------');
  json_obj := response . headers;
  l_keys := json_obj . get_keys;
  for i IN 1..l_keys . count loop
    dbms_output . put_line (l_keys (i) || ':' ||
                           json_obj . get (l_keys (i)) . to_string);
  end loop;

  -- Response status code
  dbms_output . put_line ('Status Code: ' || CHR(10) || '----------' ||
                           CHR(10) || response . status_code);
  dbms_output . put_line (CHR(10));
  for i in 1 .. response_body . count loop
    dbms_output . put_line (response_body (i) . id);
    dbms_output . put_line (response_body (i) . compartment_id);
    dbms_output . put_line (response_body (i) . name);
    dbms_output . put_line (response_body (i) . description);
    dbms_output . put_line (response_body (i) . time_created);
    dbms_output . put_line (response_body (i) . lifecycle_state);
    dbms_output . put_line (response_body (i) . inactive_status);
    dbms_output . put_line (response_body (i) . is_accessible);
    dbms_output . put_line (response_body (i) . freeform_tags . to_string());
    dbms_output . put_line (response_body (i) . defined_tags . to_string());
  end loop;
end;
/
```

### Working With Streams

The following example shows how to create and delete stream pools using the PL/SQL SDK:

```sql
-- #################################
-- ## Create stream pool ##
-- #################################
set serveroutput on
declare
  response_body       dbms_cloud oci st stream admin stream pool_t;
  response
    dbms_cloud oci st stream admin create stream pool response_t;
  stream_pool_details
    dbms_cloud oci st stream admin create stream pool details_t;
  json_obj            json_object_t;
  l_keys              json_key_list;
begin
  stream_pool_details :=
    dbms_cloud oci st stream admin create stream pool details_t();
  stream_pool_details . name := 'streampoolname';
```
stream_pool_details.compartment_id := 'compartment_OCID';

response := dbms_cloud_oci_st_stream_admin.create_stream_pool(
    create_stream_pool_details => stream_pool_details,
    opc_request_id => 'random-request-id',
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');
response_body := response.response_body;

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
        json_obj.get(l_keys(i)).to_string);
end loop;

-- Response status code
dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
   CHR(10) || response.status_code);

-- Response body
dbms_output.put_line('id: ' || response_body.id);
dbms_output.put_line('name: ' || response_body.name);
dbms_output.put_line('compartment_id: ' || response_body.compartment_id);
dbms_output.put_line('lifecycle_state: ' || response_body.lifecycle_state);
for i in 1 .. response_body.private_endpoint_settings.nsg_ids.count loop
    dbms_output.put_line(response_body.private_endpoint_settings.nsg_ids(i));
end loop;
/

-- # Delete stream pool #
set serveroutput on
declare
    response dbms_cloud_oci_st_stream_admin_delete_stream_pool_response_t;
    json_obj json_object_t;
    l_keys json_key_list;
begin
    response := dbms_cloud_oci_st_stream_admin.delete_stream_pool(
        stream_pool_id => 'stream-pool-ocid',
        credential_name => 'OCI_KEY_CRED',
        region => 'region-identifier');

    -- Response Headers
    dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
    json_obj := response.headers;
    l_keys := json_obj.get_keys;
    for i IN 1..l_keys.count loop
        dbms_output.put_line(l_keys(i)||':'||
            json_obj.get(l_keys(i)).to_string);
    end loop;
end;
DevOps Tools and Plug-ins

Oracle Cloud Infrastructure provides a number of DevOps tools and plug-ins for working with Oracle Cloud Infrastructure services. These can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery.

**Terraform Provider** - Manage "infrastructure as code" with this component that connects Terraform to a given Oracle Cloud Infrastructure service.

- **Documentation**: Terraform Provider on page 4275
- **Download**: GitHub

**OCI Modules for PowerShell** - A set of cmdlet modules that can be used with PowerShell Core to manage Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.

- **Documentation**: OCI Modules for PowerShell on page 4314
- **Download**: GitHub or PowerShell Gallery

**Ansible Collection** - Automate provisioning and configuring of Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.

- **Documentation**: Ansible Collection on page 4330
- **Download**: GitHub

**Compute Jenkins Plug-in** - Bring up and down services or nodes as required to serve Jenkins Build Jobs and dynamically allocate Oracle Cloud Infrastructure resources for continuous integration tasks.

- **Documentation**: Compute Jenkins Plug-in on page 4344
- **Download**: GitHub

**Chef Knife Plug-in** - Manage Oracle Cloud Infrastructure resources with Chef Knife, a command line tool that provides an interface between a local chef-repo and the Chef server.

- **Documentation**: Chef Knife Plug-in on page 4344
- **Download**: GitHub

**Grafana Plug-in** - Visualize metrics from the Monitoring service in your Grafana instance.

- **Documentation**: Grafana Plug-in on page 4345
- **Download**: GitHub

**Terraform Kubernetes Installer** - Provision and configure the resources needed to run a highly available and configurable Kubernetes cluster.

- **Download**: GitHub

**Kubernetes Volume Provisioner** - Enable dynamic provisioning of storage resources when running Kubernetes on Oracle Cloud Infrastructure.

- **Download**: GitHub

DevOps Integrations

- **Jenkins X Integration**: Create a new Kubernetes cluster on Oracle Cloud Infrastructure Container Engine for Kubernetes.
- **Packer Integration**: Create reusable custom images.

Other Services and Features for DevOps

Oracle Cloud Infrastructure provides other services and features relevant to DevOps professionals.

- **Container Engine for Kubernetes (OKE)** Reliably build, deploy, and manage cloud-native containerized applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing tenancy.
• **Oracle Cloud Infrastructure Registry** Store, share, and manage development artifacts like Docker images. As Oracle Cloud Infrastructure Registry is managed by Oracle, your applications are deployed reliably and you don’t have to deal with operational issues.

**Terraform Provider**

Terraform is an open source tool that allows you to programmatically manage, version, and persist infrastructure through the "infrastructure-as-code" model. Terraform configurations codify your infrastructure in declarative files that contain the steps required to provision your infrastructure and maintain its state. You can share these files among team members, treat them as code, edit, review, and version them.

Terraform uses providers to interface between the Terraform engine and the supported cloud platform. The Oracle Cloud Infrastructure (OCI) Terraform provider is a component that connects Terraform to the OCI services that you want to manage.

You can use the OCI Terraform provider to manage OCI resources wherever you use a Terraform distribution, including Terraform Cloud and the OCI Resource Manager. Oracle Public Cloud has its own Terraform provider.

Resource Manager is an Oracle Cloud Infrastructure service that uses Terraform to automate the process of provisioning your Oracle Cloud Infrastructure.

**Tip:**

You can migrate existing Terraform state files to Resource Manager using an Import State job.

See Getting Started on page 102 to begin using the Terraform provider to manage your OCI resources.

**Licensing:** This provider and samples are licensed under the Mozilla Public License 2.0; third-party content is separately licensed as described in the code.

**Availability**

The Oracle Cloud Infrastructure Terraform provider is region agnostic. You can use the Terraform provider to work with supported services in all Oracle Cloud Infrastructure regions in which they are available. Government Cloud customers should use the FIPS-compatible OCI Terraform provider.

See Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

**Contributions**

Got a fix for a bug, or a new feature you’d like to contribute? The Terraform provider is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the OCI Terraform provider is released, subscribe to the Atom feed.

**Questions or Feedback**

Refer to Troubleshooting Basics and a list of common issues to see if your question has an answer.

You can also use GitHub to file bugs and submit feature requests.

**What’s New**

Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules all have the ability to introduce changes or add new functionality.

**Terraform Updates**

Major Terraform releases might include changes in behavior you should consider when upgrading.

**Terraform v0.14**

The Oracle Cloud Infrastructure (OCI) Terraform provider now supports Terraform v0.14.

Terraform v0.14 changes the output of the `terraform plan` command and introduces a dependency lock file you can use to track the version of the (OCI) Terraform provider used to interact with your OCI resources.

Refer to the official Terraform v0.14 upgrade guide for more information.
Concise Terraform plan output

To reduce the verbosity of `terraform plan` output, Terraform output now omits any attribute that has not changed, except for some attributes whose values often contain human-recognizable identifying information.

You can temporarily re-enable verbose output by setting the environment variable `TF_X_CONCISE_DIFF=0` when you run Terraform.

Sensitive values in Terraform plan output

Because Terraform v0.14 tracks expressions whose result is derived from a sensitive input variable or sensitive output value, you might find that more values are obscured in the `terraform plan` output than would have been in earlier versions.

If a different module uses a value in its output that was derived from a sensitive variable or value, you must set `sensitive = true` in the output of the second module.

Provider dependency lock file

In Terraform v0.13 and earlier, the `terraform init` command would always install the newest version of any provider in the configuration that would meet the configured version constraints. To keep the behavior of an already tested configuration as stable as possible unless intentionally changed by the user, Terraform v0.14 introduces a new dependency lock file.

Terraform generates this file automatically after running `terraform init` in the same directory as the configuration's root module. The dependency lock file includes the specific version numbers selected for each provider, including the OCI Terraform provider. After running `terraform init` for the first time after upgrading to Terraform v0.14, you will find a new file `.terraform.lock.hcl` in your root module directory. Future initializations of Terraform automatically read and respect the entries in that file.

Because of this new feature, manually placing extra plugins into the local cache directory `.terraform/plugins` is no longer effective.

Terraform v0.12

If upgrading to Terraform v0.12, the Oracle Cloud Infrastructure (OCI) Terraform provider and some existing configurations might need to be updated as well.

See Upgrading Configurations to Terraform v0.12 on page 4294 for detailed information.

Tutorials

For step-by-step instructions and examples of using Terraform and Oracle Cloud Infrastructure, see the following tutorials:

• Set Up the OCI Terraform Provider
• Create a Compartment
• Create a Compute Instance
• Create a Virtual Cloud Network
• Set Up a Simple Infrastructure
• Create a Kubernetes Cluster
• Set up Resource Discovery
• Create Scripts and State Files with Resource Discovery

• Blog: Getting Started Using Terraform with OCI

Examples and Solutions

The Oracle Cloud Infrastructure (OCI) Terraform provider uses Terraform configuration files to manage your OCI infrastructure.

Referring to existing example configurations and sample solutions can help you understand HashiCorp Configuration Language format (HCL) and see how it is used to define OCI resources.
You can also modify examples or entire solution sets to meet your needs.

Example Configurations

We provide many example Terraform configuration files that show you how to create specific OCI resources. These examples are intended to be as simple as possible. In most cases, they contain only the specific resource and any dependencies required for it to run.

Examples are are grouped by service, including Compute, Database, Networking, Load Balancing, and several others. These do not represent production configurations or real world scenarios, but they can serve as a starting point and be modified and combined as necessary.

Sample Solutions

Oracle also provides sample solutions for Resource Manager. Resource Manager uses Terraform to automate deployment and operations for OCI resources.

Solutions can help those new to infrastructure-as-code and those who are updating production configurations. Use solutions to try out Resource Manager and inspect the underlying oracle-terraform-modules to familiarize yourself with Terraform configuration files.

Architecture Center

The Oracle Architecture Center contains reference architectures, solution playbooks, and best practices. You can filter the content to see Terraform-specific information that you can use with the OCI Terraform provider or Resource Manager.

Guides

This section describes how to configure the Oracle Cloud Infrastructure (OCI) Terraform provider for specific use cases and write Terraform configuration files that manage specific OCI resources.

See the following topics for additional information:

Authoring Configurations

Overview

Using Terraform, you can describe your Oracle Cloud Infrastructure using the HashiCorp Configuration Language format (HCL) in Terraform configuration files (see Configuration Syntax). Terraform configuration files can use either of two formats: Terraform domain-specific language (HashiCorp Configuration Language format [HCL]), which is the recommended approach, or JSON format if the files need to be machine-readable. Configuration files that use the HCL format end with the .tf file extension; those using JSON format end with the .tf.json file extension. The Terraform format is human-readable, while the JSON format is machine readable.

Use Terraform configurations to define your Oracle Cloud Infrastructure (OCI) resources, variable definitions, data sources, and a great deal more. Terraform, then, converts your OCI configurations into a set of API calls against OCI API endpoints. The key to writing Terraform configuration is understanding how to abstract the desired infrastructure conceptually into Terraform configuration syntax.

Important:

While the Oracle Cloud Infrastructure API uses camelCase extensively, Terraform does not support camelCase in configuration files. For this reason,
Configuration File Requirements

Terraform configuration (.tf) files have specific requirements, depending on the components that are defined in the file. For example, you might have your Terraform provider defined in one file (provider.tf), your variables defined in another (variables.tf), your data sources defined in yet another.

Note:
For example configuration files, see Terraform Provider Examples on the Oracle Cloud Infrastructure GitHub.

Provider Definitions

The following example using Terraform syntax illustrates the requirements for an OCI Terraform provider definition, and also shows associated variable definitions. The provider definition relies on variables so that the configuration file itself does not contain sensitive data. Including sensitive data creates a security risk when exchanging or sharing configuration files.

```terraform
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

provider "oci" {
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
  region = "${var.region}"
}
```

The `region` attribute specifies the geographical region in which your provider resources are created. To target multiple regions in a single configuration, you simply create a provider definition for each region and then differentiate by using a provider alias, as shown in the following example. Notice that only one provider, named "oci" is defined, and yet the oci provider definition is entered twice, once for the us-phoenix-1 region (with the alias "phx"), and once for the region us-ashburn-1 (with the alias "iad").

```terraform
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "compartment_ocid" {}

provider "oci" {
  region = "us-phoenix-1"
  alias = "phx"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}

provider "oci" {
  region = "us-ashburn-1"
  alias = "iad"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
}
```
```java
fingerprint = "${var.fingerprint}"
private_key_path = "${var.private_key_path}"
}
```

For more information, see Provider Configuration.

**Variable Definitions**

Variables in Terraform represent parameters for Terraform modules. In variable definitions, each block configures a single input variable, and each definition can take any or all of three optional arguments:

- **type** (optional): Defines the variable type as one of three allowed values: string, list, and map. If this argument is not used, the variable type is inferred based on default. If no default is provided, the type is assumed to be string.
- **default** (optional): Sets the default value for the variable. If no default value is provided, the caller must provide a value or Terraform throws an error.
- **description** (optional): A human-readable description of the variable.

Following are examples of several variable definitions. Some definitions include optional parameters.

```java
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

variable "AD" {
    default = "1"
    description = "Availability Domain"
}

variable "CPUCoreCount" {
    default = "2"
    type = "string"
}
```

For more information, see Input Variable Configuration. See also Input Variables.

**Output Configuration**

Output variables provide a means to support Terraform end-user queries. This allows users to extract meaningful data from among the potentially massive amount of data associated with a complex infrastructure. For example, you might be interested only in a handful of key values at any given time and defining output variables allows you to extract exactly the information that you need.

Following is a simple example in which only a few output variables (instance IP addresses and boot volume IDs) are defined:

```java
# Output the private and public IPs of the instance
output "InstancePrivateIPs" {
    value = ["${oci_core_instance.TFInstance.*.private_ip}"]
}

output "InstancePublicIPs" {
    value = ["${oci_core_instance.TFInstance.*.public_ip}"]
}

# Output the boot volume IDs of the instance
output "BootVolumeIDs" {
    value = ["${oci_core_instance.TFInstance.*.boot_volume_id}"]
}
```
For more information, see Output Variables. See also Output Configuration.

Resources

Resources are components of your Oracle Cloud Infrastructure. These resources include everything from low-level components such as physical and virtual servers, to higher-level components such as email and database providers, your DNS record.

Refer to the full reference of the OCI Terraform provider’s supported resources and data sources for usage, argument, and attribute details. The resources are grouped by service.

Declaring Resources

Following is a simple example of a resource definition that illustrates their basic structure.

```tenseindentresource "oci_core_virtual_network" "vcn1" {  
cidr_block = "10.0.0.0/16"  
dns_label = "vcn1"  
compartment_id = "$(var.compartment_ocid)"  
display_name = "vcn1" 
}
```

The resource declaration on the first line of the example uses the keyword "resource" and takes two parameters, resource type and resource name ("oci_core_virtual_network" and "vcn1" in the example). Inside the code block, then, is the resource configuration.

For more information, see Resource Configuration.

Referencing Resources in Another Stack

You can reference resources that exist in other stacks. The Terraform remote_state data source allows you to read output variables from state files.

For example, when writing a Terraform configuration for a new web application, you can make the web application use the subnet previously created from your network stack, as long as the required subnet values were output in the network stack state file. In the Terraform configuration for your new web application, do the following:

- Pull the state file of the existing network stack into the context of your current Terraform configuration.
- Load the pulled state file to a data source for remote state files.
- Populate the subnet data source in your current configuration with values from the relevant output variables of the referenced state file.
- Optionally print the identifying information for the populated data source to confirm expected values.

**Note:**

In addition to permissions required for Resource Manager operations, you'll need appropriate permissions for resource types you're referencing, in the compartment that you're referencing them. In this example, you need read permissions for network resources in the compartment where they're located.

The following Terraform configuration excerpt references a subnet in another stack.

```tenseindent# The following example assumes that the source stack (defined by `stack_id`) has output a value named `subnet_id`    # Terraform v0.12 is assumed
variable "stack_id" {} 

# Pull the state file of the existing Resource Manager stack (the network stack) into this context
data "oci_resourcemanager_stack_tf_state" "stack1_tf_state" {  
    stack_id   = "${var.stack_id}" 
} 
```

Oracle Cloud Infrastructure User Guide
local_path = "stack1.tfstate"
}

# Load the pulled state file into a remote state data source
data "terraform_remote_state" "external_stack_remote_state" {
    backend = "local"
    config = {
        path = "${data.oci_resourcemanager_stack_tf_state.stack1_tf_state.local_path}"
    }
}

# Populate a data source in this configuration using a value from the remote state data source
data "oci_core_subnet" "subnet1" {
    subnet_id = "${data.terraform_remote_state.external_stack_remote_state.outputs.subnet_id}"  
}

# Print the values of the populated data source
output "print-subnet1" {
    value = "${data.oci_core_subnet.subnet1}"  
}

Data Sources

Data sources represent read-only views of existing infrastructure intended for semantic use in Terraform configurations. Following is a simple example of a data source configuration to illustrate its basic structure:

# Gets a list of Availability Domains
data "oci_identity_availability_domains" "ADs" {
    compartment_id = "${var.tenancy_ocid}"
}

# Get DB node list
data "oci_database_db_nodes" "DBNodeList" {
    compartment_id = "${var.compartment_ocid}"
    db_system_id = "${oci_database_db_system.TFDBNode.id}"  
}

# Get DB node details
data "oci_database_db_node" "DBNodeDetails" {
    db_node_id = "${lookup(data.oci_database_db_nodes.DBNodeList.db_nodes[0], "id")}"  
}

# Gets the OCID of the first (default) vNIC
data "oci_core_vnic" "DBNodeVnic" {
    vnic_id = "${data.oci_database_db_node.DBNodeDetails.vnic_id}"  
}

For more information, see Data Source Configuration.

Filtering Data Sources

Data sources that return lists of resources support filtering semantics. To use a filter, include this block in your data source definition:

filter {
    name = ""
    values = ["""]
}
The name value corresponds to the qualified property name to filter with and the values lists can contain one or more values filter with.

Nested properties and map elements can be addressed by qualifying the property name with parent property name. Example r1 will give all the instances which have source_type image. Example r2 will give all the instances which contain a defined tag with value "42" for key CostCenter in the namespace Operations.

```hcl
data "oci_core_instances" "r1" {
  ...
  filter {
    name = "source_details.source_type"
    values = ["image"]
  }
}
data "oci_core_instances" "r2" {
  ...
  filter {
    name = "defined_tags.Operations.CostCenter"
    values = ["42"]
  }
}
```

Multiple values work as an OR type filter. In the shape example below, the resulting data source would contain both VM shapes Standard 1.1 and Standard 1.2:

```hcl
data "oci_core_shape" "t" {
  ...
  filter {
    name = "name"
    values = ["VM.Standard1.1", "VM.Standard1.2"]
  }
}
```

Multiple filters blocks can be composed to form AND type comparisons. The example below will return a data source containing running instances in the first AD of a region:

```hcl
data "oci_core_instances" "s" {
  ...
  filter {
    name = "availability_domain"
    values = ["\w*-AD-1"]
    regex = true
  }
  filter {
    name = "state"
    values = ["RUNNING"]
  }
}
```

As shown above, filters can also employ regular expressions. By setting regex = true, each item in the values list will be treated as a regular expression. Backslashes in strings for regular expression special characters need to be escaped with another slash, shown above as the first \ before \w in "\w*-AD-1".

**Note:**

Drilling into lists of structured objects is not currently supported. If these properties are targeted no results will be returned from the datasource.
Terraform offers a number of built-in functions that you can use in your configuration files. These functions allow you to modify strings, perform calculations against numeric values, manage collections, and much more.

For more information, see Functions.

For More Information

- Creating Terraform Modules
- Terraform Configurations
- Terraform Configuration Syntax

Specifying Versions

Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules you call in your configuration files all introduce changes or add new functionality from time to time. As these changes are made, new versions are released.

In order to ensure that your configurations are applied consistently to OCI resources, you can explicitly set the version of these components in Terraform configuration files.

Terraform CLI Version

If your Terraform configuration requires that you use a particular version of the Terraform CLI, you can specify that within the `terraform` block using the `required_version` setting. For example:

```terraform
terraform {
  required_version = ">= 0.12.16"
}
```

For more information, see Specifying a Required Terraform Version.

**Note:**

Resource Manager manages the Terraform version based on the stack version. Do not set a specific CLI version if you use Resource Manager.

Provider Version

You can control the version of the OCI Terraform provider that Terraform uses when interacting with OCI resources. This ability is especially helpful when your configuration relies on features introduced with a particular version of the provider or it has only been tested with a particular version of the provider.

You can use the `>=` or `=` operators to specify the version, depending on your use case.

For more information, see Specifying Provider Requirements.

Using Terraform v0.12 or earlier

Terraform v0.12 or earlier allowed you to specify `version` within the `provider` block. For example:

```terraform
provider "oci" {
  version          = ">= 3.27.0"
  region           = "${var.region}"
  ...
}
```

Using Terraform v0.13

Terraform v0.13 deprecated `version` within `provider` blocks. Instead, versions should be specified within a `required_providers` block. For example:

```terraform
terraform {
  required_providers {
    oci = {
```
Module Version

In addition to specifying the version of the Terraform CLI and the OCI Terraform provider, you can also specify the version of Terraform modules.

If a module has been upgraded to use a newer version of Terraform core, but you still use an earlier version of Terraform, you can specify a compatible version of the module. If your configurations have only been tested with a specific version of the module, you can specify that version to ensure compatibility.

Modules accept the version argument. For example:

```terraform
module "oke" {
  source  = "oracle-terraform-modules/oke/oci"
  version = "1.0.0"
  # insert required variables here
}
```

For more information, see Module Blocks.

Enabling FIPS Compatibility

You can use Terraform and a special FIPS compatible version of the Oracle Cloud Infrastructure (OCI) Terraform provider, as long as a few specific requirements and best practices are employed. This topic provides guidance on these requirements and practices.

**FIPS encryption**

To ensure the highest security standards, traffic from Terraform to OCI endpoints should transit over a TLS connection established with an HTTP client using FIPS certified encryption.

The standard OCI Terraform provider is implemented in Go. Go’s native cryptography implementations, while fully capable of establishing secure TLS connections with OCI endpoints, have not been FIPS certified.

For Terraform traffic to transit to OCI endpoints over FIPS-compliant connections, you must use a special version of the Terraform provider that leverages FIPS certified cryptography. This version of the OCI Terraform provider uses the FIPS 140-2 certified Oracle Cloud Infrastructure Cryptographic Library for Kubernetes instead of Go’s native cryptography implementation.

Installing the FIPS Compliant Terraform Provider

The FIPS compliant OCI Terraform provider is only available for Oracle Linux. You can install the provider using yum.

**Tip:**

Before installing the OCI Terraform provider, download and install Terraform from HashiCorp, or install Terraform using yum.

If any existing OCI Terraform provider packages are already installed on the Oracle Linux machine, remove them first:

```bash
yum remove terraform-provider-oci
```
To install the FIPS compatible OCI Terraform provider, run the following yum command from an Oracle Linux machine:

```
yum install terraform-provider-oci-fips
```

Operating Terraform in a Single Region

To ensure that traffic between Terraform and OCI services does not transit over public internet infrastructure, we recommend that you run Terraform and the OCI Terraform provider from a Compute instance that is hosted in the same region as the resources they create and manage.

Creating a Compute Instance

After Terraform and the OCI Terraform provider are installed on an Oracle Linux machine, you can use Terraform and the following sample Terraform configuration file to:

- Create a designated Compute instance you can use to provision additional infrastructure within the same region.
- Install Terraform and the latest FIPS compliant OCI Terraform provider on the new instance.
- Restrict communication with the instance to OCI endpoints and HTTPS using a service gateway.
- Enable instance principal authentication.

See Authoring Configurations on page 4277 for more information.

To create the compute instance:

1. Copy the `main.tf` file to your Oracle Linux machine.
2. Gather the information required to populate the Terraform configuration file's variables.
3. Refer to Oracle-Provided Images on page 629 to locate the Oracle Linux image OCID value for your region.
   Modify the `oel-image` value in the Terraform configuration file.
4. Initialize Terraform in the directory that contains the Terraform configuration file:

   ```
terraform init
   ```

5. Apply the Terraform configuration:

   ```
terraform plan
   terraform apply
   ```

**Important:**

The `instance-ip` output variable provides the IP address you will need to use to sign in to the new Compute instance.

