A VNIC might be in a different compartment from your compute instance. Either grant VNIC permissions for the entire tenancy or for the specific VNIC compartment:

```
Allow service vulnerability-scanning-service to read vnics in compartment <vnic_compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <vnic_compartment_name>
```

To create a host scan target that uses agent-based scanning, the user must have the manage instance permission for the target instances.

```
Allow group <group_name> to manage instances in compartment <compartment_name>
```

See Policy Details for the Core Services.

**Creating a Host Scan Recipe**

Use the Console to create a host scan recipe.

All recipes in the Scanning service are the **Compute** configuration type.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Scan Recipes**.
Vulnerability Scanning

2. Open the **Create Scan Recipe** dialog.
   - If no scan recipes exist, the **Welcome** page is displayed, which includes an introduction to the service.
     Click **Create Scan Recipe**, and then select the **Compartment** in which you want to create the recipe.
   - If scan recipes already exist, select the **Compartment** in which you want to create the recipe, and then click **Create**.

3. Enter a **Name** for the recipe.
   Avoid entering confidential information.

4. Select the level of **Port Scanning** for this recipe.
   - **Standard** - Check the 1000 most common port numbers.
   - **Light** (default) - Check the 100 most common port numbers.
   - **None** - Do not check for open ports.

   The Scanning service uses a network mapper that searches your public IP addresses. See Ports that are Scanned on page 5750.

5. (Optional) Disable **Agent Based Scanning** if you don't want to activate the Vulnerability Scanning agent plugin on the targets assigned to this recipe.

   The Vulnerability Scanning agent runs on the selected targets and checks the OS configuration of targets for vulnerabilities, such as missing patches.

   If you enable both **Agent Based Scanning** and **Port Scanning**, then the agent also checks for open ports that are not accessible from public IP addresses.

   **Note:**
   If you disable both **Port Scanning** and **Agent Based Scanning** in this recipe, then the Scanning service doesn't scan any targets assigned to this recipe.

6. (Optional) If **Agent Based Scanning** is enabled, then configure more agent parameters.
   a) Disable **CIS Benchmark Scanning** if you don't want the agent to check targets for compliance with industry-standard benchmarks published by the Center for Internet Security (CIS).
   b) If **CIS Benchmark Scanning** is enabled, then select the **CIS Benchmark Profile** for this recipe.
      - **Strict** - If more than 20% of the CIS benchmarks fail, then the target is assigned a risk level of **Critical**.
      - **Medium** (default) - If more than 40% of the CIS benchmarks fail, then the target is assigned a risk level of **High**.
      - **Lightweight** - If more than 80% of the CIS benchmarks fail, then the target is assigned a risk level of **High**.

7. Configure the **Schedule** for the recipe.
   The schedule controls how frequently the targets assigned to this recipe are scanned.
   Choose from **Daily** or **Weekly**.

8. (Optional) Assign tags to the recipe.
   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   To add a defined tag, you must have permissions to use the **Tag Namespace**.
   For more information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

9. Click **Create**.
   After creating a recipe, you can create scan targets and associate them with the recipe. See Creating a Host Target on page 5741.
## Updating a Host Scan Recipe

Use the Console to update an existing host scan recipe.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Scan Recipes**.
2. Select the **Compartment** that contains your recipe.
3. Click the name of the recipe.
4. Click **Edit**.
5. Modify any of these settings for your recipe.
   - **Name** (Avoid entering confidential information)
   - **Port Scanning**
   - **Agent Based Scanning**
   - **CIS Benchmark Scanning**
   - **CIS Benchmark Profile**
   - **Schedule**

The Vulnerability Scanning agent checks the OS configuration of targets for vulnerabilities, such as missing patches. The agent can also check targets for compliance with industry-standard benchmarks published by the **Center for Internet Security** (CIS).

The schedule controls how frequently the targets assigned to this recipe are scanned.

6. Click **Save Changes**
7. (Optional) Click **Tags** if you want to manage the tags for this recipe.

   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.