```

    compartment_id      = var.compartment_ocid
    display_name        = "${local.prefix}Instance"
    shape               = local.vm-shape

    source_details {
        source_type = "image"
        source_id   = local.oel-image
    }

    metadata = {
        ssh_authorized_keys = var.ssh_public_key
        user_data           = base64encode(local.user-data)
        tenancy_ocid        = var.tenancy_ocid
    }

    create_vnic_details {
        subnet_id        = oci_core_subnet.subnet1.id
        assign_public_ip = true
    }
}

output "instance-ip" {
    value = [oci_core_instance.instance1.public_ip]
}
```

**Signing in to the Instance**

Use the following SSH command to access the instance:

```bash
$ ssh -i <private_key_path> <username>@<instance_ip_address>
```

*<private_key_path>* is the full path and name of the file that contains the private key associated with the instance you want to access.

*<username>* is the default username for the instance. For Oracle Linux images, the default username is *opc*.

*<instance_ip_address>* is the instance IP address that was the output of the Terraform commands.

**Installing and Configuring Terraform on the Instance**

1. Use yum to install Terraform and the FIPS compatible OCI Terraform provider on the instance:

    ```bash
    yum install -y terraform terraform-provider-oci-fips
    ```
2. Add an environment variable to enable instance principal authentication to the bash profile:

```bash
echo "export TF_VAR_auth='InstancePrincipal'" >> ${HOME}/.bash_profile
```

3. Add an environment variable to set the target region for Terraform:

```bash
echo "export TF_VAR_region='<your_region>'" >> ${HOME}/.bash_profile
```

4. Add an environment variable to disable interprocess traffic encryption between Terraform and the OCI Terraform provider:

```bash
echo "export TF_DISABLE_PLUGIN_TLS=1" >> ${HOME}/.bash_profile
```

5. Add an environment variable to prevent Terraform from accessing the HashiCorp Checkpoint service:

```bash
echo "export CHECKPOINT_DISABLE=1" >> ${HOME}/.bash_profile
```

6. Exit the instance:

```bash
exit
```

### Implementing Security Rules

Before using the new instance to run Terraform, you should update the security rules to prevent egress traffic to any third-party endpoints other than OCI services. You can do this by removing the following egress rule from the Terraform configuration file's `security-list1` resource and running `terraform apply` from the Oracle Linux machine:

```terraform
// outbound tcp traffic on all ports
// remove this rule or comment it out to prevent egress traffic to third-party endpoints
#egress_security_rules {
#  destination = "0.0.0.0/0"
#  protocol    = "6"
#}
```

**Tip:**
You can also use the OCI Console to update your security rules on the new instance.

### Running Terraform from the Instance

After creating the instance, installing and configuring Terraform on the instance, and updating the security rules, you can use Terraform to provision additional OCI infrastructure within the same region. Copy any additional Terraform configuration files to your instance, sign in to the instance, and run your Terraform commands like any other Terraform provider:

```bash
ssh -i <private_key_path> opc@<instance_ip_address>
terraform init
terraform apply
```

### Managing Boot Volumes

This guide details the following scenarios:

1. Preserving boot volume when performing Compute instance scaling
2. Boot volume troubleshooting and repair

To read more about boot volumes, see Boot Volumes

Preserving Boot Volumes
You may want to change Compute instance shape while using the same boot volume. When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. This approach is useful for scenarios where instance shape cannot be changed while resizing instances.

To achieve this, you need to detach the boot volume from the running instance. This can be performed by either terminating the instance while preserving the boot volume or by stopping the instance and detaching the boot volume.

All terraform resources of type `oci_core_instance` have the parameter `preserve_boot_volume` set as true by default. This parameter ensures that upon termination of the instance, the attached boot volume is not terminated.

```terraform
resource "oci_core_instance" "TFInstance" {
  ...  
  state = "STOPPED"                  // set this state to stop the instance
  preserve_boot_volume = true
}

output "bootVolumeFromInstance" {
  value = [oci_core_instance.TFInstance.boot_volume_id]
}
```

Once the boot volume is detached, the OCID of the boot volume can be referred as the source of the new instance, as illustrated below:

```terraform
resource "oci_core_instance" "TFScaleInstance" {
  ...  
  source_details {
    source_type = "bootVolume"
    source_id   = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
  }
}
```

Detaching Boot Volumes for Troubleshooting and Repair

If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Once the boot volume has been detached, the OCID of the boot volume can be referred as the block volume parameter for another instance.

```terraform
resource "oci_core_volume_attachment" "TFBlockAttach" {
  ...  
  attachment_type = "iscsi"
  compartment_id  = "ocid1.compartment.oc1..exampleuniqueID"
  instance_id     = "ocid1.instance.oc1.phx.exampleuniqueID"
  volume_id       = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
}
```

Once you have resolved the issue, detach this volume from the second instance and attach it as a boot volume to the original instance.

```terraform
resource "oci_core_instance" "TFScaleInstance" {
  ...  
  source_details {
```
Migrating an Exadata DB System to the New Resource Model

The X8M generation of Exadata hardware introduces a new resource model that replaces the Exadata DB system. The new resource model uses new APIs to provision and manage its resources. The existing DB system APIs for Exadata will be deprecated by Oracle Cloud Infrastructure for all users following written notification and a transition period allowing you to switch to the new API and Console interfaces.

If you have existing Exadata DB systems in Oracle Cloud Infrastructure, you can use Terraform to switch them to the new resource model and APIs.

**Caution:**

Switching an Exadata DB system to the new resource model and APIs cannot be reversed. If you have automation for your system that utilizes the DB system APIs, you may need to update your applications prior to switching.

Switching to the new resource model:

- Does not impact the DB system's existing Exadata databases or client connections
- Does not change the underlying hardware or shape family of your Exadata Cloud Service instance
- Will not affect bare metal and virtual DB systems

After converting your DB system, you will have two new resources in place of the DB system resource: a cloud Exadata infrastructure resource, and a cloud VM cluster resource.

What to expect after switching:

- Your new cloud Exadata infrastructure resource and cloud VM cluster are created in the same compartment as the DB system they replace
- Your new cloud Exadata infrastructure resource and cloud VM cluster use the same networking configuration as the DB system they replace
- After the switch, you cannot perform operations on the old Exadata DB system resource
- Switching is permanent, and the change cannot be undone
- X6, X7, X8 and Exadata base systems retain their fixed shapes after the switch, and cannot be expanded

See [Exadata Cloud Service](#) on page 1221 for more information.

To Migrate an Exadata DB System

These migration steps use the following example, which shows an existing Exadata Cloud Service instance using the old DB system resource model:

```
resource "oci_database_db_system" "test_db_system" {
  availability_domain = data.oci_identity_availability_domain.ad.name
  compartment_id      = var.compartment_ocid
  cpu_core_count      = var.cpu_core_count
  database_edition    = var.db_edition
  time_zone           = var.time_zone

  db_home {
    database {
      admin_password = var.db_admin_password
      db_name        = "TFdb1Exa"
      character_set  = var.character_set
      ncharacter_set = var.n_character_set
    }
  }
}
```
db_workload = var.db_workload
pdb_name = var.pdb_name

db_backup_config {
    auto_backup_enabled = false
}
}
db_version = var.db_version
display_name = "MyTFDBHome1Exa"

maintenance_window_details {
    preference = "CUSTOM_PREFERENCE"

days_of_week {
    name = "MONDAY"
}

hours_of_day       = ["4"]
lead_time_in_weeks = 2

months {
    name = "APRIL"
}

weeks_of_month = ["2"]
}
disk_redundancy = var.db_disk_redundancy
shape = var.db_system_shape
subnet_id = oci_core_subnet.subnet.id
backup_subnet_id = oci_core_subnet.subnet_backup.id
ssh_public_keys = [var.ssh_public_key]
display_name = var.db_system_display_name
sparse_diskgroup = var.sparse_diskgroup
hostname = var.hostname
data_storage_percentage = var.data_storage_percentage

#data_storage_size_in_gb = var.data_storage_size_in_gb
license_model = var.license_model
node_count = data.oci_database_db_system_shapes.test_db_system_shapes[0]["minimum_node_count"]
backup_network_nsg_ids = [oci_core_network_security_group.test_network_security_group.id]
nsg_ids = [oci_core_network_security_group.test_network_security_group_backup.id, oci_core_network_security_group.test_network_security_group.id]
}

To migrate the system to the new resource model, first create the oci_database_migration resource:

// This is 1 time action to migrate test_db_system into db ExaCS
// and the test_db_system will become 'Migrated'
resource "oci_database_migration" "test_migration" {
    #Required
db_system_id = "${oci_database_db_system.test_db_system.id}"
Provisioning the `oci_database_migration` resource creates two new resources: `oci_database_cloud_exadata_infrastructure` and `oci_database_cloud_vm_cluster`.

You can get OCIDs of these two resources from the `oci_database_migration` resource:

```hcl
output "cloud_exadata_infrastructure_id" {
  value =
  oci_database_migration.test_migration.cloud_exadata_infrastructure_id
}
output "cloud_vm_cluster_id" {
  value = oci_database_migration.test_migration.cloud_vm_cluster_id
}
```

Create a Terraform configuration for the two new resources:

```hcl
resource "oci_database_cloud_exadata_infrastructure" "test_cloud_exadata_infrastructure"{}
resource "oci_database_cloud_vm_cluster" "test_cloud_vm_cluster" {}
```

Then run the Terraform import command:

```bash
terraform import
oci_database_cloud_exadata_infrastructure.test_cloud_exadata_infrastructure <cloud_exadata_infrastructure_id>
terraform import
oci_database_cloud_vm_cluster.test_cloud_vm_cluster <cloud_vm_cluster_id>
```

Terraform now manages the two new resources. After switching to the new Exadata resource model, remove the old `oci_database_db_system` config.

**Tip:**

After the migration, you can use Resource Discovery on page 4304 to create a full configuration and state file for importing these two new resources.

**Targeting Multiple Regions**

You can use a single Terraform configuration to create Oracle Cloud Infrastructure (OCI) resources in multiple regions.

**Create a Provider for Each Region**

A Terraform configuration may have only a single OCI Terraform provider block, but to apply configurations to multiple regions, you need to create multiple provider blocks.

A typical OCI Terraform provider block might look like the following:

```hcl
provider "oci" {
  region = var.region
  tenancy_ocid = var.tenancy_ocid
  user_ocid = var.user_ocid
  fingerprint = var.fingerprint
  private_key_path = var.private_key_path
}
```

**Tip:**

All parameters should be set using variables.

If you want to use more than one region within a single Terraform config, multiple providers are required. Each provider must be given an alias. For example:

```hcl
provider "oci" {
```
When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region, which is your home region. The home region has special properties. For example, IAM resources can only be created in your home region. For that reason, you should designate that region with an appropriate alias, like `home`. Use simple aliases for other regions so that users can easily map configurations to the regions that they want (for example, `region2`).

Note:
Specific regions (us-phoenix-1, us-ashburn-1, and so on) are not hardcoded into either the `region` or `alias` fields.

Provision a Resource
To provision a resource in a region, specify the aliased provider name in the resource.

For example:

```terraform
resource "oci_core_instance" "test_instance" {
  provider = oci.home
  ...
}
```

Modules and Multiple Regions
Typically, a module should use only a single region. If more regions are needed, you should use separate modules.

If the config contains multiple providers, the module should specify the provider to use by using the following format:

```terraform
module "compartments" {
  source = "./compartments"
  providers = {
    oci = "oci.home"
  }
}
```

Upgrading Configurations to Terraform v0.12
With the release of Terraform v0.12, Oracle Cloud Infrastructure Terraform providers need to be upgraded and some existing configurations may need to be updated as well.

Upgrading the Terraform Provider
Oracle Cloud Infrastructure (OCI) Terraform provider versions 3.26.0 and below are not compatible with Terraform v0.12. OCI Terraform provider version 3.27.0 is the earliest version that supports Terraform v0.12.

Note:
All OCI Terraform provider versions remain compatible with Terraform v0.11 and v0.10.
The simplest way to begin using the latest v0.12-compatible provider from the HashiCorp provider registry is to place an explicit version requirement in your provider configuration block, as shown here:

```hcl
provider "oci" {
  version          = ">= 3.27.0"
  region           = "${var.region}"
  tenancy_ocid     = "${var.tenancy_ocid}"
  user_ocid        = "${var.user_ocid}"
  fingerprint      = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}
```

For guidance using additional version configuration options, see Provider Versions.

Upgrading Terraform Configurations

Some users may find that no changes are needed to run existing Terraform configurations with v0.12.

For configurations that do need to be upgraded, see Upgrading Terraform configuration.

**Upgrading configurations while preserving v0.11 compatibility**

As recommended in Upgrading Terraform configuration, the simplest way to upgrade your configurations is to use the `terraform 0.12upgrade` command. Using the `terraform 0.12upgrade` command to upgrade your configurations, however, renders them incompatible with Terraform v0.11 and earlier.

**Caution:**

Prior to making configuration changes, it is strongly recommended that configuration and state files are backed up using version control or another preferred mechanism.

It may be possible to manually upgrade configurations to work with v0.12 while preserving compatibility with v0.11. Not all possible configurations can be made compatible with both v0.11 and v0.12. This method should only be used as a best-effort to preserve compatibility with v0.11.

The following cases detail where it is possible to convert existing v0.11 usage to be compatible with both v0.11 and v0.12.

**Attributes vs. Blocks**

In v0.11, it was possible to treat attributes and nested blocks interchangeably. Note how the attribute `metadata` and the nested block `source_details` are both assigned using only braces.

```hcl
// v0.11 compatible representation
resource "oci_core_instance" "my_instance" {
  metadata {
    ssh_authorized_keys = "${var.ssh_public_key}"  
  }

  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
    kms_key_id  = "${oci_kms_key.test_key.id}"
  }
}
```

In v0.12, attributes need to be assigned using the = operator while blocks need to be assigned using only braces. Note how the attribute `metadata` is now assigned with =. This usage is still compatible with v0.11.

```hcl
// v0.12 and v0.11 compatible representation
resource "oci_core_instance" "my_instance" {

```
metadata = {
    ssh_authorized_keys = "${var.ssh_public_key}"
}

source_details {
    source_type = "image"
    source_id = "${var.instance_image_ocid[var.region]}"
    kms_key_id = "${oci_kms_key.test_key.id}"
}

### Nested blocks with multiple elements

In v0.11, it was possible to wrap lists of nested blocks inside `[]` like this example.

```hcl
// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" {
    public_prefixes = [
        {
            cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block}" 
        },
        {
            cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block2}" 
        },
        {
            cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block3}" 
        },
    ]
}
```

In v0.12, it is required to specify each nested block individually without wrapping it in `[]`. This usage is still compatible with v0.11.

```hcl
// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" {
    public_prefixes {
        cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block}" 
    }
    public_prefixes {
        cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block2}" 
    }
    public_prefixes {
        cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block3}" 
    }
}
```

### Quotes around attribute names

In v0.11, it was possible to put quotation marks " around attribute names. Note how the `min` and `max` attributes have quotation marks around them.

```hcl
// v0.11 compatible representation
resource "oci_core_security_list" "bastion" {
    egress_security_rules {
        destination = "${var.vcn_cidr}"
        protocol   = "${local.tcp_protocol}" 
        tcp_options {
```
In v0.12, quotation marks " around attribute names are no longer allowed.

```hcl
resource "oci_core_security_list" "bastion" {
  egress_security_rules {
    destination = "${var.vcn_cidr}"
    protocol    = "${local.tcp_protocol}"
    tcp_options {
      min = 22
      max = 22
    }
  }
  ...
}
```

**Variable names starting with non-alphabetical characters**

In v0.11, it was possible to specify variable names that begin with non-alphabetical characters.

```hcl
variable "2TB" {
  default = "2048"
}
```

In v0.12, variable names must begin with alphabetical characters.

```hcl
variable "Size2TB" {
  default = "2048"
}
```

**Computing list index values**

In v0.11, division operations often resulted in integer values that could be used as a valid index in a list.

```hcl
instance_id     = "${oci_core_instance.TFInstance.*.id[count.index / var.NumParavirtualizedVolumesPerInstance]}"
```

In v0.12, division operations can result in floating point values that may no longer be valid. To avoid this situation, use the `floor` interpolation to convert floating point values to an index.

```hcl
instance_id     = "${oci_core_instance.TFInstance.*.id[floor(count.index / var.NumParavirtualizedVolumesPerInstance)]}"
```

**Using Object Storage for State Files**

You can store Terraform state files in Oracle Cloud Infrastructure (OCI) Object Storage. Doing so requires that you configure a backend using one of the Terraform backend types.
Terraform supports various backend types to allow flexibility in how state files are loaded into Terraform. (For more information, see **Terraform Backend Types**.) For our purposes, we address two of these approaches:

- Using an HTTP remote state backend
- Using an S3-compatible remote state backend

**Using an HTTP Backend**

Using the **HTTP backend type** allows you to store state using a simple REST client. With the HTTP backend type, you can easily fetch, update, and purge state using the **HTTP GET**, **POST**, and **DELETE** methods.

To configure the HTTP backend to store your OCI Terraform state files, do the following:

**Create a Pre-Authenticated Request**

Creating a pre-authenticated request in Oracle Object Storage enables accessing a bucket or object in the OCI without needing to provide credentials. To do so, you must create a pre-authenticated request that has read/write permissions to the object store where you intend to save the Terraform state file. You can do so in any of three ways: by using the Console UI, by using the command line interface (CLI), or by using the REST APIs.

**Note:**

A state file must exist in the bucket before you create the pre-authenticated request. This file can be an existing state file, or an empty file for the initial state.

For guidance, see Using Pre-Authenticated Requests on page 3482.

**Upload Existing State**

If you have an existing state file, you can upload it using Curl to make an **HTTP PUT** request to the object store URL, as shown here:

```bash
curl -X PUT -H "Content-Type: text/plain" --data-binary "@path/to/local/tfstate" http://<prefix>/<my-access-uri>
```

**Configure HTTP as a Terraform Backend**

The **HTTP backend type** stores state using a simple REST client and allows you to easily fetch, update, and purge state using the **HTTP GET**, **POST**, and **DELETE** methods.

The access URI for addressing OCI Terraform configurations must be of the form: `https://objectstorage.us-phoenix-1.oraclecloud.com/my-access-uri` (where region and access URI are specific to you).

For more example configuration and state files that reference code, and a summary of configuration variables, see **Standard Backends: HTTP**.

Following is an example Terraform configuration. The region in the URL can be something other than the Phoenix region.

```terraform
terraform {
    backend "http" {
        address = "https://objectstorage.us-phoenix-1.oraclecloud.com/<my-access-uri>"
        update_method = "PUT"
    }
}
```
Reinitialize Terraform

Finally, you must reinitialize Terraform and then run the `apply` command:

```bash
terraform init
terraform apply
```

After completing these steps, you are able to use Oracle Cloud Infrastructure as the backend for storing Terraform state files.

Using an S3-Compatible Backend

Configuring the S3-compatible backend requires that the account be enabled with S3 authentication keys, which are set on a per-user basis.

1. In the Console, open the navigation menu, then, under Governance and Administration, navigate to Identity, then Users. Under User Details, click Customer Secret Key. For guidance, see Working with Customer Secret Keys on page 2457.
2. Set the location for the credentials file. The default location is `~/.aws/credentials`. You can set an alternate location by using the S3 backend `shared_credentials_file` option.

   **Caution:** Never set the `access_key` and the `secret_key` attributes in the same Terraform backend configuration, since this creates a security risk.

3. Configure the `[default]` entry in the credentials file with the appropriate object storage credentials. The file can contain any number of credential profiles. If you provide a different profile name, you must also update the backend `profile` option in your Terraform configuration file.

   Following is an example of Object Storage credentials:

   ```
   [default]
   aws_access_key_id=ocid1.credential.oc1..exampleuniqueID
   aws_secret_access_key=mSTdaWhlbWj3ty4JZXl1m0NUZV52x1ImWjayJLJ6OH9A=
   ```

   Where `aws_access_key_id` and `aws_secret_access_key` are user-specific values provided from the Console. The key values provided in the example are not valid and provided as examples only.

4. Set the object storage endpoint value in the following format:

   ```
   https://<namespace>.compat.objectstorage.<region>.oraclecloud.com
   ```

5. Reinitialize Terraform and then run the `apply` command:

   ```bash
   terraform init
   terraform apply
   ```

Following is a full example of an Object Storage backend configuration:

```bash
terraform {
  backend "s3" {
    bucket = "terraform-states"
    key = "networking/terraform.tfstate"
    region = "us-phoenix-1"
    endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"
    shared_credentials_file = "../terraform-states_bucket_credentials"
    skip_region_validation = true
    skip_credentials_validation = true
    skip_metadata_api_check = true
    force_path_style = true
  }
}
```
Caution:

If the same bucket is used across multiple Terraform configurations, the key must be unique to avoid overwriting the state file. This example uses a single bucket (terraform-states) to store all Terraform state files, but uses a unique prefix for the object name based on the resource (networking).

Once you have configured the backend, you must run `terraform init` to finish the setup. If you already have an existing `terraform.tfstate` file, then Terraform prompts you to confirm that the current state file is the one to upload to the remote state.

Note:

The S3 backend configuration can also be used for the `terraform_remote_state` data source to enable sharing state across Terraform projects.

- Using Pre-Authenticated Requests on page 3482
- State Files
- Terraform Backend Types

Best Practices

This section documents some best practices that you can apply when you use the Oracle Cloud Infrastructure (OCI) Terraform provider to manage OCI resources.

See the following topics for more information:

- Managing Default VCN Resources on page 4300
- Referencing Availability Domains on page 4301
- Referencing Images on page 4303
- Storing Sensitive Data on page 4303
- Tagging Resources on page 4303

Managing Default VCN Resources

When you create an `oci_core_vcn` resource, it will also create the following associated resources by default.

- `oci_core_security_list`
- `oci_core_dhcp_options`
- `oci_core_route_table`

These default resources will be implicitly created even if they are not specified in the Terraform configuration. Their OCIDs are returned by the following attributes under the `oci_core_vcn` resource:

- `default_security_list_id`
- `default_dhcp_options_id`
- `default_route_table_id`

Default resources must be configured in Terraform using a separate resource type. Here are the mappings between the resource and the new resource type to use for configuring default resources:

- `oci_core_security_list` => `oci_core_default_security_list`
- `oci_core_dhcp_options` => `oci_core_default_dhcp_options`
- `oci_core_route_table` => `oci_core_default_route_table`

Default resources types are configured in the same way as their non-default counterparts. The only difference is specifying the ID of the default resource using the `manage_default_resource_id` argument.

Consequently, the compartment_id and vcn_id are no longer necessary for default resources.
The following example modifies a VCN's default DHCP options:

```hcl
resource "oci_core_vcn" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = var.compartment_ocid
  display_name = "vcn1"
}

resource "oci_core_default_dhcp_options" "default-dhcp-options" {
  manage_default_resource_id = oci_core_vcn.vcn1.default_dhcp_options_id

  // required
  options {
    type = "DomainNameServer"
    server_type = "VcnLocalPlusInternet"
  }

  // optional
  options {
    type = "SearchDomain"
    search_domain_names = [ "abc.com" ]
  }
}
```

Limitations

Default resources can only be removed when the associated `oci_core_vcn` resource is removed. When attempting a targeted removal of a default resource, the resource will be removed from the Terraform state file but the resource may still exist in OCI with empty settings.

Examples of targeted removal include:

- Removing a default resource from a Terraform configuration that was previously applied
- Running a `terraform destroy -target=<default resource>` command
- Changing the `manage_default_resource_id` for a default resource that was previously applied

Referencing Availability Domains

With respect to availability domains, we caution against a common pattern, as shown here:

```hcl```
```hcl
// Get all availability domains for the region
data "oci_identity_availability_domains" "ads" {
  compartment_id = "${var.tenancy_ocid}"
}

// Then either use it to get a single AD name based on the index:
resource "oci_core_instance" "nat" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ads.availability_domains["nat_instance_ad"], "name")}
  ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(data.oci_identity_availability_domains.ads.availability_domains)}"
  availability_domain = "${lookup(data.oci_identity_availability_domains.ads.availability_domains[count.index], "name")}"" ..
    ohbflh rawsdf 1329
```
The recommendation, then, is to explicitly list the availability domain names for the regions in your configuration. To do so, use a variable that you have defined as follows:

```hcl
variable "ad_list" {
  type = "list"
}
```

You can then use the variable as shown here:

```hcl```
// Index:
resource "oci_core_instance" "nat" {
  availability_domain = "${var.ad_list[var.nat_instance_ad_index]}"
} ...

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(var.ad_list)}"
  availability_domain = "${var.ad_list[count.index]}"
} ...
```

You can then set the `ad_list` variable directly by using the availability domain names for your tenant and region, as shown here:

```hcl```
variable "ad_list" {
  type = "list"
  default = ["kIdk:PHX-AD-1","kIdk:PHX-AD-2","kIdk:PHX-AD-3"]
}
```

The advantage of using this method is that it gives you control over your availability domain usage and prevents unexpected changes over time. However, this approach is problematic when configurations are shared between tenancies and regions, since availability domain names are tenancy- and region-specific.

A convenient alternative is to instead set the `ad_list` value by using the `oci_identity_availability_domains` data source. You should do this in the configuration, then pass them into the modules. This effectively centralizes the list of ADs, making it easy to switch to an explicit list later, should that become necessary: Note that the modules themselves should not use the `oci_identity_availability_domains` data source.

```hcl```
data "oci_identity_availability_domains" "ad" {
  compartment_id = "${var.tenancy_ocid}"
}
data "template_file" "ad_names" {
  count = "${length(data.oci_identity_availability_domains.ad.availability_domains)}"
  template = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")}"
}
module "ssm_network" {
  ad_list = "${data.template_file.ad_names.*.rendered}" ...
}
```

Regions with a Single Availability Domain

Some Oracle Cloud Infrastructure regions have a single availability domain. When writing configurations that use plural data sources, like `oci_identity_availability_domains`, ensure that you account for a single domain if required by your region.
The following example uses the `oci_identity_availability_domains` data source when listing fault domains in a single-availability domain region. The `availability_domains` index must be 0. Any other index value is invalid in this region:

```terraform
data "oci_identity_availability_domains" "AvailabilityDomains" {
  compartment_id = var.tenancy_ocid
}

data "oci_identity_fault_domains" "FaultDomains" {
  availability_domain = 
  data.oci_identity_availability_domains.AvailabilityDomains.availability_domains[0] {"name"}
  compartment_id = `${var.compartment_ocid}`
}
```

Referencing Images

When launching Compute instances, your Terraform configuration should use the same image every time you run a Terraform apply job.

To ensure this, specify the image OCID directly, rather than locating it using the `oci_core_image` data source. This is because the `oci_core_image` data source calls into the `ListImages` API, whose return values can change over time because over time images are added and older ones deleted. For a list of Oracle-provided images and their OCIDs, see Oracle-Provided Images on page 629. For more information, see Results of `oci_core_images` will change over time for Oracle-provided images.

We recommend the following pattern for specifying an image for a given region:

```terraform
variable "image_id" {
  type = "map"
  default = {
    // See https://docs.cloud.oracle.com/iaas/images/
    // Oracle-provided image "Oracle-Linux-7.4-2018.02.21-1"
    us-phoenix-1 = "ocid1.image.oc1.phx..<unique_ID>
    us-ashburn-1 = "ocid1.image.oc1.iad..<unique_ID>
    eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-1..<unique_ID>
    uk-london-1 = "ocid1.image.oc1.uk-london-1..<unique_ID>
  }
}
```

A Compute instance can use this in the following way:

```terraform
resource "oci_core_instance" "TFInstance" {
  image = `${var.image_id[var.region]}`
  ...
}
```

Storing Sensitive Data

**Caution:**

Terraform configuration files and state files may contain sensitive data.

When configuring your Oracle Cloud Infrastructure (OCI) Terraform provider, you should use variables to define your provider instead of including sensitive information within the file.

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state itself as sensitive data. Please refer to Sensitive Data in State for more details.

Tagging Resources

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate...
them, report on them, or take bulk actions on them. Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs. See Tagging Overview to familiarize yourself with concept of tagging and features available.

Managing Tags and Tag Namespaces

- See tag_namespaces for guidance on managing lifecycle of tag namespaces.
- See tags for guidance on managing lifecycle of tags.

How To Manage Tags on OCI Resources

- **Freeform tags**: Freeform tags are simple key/value map.
- **Defined tags**: Defined tags provide a key/value map and are organized by combining the tag namespaces with tag keys using dot notation. For example, a tag namespace called HumanResources could have a key named CostCenter. You then associate the namespace and key HumanResource.CostCenter and then assign the desired tag, as shown in the following example.

Propagation of tagging on resources

If your Terraform configuration has a primary resource (e.g. compute instance) with a nested secondary resource (e.g. VNIC for the compute instance) where both these resources support freeform tags or defined tags, OCI Services will propagate all the primary resource's freeform tags and defined tags to secondary resource. This could cause a drift in the Terraform state resulting in a diff after apply. To avoid this, explicitly add all the primary resource's freeform tags and defined tags on the secondary resources as part of the configuration. The same behavior can be seen while using the Tag Default or Required Tags feature. This can also be avoided by applying the Tag Default or Required Tags on all resources (primary and secondary if any) in the tenancy where Tag Default or Required Tags exist.

Resource Discovery

You can use the Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature to search for deployed resources in your compartment and export them to Terraform configuration and state files.

Resource discovery simplifies the move from manually managed infrastructure to Terraform-managed infrastructure. With a single command, you can generate a file that captures your existing compartment's baseline configuration and state.

### Important:

Resource discovery is not a migration tool. When cloning or migrating resources, configurations generated by resource discovery are a starting point. They may require changes.

Common uses cases for your new Terraform configuration and state files include:

- Duplication or rebuild of your existing infrastructure architecture in a new tenancy or region.
- Detection of state drift. Run reports to see if the state of your Terraform-managed resources has changed and differs from your base configuration.

### Note:

Terraform resource discovery is available with OCI Terraform provider version 3.50 and above.

Supported Services

Refer to Supported Services on page 4309 for the list of services the OCI Terraform provider's resource discovery feature supports. You can also see the list of supported services by running this command:

```
terraform-provider-oci -command=list_export_services
```
Developer Tools

Note:
Terraform resource discovery may not be available for all services that the OCI Terraform provider supports.

Supported Resources
Each supported service has one or more discoverable resources. You can see the list of supported resources by running this command:

```
terraform-provider-oci -command=list_export_resources
```

Using Resource Discovery
The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature uses HashiCorp's terraform-exec to import the discovered OCI resources into Terraform configuration and state files.

Prerequisites
Terraform-exec requires the Terraform CLI to be present on your system. See Download and Install Terraform on page 103 for installation details.

Note:
If you are using Terraform version v0.11, this tool cannot generate a state file. Only configurations are supported in v0.11. By default the configurations are generated in v0.12.

If you use v0.13.* of the Terraform CLI, make sure that the version is compatible with v0.12 syntax.

Additionally, you must have the OCI Terraform provider downloaded and installed. See Download and Install the Provider on page 103 for download instructions.

Adding the Tools to Your Path
To run the OCI Terraform provider as an executable and use resource discovery, you can:

- Add `terraform-provider-oci` to your system path.
- Run the provider from the directory where it is located.
- Specify the full path to the provider when you run resource discovery commands.

Because resource discovery commands use terraform-exec to call Terraform on your behalf, your system must specify the location of the Terraform CLI using either of the following methods:

- Provide the full path including name for the Terraform CLI using the `terraform_bin_path` environment variable. See Environment Variables for more information on setting variables.
- Add the Terraform CLI to your system path.

Authentication
To discover resources in your compartment, the OCI Terraform provider needs authentication information about the user, tenancy, and region with which to discover the resources. It is recommended that you specify a user that has access to inspect and read the resources to discover.

You can use API Key Authentication and Environment Variables or Instance Principal Authorization to provide the required information.

Exporting Resources
Once you have specified the location of the Terraform CLI and authentication settings, either of the following commands can be used to export a compartment’s resources:

- `terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>`
- `terraform-provider-oci -command=export -compartment_id=<compartment_OCID> -output_path=<output_path>`

These commands discover all supported resources within the compartment and generate Terraform configuration files in the given `output_path`. The generated `.tf` files contain the Terraform configuration with the resources that the command has discovered.

**Note:**
Export of compartment resources supports only the target compartment. Resources in child compartments are not discovered.

**Note:**
The `compartment_id` parameter is required if using Instance Principal Authorization.

### Parameters

You can use the following parameters to control the behavior of the resource discovery tool.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Details</th>
</tr>
</thead>
</table>
| `command`                | The command to run. Supported commands include:  
|                          | • `export` - discovers OCI resources within your compartment and generates Terraform configuration files for them  
|                          | • `list_export_resources` - lists the Terraform OCI resource types that are discovered by the export command  
|                          | • `list_export_services` - lists the allowed values for services arguments along with scope in JSON format  
| `compartment_id`         | The OCID of the compartment to export. If `compartment_id` or `compartment_name` is not specified, the root compartment is used.  
| `compartment_name`       | The name of a compartment to export. If `compartment_id` or `compartment_name` is not specified, the root compartment is used.  
| `generate_state`         | Provide this flag to import the discovered resources into a state file in addition to the Terraform configuration files.  
| `ids`                    | A comma-separated list of resource IDs to export. The ID could either be an OCID or a Terraform import ID. By default, all resources are exported.  
| `list_export_services_path` | The full path, including the filename, to use as the output for list of supported services, in JSON format. |
### Parameter Details

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>output_path</strong></td>
<td>The path to output the generated configurations and state files of the exported compartment.</td>
</tr>
<tr>
<td><strong>parallelism</strong></td>
<td>The number of threads that will be used to discover resources in parallel. The default value is 1.</td>
</tr>
<tr>
<td><strong>services</strong></td>
<td>A comma-separated list of service resources to export. If not specified, all resources within the given compartment (excluding IAM resources) are exported.</td>
</tr>
<tr>
<td><strong>tf_version</strong></td>
<td>The version of Terraform syntax to use when generating configuration files. The default is v0.12. The allowed values are:</td>
</tr>
<tr>
<td></td>
<td>• 0.11</td>
</tr>
<tr>
<td></td>
<td>• 0.12</td>
</tr>
<tr>
<td></td>
<td>If you specify 0.11 as the syntax version, you should use v0.11 of the Terraform CLI to discover resources.</td>
</tr>
<tr>
<td></td>
<td>If you use Terraform CLI v0.13 and above to discover resources, make sure the version is compatible with v0.12 syntax.</td>
</tr>
<tr>
<td></td>
<td>State files are generated in Terraform syntax matching the version of the Terraform CLI used to discover resources. The tf_version parameter does not apply to state files.</td>
</tr>
</tbody>
</table>

### Exit Status

If there is any error related to the OCI APIs or service unavailability while discovering resources, the tool moves on to find next resource. All of the errors encountered are displayed after the discovery is complete.

- **Exit code 0** - Success.
- **Exit code 1** - Failure due to errors such as incorrect environment variables, arguments or configuration.
- **Exit code 2** - Partial success. Resource discovery was not able to find all the resources because of service failures.

### Exporting Identity Resources

Some resources, such as identity resources, exist only at the tenancy level and cannot be discovered within a specific compartment. To discover such resources, use the following command, which omits any compartment parameter:

```
terraform-provider-oci -command=export -output_path=<output_path> -services=identity
```

**Note:**

When exporting identity resources, the **compartment_id** value, if provided, is ignored.

### Exporting Resources to Another Compartment

Once you have reviewed the generated Terraform configuration files and made any necessary changes, the configuration can be used with Terraform. One such use case is the re-deploying of those resources in a new compartment or tenancy, using Terraform.
To do so, specify the following environment variables:

```bash
export TF_VAR_tenancy_ocid=<target_tenancy OCID>
export TF_VAR_compartment_ocid=<target_compartment OCID>
```

Then run the following command:

```bash
terraform apply
```

Generating a Terraform State File

It is also possible to generate a Terraform state file to manage the discovered resources. To do so, run the following command, which includes the `-generate_state` flag:

```bash
terraform-provider-oci -command=export -compartment_id=<compartment OCID> -output_path=<output_path> -generate_state
```

The results of this command are both the `.tf` files representing the Terraform configuration and a `terraform.tfstate` file representing the state. See `State` for more information.

**Caution:**
The state file contains all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, treat the state file itself as sensitive data. See `Storing Sensitive Data` on page 4303 for more information.

**Note:**
The Terraform state file generated by this command is only compatible with Terraform v0.12.4 and above.

Output File Contents

The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery `export` command discovers resources that are in an active or usable state. Resources that have been terminated or otherwise made inactive are generally excluded from the generated configuration.

By default, the Terraform names of the discovered resources share the same name as the display name for that resource, if one exists.

The attributes of the resources are populated with the values that are returned by the OCI services.

In some cases, a required or optional attribute may not be discoverable from the OCI services and may be omitted from the generated Terraform configuration. This may be expected behavior from the service, which may prevent discovery of certain sensitive attributes or secrets. In such cases, a placeholder value will be set along with a comment like this:

```bash
admin_password = "" #Required attribute not found in discovery, placeholder value set to avoid plan failure
```

The missing required attributes are also added to lifecycle `ignore_changes`. This is done to avoid Terraform plan failure when moving manually-managed infrastructure to Terraform-managed infrastructure. Any changes made to such fields will not reflect in Terraform plan. If you want to update these fields, remove them from `ignore_changes`.

Resources that are dependent on availability domains will be generated under `availability_domain.tf` file. These include:

- `oci_core_boot_volume`
- `oci_file_storage_file_system`
- `oci_file_storage_mount_target`
This section provides additional information on how to use the Oracle Cloud Infrastructure (OCI) Terraform provider with the services it supports, including some best practices for those services.

Full Reference Documentation

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The resources are grouped by service within the reference.

Supported Services

The following table lists the services supported by the OCI Terraform provider and the services supported by the resource discovery feature. This list also includes the values accepted by resource discovery's services parameter.

**Deprecated Resources**

This topic covers the list of resources and data sources that have been marked deprecated by the Oracle Cloud Infrastructure (OCI) Terraform provider and their respective suggested replacements, if any.
Resources and data sources marked for deprecation will trigger warnings during Terraform plan and apply operations. For example:

The 'oci_autonomous_data_warehouse' resource has been deprecated. Please use 'oci_autonomous_database' instead.

Resources on path to deprecation may stop working in future, use the respective guide, if available, on how to migrate using the new replacements.

**Deprecated Resources and Data Sources**

Resources that have a migration path have deprecation guides available on how to rename and migrate them to their new replacements.

Data sources do not have deprecation guide as you can directly replace them in their Terraform configuration and refresh the state.

<table>
<thead>
<tr>
<th>Caution:</th>

**Deprecation Notices**

Deprecation notices for fields can be found in any of the previously released CHANGELOG. Deprecation notices are also shown as deprecated during Terraform `plan` and `apply` operations. For example:

The `size_in_mbs` field has been deprecated. Please use `size_in_gbs` instead.

**Troubleshooting**

This topic describes how to troubleshoot common Oracle Cloud Infrastructure (OCI) Terraform provider issues. Refer to Troubleshooting Basics for first steps.

**Common Issues**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>See Terraform state drift with tag defaults and tags for secondary resources for a known issue with tags related to Terraform.</td>
</tr>
</tbody>
</table>

**Automatic Retries**

While applying, refreshing, or destroying a plan, Terraform may encounter some intermittent OCI errors (such as 429 or 500 errors) that could succeed on retry. By default, the OCI Terraform provider automatically retries such operations for up to 10 minutes. The following fields can be specified in the provider block to further configure the retry behavior:

- `disable_auto_retries` - Disable automatic retries for retriable errors.
- `retry_duration_seconds` - The minimum duration (in seconds) to retry a resource operation in response to HTTP 429 and HTTP 500 errors. The actual retry duration may be slightly longer due to jittering of retry operations. This value is ignored if the `disable_auto_retries` field is set to true.

**Concurrency Control using Retry Backoff and Jitter**

To alleviate contention between parallel operations against OCI services; the OCI Terraform provider schedules retry attempts using quadratic backoff and full jitter. Quadratic backoff increases the maximum interval between subsequent retry attempts, while full jitter randomly selects a retry interval within the backoff range.

For example, the wait time between the first and second retry attempts is chosen randomly between 1 and 8 seconds. The wait time between the second and third retry attempts is chosen randomly between 1 and 18 seconds. Regardless of the number of retry attempts, the retry interval time is capped after the 12th attempt at 288 seconds.

Note that the `retry_duration_seconds` field only affects retry duration in response to HTTP 429 and 500 errors; as these errors are more likely to result in success after a long retry duration. Other HTTP errors (such as 400, 401, 403, 404, and 409) are unlikely to succeed on retry. The `retry_duration_seconds` field does not affect the retry behavior for such errors.

**Resources are destroyed when applying changes**

Existing OCI resources might be destroyed and re-created when Terraform configurations attempt to update a resource property that is not updatable. Terraform warns you when changes will destroy a resource. Always run `terraform plan` before applying changes to see what resources will be affected. See Destructive Changes for more information.

**"NotAuthenticated" error when using Terraform**

If the Terraform CLI returns an error message like the following:

```plaintext
* oci_core_vcn.resource1: Service error:NotAuthenticated. The required information to complete authentication was not provided or was incorrect.
  http status code: 401
```

- Verify you have properly set `user_ocid`, `tenancy_ocid`, `fingerprint` and `private_key_path`. 
• Verify your `private_key_path` is pointing to your private key and not the corresponding public key.
• Verify you have added the corresponding public key to the user account you have specified with `user_ocid`.
• Verify the public/private key pairs you are using are of the correct format. See Required Keys for details on the correct format and how to generate keys.
• Verify the user account is part of a group with the appropriate permissions to perform the actions in the plan you are executing.
• Verify your Tenancy has been subscribed to the Region you are targeting in your plan.

"TCP...i/o timeout" message when connecting via proxy

If the Terraform CLI returns an error message like the following:

* provider.oci: ... dial tcp 134.70.16.0:443: i/o timeout

Then you may not have properly configured your proxy settings. The OCI Terraform provider supports `http_proxy`, `https_proxy` and `no_proxy` variables where the inclusion or exclusion lists can be defined as follows:

```bash
export http_proxy=http://www.your-proxy.com:80/
export https_proxy=http://www.your-proxy.com:80/
export no_proxy=localhost,127.0.0.1
```

"Timeout while waiting for state" message

If the Terraform CLI returns an error message like the following:

* oci_database_backup.mydb: timeout while waiting for state to become 'ACTIVE' (last state: 'CREATING', timeout: 15m0s)

Then the OCI service is indicating that the resource has not yet reached the expected state after polling for some time.

You may need to increase the operation timeout for your resource to continue polling for longer. See Operation Timeouts for details on how to do this.

"Field cannot be set" error message

If the Terraform CLI returns an error message like the following:

* Error: "field_name": this field cannot be set

You are likely using an older version of the OCI Terraform provider and the field you are trying to set was released in a later version. Use the following command to check your Terraform provider version.

```bash
terraform -version
```

The OCI Terraform provider documentation reflects the latest version.

"No such file" error after upgrading the OCI Terraform provider

If the Terraform CLI returns an error message like the following:

Error asking for user input: 1 error(s) occurred:

* provider.oci: dial unix /var/folders/6r/8fk5dmbj4_z3s10mc_y_fhjw0000gn/T/plugin811254328|netrpc: connect: no such file or directory

You are likely using a version of the OCI Terraform provider that is not compatible with the Terraform binary you have installed. For OCI Provider versions v3.x.x and above, a minimum Terraform version of v.0.10.1 is required.
"x509: certificate signed by unknown authority" error message

If the Terraform CLI returns an error message like the following:

```
Error: Get https://iaas.<region>.oraclecloud.com/20160918/services: x509:
  certificate signed by unknown authority
  on ../modules/network/modules/main/main.tf line 3...
```

Ensure that Terraform is using trusted TLS certificates and the certificate chain is valid. See Terraform runs failing with "x509: certificate signed by unknown authority" error for more information. If using MacOS Catalina, refer to the MacOS section of the document for more specifics on resolving certificate issues.

"Could not get info about the first DbHome in the dbSystem" error message when importing db_home

If the oci_database_db_system being imported is missing a primary db_home, an empty placeholder for db_home is set in the Terraform state file. To keep configurations consistent with the imported state, add an empty placeholder for db_home to your configuration. For example:

```ruby
# Add this placeholder into your oci_database_db_system configuration to
# indicate that the primary db home is empty.
db_home {
  database {
    admin_password = ""
  }
}
```

Errors about service limits

While using Terraform, you may encounter errors indicating that you have reached or exceeded the service limits for a resource.

To understand more about your OCI service limits and how to request a limit increase, see Service Limits

OCI Modules for PowerShell

The Oracle Cloud Infrastructure Modules for PowerShell is a set of cmdlet modules that can be used with PowerShell Core to manage Oracle Cloud Infrastructure resources. You can invoke these cmdlets from the PowerShell command-line and with the associated PowerShell scripting language.

Requirements

To use the OCI Modules for PowerShell, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies you may want to use, see Common Policies on page 2142.
- A configuration file and key pair used for signing API requests, with the public key uploaded to Oracle Cloud using Oracle Cloud Infrastructure Console. Only the user calling the API should possess the private key.
- A supported version of PowerShell installed on Windows, Linux, or macOS operating systems.

**Note:**
For installation instructions, see Installing PowerShell.

Supported PowerShell Versions

To use the OCI Modules for PowerShell, you must have the following:

- PowerShell Core version 6.0 or higher
Services Supported

- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Big Data
- Blockchain Platform
- Budgets
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Cloud Guard
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- Digital Assistant
- DNS
- Email Delivery
- Events
- File Storage
- Functions
- Golden Gate
- Health Checks
- IAM
- Integration
- Vault
- Limits
- Load Balancing
- Logging
- Logging Analytics
- Logging Search
- Logging Ingestion
- Management Agent Cloud
- Management Dashboard
- Marketplace
- Monitoring
- Object Storage
- OCI Registry
- Operations Insights
- Optimizer
- Organizations
• OS Management
• Quotas
• Resource Manager
• Roving Edge Infrastructure
• Search
• Secret Management (for the Vault)
• Service Connector Hub
• Streaming
• Support Management
• Usage
• VMWare Solution
• Web Application Acceleration and Security
• Work Requests (Compute, Database)

Getting Started
This topic describes how to install and configure the OCI Modules for PowerShell.

Prerequisites
Be sure to satisfy all the requirements listed here.

Installing Modules
1. Start a PowerShell session:
   a. On Windows, launch PowerShell from the Start Menu.
   b. On Linux or MacOS, run pwsh from a shell prompt:

   ```
   $ pwsh
   PowerShell 7.0.3
   Copyright (c) Microsoft Corporation. All rights reserved.
   https://aka.ms/powershell
   Type 'help' to get help.
   PS /Users/username>
   ```

   2. Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual PowerShell module named OCI.PSModules.<ServiceName>.

   3. Continue to either Installing from PowerShell Gallery or Installing from GitHub on page 4317.
Installing from PowerShell Gallery

1. By default, PowerShell Gallery ("PS Gallery") is configured as a PSRepository. This can be verified by running the `Get-PSRepository` command:

   ```
   PS /> Get-PSRepository
   Name                      InstallationPolicy   SourceLocation
   ----                      ------------------   --------------
   PSGallery                 Untrusted            https://www.powershellgallery.com/api/v2
   ```

2. You can set PS Gallery as a trusted repository to avoid prompts every time you attempt to install a module from PS Gallery:

   ```
   PS /> Set-PSRepository -Name PSGallery -InstallationPolicy Trusted
   ```

3. PowerShell modules that correspond to a supported OCI service are called service modules. To install a service module run the `Install-Module` command. This example installs the service module for the OCI Identity service:

   ```
   PS /> Install-Module -Name OCI.PSModules.Identity
   ```

   **Note:**
   Each service module depends on the `OCI.PSModules.Common` (Common Module), which offers functionality common to all service modules. Installing a service module will also install the corresponding version of `OCI.PSModules.Common` for that service module.

4. Installed modules can be found in the path specified by the `$Env:PSModulePath` environment variable, or by running the `Get-Module` command with the `ListAvailable` parameter.

   ```
   PS /> Get-Module -ListAvailable
   ```

Installing from GitHub

To install the OCI PowerShell modules from GitHub:

1. Download the latest OCI Modules artifacts and extract them into a local directory.

   **Note:**
   Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual PowerShell module named `OCI.PSModules.<ServiceName>`.

2. Register the extracted directory as the local PowerShell repository:

   ```
   PS /> Register-PSRepository -Name "LocalRepo" -SourceLocation \<extractedlocation>
   ```

3. Find the modules available in the local repository:

   ```
   PS /> Find-Module -Repository "LocalRepo"
   ```
4. Install a specific module:

```
PS /> Install-Module -Name OCI.PSModes.Module.Objectstorage -Verbose -Repository LocalRepo
```

**Note:**
Each service module depends on the OCI.PSModes.Module.Common (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of OCI.PSModes.Module.Common for that service module.

5. Installed modules can be found in the path specified by the $Env:PSModulePath environment variable, or by running the Get-Module command with the ListAvailable parameter.

```
PS /> Get-Module -ListAvailable
```

**Installing with Yum**

If you are using Oracle Linux version 7.x, the OCI PowerShell Modules packages can be installed with yum.

1. To install the OCI PowerShell modules using yum:

```
$sudo yum install oci-powershell-modules
```

2. Start a PowerShell Session and register the downloaded directory /usr/lib/dotnet/NuPkgs as a local PowerShell repository using the following command:

```
$pwsh
PS /> Register-PSRepository -Name "LocalRepo" -SourceLocation /usr/lib/dotnet/NuPkgs
```

3. Find the modules available in the local repository using the following command:

```
PS /> Find-Module -Repository "LocalRepo"
```

4. Install a specific module:

```
PS /> Install-Module -Name OCI.PSModes.Module.Objectstorage -Verbose -Repository LocalRepo
```

**Note:**
Each service module depends on the OCI.PSModes.Module.Common (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of OCI.PSModes.Module.Common for that service module.

5. Installed modules can be found in the path specified by the $Env:PSModulePath environment variable, or by running the Get-Module command with the ListAvailable parameter.

```
PS /> Get-Module -ListAvailable
```

**Setup**

Follow these installation steps if you haven't installed the required modules.

Before invoking cmdlets in OCI Modules, you need to set up the configuration file, and then optionally import the required modules into a PowerShell session.

**Configuration File**
A configuration file provides essential configuration information, like user credentials and tenancy OCID. This configuration information is used by the OCI Modules for PowerShell to authenticate and interact with Oracle Cloud services. You can create this file using a setup cmdlet, or manually using a text editor.

**Set-OCIClientConfig**

The `Set-OCIClientConfig` cmdlet included in the Common module will walk you through setting up a configuration file. This cmdlet prompts you for information required by the configuration file, including the key pair used to sign API requests.

For more information about how to find the required information, see:

- Where to Get the Tenancy's OCID and User's OCID
- Regions and Availability Domains

**Manual Setup**

If you want to set up the API signing key pair manually and write your own configuration file, see SDK and Tool Configuration and Required Keys.

**Note:**

Use the `New-OCIClientKeys` cmdlet to generate a API signing key pair to include in the configuration file.

**Importing Modules**

PowerShell will automatically import the module (and its dependencies) into your session the first time you run any command from the installed module. To explicitly import a module, run the `Import-Module` command.

For example, to import the version 1.0.0 of the Identity service module:

```powershell
PS /> Import-Module OCI.PSModules.Identity -RequiredVersion 1.0.0 -Verbose
```

To find all imported modules in your current PowerShell Session, run the `Get-Module` command:

```powershell
PS /> Get-Module
```

<table>
<thead>
<tr>
<th>ModuleType</th>
<th>Name</th>
<th>ExportedCommands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>OCI.PSModules.Identity</td>
<td>{Add-OCIIdentityUserToGroup, Enable-OCIIdentityMfaTotpDevice}</td>
</tr>
</tbody>
</table>

**Note:**

Each service module depends on the `OCI.PSModules.Common` (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of `OCI.PSModules.Common` for that service module.