   To add a defined tag, you must have permissions to use the **Tag Namespace**.

   For more information about tagging, see **Resource Tags**. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

## Moving a Scan Recipe to a Different Compartment

Use the Console to move a scan recipe from one compartment to another.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Scan Recipes**.
2. Select the **Compartment** that contains your recipe.
3. Click the name of the recipe.
4. Click **Move Resource**.
5. Choose the destination compartment.
6. Click **Move Resource**.

After you move the recipe to the new compartment, inherent policies apply immediately and affect access to the recipe through the Console. For more information, see **Managing Compartments**.

## Deleting a Scan Recipe

Use the Console to delete a scan recipe.

To delete a scan recipe, it must not be associated with any scan targets. See **Deleting a Target** on page 5743.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Scan Recipes**.
2. Select the **Compartment** that contains your recipe.
3. Click the name of the recipe.
4. Click **Delete**.
5. When prompted for confirmation, click **Delete**.
Using the CLI

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list all host scan recipes in a compartment:

    oci vulnerability-scanning host scan recipe list --compartment-id <compartment_ocid>

For example:

    oci vulnerability-scanning host scan recipe list --compartment-id ocid1.compartment.oc1..exampleuniqueID

To view the details of a specific host scan recipe:

    oci vulnerability-scanning host scan recipe get --host-scan-recipe-id <recipe_ocid>

For example:

    oci vulnerability-scanning host scan recipe get --host-scan-recipe-id ocid1.vsshostscanrecipe.oc1..exampleuniqueID

To create a host scan recipe:

    oci vulnerability-scanning host scan recipe create --display-name <name> --compartment-id <compartment_ocid> --agent-settings '{"scanLevel": "<agent_scan_level>")' --cis-benchmark-settings '{"scanLevel": "<CIS_scan_level>")' --port-settings '{"scanLevel": "<port_scan_level>")' --schedule '{"type": "<daily_or_weekly>")'

For example:

    oci vulnerability-scanning host scan recipe create --display-name MyRecipe --compartment-id ocid1.compartment.oc1..exampleuniqueID --agent-settings '{"scanLevel": "STANDARD")' --cis-benchmark-settings '{"scanLevel": "MEDIUM")' --port-settings '{"scanLevel": "STANDARD")' --schedule '{"type": "DAILY")'

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see SDKs and the CLI.

Use the following operations to manage host scan recipes:

- ListHostScanRecipes
- GetHostScanRecipe
- CreateHostScanRecipe
- UpdateHostScanRecipe
- ChangeHostScanRecipeCompartment
- DeleteHostScanRecipe

Note:
The HostEndpointProtectionSettings have no effect and are reserved for future use.
Managing Host Targets

Use Oracle Vulnerability Scanning Service to create and manage host targets and to assign them to scan recipes. A host target is a collection of compute instances that you want routinely scanned for security vulnerabilities.

The Scanning service detects vulnerabilities in the following platforms and using the following vulnerability sources.

<table>
<thead>
<tr>
<th>Platform</th>
<th>National Vulnerability Database (NVD)</th>
<th>Open Vulnerability and Assessment Language (OVAL)</th>
<th>Center for Internet Security (CIS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Linux</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>CentOS</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Windows</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

You have two options when selecting the compute instances for a host target.

- Scan one or more specific compute instances within a compartment.
- Scan all compute instances within a compartment and its subcompartments.

If you create a target for the root compartment, then all compute instances in the entire tenancy are scanned.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyInstance are in CompartmentB.

Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

Allow group SecurityAdmins to manage vss-family in compartment SalesApps

See Scanning IAM Policies on page 5763.

**Required IAM Policy for Host Scanning**

If you enable agent-based scanning in your recipe, then you must give the Scanning service permission to deploy the Oracle Cloud Agent to your target compute instances.