**Updating Modules**

New versions of the OCI PowerShell modules release weekly. To update the installed OCI PowerShell modules to the latest version, run the `Update-Module` command.
Before updating any OCI module, you should first uninstall the module. To avoid dependency conflicts when importing modules into PowerShell session, update all installed OCI Modules to the same version.

```
PS /> Update-Module -Name "OCI.PSModules.*" -Verbose
```

### Uninstalling Modules

To remove any installed module, you can either use the `Uninstall-Module` cmdlet or delete the module folder located in the path in the `$Env:PSModulePath` environment variable.

For example:

```
PS /> Uninstall-Module -Name OCI.PSModules.Identity
```

### Next Steps

Now that you’ve taken care of installation and setup, you can proceed directly to Working with Cmdlets, or continue to Advanced Concepts on page 4324.

### Working with Cmdlets

The OCI Modules for PowerShell cmdlets are built on the Oracle Cloud Infrastructure SDK for .NET. These cmdlets make calls to Oracle Cloud Infrastructure REST APIs with the passed cmdlet parameter values.

```
Note:

Cmdlet parameters are named corresponding to the respective REST API parameters as listed in the API reference.
```

The OCI REST APIs use HTTPS requests and responses. For more information, see About the API.

### Cmdlet Discovery

OCI Cmdlets are named using a `verb -noun` pair pattern, where `verb` is the operation performed on the resource denoted by the `noun`, which usually includes the service name followed by the name of the resource in that service.

For example, the following command returns all cmdlets available to work with a Compute Instance resource in the Compute service, which is part of the OCI Core PowerShell module:

```
PS /> Get-Command -Module OCI.PSModules.Core -Noun "*ComputeInstance*"
```

<table>
<thead>
<tr>
<th>CommandType</th>
<th>Name</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmdlet</td>
<td>Get-OCIComputeInstance</td>
<td>0.1.0</td>
</tr>
<tr>
<td></td>
<td>OCI.PSModules.Core</td>
<td></td>
</tr>
<tr>
<td>Cmdlet</td>
<td>Get-OCIComputeInstanceConsoleConnection</td>
<td>0.1.0</td>
</tr>
<tr>
<td></td>
<td>OCI.PSModules.Core</td>
<td></td>
</tr>
<tr>
<td>Cmdlet</td>
<td>Get-OCIComputeInstanceConsoleConnectionsList</td>
<td>0.1.0</td>
</tr>
<tr>

</tbody>
</table>
Sample Cmdlet

This example shows how to invoke a simple OCI cmdlet that calls the GetNamespace operation of the OCI Object Storage service. This operation returns the name of the Object Storage namespace for the user making the request.

Note:
Install and import the ObjectStorage service before trying out this example. For more information, see Installation.

PS /> Get-OCIObjectStorageNamespace
us-phx-test-namespace

Cmdlet Help

To get help information for a cmdlet, use the Get-Help cmdlet, passing in the name of the cmdlet as a parameter.

Note:
For more detailed help information, use the -Full parameter.

This example shows help output for the Get-OCIObjectStorageNamespace cmdlet:

PS /> Get-Help Get-OCIObjectStorageNamespace
NAME
Get-OCIObjectStorageNamespace

SYNOPSIS
Invokes ObjectStorage service - GetNamespace operation.

SYNTAX

DESCRIPTION
Each Oracle Cloud Infrastructure tenant is assigned one unique and uneditable Object Storage namespace. The namespace is a system-generated string assigned during account creation. For some older tenancies, the namespace string may be the tenancy name in all lower-case letters. You cannot edit a namespace. GetNamespace returns the name of the Object Storage namespace for the user making the request. If an optional compartmentId query parameter
Developer Tools

is provided, GetNamespace returns the namespace name of the corresponding tenancy, provided the user has access to it.

REMARKS
To see the examples, type: "Get-Help Get-OCIObjectStorageNamespace - Examples"
For more information, type: "Get-Help Get-OCIObjectStorageNamespace - Detailed"
For technical information, type: "Get-Help Get-OCIObjectStorageNamespace -Full"
For online help, type: "Get-Help Get-OCIObjectStorageNamespace -Online"

Common Parameters

This section describes the optional global cmdlet parameters common to all cmdlets present in any OCI PowerShell service module.

**ConfigFile**
The path to the configuration file that supplies credentials for the Oracle Cloud.

**Endpoint**
Indicates the service endpoint to use for OCI API calls, including any required API version path. For example, https://audit.us-ashburn-1.oraclecloud.com

**FullResponse**
By default, OCI Cmdlets output the response body of the REST API operation. Including the FullResponse switch parameter indicates that the cmdlet should output the complete response returned by the API operation wrapped in its associated .NET type (an object containing API response headers in-addition to an optional response body).

**NoRetry**
A switch parameter to disable default retry logic for calls to services.

By default, OCI Modules for PowerShell retry failed API calls that return status codes 400, 401, 404, 409, 429 and 500. Retry attempts use an exponential backoff algorithm with a maximum of 5 attempts over a maximum time span of 10 minutes. Include this switch parameter in the cmdlet invocation to disable the default retry logic.

**Profile**
Specifies which profile to load from the configuration file. This parameter expects a case-sensitive profile name existing in the configuration file.

**Region**
Specifies the Region-ID of the region to make calls against. For example: us-phoenix-1 or ap-singapore-1.

**TimeOutInMillis**
Specifies the maximum wait time in milliseconds for the API request to complete. The default value is 100,000 milliseconds (100 seconds).
**AuthType**

Defines the type of authentication to use for making API requests. By default the API Key in your config file is used. Valid values are ApiKey or InstancePrincipal.

**Cmdlet Input and Output**

This section describes how the OCI Cmdlets process input and output.

**Cmdlet Input**

OCI Cmdlets currently accept inputs from command line parameters or through pipeline by property names. To see an example on passing inputs through pipeline by property name refer this sample.

**Cmdlet Output**

By default, OCI Cmdlets return only the API response body encapsulated in an associated .NET type. For use cases that require the users to inspect the complete API response including the response headers, use the `FullResponse` switch parameter in the cmdlet invocation.

In the following example, the `GetConfiguration` operation in the OCI Audit service returns a Configuration resource in the response body.

```
Note:
To run the following example, import OCI.PSMODULES.Audit.
```

```
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId | gm
TypeName: Oci.AuditService.Models.Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>RetentionPeriodDays</td>
<td>Property</td>
<td>System.Nullable[int] RetentionPeriodDays</td>
</tr>
<tr>
<td>(get;set;)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

In the example output above, the default invocation only returns the .NET object that encapsulates the API response body.

To get an output object that includes the complete API response include the `-FullResponse` parameter in the cmdlet invocation. For example:

```
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId - FullResponse | gm
```

```
TypeName: Oci.AuditService.Responses.GetConfigurationResponse

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>(get;set;)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Asynchronous Calls

For Oracle Cloud APIs that return an asynchronous work request response, with opc-work-request-id in the response header and no response body, OCI PowerShell Cmdlets return a Oci.PSModules.Common.Cmdlets.WorkRequest object containing the OpcWorkRequestID property.

For example:

TypeName: Oci.PSModules.Common.Cmdlets.WorkRequest

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>-----------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>OpcWorkRequestId</td>
<td>Property</td>
<td>string OpcWorkRequestID {get;set;}</td>
</tr>
</tbody>
</table>

Error Handling

If an error occurs when running an OCI Cmdlet, the cmdlet throws a terminating error with an error record containing the exception and an error message about the underlying cause.

Advanced Concepts

This section covers PowerShell SDK concepts.

Managing Session Preferences

The OCI Modules for PowerShell support the use of environment variables in a PowerShell session to specify values some optional common parameters. These environment variables can be configured directly in the PowerShell session or by using the Set-OCIClientSession cmdlet. Values assigned to these environment variables are used for making API calls only in the PowerShell session in which they are set.

Set Environment Variables Directly from PowerShell

The following environment variables can be used to specify values for some parameters used by the OCI Modules for PowerShell:

<table>
<thead>
<tr>
<th>Cmdlet Parameter</th>
<th>Environment Variable Name</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>OCI_PS_REGION</td>
<td>If a value is not specified, region value from the user preferred profile is used.</td>
</tr>
<tr>
<td>Profile</td>
<td>OCI_PS_PROFILE</td>
<td>If a value is not specified, the DEFAULT profile is used.</td>
</tr>
<tr>
<td>ConfigFile</td>
<td>OCI_PS_CONFIG</td>
<td>If a value is not specified, config file at ~/.oci/config will be used.</td>
</tr>
<tr>
<td>NoRetry</td>
<td>OCI_PS_NORETRY</td>
<td>If a value is not specified, default retry strategy is used to attempt retries.</td>
</tr>
<tr>
<td>TimeOutInMillis</td>
<td>OCI_PS_TIMEOUT</td>
<td>If a value is not specified, the default value of 100,000 milliseconds (100 seconds) is used.</td>
</tr>
<tr>
<td>AuthType</td>
<td>OCI_PS_AUTH</td>
<td>If a value is not specified, the API key defined in the config file is used.</td>
</tr>
</tbody>
</table>

For example, to set the region:

PS /> $Env:OCI_PS_REGION="us-phoenix-1"
Set Environment Variables using Cmdlets

You can use the Set-OCIClientSession and Get-OCIClientSession cmdlets to set and retrieve the session preference environment variables.

Set-OCIClientSession

This cmdlet sets the Region, Profile and Config file preferences for the PowerShell session through the environment variables shown above.

Note:
Import OCI.PSMODULES.Common before running the following example.

```
PS > Set-OCIClientSession -RegionId "us-ashburn-1" -Profile "Test" -Config "~/.oci/testconfig"

RegionId     Profile Config
--------     ------- -----
us-ashburn-1 Test    ~/.oci/testconfig
```

To remove a session preference environment variable, run the Clear-OCIClientSession cmdlet with the appropriate parameters.

Get-OCIClientSession

The Get-OCIClientSession cmdlet in the common module is used to retrieve the session preference values set for the common parameters from the current PowerShell session.

```
PS > Get-OCIClientSession

RegionId     Profile Config
--------     ------- -----
us-ashburn-1 Test
```

Parameter Precedence

When evaluating parameters, the OCI Modules for PowerShell follows this order of precedence:

1. The value specified in the cmdlet parameter.
2. The value specified in the session preferences.
3. The value specified in the user-selected profile of the OCI configuration file located at ~/.oci/config.

Note:
The OCI Modules for PowerShell use the DEFAULT profile as a fall back profile. Any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile.

History Store

By default, OCI Cmdlets output the response body of the underlying REST API operation. The history store provides users with a PowerShell variable that can be used to look into OCI Cmdlet invocations and their complete API responses from OCI services.

Note:
Each PowerShell session gets its own history store.

You can use the history store to:

- Use the previous Cmdlet’s response object values in the next Cmdlet
Developer Tools

- Inspect the complete API response, including the response headers - for example, the use of e-tags for optimistic concurrency, or the OpcNextPage header for pagination
- Examine cmdlet invocation sequences for diagnostic purposes

The history store is encapsulated as an

For more information, see the History Store example on GitHub.

History Store Properties

This section explains the properties contained in the history store object stored in $OCICmdletHistory.

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>LastResponse</td>
<td>Property</td>
<td>psobject LastResponse {get;}</td>
</tr>
<tr>
<td>Size</td>
<td>Property</td>
<td>int Size {get;}</td>
</tr>
</tbody>
</table>

Size

Indicates the maximum number of commands that can be saved in the history store. The default value is 20. Valid values are from 1 and 100000 (inclusive). To modify the size of history store, use Set-OCICmdletHistory.

**Note:**

We recommend keeping the history size to a minimum to limit memory usage.

Entries

The Oci.PSModules.Common.Cmdlets.CmdletHistory.OCICmdletHistory object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartTime</td>
<td>System.DateTime</td>
<td>Start time of cmdlet execution.</td>
</tr>
<tr>
<td>EndTime</td>
<td>System.DateTime</td>
<td>End time of cmdlet execution.</td>
</tr>
<tr>
<td>Command</td>
<td>System.Management.Automation.InvocationInfo</td>
<td>Describes how and where this command was invoked.</td>
</tr>
</tbody>
</table>

LastResponse

History Store Cmdlets

Oci.PSModules.Common module provides the following cmdlets for working with the History Store. See the GitHub example.
Get-OCICommandHistory
Gets the cmdlet history stored in the current PowerShell session.

Set-OCICommandHistory
Sets properties of the history store.

Clear-OCICommandHistory
Deletes the cmdlet history stored in the current PowerShell session.

Pagination

OCI Cmdlets that invokes list API operations have the ability to paginate results, allowing you to retrieve the available results in batches (automatically following pagination tokens) until no more records are available.

Note:
Examples in this topic call the ListImages operation in the OCI Compute service. Be sure to import OCI.PSMODULES.Core before trying out the examples in this section.

Get First Page Results

The default behavior of a cmdlet that supports pagination is to get only the first page of results when invoked without the -Page parameter specified.

For example, to get the first page of compute images available invoke the Get-OCIComputeImagesList with your Compartment ID:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId | Measure-Object
Count             : 100
```

The above example implicitly sets the -Page parameter to NULL.

Note:
The maximum number of results per page is defined by the service and can be found in the service API reference.

Limit Results

The -Limit parameter specifies the maximum number of results returned per page.

This example sets the maximum number of results returned per page to 5:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 5 | Measure-Object
Count             : 5
```

Get Next Page Results

The -Page parameter is used to get the next page of results by passing the pagination token from the `opc-next-page` response header contained in the previous cmdlet response.

Note:
You can use the history store to get the previous cmdlet response.
This example shows how to retrieve the results remaining from a previous paginated call by passing the `$OCICmdletHistory.LastResponse.OpcNextPage` property from the history store as the argument to the `-Page` parameter:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Page $OCICmdletHistory.LastResponse.OpcNextPage | Measure-Object
Count : 100
```

### Get All Results

OCI Cmdlets that support pagination can auto paginate and fetch results from all available pages. Let the cmdlet do the pagination by passing `-All` switch parameter when running the cmdlet.

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -All | Measure-Object
Count : 293
```

### Waiters and Asynchronous Calls

Most Oracle Cloud Infrastructure resources, such as compute instances, have *lifecycles*. In many cases, you want your command to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action. You can poll a resource to determine its state.

OCI Modules for PowerShell offer waiter parameters that allow your cmdlet to wait until a resource reaches a desired state. A cmdlet with waiter parameters can be invoked in a blocking manner to wait until either one of the desired states is reached or a timeout is exceeded. Waiters abstract the polling logic that you would otherwise have to add before taking further actions on a resource or a work request.

For example, when you call `LaunchInstance` in the Compute service, the response header contains a `work-request-id`. The OCI Modules for PowerShell uses this ID when you specify the `-WaitForStatus` parameter, which causes your script to wait until the work request succeeds before proceeding.

For example:

```
#Create a new compute instance and wait for the instance work request to succeed or fail,
#polling every 60 seconds and attempting 20 times max
$ComputeInstance = New-OCIComputeInstance -LaunchInstanceDetails $LaunchDetails -WaitForStatus Succeeded,Failed -MaxWaitAttempts 20 -WaitIntervalSeconds 60
```

### Waiter parameters

This section describes the parameters used for asynchronous calls.

**WaitForStatus**

Specify this parameter to perform the action and then wait until the resource reaches the desired lifecycle state. Multiple states can be specified, returning when the resource reaches one of the desired states.

**WaitIntervalSeconds**

Check every `WaitIntervalSeconds` to see whether the resource has reached one of the desired states. Default value for this parameter is 30 seconds.

**MaxWaitAttempts**

Maximum number of attempts to be made until the resource reaches one of the desired states. Default value for this parameter is 3 attempts.
Currently, OCI Cmdlets do not accept maximum wait time for cmdlets that support waiters. You can work around this limitation by controlling the values of MaxWaitAttempts and/or WaitIntervalSeconds.

On successful completion, the cmdlet returns the original response object received. In case of an error like the resource failing to reach the desired state within the given limits, an exception containing the error message would be thrown.

Stream Inputs and Outputs

Some OCI Cmdlets interact with APIs that accept or return stream type objects (for example, the InvokeFunctions operation in the Functions service). These OCI cmdlets accept parameters that can take a file path and implicitly convert files to streams and back.

You can either pass a stream parameter or the equivalent file parameter, but not both.

The file input parameter is named after the corresponding stream input parameter and file output parameter is named as OutputFile.

For an example, see the help text for the Invoke-OCIFunctionsInvokeFunction cmdlet in OCI.PSModules.Functions.

This sample on GitHub shows how to work with streams.

Logging

To facilitate troubleshooting, OCI Modules for PowerShell supports logging debug- and verbose-level messages on the console in addition to error messages. This feature has been integrated with the standard PowerShell Debug and Verbose parameters.

Pass the -Debug or -Verbose parameters in the cmdlet invocation to see log messages on the console.

For example:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Verbose
#More Verbose
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Debug
```

Authenticating with Instance Principals

Instance principals is an IAM service feature that enables instances to be authorized actors (or principals) that can perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

For more information on instance principals, see Calling Services from an Instance.

To enable instance principal authentication from OCI Cmdlets, call authorize the instance and set the AuthType parameter. For example:

```
PS /> Get-OCIIdentityRegionsList -AuthType InstancePrincipal
```
Examples

Examples of OCI PowerShell Cmdlet usage can be found on GitHub, including:

- Creating an instance using waiters
- Accessing OCI cmdlet history store
- Using OCI cmdlet common parameters
- Downloading an object from Object Storage
- Setting preferred region and profile per session
- List all available Compute Images
- Searching resources using polymorphic objects

If you'd like to see another example not already covered, file a GitHub issue.

Running Examples

1. Clone the OCI PowerShell Modules project from GitHub.
   
   PS /> git clone https://github.com/oracle/oci-powershell-modules.git

2. Navigate to the examples folder inside the cloned repository.
   
   PS /> cd ./oci-powershell-modules/Examples

3. Install the required modules. Find additional details about setting up and running examples from the README page.

4. Run the example scripts after setting the required environment variables.
   
   PS /oci-powershell-modules/Examples> ./Waiter_Core.ps1

Ansible Collection

This topic provides information about the Oracle Cloud Infrastructure (OCI) Ansible collection.

Collections are Ansible’s recommended method of packaging and releasing modules, roles, playbooks, and documentation. See Getting Started on page 4331 to begin using our Ansible collection.

OCI supports the use of Ansible modules to automate cloud infrastructure provisioning and configuration, orchestration of complex operational processes, and deployment and update of your software assets.

Ansible tracks your resources using inventory lists. The inventory can be a simple static .ini file or dynamically created, where a plugin assembles an up-to-date infrastructure inventory. For more information, see Working with Ansible Inventory on page 4333.

Ansible playbooks automate configuration, deployment, and orchestration tasks. Ansible playbooks use a declarative language (YAML) that allows you to describe infrastructure configuration, deployment policy, and the orchestration of complex process steps. OCI provides a set of Example Playbooks for your review.

The OCI Ansible collection supports Ansible Tower and AWX. For more information on how to set up the collection with Ansible Tower, refer to the Using Oracle Cloud Infrastructure with Ansible Tower and AWX blog post. To install the free version of Ansible Tower (AWX) on an OCI Compute instance, you can use our solution on GitHub.

- **Services supported**: Refer to the list of currently supported services for details.
- **Licensing**: Copyright © 2020, Oracle and/or its affiliates. This software is made available to you under the terms of the GPL 3.0 license or the Apache 2.0 license. See LICENSE.txt for details.
- **Documentation**: Additional OCI Ansible collection documentation is available on readthedocs.io and GitHub.
- **Download**: To download our Ansible collection, follow the steps in Getting Started on page 4331.

Notifications

To be notified when new versions of our Ansible collection are released, subscribe to the Oracle Cloud Infrastructure Ansible collection Atom feed.
Questions or Feedback

Ways to get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Use the oci-ansible and oracle-cloud-infrastructure tags in your post.
- Developer Tools section of the Oracle Cloud forums.

Getting Started

This topic discusses how to get started using the Oracle Cloud Infrastructure (OCI) Ansible collection. The OCI Ansible collection replaces our legacy Ansible modules.

Note:

If you currently use our legacy Ansible modules and would like to start using collections, refer to our migration guide.

To start using Ansible with OCI, ensure that you meet the prerequisites, then install the Ansible collection using yum or manually.

Tip:

You can use Resource Manager to preinstall the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes Ansible, the OCI Ansible collection and its dependencies, and preconfigures the required authorization.

Both Ansible and our Ansible collection also come preinstalled and preauthenticated on Cloud Shell.

Prerequisites for Using Ansible with Oracle Cloud Infrastructure

- You must have an Oracle Cloud Infrastructure account.
- You must have a user in that account in a security group with a policy that grants necessary permissions for working with resources in the account compartments. For guidance, see How Policies Work on page 2136.
- You must have the necessary credentials and OCID information.

Installing the Ansible Collection with yum

You can use yum to install the Oracle Cloud Infrastructure Ansible collection RPM.

The Ansible collection RPM installs the OCI Ansible collection and its required dependencies: the OCI SDK for Python and Ansible.

Note:

This installation uses Python version 3.6 and Ansible version 2.9 or later.

The following example shows how to use yum to install the Ansible collection RPM:

```bash
yum -y install oraclelinux-developer-release-el7 & & sudo yum install oci-ansible-collection
```

After installing the RPM, you must configure the SDK and CLI configuration file as explained in Configuring Authentication on page 4333.

To test the installation of the RPM and configuration of the SDK, you can run a sample playbook. For example:

```bash
ansible-playbook-3 /usr/share/doc/oci-ansible-collection-<version>/samples/object_storage/get_namespace/sample.yaml
```

Manual Installation

Installing the Oracle Cloud Infrastructure SDK for Python
1. Download and install the SDK for Python by following instructions in the topic, SDK for Python. For additional guidance, see Downloading and Installing the SDK.

2. After installing the SDK for Python, you must configure it using instructions in the topic Configuring the SDK.

Installing and Configuring Ansible

- To install Ansible, follow the instructions provided in the Ansible Installation Guide.
- For guidance configuring Ansible, see Configuring Ansible.

**Note:**
The OCI Ansible collection requires Ansible version 2.9 or later. If you are using an earlier version of Ansible, refer to the documentation for our legacy modules.

Installing the Oracle Cloud Infrastructure Ansible Collection

Install the OCI Ansible collection from Ansible Galaxy by using the following command:

```
$ ansible-galaxy collection install oracle.oci
```

If you've already installed the collection, you can update its modules to the latest version by adding the `--force` flag to the command. For example:

```
$ ansible-galaxy collection install --force oracle.oci
```

Sample Playbooks

Sample playbooks are available in the Oracle Cloud Infrastructure Ansible collection GitHub project. The samples library is updated regularly with the addition of new samples. See Example Ansible Playbooks on page 4338 for more information.

Writing a Sample Playbook

After your installation is complete, or if you're using the Cloud Shell, you can write a sample playbook that uses Ansible modules. Following is an example playbook (named `list_buckets.yml`) that uses the `oci_object_storage_bucket_facts` module to fetch facts pertaining to the buckets in your compartment.

```yaml
---
- name: List summary of existing buckets in OCI object storage
collections:
- oracle.oci
collection: local
hosts: localhost
tasks:
- name: List bucket facts
  oci_object_storage_bucket_facts:
    namespace_name: '<yournamespace>'
    compartment_id: '<yourcompartmentocid>'
    register: result
- name: Dump result
dump:
  msg: '{{result}}'
```

Executing the Playbook

Execute the Ansible playbook using Python by invoking this command:

```
$ ansible-playbook list_buckets.yml
```

How to Obtain Module Documentation

Detailed information about using our Ansible modules is available on readthedocs.io.
To obtain access to detailed information about using Ansible modules in the CLI, use the `ansible-doc` command on the module's name. For example, to get the documentation for the `oci_object_storage_bucket_facts` module, execute the following command:

```
$ ansible-doc oracle.oci.oci_object_storage_bucket_facts
```

### Configuring Authentication

When creating and configuring Oracle Cloud Infrastructure resources, Ansible modules use authentication information that is outlined in the [SDK and CLI Configuration File](#) on page 4184.

**Caution:**

User Credentials on page 2360 that are referenced in Oracle Cloud Infrastructure SDK configuration files grant access to Oracle Cloud Infrastructure resources. Therefore, it is important to secure the credentials to prevent unauthorized access to these resources. To secure the credentials on the controller node where your Ansible playbooks run, follow guidelines outlined in the document [Securing IAM](#) on page 3688 (see section entitled "IAM Credentials").

Ansible modules permit you to override authentication information specified in the SDK configuration file by using module options and environment variables. Documentation for authentication overrides is provided internally, as described in [How to Obtain Module Documentation](#). However, using environment variables and Ansible module options to override authentication information must be avoided in production scenarios.

We recommend using Oracle Cloud Infrastructure SDK configuration files to specify authentication information. To support multiple users, use the "profiles" feature in the SDK configuration file. When distributing roles that use Ansible modules, ensure that no IAM credentials are included with the roles.

### For More Information

- [Using collections](#)

### Working with Ansible Inventory

Ansible tracks configuration resources by preserving lists, called inventory lists, as simple files (also sometimes called a *hostfile*). These inventory lists can be static or dynamic. Dynamic lists can automatically update when inventory resources are added, deleted, or moved.

Because many Oracle Cloud Infrastructure (OCI) resources are added and deleted over time, static inventory lists can easily become obsolete. Tools such as Terraform or the OCI SDKs also may affect your resources.

Oracle Cloud Infrastructure provides a dynamic inventory plugin for maintaining accurate Ansible inventory.

For more information about Ansible inventory files, see [Working with Inventory](#) and [Working with Dynamic Inventory](#).

#### Enabling the Inventory Plugin

The OCI inventory plugin, like most inventory plugins shipped with Ansible, is disabled by default. Plugins must be enabled in your `ansible.cfg` file to function.

Enable the OCI inventory plugin by adding it to your `ansible.cfg` file. For example:

```
[inventory]
enable_plugins = oracle.oci.oci
```

If you still use our legacy Ansible modules, your `ansible.cfg` file should contain the following entry instead:

```
[inventory]
enable_plugins = oci
```

### Configuring the Inventory Plugin
The only requirement for using the OCI inventory plugin after it is enabled is to provide an inventory source you have permissions to parse. Inventory sources are defined in a YAML configuration file. See User Permissions on page 4337 for more information.

To start using the inventory plugin with a YAML configuration source, create a file with with one of the following accepted filenames:

- `<filename>.oci.yml`
- `<filename>.oci.yaml`

Add plugin: `oracle.oci.oci` to the YAML configuration file.

The minimum inventory source file needed to run the OCI inventory plugin looks like this, for example:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci

# Optional fields to specifyoci connection config:
config_file: ~/.oci/config
config_profile: DEFAULT
```

This example uses the `config_file` and `config_profile` parameters so the plugin can use authentication information that is outlined in the SDK and CLI Configuration File on page 4184. Some parameters can also be provided as environment variables.

For a complete list of parameters and environment variables that the plugin supports, see OCI Inventory Plugin. The Example Configuration on page 4334 include many of the available parameters.

**Important:**

By default, the OCI inventory plugin discovers and lists only Compute instances that have a public IP address. See Hostname Format on page 4338 for more information.

**Order of Precedence**

The inventory plugin uses the following order of precedence when an option is provided in more than one location:

1. YAML file settings.
2. Environment variables.
3. Configuration settings in the selected profile in your OCI configuration file.

**Example Configuration**

The following inventory source file includes examples of many of the available parameters:

```yaml
# Fetch all hosts
plugin: oracle.oci.oci

# OCI Config information
config_file: ~/.oci/config
config_profile: DEFAULT

# Optional fields
# ----------------------------
# Example select regions
regions:
  - us-ashburn-1
  - us-phoenix-1

# Enable threads to speedup lookup
enable_parallel_processing: yes
```
# Select compartment by ocid or name
compartments:
  - compartment_ocid: ocid1.compartment.oc1..<compartment_OCID>
    fetch_hosts_from_subcompartments: false
  - compartment_name: "<compartment_name>"
    parent_compartment_ocid: ocid1.tenancy.oc1..<compartment_OCID>

# Example filtering using hostname IP
hostnames:
  - "10.145.214.11"

# Example filtering using hostname_format
# The default hostname_format value is public_ip
hostname_format: "private_ip"

# Example group results by key
keyed_groups:
  - key: availability_domain

# Example using filters
filters:
  - availability_domain: "IwGV:US-ASHBURN-AD-3"
  - display_name: "instance20190506231645"
  - lifecycle_state: "RUNNING"
  - defined_tags: {
      "ansible_tag_2": {
              "ansibletag448": "test_value"
      }
  }
  - freeform_tags: {
      "Environment": "Production"
  }

# Enable Cache
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci-cache
cache_prefix: oci_

# DB Hosts
fetch_db_hosts: true

Enabling Caching

Caching can be enabled to speed lookups. You can set caching options for an individual YAML configuration source or for multiple inventory sources using environment variables or Ansible configuration files. If you enable caching for an inventory plugin without providing inventory-specific caching options, the inventory plugin uses fact-caching options.

Here is an example of enabling caching for an individual YAML configuration file:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci-cache
cache_prefix: oci_

# DB Hosts
fetch_db_hosts: true
```

Using the Inventory Plugin
Ansible inventory plugins allow you to define the data sources used to compile an inventory of hosts that Ansible uses to target tasks. These data sources are accessed by using either the \(-i /path/to/file\) or the \(-i 'host1, host2'\) command line parameters, or from other configuration sources.

You can run the inventory with this command, for example:

```
ansible-inventory -i <filename>.oci.yml --graph
```

This produces output similar to the following:

```
@all:
  --@oci:
    --compute_instance1
    --compute_instance2
  @ungrouped:
```

**Important:**

By default, the inventory is generated for all the compartments in the tenancy. You must have COMPARTMENT_INSPECT permission on the root compartment for this script to be able to access all compartments. However, when compartment_ocid is specified, the inventory is generated for only the specific compartment, so you only need COMPARTMENT_INSPECT permission on the specified compartment. For more information, see How Policies Work on page 2136.

To fetch all instance details, you must also have permission to list and read instances and VNICs, and read VCNs and subnets. See User Permissions on page 4337 for more information.

You can add inventory plugins to your plugin path and set the default inventory path to simplify your commands. Add the default inventory path to the [defaults] section of your ansible.cfg file, or use the ANSIBLE_INVENTORY environment variable to point your inventory sources. You can then run the following command to yield the same output as when you pass your YAML configuration sources directly:

```
ansible-inventory --graph
```

Inventory plugins normally only execute at the start of a run, before playbooks, plays, and roles are loaded. You can ‘re-execute’ a plugin by using the meta: refresh_inventory task, which clears out the existing inventory and rebuilds it.

**Inventory Output**

The inventory list that is generated by the inventory plugin is grouped using the following attributes:

- The region in which the Compute instance resides
- The name of the compartment the Compute instance belongs to
- The Availability Domain the Compute instance is in
- The vcn_id of the VCN the compute instance is in
- The subnet_id of the subnet the Compute instance is in
- The security_list_ids of the subnet the Compute instance is in
- The image_id of the image used to launch the Compute instance
- Shape of the Compute instance
- The Compute instance’s free-form tags, with the group name set to tag_<tag_name>=<tag_value>
- The Compute instance’s defined tags, with the group name set to <tag_namespace>#<tag_name>=<tag_value>
- OCI Compute instance metadata (key-value pairs), with the group name set to <metadata-key>=<metadata-value>
• OCI Compute instance extended metadata (key-value pairs), with the group name set to `<metadata-key>=<metadata-value>`

Using Dynamic Groups

You can create dynamic groups using host variables with the constructed `keyed_groups` option. The option groups can also be used to create groups and create and modify host variables.

For example:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
regions:
  - us-phoenix-1
  - us-ashburn-1
keyed_groups:
  # add hosts to tag_Name_value groups for each oci host's tags.Name variable
  - key: tags.Name
    prefix: tag_Name_
    groups:
      # add hosts to the group development if any of the dictionary's keys or values is the word 'devel'
      development: "'devel' in (tags|list)"
```

This example produces output similar to the following:

```
@all:
  |--@oci:
  |  |--compute_instance1
  |  |--compute_instance2
  |  |--...
  |  |--@development:
  |  |  |--compute_instance1
  |  |  |--compute_instance2
  |  |--@tag_Name_Dev_Instance:
  |  |  |--compute_instance1
  |  |--@tag_Name_Test_Server:
  |  |  |--compute_instance2
  |  |--@ungrouped
```

If a host does not have the variables specified in the configuration (such as tags.Name, tags, private_ip_address), the host is not added to groups other than those that the inventory plugin creates and the ansible_host host variable is not modified.

Database Hosts

Database nodes can be now be fetched by setting the option `fetch_db_hosts`. Database nodes are servers running database software. For example:

```yaml
# demo.oci.yml
# DB Hosts
plugin: oracle.oci.oci
fetch_db_hosts: true
```

Troubleshooting the Inventory Plugin

If the inventory list generated by the OCI inventory plugin does not include every Compute instance in your tenancy, review the following information.

User Permissions
Ensure that the user has the policy permissions to list the Compute instances. The user OCID is specified using either the OCI_USER environment variable, or the profile section in your SDK and CLI configuration file.

To see a list of permissions for API operations, see Details for the Core Services.

The inventory plugin makes API calls for the following operations:

- ListCompartments
- ListVNICAttachments
- GetSubnet
- GetVCN
- GetVNIC
- GetInstance

### Hostname Format

**Important:**

The default value for the `hostname_format` parameter is `public_ip`.

The inventory generated by the OCI inventory plugin contains only Compute instances that have a `public IP address` by default. This is useful in cases where the Ansible controller node is outside of the VCN, since Ansible can only reach instances that have public IP addresses.

When running Ansible from a Compute instance *within* your VCN that has access to all of the subnets within your VCN, including Compute instances that have private IP addresses, you must set the `hostname_format` to `private_ip` to list compute instances using their private IP addresses. The Example Configuration on page 4334 shows this configuration option.

### For More Information

Detailed information about using the OCI inventory plugin is available on readthedocs.io.

You can also use the following command to see the plugin documentation:

```bash
ansible-doc -t inventory oracle.ociOCI
```

Refer to the [official Ansible documentation](https://docs.ansible.com/ansible/latest/intro_inventory.html) for more information about inventory plugins.

### Example Ansible Playbooks

This topic provides a catalog of sample Ansible playbooks for Oracle Cloud Infrastructure (OCI) that illustrate how to carry out common infrastructure provisioning and configuration tasks using our Ansible collection.

These samples and solutions are organized in sections associated with OCI services. You can find a brief description of each playbook along with links to each sample on the [Oracle GitHub repository](https://github.com/oracle/oci-docs/tree/master/ansible/). Be sure to review the `Readme.md` file that is included in each playbook's root directory for additional instructions.

See Getting Started on page 4331 to begin using our Ansible collection.

### Samples

**Block Volume**

**Attaching a block volume to a Compute instance**

This sample playbook shows how to attach a block volume to a Compute instance using the iSCSI volume attachment type, and then connect it to the Compute instance using `iscsiadm`. The sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from the key pair for connecting to the instance, and then launch the instance.
- Create a new Block Volume for the instance, attach the volume to the instance, and specify iSCSI as the volume attachment type.
• Connect to and then mount the volume from the Compute instance by executing iscsiadm commands over SSH using an Ansible module.

Go to the sample on Oracle GitHub.

**Compute**

**Launching an Always Free Compute instance**

This sample shows how to launch and access an Always Free Compute instance from the internet using SSH using OCI Ansible collections.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Connect to the newly launched instance using SSH.

Go to the sample for Always Free on Oracle GitHub.

**Launching a Compute instance using App Catalog**

This sample shows how a public Compute instance can be launched using app_catalog and accessed from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Fetch app_catalog and its versions and create a subscription for it.
• Launch the instance using app_catalog and connect to it using SSH.

Go to the sample on Oracle GitHub.

**Creating an instance pool**

This sample shows how to manage your Compute instances using resources such as instance configurations and instance pools that are provided using OCI Ansible collections. Instance pools help you create and provision multiple Compute instances within the same region based on a single instance configuration.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Create an instance configuration that defines settings for creating a Compute instance as part of the instance pool. The configuration provides details such as base image, shape, and metadata.
• Use the instance pool to launch Compute instances based on the instance configuration.
• Connect to one of the Compute instances using SSH.

Go to the sample on Oracle GitHub.

**Creating instance Console connections and capturing Console history**

This sample shows how a serial and VNC console connection can be created for a Compute instance, and how the serial console data can be captured and fetched from a Compute instance using OCI Ansible collections. For more information about Console connections, see Troubleshooting Instances Using Instance Console Connections.

This sample shows how to do the following:
• Generate a temporary SSH key pair for the serial Console connection.
• Create an instance Console connection for a Compute instance.
• Capture serial Console data for a Compute instance, and then save the data to a local machine so you can troubleshoot and debug issues.

Go to the sample on Oracle GitHub.

**Launching a Compute instance**

This sample shows how to launch and access a public Compute instance from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:

• Generate a temporary, host-specific SSH key pair.
• Specify the public key from the key pair for connecting to the instance, and then launch the instance.
• Connect to the newly launched instance using SSH.

Go to the sample on Oracle GitHub.

**Enabling internet access from a Compute instance using the OCI NAT Gateway**

This sample shows how you can use OCI Ansible collections to enable internet access from Compute instances in a private subnet using a NAT Gateway in a public subnet. For more information about NAT gateways, see NAT Gateway on page 3247 and Access Resources on the Public Internet Through an Oracle Cloud Infrastructure NAT Gateway.

This sample shows how to do the following:

• Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, and the necessary security lists and route rules.
• Provision a bastion instance in the public subnet and a private instance in the private subnet.

Once set up, the private instance will have outbound Internet access through the NAT gateway, and will be accessible using SSH from the bastion instance.

Go to the sample on Oracle GitHub.

**Enabling internet access from a Compute instance using an OCI NAT Instance**

This sample shows how you can use OCI Ansible collections to enable internet access from Compute instances in a private subnet using a NAT instance in a public subnet as discussed here and in the whitepaper here.

This sample shows how to do the following:

• Set up the topology described in the whitepaper by creating the VCN, the internet gateway, the public and private subnets, and the necessary security lists and route rules. A NAT instance is provisioned in the public subnet and a private instance is provisioned in the private subnet.
• After the setup, the private instance has outbound internet access through the NAT instance in the public subnet.

Go to the sample on Oracle GitHub.

**Accessing Object Storage from a private instance using a service gateway**

This sample playbook shows how you can use OCI Ansible collections to enable private access to an Object Storage from a Compute instance using a service gateway. For more information about service gateways, see Access to Oracle Services: Service Gateway on page 3256. To read a blog post discussing how to connect Compute instances using the service gateway, see Connect Private Instances with Oracle Services Through an Oracle Cloud Infrastructure Service Gateway.
This sample shows how to do the following:

- Set up a user, group, and the policies required for managing buckets.
- Create and upload the required API keys to the user.
- Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, as well as the required security lists and route tables. A bastion instance is provisioned in the public subnet, and a private instance is provisioned in the private subnet.
- Provision a Compute instance in the private subnet,
- Install the OCI command line interface (CLI) and configure the CLI using the cloud init script.
- Disable the NAT gateway to restrict public access to the private instance.
- Create a bucket from the private instance using the OCI CLI, then verify that the bucket is created.

Following this setup, the private instance has private access to Object Storage.

Go to the sample on Oracle GitHub.

Container Engine for Kubernetes

**Creating a cluster using Container Engine for Kubernetes**

This sample creates a cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes (OKE) using OCI Ansible collections.

This sample shows how to do the following:

- Create and configure a VCN and related resources required for setting up an OKE cluster.
- Create a cluster.
- Create a node pool.
- Download the kubeconfig file for the cluster.

Go to the sample on Oracle GitHub.

Database

**Creating an Always Free Autonomous Database**

This sample shows how you can use the OCI Ansible collection to create an Always Free Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. See [Overview of Autonomous Databases](#) on page 1149 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
- Stop and start an Autonomous Database.
- Delete an Autonomous Database.

Go to the sample on Oracle GitHub.

**Setting up an Autonomous Database**

This sample shows how you can use the OCI Ansible collection to create an Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. Refer to the [Overview of Autonomous Databases](#) on page 1149 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
Creating a Bare Metal and Virtual Machine DB system

This sample shows how you can use the OCI Ansible collection to create Bare Metal and Virtual DB systems. For more information about OCI co-managed DB Systems, see Bare Metal and Virtual Machine DB Systems on page 1352.

This sample shows how to do the following:

- Set up a Virtual Machine DB System.
- Get facts of a specific DB System and list available DB Homes.
- List all the databases available in specified DB Home and get facts of specific database.
- Collect DB Node's VNIC information of a specified DB system.
- Extract Public and Private IPs of the DB Node from VNIC.
- Create a backup from initial database.
- Restore a database from latest backup.
- Create a new database from backup.
- Update database fields.

Go to the sample on Oracle GitHub.

File Storage

Creating and mounting a file system

This sample shows how you can use the OCI Ansible collection to create and access a File Storage file system through compute instances.

This sample shows how to do the following:

- Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
- Generate the certificates required by instances.
- Create File Storage components such as mount target, file system, export, and snapshot.
- Mount the file system through a Compute instance and access the contents through another Compute instance.

Go to the sample on Oracle GitHub.

Exporting multiple file systems and mount targets

This sample shows how you can use the OCI Ansible collection to export one file system using two different export paths on two different mount targets. It also demonstrates how a single mount target can export paths from two different file systems.

This sample shows how to do the following:

- Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
- Generate the certificates required by instances.
- Create File Storage components such as mount target, file system, export, and snapshot.
- Export one file system to two different mount targets.
- Export paths from a single mount target to two different file systems.
- Mount the file system through a compute instance.

Go to the sample on Oracle GitHub.

Identity
**Adding a user and group**

This sample shows how you can use the OCI Ansible collection to perform basic Oracle Cloud Infrastructure Identity and Access Management (IAM) tasks. The sample assumes the default user configured in the OCI configuration is in the Administrator group or has the required access for managing users, groups, policies.

This sample shows how to do the following:

- Create a new group.
- Create a policy.
- Create a user then add it to the group and policy.
- Create user password.
- Generate SSH keys and assign them to the user.

**Go to the sample on Oracle GitHub.**

**Load Balancing**

**Creating a load balancer**

This sample shows how you can use the OCI Ansible collection to create a public load balancer.

This sample shows how to do the following:

- Generate all network-related dependencies, like a VCN and subnets.
- Generate the certificates required by the load balancer.
- Create a public load balancer.

**Go to the sample on Oracle GitHub.**

**Networking**

**Provisioning a VCN with private subnets**

This sample shows how you can use the OCI Ansible collection to provision a virtual cloud network (VCN) with two private subnets in different availability domains and an IPSec VPN. The IPSec VPN uses a *dynamic routing gateway* (DRG), *customer-premises equipment* (CPE), and an IPSec connection. The provisioned resources are illustrated in this networking scenario.

This sample shows how to provision the following resources:

- A VCN
- Two private subnets
- A dynamic routing gateway
- *Customer-premises equipment*
- An IPSec connection between DRG & CPE

Finally, it retrieves IPSec connection configuration information and status.

**Go to the sample on Oracle GitHub.**

**Object Storage**

**Getting a namespace**

This sample playbook shows how to use the OCI Ansible collection to get the tenancy namespace in Object Storage.

**Go to the sample on Oracle GitHub.**

**Listing objects and buckets**

This sample playbook shows how to use the OCI Ansible collection to list all Object Storage objects from all buckets in a namespace.
Go to the sample on Oracle GitHub.

Deleting objects
This sample playbook shows how to use the OCI Ansible collection to delete objects created within a specified range of days from all buckets in a namespace. You can modify the sample so that it deletes objects older than a specified number of days, which helps you prune old or unwanted objects stored in the Object Storage service.

Go to the sample on Oracle GitHub.

Solutions

MuShop
MuShop is a showcase of several Oracle Cloud Infrastructure (OCI) services in a unified reference application. The sample application implements an e-commerce platform built as a set of microservices. The accompanying content can be used to get started with cloud native application development on OCI.

MuShop can be deployed in different ways to explore OCI based on your subscription. OCI offers Always Free tier with resources that can be used indefinitely.

This project is an example of how you can build OCI infrastructure using the OCI Ansible collection.

Grafana Plug-in
This topic provides instructions for installing, configuring, and using the Oracle Cloud Infrastructure Data Source for Grafana, otherwise referenced as the Grafana Plug-in.

Grafana Plug-in Overview
Grafana is an open-source visualization and alerting tool that you can use for analytics and monitoring of time-series data (metrics). While metrics from Oracle Cloud Infrastructure Monitoring are visible in metrics charts through the Console, you can use Oracle Cloud Infrastructure Data Source for Grafana ("the Grafana Plug-in") to view metrics from resources across providers on a single Grafana dashboard.

Prerequisites for Using the Grafana Plug-in
- An Oracle Cloud Infrastructure account.
- A user in that account, in a security group with an IAM policy that grants necessary permissions for working with resources in the account compartments. The policy must give you access to the metric namespaces emitting metrics (such as Compute) as well as the related resources (such as a set of Compute instances). If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. Administrators: For common policies that give groups access to metrics, see Let users access monitoring metrics in a compartment on page 2155 and Restrict user access to a specific metric namespace on page 2156. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group through its matching rules, and then create a policy that allows that dynamic group access to metrics. To allow access across compartments, create the policy in the tenancy. Because of the concept of policy inheritance, instances in the indicated dynamic group can then access metrics in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy. See Let instances make API calls to access monitoring metrics in the tenancy on page 2156.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.
- Required keys and Oracle Cloud Infrastructure IDs (OCIDs). For guidance, see "Required Keys and OCIDs" in the Oracle Cloud Infrastructure User Guide.

Download and Install the Grafana Plug-in

Note:
Grafana must be installed before you can install the Grafana Plug-in. Version 3.0 or later required.
Authentication for metric access depends on where Grafana is running. If you are running Grafana on a local machine outside Oracle Cloud Infrastructure, you must call the Monitoring API using the Command Line Interface (CLI).
If you are running Grafana on an Oracle Cloud Infrastructure Compute instance that you created, then you can add the instance to a dynamic group by configuring a matching rule. In all scenarios, you have the option of calling the API using the CLI.

For instructions on installing the Grafana Plug-in (Oracle Cloud Infrastructure Data Source for Grafana), see https://github.com/oracle/oci-grafana-plugin.

**Configure the Grafana Plug-in**

This section describes how to add the Grafana Plug-in and set up a dashboard.

To configure the Grafana Plug-in

**Note:**

When installed locally, the Grafana plug-in accesses metrics using calls to the Monitoring API.

1. Set up the CLI for accessing Oracle Cloud Infrastructure APIs.
   You'll need to access the Monitoring API for authentication.
2. Navigate to the Grafana homepage at the following URL.
   http://localhost:3000
3. Add the Grafana Plug-In (Oracle Cloud Infrastructure Data Source for Grafana).
   In addition to the steps below, see the Grafana instructions for adding data sources at http://docs.grafana.org/guides/getting_started/.
   a. In Grafana, on the Home Dashboard, click the gear icon on the left.
   b. Click **Add data source**.
   c. In the Filter text box, type: oracle-oci-datasource
   d. In the filtered list, select **oracle-oci-datasource**.
   e. In the Settings page, fill in your **Tenancy OCID**, **Default Region**, and **Environment**. For Environment choose **local**.
4. Set up a dashboard of the type "Graph."
5. (Optional) To confirm access to metrics from Oracle Cloud Infrastructure, update your dashboard query ("Metrics") with a specific region, compartment, namespace, metric. You can also add one or more dimensions.

Congratulations. You can now view your Oracle Cloud Infrastructure metrics in Grafana!

**Environment options**

**local** is for Grafana deployments outside Oracle Cloud Infrastructure.

**OCI Instance** is for Grafana deployments on Oracle Cloud Infrastructure resources.

The data source is now added, enabling you to set up a dashboard showing metrics from Oracle Cloud Infrastructure.

**Troubleshoot the Plug-In**

If the dashboard query ("Metrics") fails to populate with options, or if you have other issues accessing metrics, then the IAM policy used to access metrics may be malformed, or it may not include all required matching rules for your dynamic group (for running Grafana on an Oracle Cloud Infrastructure Compute instance that you created).

To resolve this issue, do the following.

- Review your IAM policy to ensure that it matches prerequisites.
- If you updated your IAM policy, then restart the Grafana server and refresh the Grafana homepage.
Other Tools

Tools and Plug-ins for SDKs and CLI

Oracle Cloud Infrastructure provides additional developer tools for automating processes and facilitating development.

**Toolkit for Eclipse** - The toolkit is an open source plug-in for the Eclipse Integrated Development Environment (IDE) that enables Java developers to code and deploy applications more quickly and efficiently.

- **Documentation**: [Toolkit for Eclipse](#) on page 4363
- **Download**: To build and install the Toolkit, clone the GitHub repository then follow instructions in [Getting Started with Toolkit for Eclipse](#).

**Oracle Developer Tools for Visual Studio** - The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can use the tools to view and manage your Oracle Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

- **Documentation**: [Oracle Developer Tools for Visual Studio](#) on page 4365
- **Download**: Refer to the documentation.

**HDFS Connector for Object Storage** - Read and write data with your Apache Hadoop application to and from the Oracle Cloud Infrastructure Object Storage service. Building the connector relies on Maven artifacts that are provided by the SDK for Java.

- **Documentation**: [HDFS Connector for Object Storage](#) on page 4347
- **Download**: [GitHub](#)

**Toolkit for Data Science** - The Oracle Accelerated Data Science (ADS) SDK is a Python library that is included as part of the Oracle Cloud Infrastructure Data Science service. ADS offers a friendly user interface that covers all the steps involved in the life-cycle of machine learning models, from connecting to different sources to using AutoML for model training to model evaluation and explanation. ADS also provides a simple interface to access the Oracle Cloud Infrastructure Data Science service model catalog and other Oracle Cloud Infrastructure services, including Object Storage.

- **Documentation**: [Oracle Accelerated Data Science (ADS) Python Library](#)
- **Download**: Oracle ADS Python library is pre-installed in the Oracle Cloud Infrastructure Data Science notebook session resource environment. It is not publicly available.

**HDFS Connector for Object Storage**

The Hadoop Distributed File System (HDFS) connector lets your Apache Hadoop application read and write data to and from the Oracle Cloud Infrastructure Object Storage service.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

- **Services supported**: Object Storage
- **Download**: [GitHub](#) or [Maven](#)
- **API Documentation**: [HDFS Connector API Reference](#)

**Requirements**

To use the HDFS connector, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions for any bucket you want to use. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](#) on page 57. For a basic Object Storage policy, see [Let Object Storage admins manage buckets and objects](#) on page 2149.
- Java 8
• A TTL value of 60. For more information, see Configuring JVM TTL for DNS Name Lookups on page 4348.

Credentials and Passwords
If you use an encrypted PEM file for credentials, the passphrase will be read from configuration using the `getPassword` Hadoop Configuration method. The `getPassword` option checks for a password in a registered security provider. If the security provider doesn't contain the requested key, it will fallback to reading the plaintext passphrase directly from the configuration file.

Configuring JVM TTL for DNS Name Lookups
The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called time-to-live (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the `networkaddress.cache.ttl` property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, -1, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

• To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

```
networkaddress.cache.ttl=60
```

• To set TTL only for your application, set the following in your application's initialization code:

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

Installation
Copy the bundled jars from lib and third-party/lib the to each node of the Hadoop cluster so that they are included in Hadoop’s CLASSPATH.

SDK for Java and Maven Artifacts
Building an HDFS connector relies on Maven artifacts that are provided by the Oracle Cloud Infrastructure SDK for Java. To obtain the artifacts, you must download the SDK for Java and build it locally. You can then build the HDFS connector.

Important:
The SDK for Java file version that you download from the Oracle Releases page must match the HDFS connector version, which you can find in the `hdfs-connector/pom.xml` file in the dependency tag block that has the `groupId` attribute.

HDFS Connector and Maven Artifacts
The HDFS connector is available on Maven Central and JCenter.

To use the HDFS connector in your project, import the following project dependency. For example:

```
<dependency>
  <groupId>com.oracle.oci.sdk</groupId>
  <artifactId>oci-hdfs-connector</artifactId>
  <!-- Replace the version below with your required version -->
  <version>2.9.2.0</version>
</dependency>
```
Properties

You can set the following HDFS connector properties in the core-site.xml file. The BmcProperties page lists additional properties that you can configure for a connection to Object Storage.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>fs.oci.client.hostname</td>
<td>The URL of the host endpoint.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>For example, <a href="https://www.example.com">https://www.example.com</a>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>fs.oci.client.auth.tenantId</td>
<td>The OCID of your tenancy.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>To get the value, see Required Keys and OCIDs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>fs.oci.client.auth.userId</td>
<td>The OCID of the user calling the API.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>To get the value, see Required Keys and OCIDs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>fs.oci.client.auth.fingerprint</td>
<td>The fingerprint for the key pair being used.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
<tr>
<td></td>
<td>To get the value, see Required Keys and OCIDs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>fs.oci.client.auth.pemfilepath</td>
<td>The full path and file name of the private key used for authentication. The file should be on the local file system.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
</tbody>
</table>
You can specify that a property value applies to a specific bucket by appending 
<bucket_name>.
<namespace_name> to the property name.

This example shows how properties can be configured in a core-site.xml file (the OCIDs are shortened for brevity):

```xml
<configuration>
  ...
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-ashburn-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.hostname.myBucket.myNamespace</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value><!-- Use Phoenix for myBucket@myNamespace -->
  </property>
  <property>
    <name>fs.oci.client.auth.tenantId</name>
    <value>ocid1.tenancy.oc1..exampleuniqueID</value>
  </property>
  <property>
    <name>fs.oci.client.auth.userId</name>
    <value>ocid1.user.oc1..exampleuniqueID</value>
  </property>
  <property>
    <name>fs.oci.client.auth.fingerprint</name>
  </property>
  <property>
    <name>fs.oci.client.auth.pemfilepath</name>
    <value>~/.oci/oci_api_key.pem</value>
  </property>
  ...
</configuration>
```

**Using Instance Principals for Authentication**

Oracle provides *instance principals* so that you no longer need to configure user credentials or provide PEM files on services running on instances. Each of these instances has its own identity and authenticates by using certificates added to the instance by instance principals.

To use instance principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator`.

Because using instance principals provides your instance with a custom authenticator, it is no long necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
The following example code illustrates using instance principals for authentication with the HDFS connector:

```xml
<?xml version="1.0"?>
<configuration>
    <property>
        <name>fs.oci.client.hostname</name>
        <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
    </property>
    <property>
        <name>fs.oci.client.custom.authenticator</name>
        <value>com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator</value>
    </property>
</configuration>
```

For more information about instance principals, see [Announcing Instance Principals for Identity and Access Management](#).

### Configuring a HTTP Proxy

You can set the following optional properties in the `core-site.xml` file to configure a HTTP proxy:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>fs.oci.client.proxy.uri</td>
<td>The URI of the proxy endpoint. For example, <a href="http://proxy.mydomain.com:80">http://proxy.mydomain.com:80</a>.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>fs.oci.client.proxy.username</td>
<td>The username to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>fs.oci.client.proxy.password</td>
<td>The password to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>fs.oci.client.multipart.allowed</td>
<td>Enables the upload manager to support multipart uploads.</td>
<td>Boolean</td>
<td>No</td>
</tr>
<tr>
<td>fs.oci.client.multipart.minobjectsize.mb</td>
<td>Specifies the minimum object size in mebibytes in order to use the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
<tr>
<td>fs.oci.client.multipart.partsize.mb</td>
<td>Specifies the part size in mebibytes for the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
</tbody>
</table>

**Note:**

Configuring a proxy enables use of the ApacheConnectorProvider when making connections to Object Storage. It buffers requests into memory and can impact memory utilization when uploading large objects. It is recommended to enable multipart uploads and adjust the multipart properties to manage memory consumption.
Large Object Uploads

Large objects are uploaded to Object Storage using multipart uploads. The file is split into smaller parts that are uploaded in parallel, which reduces upload times. This also enables the HDFS connector to retry uploads of failed parts instead of failing the entire upload. However, uploads may transiently fail, and the connector will attempt to abort partially uploaded files. Because these files accumulate (and you will be charged for storage), list the uploads periodically and then after a certain number of days abort them manually using the SDK for Java.

Information about using the Object Storage API for managing multipart uploads can be found in Using Multipart Uploads on page 3477.

Note:

If you prefer not to use multipart uploads, you can disable them by setting the `fs.oci.client.multipart.allowed` property to false.

Best Practices

The following sections contain best practices to optimize usage and performance.

Directory Names

There are no actual directories in Object Storage. Directory grouping is a function of naming convention, where objects use / delimiters in their names. For example, an object named `a/example.json` implies there is a directory named `a`. However, if that object is deleted, the `a` directory is also deleted implicitly. To preserve filesystem semantics where the directory can exist without the presence of any files, the HDFS connector creates an actual object whose name ends in / with a path that represents the directory, (that is, create an object named `a/`). Now, deleting `a/example.json` doesn't affect the existence of the `a` directory, because the `a` object maintains its presence. However, it's entirely possible that somebody could delete that `a` object without deleting the files/directories beneath it. The HDFS connector will only delete the folder object if there are no objects beneath that path. The folder object itself is zero bytes.

Inconsistent Filesystem

Deleting a directory means deleting all objects that start with the prefix representing that directory. HDFS allows you to query for the file status of a file or a directory. The file status of a directory is implemented by verifying that the folder object for that directory exists. However, it's possible that the folder object has been deleted, but some of the objects with that prefix still exist. For example, in a situation with these objects:

- `a/b/example.json`
- `a/b/file.json`
- `a/b/

HDFS would know that directory `/a/b/` exists and is a directory, and scanning it would result in `example.json` and `file.json`. However, if object `a/b/` was deleted, the filesystem would appear to be in an inconsistent state. You could query it for all files in directory `/a/b/` and find the two entries, but querying for the status of the actual `/a/b/` directory would result in an exception because the directory doesn't exist. The HDFS connector does not attempt to repair the state of the filesystem.

File Creation

Object Storage supports objects that can be many gigabytes in size. Creating files will normally be done by writing to a temp file and then uploading the contents of the file when the stream is closed. The temp space must be large enough to handle multiple uploads. The temp directory used is controlled by the `hadoop.tmp.dir` configuration property.
Read/Seek Support

When in-memory buffers are enabled (fs.oci.io.read.inmemory), seek is fully supported because the entire file is buffered into a byte array. When in-memory buffer is not enabled (likely because object sizes are large), seek is implemented by closing the stream and making a new range request starting at the specified offset.

Directory Listing

Listing a directory is essentially a List bucket operation with a prefix and delimiter specified. To create an HDFS FileStatus instance for each key, the connector performs an additional HEAD request to get ObjectMetadata for each individual key. This will be required until Object Storage supports richer list operation data.

URI Format for Filesystems and Files

HDFS filesystems and files are referenced through URIs. The scheme specifies the type of filesystem, and the remaining part of the URI is largely free for the filesystem implementation to interpret as it wants.

Because Object Storage is an object store, its ability to name objects as if they were files in a filesystem is used to mimic an actual filesystem.

Root

The root of Object Storage filesystem is denoted by a path where the authority component includes the bucket name and the namespace name, as shown:

Note:

In the examples, "MyBucket" and "MyNamespace" are placeholders and should be replaced with appropriate values.

oci://MyBucket@MyNamespace/

This is always the root of the filesystem. The reason for using authority for both bucket and namespace is that HDFS only allows the authority portion to determine where the filesystem is; the path portion denotes just the path to the resource (so "oci//MyNamespace/MyBucket" won't work, for example). Note that the @ character is not a valid character for buckets or namespaces, and should allow the authority to be parsed correctly.

Sub-directories

Sub-directories do not actually exist, but can be mimicked by creating objects with / characters. For example, two files named a/b/c/example.json and a/b/d/path.json would appear as if they were in a common directory a/b. This would be achieved by using the Object Storage prefix- and delimiter-based querying. In the given example, referencing a sub-directory as a URI would be:

oci://MyBucket@MyNamespace/a/b/

Objects/Files

An object named a/b/c/example.json is referenced as:

oci://MyBucket@MyNamespace/a/b/c/example.json
Logging

Logging in the connector is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following example shows how to enable basic logging to standard output.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath
3. Add the following VM arg to enable debug level logging (by default, info level is used):
   
   -Dorg.slf4j.simpleLogger.defaultLogLevel=debug

You can configure more advanced logging options by using the log4j binding.

Sample Hadoop Job

hadoop_sample_hdfs:

```java
package com.oracle.oci.hadoop.example;

import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;
import org.apache.commons.io.IOUtils;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.FSDataInputStream;
import org.apache.hadoop.fs.FSDataOutputStream;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.io.IntWritable;
import org.apache.hadoop.io.Text;
import org.apache.hadoop.mapreduce.Job;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import com.oracle.oci.hdfs.BmcFilesystem;
import lombok.RequiredArgsConstructor;

@RequiredArgsConstructor
public class SampleOracleBmcHadoopJob {
    private static final String SAMPLE_JOB_PATH = "/samplehadoopjob";
    private static final String INPUT_FILE = SAMPLE_JOB_PATH + "/input.dat";
    private static final String OUTPUT_DIR = SAMPLE_JOB_PATH + "/output";

    // non-static since this is the runner class it needs to initialize
    after we set the properties
    private final Logger log = LoggerFactory.getLogger(SampleOracleBmcHadoopJob.class);

    /**
     * Runner for sample hadoop job. This expects 3 args: path to
     * configuration file, Object Store namespace, Object
     * Store bucket. To run this, you must:
     * *(@code
     * Create a standard hadoop configuration file
     */
* Create the bucket ahead of time.
*}

* This runner will create a test input file in a file '/
samplehadoopjob/input.dat', and job results will be written
* to '/samplehadoopjob/output'.
* @param args
* 1) path to configuration file, 2) namespace, 3) bucket
* @throws Exception
*/

        IOUtils.copy(input, baos);
        log.info("\n=====
" + baos.toString() + "=====");
        input.close();
    }
}

package com.oracle.oci.hadoop.example;
Troubleshooting

This section contains troubleshooting information for the HDFS connector.

Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the HDFS connector. For information about common service errors returned by OCI, see API Errors.
Java Encryption Key Size Errors

The HDFS connector can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256. Use one of the following workarounds to fix this issue:

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Contributions

Got a fix for a bug, or a new feature you'd like to contribute? The SDK is open source and accepting pull requests on GitHub.

Notifications

If you wish to be notified when a new version of the HDFS connector is released, subscribe to the Atom feed.

Questions or Feedback

Ways to get in touch:

Using the HDFS Connector with Spark

Introduction

This article provides a walkthrough that illustrates using the Hadoop Distributed File System (HDFS) connector with the Spark application framework. For the walkthrough, we use the Oracle Linux 7.4 operating system, and we run Spark as a standalone on a single computer.

Prerequisites

Following are prerequisites for completing the walkthrough:

- You must have permission to launch a Compute instance. For guidance, see Launching an Instance.
- You must be able to connect to the service instance that you've launched. For guidance, see Connecting to an Instance.
- You must have the appropriate OCID, fingerprint, and private key for the Identity and Access Management (IAM) user that you will use to interact with an Object Storage. For guidance, see SDK and Tool Configuration; see also Resource Identifiers.
- You must have an Object Storage bucket that you can connect to.
- The IAM user must be able to read and write to that bucket using the Console.

Using Spark

Install Spark and Dependencies

Note:

For the purpose of this example, install Spark into the current user's home directory. Note that for production scenarios, you would not do this.

Note:

Versions 2.7.7.0 and later no longer install all of the required third party dependencies. Required third party dependencies are bundled under the
1. Launch an instance of your Compute service. For guidance, see Launching an Instance.
2. Ensure that your service instance has a public IP address so that you can connect using a Secure Shell (SSH) connection. For guidance, see Instance Console Connections.
3. Connect to your service instance using an SSH connection.
4. Install Spark and its dependencies, Java and Scala, by using the code examples that follow.

```bash
# We'll use wget to download some of the artifacts that need to be installed
sudo yum install wget

# First install Java
sudo yum install java-1.8.0-openjdk.x86_64
export JAVA_HOME=/usr/lib/jvm/jre-1.8.0-openjdk
# Should be something like: OpenJDK Runtime Environment (build 1.8.0_161- b14)
java -version

# Then install Scala
sudo yum install scala-2.12.4.rpm
# Should be something like: Scala code runner version 2.12.4 -- Copyright 2002-2017, LAMP/EPFL and Lightbend, Inc.
scala -version

# Then download Spark
wget https://archive.apache.org/dist/spark/spark-2.2.1/spark-2.2.1-bin-hadoop2.7.tgz
tar xvf spark-2.2.1-bin-hadoop2.7.tgz
export SPARK_HOME=$HOME/spark-2.2.1-bin-hadoop2.7
export PATH=$PATH:$SPARK_HOME/bin

# Start a Spark master
cd $SPARK_HOME
./sbin/start-master.sh
```

Download the HDFS Connector and Create Configuration Files

**Note:**

For the purposes of this example, place the JAR and key files in the current user's home directory. For production scenarios you would instead put these files in a common place that enforces the appropriate permissions (that is, readable by the user under which Spark and Hive are running).

Download the HDFS Connector to the service instance and add the relevant configuration files by using the following code example. For additional information, see HDFS Connector for Object Storage https://docs.cloud.oracle.com/Content/API/SDKDocs/hdfsconnector.htm?Highlight=hdfs.

```bash
wget https://github.com/oracle/oci-hdfs-connector/releases/download/v2.9.2.1/oci-hdfs.zip
unzip oci-hdfs.zip -d oci-hdfs

cd $HOME
mkdir .oci
# Create or copy your API key into the $HOME/.oci directory

cd $SPARK_HOME/conf
# Create a core-site.xml (e.g. by transferring one you have, using vi etc.). Consult
```
# https://docs.cloud.oracle.com/Content/API/SDKDocs/hdfsconnector.htm#two
# for what this should look like

cp spark-defaults.conf.template spark-defaults.conf

In the spark-defaults.conf file, add the following at the bottom:

```bash
cp spark-defaults.conf.template spark-defaults.conf
```

**Prepare Data**

For testing data, we will use the MovieLens data set.

2. Unzip the download file.
3. Upload the movies.csv file to your Object Storage bucket.

**Test Using the Spark Shell**

With the data ready, we can now launch the Spark shell and test it using a sample command:

```bash
  cd $SPARK_HOME
  ./bin/spark-shell
```

```
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
java.io.IOException: No FileSystem for scheme: oci
```

You receive an error at this point because the oci:// file system schema is not available. We need to reference the JAR file before starting the Spark shell. Here's an example for doing so:

```bash
  ./bin/spark-shell --jars $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar --
driver-class-path $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar
```

```bash
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
res0: org.apache.spark.rdd.RDD[(String, String)] = oci://
PipedUploadTest@sampletenancy/ MapPartitionsRDD[1] at wholeTextFiles at
<console>:25
```

```bash
scala> sc.textFile("oci://PipedUploadTest@sampletenancy/
movies.csv").take(20).foreach(println)
```

```
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
10,GoldenEye (1995),Action|Adventure|Thriller
11,"American President, The (1995)",Comedy|Drama|Romance
12,Dracula: Dead and Loving It (1995),Comedy|Horror
13,Balto (1995),Adventure|Animation|Children
14,Nixon (1995),Drama
15,Cutthroat Island (1995),Action|Adventure|Romance
16,Casino (1995),Crime|Drama
17,Sense and Sensibility (1995),Drama|Romance
18,Four Rooms (1995),Comedy
```
The command is successful so we are able to connect to Object Storage. Note that if you do not wish to pass the --jars argument each time the command executes, you can instead copy the oci-hdfs-full JAR file into the $SPARK_HOME/jars directory.

**Start the Spark Thrift Server**

Start the Spark Thrift Server on port 10015 and use the Beeline command line tool to establish a JDBC connection and then run a basic query, as shown here:

```bash
cd $SPARK_HOME
./sbin/start-thriftserver.sh --hiveconf hive.server2.thrift.port=10015
```

Once the Spark server is running, we can launch Beeline, as shown here:

```bash
cd $SPARK_HOME
./bin/beeline
```

Beeline version 1.2.1.spark2 by Apache Hive

```
beeline>
```

Next, connect to the server, as shown here:

```
beeline> !connect jdbc:hive2://localhost:10015 testuser testpass
```

None exist presently; however, we can create a table and link it to the movies.csv file that we downloaded and placed in the Object Storage bucket, as shown here:

```
0: jdbc:hive2://localhost:10015> create table test_table (movieId integer, title string, genres string) using csv options (path "oci://myBucket@myTenant/movies.csv", header "true", delimiter ",");
```

```
0: jdbc:hive2://localhost:10015> describe formatted test_table;
```

For the purposes of this example, we have not configured any security, so any user name and password will be accepted. For production scenarios you would not do this.
<table>
<thead>
<tr>
<th>col_name</th>
<th>comment</th>
<th>data_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>movieId</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>title</td>
<td></td>
<td>string</td>
</tr>
<tr>
<td>genres</td>
<td></td>
<td>string</td>
</tr>
</tbody>
</table>

# Detailed Table Information

<table>
<thead>
<tr>
<th>Database</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>test_table</td>
</tr>
<tr>
<td>Owner</td>
<td>opc</td>
</tr>
<tr>
<td>Created</td>
<td>Thu Mar 01 20:45:18 GMT 2018</td>
</tr>
<tr>
<td>Last Access</td>
<td>Thu Jan 01 00:00:00 GMT 1970</td>
</tr>
<tr>
<td>Type</td>
<td>EXTERNAL</td>
</tr>
<tr>
<td>Provider</td>
<td>csv</td>
</tr>
</tbody>
</table>

| Location          | oci://PipedUploadTest@sampletenancy/movies.csv |
| Serde Library     | org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe |
| InputFormat       | org.apache.hadoop.mapred.SequenceFileInputFormat |
| OutputFormat      | org.apache.hadoop.hive.ql.io.HiveSequenceFileOutputFormat |

| Storage Properties | [delimiter=,, header=true, serialization.format=1] |

Note that the table stores its data externally in Object Storage and the data can be accessed using the HDFS Connector (the oci:// file system scheme). Now that we have a table, we can query it:

```sql
0: jdbc:hive2://localhost:10015> select * from test_table limit 10;
+----------+-------------------------------------+-------------------------------------+
<table>
<thead>
<tr>
<th>movieId</th>
<th>title (1995)</th>
<th>genres</th>
</tr>

**Toolkit for Eclipse**

The Oracle Cloud Infrastructure Toolkit for Eclipse is an open source plug-in for the Eclipse Integrated Development Environment (IDE). The toolkit provides a set of features that help developers connect to Oracle Cloud Infrastructure from within Eclipse. For example, you can use the toolkit to deploy an application to a VM in the cloud by using the Oracle Container Engine for Kubernetes, or upload multiple files to Object Storage with one click. The Compute feature enables you to start a compute instance or restart it if needed. You can also switch between multiple accounts and regions from the Eclipse IDE.

**Download**: To install the Toolkit, download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub, then follow the instructions in Getting Started with Toolkit for Eclipse on page 4364.

**Requirements**

To use the Oracle Cloud Infrastructure Toolkit for Eclipse, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 57. For a list of typical policies you may want to use, see Common Policies on page 2142.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 4179.
- SDK for Java on page 4225
- Eclipse IDE for Java Developers 4.3 or later

**Services Supported**

- Compute
- Object Storage
- Autonomous Database
- Container Engine for Kubernetes

**Contact Us**

**Contributions**

Got a fix for a bug or a new feature you’d like to contribute? The plug-in is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the toolkit is released, subscribe to the Atom feed.
Questions or Feedback

- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Getting Started with Toolkit for Eclipse

Downloading the Toolkit

You can download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub.

Installing the Toolkit

After downloading the toolkit, launch the Eclipse IDE.

1. From the top navigation bar, select Help > Install New Software...
2. In Install dialog, click Add...
3. In the Add Repository dialog, click Archive...
4. In the right pane of the Repository Archive window, select the zip file containing the toolkit. Click Open.
5. In the Add Repository dialog click Add.
6. In the Available Software dialog, select Oracle Cloud Infrastructure Toolkit for Eclipse, then click Next.
7. In the Install Details dialog, click Finish.

Configuring the Toolkit

Oracle Cloud Infrastructure Preferences

Before you can use the toolkit, you must configure the Oracle Cloud Infrastructure Preferences in the Eclipse IDE. This process will provide the necessary identifiers and credentials so the toolkit can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs on page 4179.

1. From the top navigation bar, select Preferences > Oracle Cloud Infrastructure Preferences.
2. For Profile Name, provide a short descriptive name.
3. From the Region dropdown, select your region.
4. Enter your User OCID and Tenancy OCID. For information on how to locate this information, see Where to Get the Tenancy's OCID and User's OCID on page 4184.
5. For Key File, click Browse and select the appropriate file. For more information, see How to Generate an API Signing Key on page 4180.
6. Enter the Fingerprint for the Key File. For more information, see How to Get the Key's Fingerprint on page 4183.
7. Enter the Passphrase, if you created one for the key pair. If not, leave this field blank.
8. Click Save Profile.
9. Click Apply and Close.

Proxy Settings

If you are on a network that uses a proxy to connect to the internet, you must configure Eclipse proxy settings. For more information, see Network Connections in the Eclipse IDE Documentation.

Uninstalling the Toolkit

Launch the Eclipse IDE.

1. From the top navigation bar, select Help > About Eclipse IDE
2. Click Installation Details.
3. In the Installation Details window, select the Installed Software tab.
4. Select Oracle Cloud Infrastructure Toolkit for Eclipse and click Uninstall...
5. In the Uninstall dialog, confirm the items to be uninstalled then click Finish.
6. Click **Restart**.

**Using Toolkit for Eclipse**

After configuring the **Oracle Cloud Infrastructure Preferences** on page 4364, you can connect to your tenancy via Eclipse and use the Oracle Cloud Infrastructure Explorer to view and update your resources. You can also switch between different accounts saved in the profile.

To change the region, click the region icon in the Explorer navigation bar and select from the dropdown.

To change the compartment, click the compartment icon and select from the dropdown.

**Using the Toolkit for Eclipse with Compute Instances**

In the Oracle Cloud Infrastructure Explorer, double-click **Compute** to view available resources.

Double-click **Instances** to display a list of instances. You can right-click each one in the list to start, stop, or reboot it.

You can also double-click **Block Volumes** to view a list of block volumes.

**Using the Toolkit for Eclipse with Object Storage**

In the Oracle Cloud Infrastructure Explorer, double-click **Object Storage** to view available resources.

**Working with Buckets**

To create a bucket, right-click **Object Storage** and select **Create New Bucket**.

To view content and details, double-click or right-click the bucket and select **Open Bucket**.

To delete a bucket, view the bucket's details and click **Delete Bucket**.

**Working with Objects**

To upload an object, select the destination bucket and view its details. Right-click the Object list and select **Upload Object**. You can also drag one or more files to the Object list to upload.

To download one or more objects, right-click and select **Download Object**.

To delete one or more objects, right-click and select **Delete Object**.

**Deploy Applications using Oracle Container Engine for Kubernetes**

**Prerequisites**

1. Install **Docker Desktop v2.2.0.0** or higher.
2. Verify that Docker desktop is running, and that the Docker CLI client and Kubernetes CLI client (kubectl) are available in the command line.
3. Install the **Oracle Cloud Infrastructure command line client (OCI CLI)**.
4. Verify that OCI CLI works by typing “oci” on command prompt. This should return a list of all the services supported by OCI CLI.

**Deploy an Application to Container Engine for Kubernetes**

1. In the Oracle Cloud Infrastructure Explorer, double-click **Container Engine for Kubernetes**.
2. Double-click **Container Cluster (OKE)** to display a list of available clusters. A cluster should be created prior to this step in the console.
3. Right click on the cluster name and select **Deploy Docker Image to OKE**.
4. Follow the deployment wizard steps to to deploy the application.

**Oracle Developer Tools for Visual Studio**

The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can **use the tools to view and manage your Oracle**
Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

Requirements

To use the Oracle Developer Tools for Visual Studio, you must have the following:

• An Oracle Cloud Infrastructure account
• A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 57. For a list of typical policies you may want to use, see Common Policies on page 2142.
• A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 4179.
• The Oracle Cloud Infrastructure Command Line Interface (CLI) on page 4192 installed and configured.
• Microsoft Visual Studio 2019 or later
• Docker Desktop v2.2.0.0 or higher

Questions or Feedback

For questions or to provide feedback, please use one of the following resources:

• The Developer Tools section of the Oracle Cloud forums
• My Oracle Support

Getting Started with Oracle Developer Tools for Visual Studio

Installing the Extension

The Oracle Developer Tools for Visual Studio is available in the Visual Studio Marketplace.

1. From the Visual Studio menu, select Extensions->Manage Extensions
2. From the list on the left side of the dialog, select Online and then Visual Studio Marketplace
4. Click on the Download button next to the extension.
5. A browser window opens with instructions to download the installer.

Configuring the Toolkit

Oracle Developer Tools for Visual Studio Preferences

Before you can use the developer tools, you must configure the Oracle Cloud Infrastructure Preferences. This process will provide the necessary identifiers and credentials so the developer tools can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs on page 4179.

1. The deployment wizard requires an Oracle Cloud Infrastructure user credentials configuration file. For more information, see SDK and CLI Configuration File on page 4184.
2. Run the “docker desktop” app, and ensure it has the Linux Containers option selected.
3. If behind a proxy, set the proxy values http_proxy and https_proxy in the environment variables for Windows and in the Docker Desktop settings (see the Resources->Proxies menu).

Uninstalling the Toolkit

1. From the Visual Studio menu, select Extensions, then Manage Extensions.
2. From the list on the left side of the dialog, select Installed.
3. Select "Oracle Developer Tools for Visual Studio 2019" from the middle menu and click on the Uninstall button that appears next to it.
Using the Oracle Developer Tools for Visual Studio

This topic shows how to use the Oracle Developer Tools for Visual Studio's Deployment wizard to deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

Note:
The Oracle Developer Tools for Visual Studio has additional functionality that is not covered in this document. For more information, see Oracle Developer Tools for Visual Studio.

Prerequisites

This topic assumes a working knowledge of OCI Container Engine for Kubernetes. The tutorials below will help understand some of the technologies and backend framework used by the wizard for deployment.

- Pushing an Image to Oracle Cloud Infrastructure Registry
- Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes
- Deploying an Application to OKE

Overview

Using the Oracle Developer Tools for Visual Studio assumes you've already created a docker image for your application. This workflow generally looks like this:

- Build your web application.
- Build a docker image for your application locally. For more information, see the Docker documentation.
- Push the docker image of the web application to the Oracle Cloud Infrastructure Registry. For more information on pushing a docker image to OCIR, see Push an Image to Oracle Cloud Infrastructure Registry.
- Create a cluster in Oracle Cloud using Oracle Container Engine Service for Kubernetes. See Create a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes and download the resulting kubeconfig file.
- Create a named secret containing OCI credentials to be used for Kubernetes deployment. For more information, see Pull an Image from Oracle Cloud Infrastructure Registry when Deploying a Load-Balanced Application to a Cluster.

Deploy an Application Using the Oracle Deployment Wizard

1. From the Visual Studio Extensions menu, select Oracle Cloud App Deployment -> Deploy to Oracle Cloud. The Oracle Deployment Wizard displays.
2. Click Next.
3. Select an Authentication Profile (make sure that this profile matches the OCI CLI profile) and click Next.
4. Select a deployment option:

   a. **Redeploy using an existing deployment configuration:** This deployment choice should be used for re-deployment of a web application when there are no deployment configuration changes. If the developer needs to make changes only to his/her web application and then re-deploy, they can do so using this option. This option allows developers to do quick deployment in a few clicks with no new information asked for.

   b. **Redeploy with a different deployment configuration:** This deployment choice should be used for re-deployment of a web application when there are deployment configuration changes. Scenarios where this is an
appropriate choice include deploying on a different cluster, using a different Docker image, or a change in the Kubernetes configuration.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If selecting a different cluster during re-deployment, delete the Kubernetes resources for your previous deployment using the &quot;kubectl delete&quot; command.</td>
</tr>
</tbody>
</table>

c. Create a new deployment: Use this option when deploying your web application for the first time using this wizard. The name for this deployment should be unique, must be no longer than 63 characters, must start and end with a lowercase letter or number, and may contain lowercase letters, numbers, and hyphens.

5. On the Select A Cluster panel, select an existing Kubernetes cluster from any of the compartments in your tenancy (the wizard does not support creating a cluster, so you should create a cluster using the console first). Click Next.

6. On the Specify Deployment Details panel, you can modify existing deployment details.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The deployment file created by the wizard can be modified in any editor and used for re-deployments using the wizard.</td>
</tr>
</tbody>
</table>

   a. Select a Docker image from the drop-down list.

   b. Select a Kubernetes Secret Name from the drop-down list.

7. Click Next.

8. Verify your deployment details, and then click Deploy. The window will actively update with the deployment status as it progresses. You can dismiss this dialog and check the deployment status later by selecting Oracle Cloud App Deployment -> Check Deployment Status from the Visual Studio menu.

Deleting A Deployment

The wizard doesn't support deleting a deployment using the Visual Studio IDE. To delete a deployment:

1. Delete the deployment from the OKE cluster using the following command: `kubectl delete -f <path-to-deployment-file> --kubeconfig <path-to-kubeconfig-file>` If the deployment file is not present, you can use the following command: `kubectl delete deploy/<deployment_name> svc/<service_name>`

2. Delete the folder in `~/.oci/visualstudiowebapps/<your-application-deployment-name>` from the client machine.

Appendix and Reference

This section covers general SDK concepts and references.

- REST APIs on page 4368
- Client-Side Encryption on page 4393 - Discusses how client-side encryption works for the Oracle Cloud Infrastructure SDK for Python and the SDK for Java.

REST APIs

The Oracle Cloud Infrastructure APIs are typical REST APIs that use HTTPS requests and responses. This topic describes basic information about using the APIs.

API Reference and Endpoints

For links to the Oracle Cloud Infrastructure API reference and a list of the regional API endpoints, see API Reference and Endpoints.
API Version

The base path of the endpoint includes the desired API version (for example, 20160918). Here's an example for a POST request to create a new VCN in the Ashburn region:

```
POST https://iaas.us-ashburn-1.oraclecloud.com/20160918/vcns
```

Request Signing Required

All Oracle Cloud Infrastructure API requests must be signed for authentication purposes. For information about the required credentials and how to sign the requests, see Request Signatures on page 4383.

HTTPS and TLS 1.2 Required

All Oracle Cloud Infrastructure API requests must support HTTPS and SSL protocol TLS 1.2.

Maximum Allowed Client Clock Skew

HTTP status code 401 (NotAuthenticated) is returned if the client's clock is skewed more than 5 minutes from the server's. To determine the server's clock time, use this curl command with the API endpoint:

```
curl -s --head <endpoint> | grep Date
```

For example:

```
curl -s --head https://iaas.us-phoenix-1.oraclecloud.com | grep Date
```

Request and Response Format

The Oracle Cloud Infrastructure APIs use standard HTTP requests and responses. Each may contain Oracle-specific headers for pagination, entity tags (ETags), and so on as described elsewhere in this topic and in the API documentation.

Each response includes a unique Oracle-assigned request ID (for example, bb3f3275-f356-462a-93c4-bf40fb82bb02) in the opc-request-id response header. If you need to contact Oracle about a particular request, please provide this request ID.

Many of the API operations require JSON in the request body or return JSON in the response body. The specific contents of the JSON are described in the API documentation for the individual operation. Notice that the JSON is not wrapped or labeled according to the operation's name or the object's name or type.

**Note:**

Make sure to set the Content-Type header to application/json in your POST and PUT requests that contain JSON in the body.

Example CreateVcn Request

```
POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/vcns
host: iaas.us-phoenix-1.oraclecloud.com
opc-retry-token: 239787fs987
Content-Type: application/json
HTTP headers required for authentication
Other HTTP request headers per the HTTP spec
{
  "compartmentId": "ocid1.compartment.oc1..aaaaaaauwjnv47knr7uuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq",
  "displayName": "Apex Virtual Cloud Network",
  "cidrBlock": "172.16.0.0/16"
}
```
Example CreateVcn Response

```
200 OK
opc-request-id: 6c4d01a6-f764-4325-a3f8-720c8b5cae7b
{
    "id": "ocid1.vcn.oc1.phx.aaaaaaaa4ex5pqjtkjhd4h4gcnk07vx5uto5puj5noa5awznspwjt3pqyq",
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspl6oxosfbeb3vy72fi4swgrkvuvq",
    "displayName": "Apex Virtual Cloud Network",
    "cidrBlock": "172.16.0.0/16"
    "defaultRouteTableId": "ocid1.routetable.oc1.phx.aaaaaaaaba3pv6wkr4jqaee5f44n2b2m2yt2j6rx32uzr4h25vqstifsfsdq",
    "defaultSecurityListId": "ocid1.securitylist.oc1.phx.aaaaaaaac6h4ckr3ncbxmvminfvzjbr7owu5hfzbtu33kfe7hgcs5fj",
    "defaultDhcpOptionsId": "ocid1.dhcpoptions.oc1.phx.aaaaaaaawglzn7s5sogyfzn125a4vxgu76c2hrvzyd3psn6vcx331zmu2xx",
    "state": "PROVISIONING",
    "timeCreated": "2016-07-22T17:43:01.389+0000"
}
```

Error Format

If a request results in an error, the response contains a standard HTTP response code with 4xx for client errors and 5xx for server errors. The body also includes JSON with an error code and a description of the error. For example:

```
{
    "code": "InvalidParameter",
    "message": "Description may not be empty; description size must be between 1 and 400"
}
```

For a list of common errors across all services, see API Errors.

Request Throttling

Oracle Cloud Infrastructure applies throttling to many API requests to prevent accidental or abusive use of resources. If you make too many requests too quickly, you might see some succeed and others fail. Oracle recommends that you implement an exponential back-off, starting from a few seconds to a maximum of 60 seconds. When a request fails due to throttling, the system returns response code 429 and the following error code and description:

```
{
    "code": "TooManyRequests",
    "message": "User-rate limit exceeded."
}
```

Polling for Resource Status

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your code to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action.

You can poll a resource to determine its state. For example, when you call GetInstance, the response body contains an instance resource that includes the lifecycleState attribute. You might want your code to wait until the instance's lifecycleState is RUNNING before proceeding.

Different resources take different amounts of time to transition between states. Therefore, the optimal frequency and duration parameters for a polling strategy can vary among resources. The Oracle Cloud Infrastructure SDK waiters use the following default strategy:

- Use an exponential back-off, starting from a few seconds to a maximum of 30 seconds between poll attempts.
- Poll up to 20 minutes, and then stop.
Or more information on waiters, see:

- SDK for Java waiters documentation
- SDK for Ruby waiters documentation

**Where to Find Your Tenancy's OCID**

If you use the API, you'll need your tenancy's OCID in order to sign the requests (see Request Signatures on page 4383). You'll also need it for some of the IAM API operations. An OCID is an Oracle Cloud ID (see Resource Identifiers).

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu and click Tenancy: `<your_tenancy_name>`.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

The tenancy OCID looks something like this (notice the word "tenancy" in it):

`ocid1.tenancy.oc1..<unique_ID>`.

**List Pagination**

Most List operations paginate results. For example, results are paginated for the ListInstances operation in the Core Services API. When you call a paginated List operation, the response indicates more pages of results by including the `opc-next-page` header.

**Note:**

A page can be empty even when more results remain. Anytime the `opc-next-page` header appears, there are more list items to get. For more information about resource list control, see Overview of Search on page 3626.

List pagination for Object Storage ListObjects works differently because the pagination controls are also used for object name filtering. ListObjects returns nextStartWith instead of `opc-next-page` in the response body. To paginate through more objects, use the returned `nextStartWith` value with the start parameter. To filter which objects ListObjects returns, use the start and end parameters.

To get the next page of results

Make a new GET request against the same URL, modified by setting the page query parameter to the value from the `opc-next-page` header. Repeat this process until you get a response without an `opc-next-page` header. The absence of this header indicates that you have reached the last page of the list.
Note:

For an alternative to writing pagination code, see the functions in the pagination module provided with the SDK for Python.

To get the previous page of results

(Available with some APIs.) Make a new GET request against the same URL, modified by setting the page query parameter to the value from the opc-prev-page header. Repeat this process until you get a response without an opc-prev-page header. The absence of this header indicates that you have reached the first page of the list.

Note:

For an alternative to writing pagination code, see the functions in the pagination module provided with the SDK for Python.

To change the maximum number of results per page

In the GET request, set the limit to the number of items you want returned in the response.

Note:

The service will return no more than the number specified as limit, but might not return that exact number.

Retry Token

For some operations you can provide a unique retry token (opc-retry-token) so the request can be retried in case of a timeout or server error without the risk of executing that same action again. The token expires after 24 hours, but can be invalidated before then due to conflicting operations (for example, if a resource has been deleted and purged from the system, then a retry of the original creation request may be rejected).

ETags for Optimistic Concurrency Control

The API supports etags for the purposes of optimistic concurrency control. The GET and POST calls return an etag response header with a value you should store. When you later want to update or delete the resource, set the if-match header to the ETag you received for the resource. The resource will then be updated or deleted only if the ETag you provide matches the current value of that resource's ETag.

Null vs. Empty Strings for Optional Parameters

If you send an empty string (""") as the value of an optional parameter, the API validates the value as normal (for example, checks against minimum and maximum allowed length, and so on). Often the minimum allowed length is 1, so an error would be returned. If you don't set the value (it's null), the API performs no validation, and some other action may occur. For example: if you don't set a value for the displayName when creating a new VCN object, the service will auto-generate a value.

API Errors

Common Errors Returned by All Services

The following table lists the common errors returned by all the services for Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
<th>Retry</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>CannotParseRequest</td>
<td>The request is incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>InvalidParameter</td>
<td>A parameter is invalid or incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>LimitExceeded</td>
<td>Fulfilling this request exceeds the Oracle-defined limit for this tenancy for this resource type.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>MissingParameter</td>
<td>A required parameter is missing.</td>
<td>No.</td>
</tr>
<tr>
<td>HTTP Status Code</td>
<td>Error Code</td>
<td>Description</td>
<td>Retry</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>400</td>
<td>QuotaExceeded</td>
<td>Fulfilling this request exceeds the administrator-defined quota for this compartment for this resource.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>RelatedResourceNotAuthorizedOrNotFound</td>
<td>A resource specified in the body of the request was not found, or you do not have authorization to access that resource.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>401</td>
<td>NotAuthenticated</td>
<td>The required authentication information was not provided or was incorrect. There are other reasons why this error code is generated. For more information, see HTML Status Code 401.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>402</td>
<td>SignUpRequired</td>
<td>This operation requires opt-in before it may be called.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>NotAuthorized</td>
<td>You do not have authorization to update one or more of the fields included in this request.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>NotAuthorizedOrNotFound</td>
<td>A resource specified via the URI (path or query parameters) of the request was not found, or you do not have authorization to access that resource. For more information, see HTML Status Code 404.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>404</td>
<td>NotFound</td>
<td>There is no operation supported at the URI path and HTTP method you specified in the request.</td>
<td>No.</td>
</tr>
<tr>
<td>405</td>
<td>MethodNotAllowed</td>
<td>The target resource does not support the HTTP method.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>IncorrectState</td>
<td>The requested state for the resource conflicts with its current state.</td>
<td>Yes, with backoff. Refer to the error description for any required actions before you retry.</td>
</tr>
<tr>
<td>409</td>
<td>InvalidatedRetryToken</td>
<td>The provided retry token was used in an earlier request that resulted in a system update, but a subsequent operation invalidated the token. This can happen, for example, in cases where an entity created with the same token has since been deleted. If the system state change that is associated with this request should be performed again, retry it using a different token.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>NotAuthorizedOrResourceAlreadyExists</td>
<td>You do not have authorization to perform this request, or the resource you are attempting to create already exists. This error code is returned only from create operations, where it is returned instead of the more general NotAuthorizedOrNotFound error code.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>412</td>
<td>NoEtagMatch</td>
<td>The ETag specified in the request does not match the ETag for the resource.</td>
<td>No.</td>
</tr>
</tbody>
</table>
### Error Details and Troubleshooting

#### HTTP status code: 401

- **Missing or incorrect authentication information.** Verify that all the required information (tenant OCID, user OCID, fingerprint, and private key) is provided and accurate. Verify that the public key corresponding to the fingerprint has been uploaded for the user. For more information, see [Required Keys and OCIDs](#) on page 4179.
- **Clock skew.** This status code is returned if the client's clock is skewed more than five (5) minutes from the server's clock. For more information, see [Maximum Allowed Client Clock Skew](#) on page 4369.
- **API request signature error.** This status code is returned if a required header is missing from a signing string. For more information, see [Request Signatures](#) on page 4383.

#### Error Codes: NotAuthorizedOrNotFound, RelatedResourceNotAuthorizedOrNotFound, NotAuthorizedOrResourceAlreadyExists

- **Authorization error.** Verify that the user is in a group that has the permissions to work with resources in a compartment.
- **Compartment or resource not found.** Verify that the compartment or resource exist and is referenced correctly. For example, this status code is returned for either of the following errors:
  - **CompartmentNotFoundException** if a compartment doesn't exist
  - **VolumeNotFoundException** if a volume doesn't exist

### Asynchronous Work Requests

This topic describes asynchronous work requests for long-running operations against Oracle Cloud Infrastructure services. It also provides guidance on obtaining request status, and for inspecting the request response to enable filtering for affected resources.

#### Overview

API calls to Oracle Cloud Infrastructure services can launch long-running operations that do not complete the client's request before a response is returned. In these cases, the service spawns an asynchronous work request that allows for visibility into the progress of long-running, asynchronous operations. The response to the REST API call contains a work request ID in the `opc-work-request-id` header, which allows you to monitor its progress and status. The work request itself remains in a queue until the operation has completed.

You can monitor the status of the work request at any time by calling `GetWorkRequest` and passing in the work request ID.
Note:

The Compute, Data Catalog, and Database services support work requests using Work Requests API, which contains the GetWorkRequest operation.

Other services that support work requests use operations in the service APIs. These service APIs each include operations that work in a similar manner to the GetWorkRequest operation used by the Work Requests API.

Two features of the request response are of particular interest: the status of the work request, and a list of the resources that are affected by the work request. The status is important because asynchronous work requests must know when an operation has completed, is still running, or whether it has failed altogether.

To retrieve information about work request failures or errors, each service provides APIs for fetching information about errors, and logs. For links to API reference documentation for each of the service, see the section For More Information on page 4383.

Also important in cases where a work request operation affects several resources is having a list of the resources that a work request affects, along with each one's entityType and actionType attributes.

Work Request Status

Asynchronous work requests allow you to monitor their progress by providing a status attribute on the WorkRequest object. Each of the supported services provides its own API for obtaining status, as listed in the following sections.

Note:

There is a ContainerEngineWaiters class that allows you to create a callback using the forWorkRequest method. Use this API to forward a notification when an operation's status changes, for example, from IN_PROGRESS to COMPLETED.

The following table lists status attributes that are supported by the WorkRequest object on the respective services.

<table>

</table>
Filtering the Request Response

You sometimes need to know which resources are affected by a given asynchronous work request. In cases where the request response includes just one or two affected resources, the body of the request response is probably sufficient. However, in cases where a request response affects a great many resources, you must filter the response to identify the resources that you're interested in.

Filtering of resources listed in a work request response relies on two attributes of the `WorkRequestResource` type: `entityType` and `actionType`.

- **entityType**: Represents the resource type which the work request affects. This is an optional attribute, but each resource can have only one `entityType`.
- **actionType**: Represents how the specified resource is affected by the operation associated with the work request. Each service specifies a fixed list of allowable `actionType` values (shown in the sections following).

To obtain resource information on a work request, call `GetWorkRequest` and pass in the work request ID. The call returns a response in JSON format. Following is an example from calling `GetWorkRequest` on the Object Storage service.

```json
{
    operationType: "COPY_OBJECT",
    status: "IN_PROGRESS",
    id: "f54527d6-029b-4221-9046-a81b7686202",
    resources: [
        {
            entityType: "object",
            actionType: "READ",
            entityUri: "/n/mynamespace/b/backups/o/myobject"
        },
        {
            entityType: "object",
            actionType: "WRITTEN",
            entityUri: "/n/mynamespace/b/backups/o/copyofmyobject"
        }
    ],
    timeAccepted: 2017-10-13T17:23:46.000Z,
    timeStarted: 2017-10-13T17:23:52.198Z,
    percentComplete: 10.0
}
```

**Note:**

Different services provide slightly different responses. See the reference documentation for each service's work request API for details. Links to each are provided in the *For More Information* on page 4383 section.

The following table lists the entity types and action types that are supported by Oracle Cloud Infrastructure services.
<table>
<thead>
<tr>
<th>Service Name</th>
<th>Operation</th>
<th>entityType</th>
<th>actionType</th>

### Request/Response Sample

Following is a sequence of REST API calls to create a cluster, which is a common long-running operation. The caller retrieves the work request ID from the response to the initial POST call and then periodically polls the WorkRequest to determine the status of the operation. The request/response sequence that follows depicts this workflow:

1. The user issues a `CreateCluster` API call.
2. The service responds with status code 202, indicating that the request has been accepted and returns a work request ID in the `Opc-Work-Request-Id` header.
3. Next, the user issues a `GET` call on the work request ID to obtain the status of the work request.
4. The service responds with status code 200, indicating in the response body that the `CLUSTER_CREATE` operation has the status ACCEPTED.
5. With continued polling, we see another `GET` call for the work request.
6. The service responds with status code 200. The response body reports that the operation SUCCEEDED.

**Step 1.** Initial API call to initiate a `CLUSTER_CREATE` operation.

```bash
POST https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/clusters
Accept: application/json
authorization: <Redacted>
content-length: 480
Content-Type: application/json
date: Mon, 02 Jul 2018 18:20:03 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: D7A390ED909C47038C438BA3629FB612
```
Step 2. The response to the initial API call, which contains the work request ID in the `Opc-Work-Request-Id` header.

202
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 0
Date: Mon, 02 Jul 2018 18:20:04 GMT
Opc-Request-Id: D7A390ED909C47038C438BA3629FB612/33EEDCAAB2E84508B34AA75CD0FD86F4/8261D1CC89814E9BB9344D761D7F75C/515298
Opc-Work-Request-Id: ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID
Uri: /20180222/clusters
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:53077

Step 3. Because this is a long-running operation, the user periodically polls the work request using a GET call to determine its status.

GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:20:04 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: E8F20DAC443346B3B0EA599F367EE294
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)

Step 4. The GET call returns the following response, which indicates in the response body that the `CLUSTER_CREATE` operation has a status of `ACCEPTED`.

200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 717
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:20:05 GMT
Etag: 56a41efaf33d81a54933495ee910c24d7bce7a83adf18810f95e07bdd2055805
Opc-Request-Id: E8F20DAC443346B3B0EA599F367EE294/8B19C9FC3B4442CEA14685D1973D0856/0BA60B0711764DE4A4375C5
Retry-After: 30
Uri: /20180222/workRequests/_id_
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
Step 5. The operation continues, and the user continues to poll the work request using the GET method.

GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:24:13 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: 64595B97E39A471A886DA29966BB6B1D
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)

Step 6. The last GET call produced the following response, which indicates that the operation has completed. Note the entityType is "cluster" and the actionType is "CREATED".

200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 750
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:24:14 GMT

Request Signatures

This topic describes how to sign Oracle Cloud Infrastructure API requests.

Signing samples are included for the following:

- Java on page 4387
- Python on page 4389
- TypeScript on page 4389
- JavaScript on page 4390
- Ruby on page 4391
- Go on page 4391
- C# on page 4393

Signature Version 1

The signature described here is version 1 of the Oracle Cloud Infrastructure API signature. In the future, if Oracle modifies the method for signing requests, the version number will be incremented and your company will be notified.

Required Credentials and OCIDs

You need an API signing key in the correct format. See Required Keys and OCIDs on page 4179.
Caution:

Client Clock Skew

If the client's clock is skewed more than 5 minutes, a 401 (NotAuthenticated) HTTP status code is returned. This will affect your API requests. For more information, see Maximum Allowed Client Clock Skew.

You also need the OCIDs for your tenancy and user. See Where to Get the Tenancy's OCID and User's OCID on page 4184.

Summary of Signing Steps

In general, these are the steps required to sign a request:

1. Form the HTTPS request (SSL protocol TLS 1.2 is required).
2. Create the signing string, which is based on parts of the request.
3. Create the signature from the signing string, using your private key and the RSA-SHA256 algorithm.
4. Add the resulting signature and other required information to the Authorization header in the request.

See the remaining sections in this topic for details about these steps.

Specification You Need to Be Familiar With

To learn how to perform steps 2-4 in the process above, refer to draft-cavage-http-signatures-08. It's a draft specification that forms the basis for how Oracle handles request signatures. It describes generally how to form the signing string, how to create the signature, and how to add the signature and required information to the request. The remaining sections in this topic assume you're familiar with it. Important details of the Oracle Cloud Infrastructure implementation of the reference are listed in the next section.

Special Implementation Details

The following sections describe important items to note about the Oracle Cloud Infrastructure implementation of the spec.

Authorization Header

The Oracle Cloud Infrastructure signature uses the "Signature" Authentication scheme (with an Authorization header), and not the Signature HTTP header.

Required Headers

This section describes the headers that must be included in the signing string.

Note:

Error if Required Header is Missing

If a required header is missing, your client will receive a 401 "Unauthorized" response.

For GET and DELETE requests (when there's no content in the request body), the signing string must include at least these headers:

- (request-target) (as described in draft-cavage-http-signatures-08)
- host
- date or x-date (if both are included, Oracle uses x-date)

For PUT and POST requests (when there's content in the request body), the signing string must include at least these headers:

- (request-target)
- host
- date or x-date (if both are included, Oracle uses x-date)
• x-content-sha256 (except for Object Storage PUT requests; see the next section)
• content-type
• content-length

Caution:
For PUT and POST requests, your client must compute the x-content-sha256 and include it in the request and signing string, even if the body is an empty string. Also, the content-length is always required in the request and signing string, even if the body is empty. Some HTTP clients will not send the content-length if the body is empty, so you must explicitly ensure your client sends it. If date and x-date are both included, Oracle uses x-date. The x-date is used to protect against the reuse of the signed portion of the request (replay attacks).

The one exception is for Object Storage PUT requests on objects (see the next section).

Special Instructions for Object Storage PUT
For Object Storage PutObject and UploadPart PUT requests, the signing string must include at least these headers:
• (request-target)
• host
• date or x-date (if both are included, Oracle uses x-date)

If the request also includes any of the other headers that are normally required for PUT requests (see the list above), then those headers must also be included in the signing string.

Case and Order of Headers
The headers must be all lowercase in the signing string.
The order of the headers in the signing string does not matter. Just make sure to specify the order in the headers parameter in the Authorization header, as described in the draft-cavage-http-signatures-05.

Caution:
The (request-target) includes the path and query string from the request. Oracle expects that you will create the signing string with the query parameters in the same order as they appear in the request. If the request query parameters change order after signing occurs, authentication will fail.

URL Encoding of Path and Query String
When forming the signing string, you must URL encode all parameters in the path and query string (but not the headers) according to RFC 3986.

Key Identifier
You must set keyId="<TENANCY OCID>/<USER OCID>/<KEY FINGERPRINT>" in the Authorization header that you add to the request. To get those values, see Where to Get the Tenancy's OCID and User's OCID on page 4184. An example keyId looks like this (wrapped to better fit the page):

ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/key_fingerprint

Signing Algorithm
The signing algorithm must be RSA-SHA256, and you must set algorithm="rsa-sha256" in the Authorization header (notice the quotation marks).
**Signature Version**

You should include `version="1"` in the `Authorization` header (notice the quotation marks). If you do not, it's assumed that you're using whatever the current version is (which is version 1 at this time).

**Example Header**

Here's an example of the general syntax of the `Authorization` header (for a request with content in the body):

```plaintext
Authorization: Signature
version="1",keyId="/tenancy_ocid/<user_ocid>/<key_fingerprint>",algorithm="rsa-sha256",headers="(request-target) date x-content-sha256 content-type content-length",signature="Base64(RSA-SHA256(<signing_string>))"
```

**Test Values**

Here's an example key pair, two example requests, and the resulting `Authorization` header for each.

**Caution:** The example signatures use the RSA 2048-bit keys below. Use these keys only for testing your signing code, not for sending production requests.

```
-----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDCFENGw33yGihy92pDjZQh10C36rPjJ+cVfSC8+q28hxA161QFNUd13wuCTUcqQd2qsBe/2hFyc2DCJjg0h1L78+6Z4UMR7EOcfpdeU9HF3m hs+FUR45uBJeDK1HSFHD8bHkD6kv8FPgfJtotc+2xjJwoYi+1hp1fIekaxsyQIDAQAB
-----END PUBLIC KEY-----

-----BEGIN RSA PRIVATE KEY-----
MIICXgIBAAKBgQDCFENGw33yGihy92pDjZQh10C36rPjJ+cVfSC8+q28hxA161QFNUd13wuCTUcqQd2qsBe/2hFyc2DCJjg0h1L78+6Z4UMR7EOcfpdeU9HF3m hs+FUR45uBJeDK1HSFHD8bHkD6kv8FPgfJtotc+2xjJwoYi+1hp1fIekaxsyQIDAQABAoGBAJR8ZkCIVu55zv+udt17TSnordITvoXXJnK72Z+UvMNUCDN2Qc4sBiAqwLw1cSkt5DsKZ8UETpYPy8pYNnDEz2Dyiae9+xEpuyheW2oH42x71wqBtoKkgwrXa/pzdpuiucRRjk6vE6YY7EBBs/g7uanVpGibOVAESqHIAEkE7DkjVH28WDUsf1nqvfr2jk6CT7n1cE3jGJz2Z7z1ZmBMhFODNMLURXR/Zm3pR5m0tCmbgQ5Rk9u412jtidPIwBAJN73v8pknth48bbQo/fKe16uEyybPttA5/uhHuKZ6F7F70uKogcmJSjubOc5t6h11vSl0QZjqZMEOwr+wKSMCQQQCC4kXjEsABvA770p6HtG/E1En7kpyUXRNvFsD0E0czJBBv/aRFUJxuxR91j4h2Ec9SAs7AsKMgq5OXb515Jj36xakEAqIT7aFOYBFwggQAskWNKLVy5gkbAZRTelBacPMuQd11DfdtVApqPAZ01y0RKmWGaFkaoqFQXKCWy0u1VknqJAXr1gySFci/2ueKfIE1QqIILS8V801pFLRnb1pzI7UyQxntAEFYM560yJ1zUpObv14cScGd36t1SMMvxLOVTA==
-----END RSA PRIVATE KEY-----
```

The public key is stored under keyId:

```
ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/<key_fingerprint>
```

For the following GET request (line breaks inserted between query parameters for easier reading; also notice the URL encoding as mentioned earlier):

```
GET https://iaas.us-phoenix-1.oraclecloud.com/20160918/instances
?availabilityDomain=Pjwf%3A%20PHX-AD-1
&compartmentId=ocid1.compartment.oc1...<unique_ID>
&displayName=TeamInstances
&volumeId=ocid1.volume.oc1.phx.<unique_ID>
```

Date: Thu, 05 Jan 2014 21:31:40 GMT
The signing string would be (line breaks inserted into the (request-target) header for easier reading):

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): get /20160918/instances?availabilityDomain=Pjwf%3A%20PH
X-AD-1&compartmentId=ocid1.compartment.oc1..aaaaaaam3we6vnherjrq5q2i
dncddf1vjsnog7ml6rtdb25g1chfeyjxa&displayName=TeamXInstances&
volumeId=ocid1.volume.oc1.phx.abyhqljrqtttnl73nrmrfwaux7kcvzfs3s66izvxf2h
41gyvynsdnoiwr5q
host: iaas.us-phoenix-1.oraclecloud.com

The Authorization header would be:
Signature version="1",headers="date (request-target) host",keyId="ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/
<key_fingerprint>,algorithm="rsa-sha256",
signature="<your_signature>"

For the following POST request:
POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/volumeAttachments
Date: Thu, 05 Jan 2014 21:31:40 GMT
{
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "instanceId": "ocid1.instance.oc1.phx.<unique_id>",
    "volumeId": "ocid1.volume.oc1.phx.<unique_id>"
}

The signing string would be:

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): post /20160918/volumeAttachments
host: iaas.us-phoenix-1.oraclecloud.com
content-length: 316
content-type: application/json
x-content-sha256: V9Z20UJTvkvpJ50f1BzKE32+6m2zJjweHpDMX/U4UY0=

The Authorization header would be:
Signature version="1",headers="date (request-target) host content-length content-type x-content-sha256",
keyId="ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1.<unique_ID>/
<your_fingerprint>",
algorithm="rsa-sha256",signature="<your_signature>"

Sample Code

This section shows the basic code for signing API requests.

        // Pre-Requirement: Allow setting of restricted headers. This is required to allow the
        // to set the host header that gets computed during signing of the request.
        System.setProperty("sun.net.http.allowRestrictedHeaders", "true");

        // 1) Create a request signing filter instance
        RequestSigningFilter requestSigningFilter =
                RequestSigningFilter.fromConfigFile(configurationFilePath, profile);

        // 2) Create a Jersey client and register the request signing filter
        Client client =
                ClientBuilder.newBuilder().build().register(requestSigningFilter);

        // 3) Target an endpoint. You must ensure that path arguments and query
        // params are escaped correctly yourself
        WebTarget target =
                client.target("https://iaas.us-phoenix-1.oraclecloud.com")
                        .path("20160918")
                        .path("instances")
                        .path(UrlEscapers.urlPathSegmentEscaper().escape(instanceId));

        // 4) Set the expected type and invoke the call
        Invocation.Builder ib = target.request();
        ib.accept(MediaType.APPLICATION_JSON);
        Response response = ib.get();

        // 5) Print the response headers and the body (JSON) as a string
        MultivaluedMap<String, Object> responseHeaders = response.getHeaders();
        System.out.println(responseHeaders);
        InputStream responseBody = (InputStream) response.getEntity();
        try (final BufferedReader reader = new BufferedReader(new InputStreamReader(responseBody, StandardCharsets.UTF_8))) {
            StringBuilder jsonBody = new StringBuilder();
            String line;
            while ((line = reader.readLine()) != null) {
                jsonBody.append(line);
            }
            System.out.println(jsonBody.toString());
        }
    }
}

Go

The following example shows how to create a default signer.

```
Note:
The SDK for Go exposes a stand-alone signer that you can use to sign custom
requests. You can find related code at http_signer.go.

}

Client-Side Encryption

The Oracle Cloud Infrastructure SDK for Python and SDK for Java support Client Side Encryption, which encrypts your data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

By default, the SDK generates a unique data key for each data object that it encrypts. Data is encrypted using a secure, authenticated, symmetric AES/GCM key algorithm with a 256-bit key length.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the CreateKey or ImportKey operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.
Java Prerequisites

The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171, and 6u16. For those versions and later the policy files are included but not enabled by default.

Current versions of the JDK do not require these policy files. They are provided here for use with older versions of the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.

Examples

The following code example show how to encrypt a string:

Java

```java
// String encryption example
final byte[] plainText = "Hello World".getBytes();
String masterKeyId = "OCID....";
Map<String, String> context = Collections.singletonMap("Example", "value");

OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider, Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new KmsMasterKeyProvider(kmsMasterKey);

// Encrypt the data and embed the master key ID in the header
final OciCryptoResult encryptResult =
    ociCrypto.encryptData(kmsMasterKeyProvider, plainText, context);
final byte[] cipherText = encryptResult.getResult();

// Decrypt the data
final OciCryptoResult decryptResult =
    ociCrypto.decryptData(kmsMasterKeyProvider, cipherText);
```

Python

```python
import oci
# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
data_to_encrypt_bytes = b"This is a secret message"

config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id)

kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

crypto_result = crypto.encrypt(kms_master_key_provider,
data_to_encrypt_bytes)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
```
The following examples show how to encrypt a file stream:

**Java**

```java
// Create Encryption file stream
FileInputStream in = new FileInputStream(srcFile);
OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
KmsMasterKeyProvider(kmsMasterKey);
OciCryptoInputStream encryptingStream =
ociCrypto.createEncryptingStream(kmsMasterKeyProvider, in);

// Write the encrypted data to file
FileOutputStream out = new FileOutputStream(srcFile + ".encrypted”);
IOUtils.copy(encryptingStream, out);
encryptingStream.close();
out.close();

// For decryption, no need to pass key info
KmsMasterKeyProvider kmsMasterKeyProvider = new
KmsMasterKeyProvider(authenticationProvider);
// Create the Decryption file stream.
in = new FileInputStream(srcFile + ".encrypted”);
OciCryptoInputStream decryptingStream =
ociCrypto.createDecryptingStream(kmsMasterKeyProvider, in);

// Return the plaintext data
out = new FileOutputStream(srcFile + ".decrypted”);
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
out.close();
```

**Python**

```python
import oci
import shutil
# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
file_to_encrypt = "/file/to/encrypt/message.txt"
output_encrypted_file = "/tmp/message.txt.encrypted"
output_decrypted_file = "/tmp/message.txt.decrypted"

# setup OCI KMS keys
config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id
)
kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)
```
# encrypt stream example
with open(output_encrypted_file, 'wb') as output_stream,
open(file_to_encrypt, 'rb') as stream_to_encrypt:
    with crypto.create_encryption_stream(
        kms_master_key_provider,
        stream_to_encrypt
    ) as encryption_stream:
        shutil.copyfileobj(encryption_stream, output_stream)

# decrypt stream example
with open(output_decrypted_file, 'wb') as output_stream,
open(output_encrypted_file, 'rb') as stream_toDecrypt:
    with crypto.create_decryption_stream(
        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)
Glossary

A

AD-specific subnet
A subnet that is specific to a particular availability domain (AD). Historically all subnets were AD-specific. Compare with regional subnets, which Oracle recommends over AD-specific subnets.

alarm
The trigger rule and query to evaluate and related configuration, such as notification details to use when the trigger is breached. Alarms passively monitor your cloud resources using metrics in Monitoring.

API key
A credential for securing requests to the Oracle Cloud Infrastructure REST API.

application (Application Migration)
A combination of the artifacts and configuration deployed on one or more service instances running in the source environment.

attach
Link a volume and instance together. Allows an instance to connect and mount the volume as a hard drive.

Attribute
An attribute describes a data item with a name and data type. For example, a column in a table or a field in a file.

auth token
Oracle Cloud Infrastructure-generated token you use to authenticate with third-party APIs, such as a Swift client.

availability domain
One or more isolated, fault-tolerant Oracle data centers that host cloud resources such as instances, volumes, and subnets. A region contains one or more availability domains.

B

backend set
A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy.

bare metal IaaS
A cloud infrastructure that allows you to utilize hosted physical hardware, as opposed to traditional software-based virtual machines, ensuring a high level of security and performance.

block storage volume
A virtual disk that provides persistent storage space for instances in the cloud.

bucket
A logical container for storing objects.
C

Category
A category is created in a glossary to group logically related business terms. You can create a category within a category to group your terms.

CHAP
Stands for Challenge-Handshake-Authentication-Protocol. It is a security protocol used by iSCSI for authentication between a volume and an instance.

Cloud Block Storage
A service that allows you to add block storage volumes to an instance in order to expand the available storage on that resource.

cloud network
A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

cluster network
A pool of high performance computing (HPC) instances that are connected with a high-bandwidth, ultra low-latency network.

compartment
A collection of related resources that can be accessed only by certain groups that have been given permission by an administrator in your organization.

Compute
A service that lets you provision and manage compute hosts, known as instances.

connect
Make an attached volume usable by an instance's guest OS.

CPE
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when setting up VPN Connect (an IPSec VPN) between Oracle and your on-premises network.

CPE Configuration Helper
A feature of the Oracle Console that generates information that a network engineer can use to configure the customer-premises equipment (CPE) at their end of a VPN connection.

cross-connect
Used with Oracle Cloud Infrastructure FastConnect, specifically if you're using a third-party provider or colocated with Oracle in a FastConnect location. A cross-connect is the physical cable connecting your existing network to Oracle in the FastConnect location.

cross-connect group
Used with Oracle Cloud Infrastructure FastConnect, specifically if you're using a third-party provider or colocated with Oracle in a FastConnect location. A cross-connect group is a link aggregation group (LAG) that contains at least one cross-connect.

customer-premises equipment
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when setting up VPN Connect (an IPSec VPN) between Oracle and your on-premises network.
D

Data Asset (Data Catalog and Data Integration)

Represents a data source, such as a database, an object store, a file or document store, a message queue, or an application.

Data Catalog Tags

Tags are free-form labels or keywords you create to be able to logically identify data objects. Tags help in metadata classification and discovery. You create tags for data assets, data entities, and attributes. Using tags, you can search for all data objects tagged with a specific tag name.

Data Entity (Data Catalog and Data Integration)

A data entity is a collection of data such as a database table or view, or a single logical file and normally has many attributes that describe its data.

data point (Monitoring service)

A timestamp-value pair for the specified metric. Example: 2018-05-10T22:19:00Z, 10.4

DB System

A dedicated bare metal instance running Oracle Linux, optimized for running one or more Oracle databases.
A DB System is a Database Service resource.

DHCP options

Configuration information that is automatically provided to the instances when they boot up.

dimension (Monitoring service)

A qualifier provided in a metric definition. Example: Resource identifier (resourceId), provided in the definitions of oci_computeagent metrics.

display name

A friendly name or description that helps you easily identify the resource.

DRG

An optional virtual router that you can add to your VCN to provide a path for private network traffic between your VCN and on-premises network.

DRG attachment

When you attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN), the result is a DRG attachment object. To detach the DRG, you delete that attachment object.

drift (Resource Manager)

Difference between the actual, real-world state of your infrastructure and the stack's last executed configuration.

dynamic group

A special type of IAM group that contains instances that match rules that you define (thus the membership can change dynamically as matching instances are terminated or launched). These instances act as "principal" actors and can make API calls to Oracle Cloud Infrastructure services according to IAM policies that you write for the dynamic group.

dynamic routing gateway

An optional virtual router that you can add to your VCN to provide a path for private network traffic between your VCN and on-premises network.
A glossary is a collection of business concepts in your company. Glossary constitutes of categories and business terms.

group
A collection of users who all need a particular type of access to a set of resources or compartment.

guest operating system
An operating system installed on a cloud instance.

guest OS
An operating system installed on a cloud instance.

Harvest
Process that extracts technical metadata from your connected data sources into your Data Catalog repository.
health check

A test to confirm the availability of backend servers.

I

IaaS

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

IAM

The service for controlling authentication and authorization of users who need to use your cloud resources.

Identity and Access Management Service

The service for controlling authentication and authorization of users who need to use your cloud resources. Also called "IAM".

identity provider

A service that provides identifying credentials and authentication for federated users.

IdP

Short for "identity provider", which is a service that provides identifying credentials and authentication for federated users.

image

A template of a virtual hard drive that determines the operating system and other software for an instance.

Infrastructure-as-a-Service

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

instance

A bare metal or virtual machine (VM) compute host. The image used to launch the instance determines its operating system and other software. The shape specified during the launch process determines the number of CPUs and memory allocated to the instance.

instance wallet

An Autonomous Database instance wallet contains only credentials and keys for a single database instance.

internet gateway

An optional virtual router that you can add to your VCN. It provides a path for network traffic between your VCN and the internet.

interval (Monitoring service)

The time window used to convert the given set of raw data points. Example: 5 minutes

IPSec connection

The secure connection between a dynamic routing gateway (DRG) and customer-premises equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components forming a site-to-site VPN between a virtual cloud network (VCN) and your on-premises network.

IPv6

An object that contains an IPv6 address and related properties. Currently IPv6 addressing is supported only in the US Government Cloud. Only instances in IPv6-enabled VCNs and IPv6-enabled subnets can have IPv6 addresses.
Glossary

IQN
A unique ID assigned to an iSCSI device. Used when connecting a volume to an instance.

iSCSI
A TCP/IP based standard used for communication between a volume and attached instance.

iSCSI Qualified Name
A unique ID assigned to an iSCSI device. Used when connecting a volume to an instance.

K
key pair
A security mechanism consisting of a public key and a private key. Required (for example) for Secure Shell (SSH) access to an instance.

L
listener
An entity that checks for incoming traffic on the load balancer's public floating IP address.

local peering gateway
A component on a VCN for routing traffic to a locally peered VCN. "Local" peering means the two VCNs are in the same region. Compare with a remote peering connection.

local VCN peering
The process of connecting two VCNs in the same region so that their resources can communicate without routing the traffic over the internet or through your on-premises network.

LPG
A component on a VCN for routing traffic to a locally peered VCN. "Local" peering means the two VCNs are in the same region. Compare with a remote peering connection.

M
message (Notifications and Monitoring services)
An alert published to all subscriptions in the specified topic. Each message is delivered at least once per subscription.

metric
(Monitoring service) A measurement related to health, capacity, or performance of a given resource.
Example: CpuUtilization

metric definition (Monitoring service)
A set of references, qualifiers, and other information provided by a metric namespace for a given metric.

metric namespace (Monitoring service)
Indicator of the resource, service, or application that emits the metric. Provided in the metric definition.
Example: oci_computeagent

metric stream (Monitoring service)
An individual set of aggregated data for a metric. Typically specific to a resource.
migration (Application Migration)
The end-to-end workflow of moving an application from a source environment to Oracle Cloud Infrastructure.

Monitoring Query Language (Monitoring service)
The syntax used for metric and alarm queries.

Mount Point
A directory from which a client may access a remote File Storage Service file system.

Mount Target
An NFS endpoint that allows a file system to be accessed by clients.

MQL (Monitoring service)
Monitoring Query Language. The syntax used for metric and alarm queries. In the Console, MQL syntax of queries is displayed in Advanced Mode.

N
NAT gateway
An optional virtual router that you can add to your VCN to perform Network Address Translation (NAT). A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

Network security group
One method for implementing security rules in a VCN. A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources. See also security rules and security lists.

Network source
A group of IP addresses that can be used in policy to restrict access.

Notification destination (Monitoring service)
Protocol and other details for sending messages when the alarm transitions to another state, such as from "OK" to "FIRING."

NSG
One method for implementing security rules in a VCN. A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources. See also security rules and security lists.

O
Object
Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

OCID
An Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). This ID is included as part of the resource's information in both the Console and API.

One-time password
A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.
**Oracle Cloud Identifier**

An Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). This ID is included as part of the resource's information in both the Console and API.

**OTP**

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.

**P policy**

An IAM document that specifies who has what type of access to your resources. It is used in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named "policy" document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

**policy statement**

Policies can contain one or more individual statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

**primary IP**

The private IP that is automatically created and assigned to a VNIC during creation.

**primary VNIC**

The VNIC that is automatically created and attached to an instance during launch.

**private IP**

An object that contains a private IPv4 address and related properties such as a hostname for DNS. Each instance automatically comes with a primary private IP, and you can add secondary ones.

**private peering**

One of the ways to use FastConnect. Private peering lets you extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud, or a lift and shift scenario). Communication across the connection is with IPv4 private addresses (typically RFC 1918).

**private subnet**

A subnet in which instances are not allowed to have public IP addresses

**private virtual circuit**

A FastConnect virtual circuit that supports private peering.

**public IP**

An object that contains a public IP address and related properties. You control whether each private IP on an instance has an assigned public IP. There are two types: reserved public IPs and ephemeral public IPs.

**public peering**

One of the way to use FastConnect. Public peering lets your on-premises network access public services in Oracle Cloud Infrastructure without using the internet. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, or public load balancers in your VCN. Communication across the connection is with IPv4 public IP addresses. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection.

**public subnet**

A subnet in which instances are allowed to have public IP addresses. When you launch an instance in a public subnet, you specify whether the instance should have a public IP address.
**public virtual circuit**
A FastConnect virtual circuit that supports public peering.

**Q**

**query (Monitoring service)**
The expression to evaluate for returning aggregated data. A valid query includes a metric, statistic, and interval. In the Console, you can view a query in Basic Mode or Advanced Mode. The latter displays the Monitoring Query Language (MQL) syntax.

**R**

**realm**
A logical collection of regions. Realms are isolated from each other and do not share any data. Your tenancy exists in a single realm and can access the regions that belong to that realm.

**region**
A collection of availability domains located in a single geographic location.

**regional subnet**
A subnet that spans all availability domains (ADs) in the region. Oracle recommends using regional subnets because they are more flexible and make it easier to implement failover across ADs. Compare with AD-specific subnets.

**regional wallet**
An Autonomous Database regional wallet contains credentials and keys for all Autonomous Databases in a specified region.

**remote peering connection**
A component on a dynamic routing gateway (DRG) for routing traffic to a remotely peered VCN. "Remote" peering means the two VCNs are in different regions. Compare with a local peering gateway.

**remote VCN peering**
The process of connecting two VCNs in different regions so that their resources can communicate without routing their traffic over the internet or through your on-premises network.

**reserved public IP**
A public IP address (and related properties) that you create in your tenancy and assign to your instances in a given region as you like. It persists in your tenancy until you delete it. It can be assigned to any private IP on a given VNIC, not just the primary private IP. Compare with ephemeral private IP.

**resolution (Monitoring service)**
The period between time windows, or the regularity at which time windows shift. Example: 1 minute

**resource**
The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure.

**route table**
Virtual route table for your VCN that provides mapping for the traffic from subnets via gateways to external destinations.

**RPC**
A component on a dynamic routing gateway (DRG) for routing traffic to a remotely peered VCN. "Remote" peering means the two VCNs are in different regions. Compare with a local peering gateway.
S

**secondary IP address**
An additional private IP you've added to a VNIC on an instance. Each VNIC automatically comes with a primary private IP that cannot be removed.

**secondary VNIC**
An additional VNIC you've added to an instance. Each instance automatically comes with a primary VNIC that cannot be removed.

**security list**
One method for implementing security rules in a VCN. A security list consists of security rules that apply to all resources in any subnet that uses the security list. See also security rules and network security groups.

**security rule**
Virtual firewall rules for your VCN. Each security rule specifies a type of ingress or egress traffic allowed in or out of a resource or VNIC. Also see network security groups and security lists.

**service gateway**
An optional virtual router that you can add to your VCN. The gateway enables on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

**shape**
A template that determines the number of CPUs, amount of memory, and other resources that are allocated to an instance.

**source (Application Migration)**
The environment from which the application is being migrated.

**statement**
Policies can contain one or more individual statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

**statistic**
The aggregation function applied to the given set of raw data points. Example: SUM

**subnet**
Subdivision of your VCN used to separate your network into multiple smaller, distinct networks.

**subscription (Notifications service)**
An endpoint for a topic; typically a URL or email address. Published messages are sent to each subscription for a topic.

**suppression (Monitoring service)**
A configuration to avoid publishing messages during the specified time range. Useful for suspending alarm notifications during system maintenance.

**Swift password**
(Deprecated. Use an auth token to authenticate with your Swift client.) Swift is the OpenStack object store service. A Swift password enables you to use an existing Swift client with Oracle Cloud Infrastructure Object Storage.
T

tenancy

The root compartment that contains all of your organization’s compartments and other Oracle Cloud Infrastructure cloud resources.

tenant

The name assigned to a particular company's or organization's overall environment. Users provide their tenant when signing in to the Console.

Term

Terms are the actual definitions of business concepts as agreed upon by different business stakeholders in your company. You use terms to organize your data entities and attributes.

topic (Notifications service)

A communication channel for sending messages to the subscriptions in the topic.

transit routing

A network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with a FastConnect private virtual circuit or VPN Connect, and then configure the VCN routing so that traffic transits through the VCN to its destination beyond the VCN. You can use transit routing to access multiple VCNs from your on-premises network over a single FastConnect or VPN Connect. Or you can use it to give your on-premises network private access to Oracle services so that on-premises hosts use their private IP addresses and the traffic does not go over the internet.

trigger rule (Monitoring service)

The condition that must be met for the alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

U

user

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources.

V

VCN

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual circuit

Used with Oracle Cloud Infrastructure FastConnect. An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure.

virtual cloud network

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual machine

A software-based emulation of a full computer that runs within a physical host computer.
**virtual network interface card**

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources also automatically get a VNIC upon creation (examples: load balancers, DB systems).

**VM**

A software-based emulation of a full computer that runs within a physical host computer.

**VNIC**

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources also automatically get a VNIC upon creation (examples: load balancers, DB systems).

**volume**

A detachable block storage device that allows you to dynamically expand the storage capacity of an instance.

**work request**

An object that reports on the current state of an asynchronous service request.
You can find the Oracle Cloud Infrastructure Release Notes online.