The Scanning service must also be able to read the VNIC (virtual network interface card) on your target compute instances.
Vulnerability Scanning

To grant this permission for all compute instances in the entire tenancy:

Allow service vulnerability-scanning-service to manage instances in tenancy
Allow service vulnerability-scanning-service to read compartments in tenancy
Allow service vulnerability-scanning-service to read vnics in tenancy
Allow service vulnerability-scanning-service to read vnic-attachments in tenancy

To grant this permission for all compute instances in a specific compartment:

Allow service vulnerability-scanning-service to manage instances in compartment <compartment_name>
Allow service vulnerability-scanning-service to read compartments in compartment <compartment_name>
Allow service vulnerability-scanning-service to read vnics in compartment <compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <compartment_name>

A VNIC might be in a different compartment from your compute instance. Either grant VNIC permissions for the entire tenancy or for the specific VNIC compartment:

Allow service vulnerability-scanning-service to read vnics in compartment <vnic_compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <vnic_compartment_name>

To create a host scan target that uses agent-based scanning, the user must have the manage instance permission for the target instances.

Allow group <group_name> to manage instances in compartment <compartment_name>

See Policy Details for the Core Services.

Creating a Host Target

Use the Console to create a host scan target.

At least one host scan recipe must be in your tenancy before creating a target. See Managing Host Scan Recipes on page 5735.

If your host scan recipe is configured for Agent Based Scanning, you must give the Scanning service permission to deploy the agent before creating a target. See Required IAM Policy for Host Scanning on page 5736.

A compute instance is associated with a VCN (virtual cloud network) and a subnet. If a compute instance in your target is on a private subnet or has no public IP address, the VCN must include a service gateway and a route rule for the service gateway. See Access to Oracle Services: Service Gateway.

2. Select the Compartment in which you want to create the target.

   Note:
   The compute instances that you assign to this target can be in a different compartment than the target.

3. Click Create.
   All targets in the Scanning service are the Compute configuration type.
4. Enter a Name and Description for the target.
   Avoid entering confidential information.
5. Select a **Scan Recipe** for the target.
6. Select the **Target Compartment** that contains the compute instances you want to scan.
7. Choose compute instances for this target.
   - **All compute instances in the selected target compartment and its subcompartments**
   - **Specific compute instances in the selected target compartment** - Select individual compute instances.

You can't create a target with a compartment or a compute instance that is already specified in another target. However, multiple targets can scan the same compute instance.

### Note:
Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

8. (Optional) Assign tags to the target.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   - To add a defined tag, you must have permissions to use the **Tag Namespace**.
   - For more information about tagging, see **Resource Tags**. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

9. Click **Create**.

After creating a target, the Scanning service checks your compute instances for security vulnerabilities and open ports based on the parameters and schedule that is configured in the recipe. You can view the results of these scans in reports:
- **Host Scans** on page 5744
- **Host Vulnerabilities Reports** on page 5752

You can also use Cloud Guard to view the results of your scans. See **Scanning with Cloud Guard** on page 5757.

### Updating a Host Target
Use the Console to update an existing host scan target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Edit**.
5. Modify any of these settings for your target.
   - **Name**
   - **Description**
   - **Scan Recipe**
   - **Target Compartment**

   Avoid entering confidential information.

6. Update the compute instances for this target.
   - **All compute instances in the selected target compartment and its subcompartments**
   - **Specific compute instances in the selected target compartment** - Select individual compute instances

   You can't update a target with a compartment or a compute instance that is already specified in another target. However, multiple targets can scan the same compute instance.

7. Click **Save Changes**
8. (Optional) Click **Tags** if you want to manage the tags for this target.
   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   To add a defined tag, you must have permissions to use the **Tag Namespace**.
   For more information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

### Viewing the Compute Instances for a Host Target
Use the Console to view the compute instances associated with an existing host scan target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
   The **Compute Instances** table displays.
4. Click the name of a specific compute instance to view its details.

### Moving a Target to a Different Compartment
Use the Console to move a scan target from one compartment to another.

Moving a target does not also move the compute instances in the target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Move Resource**.
5. Choose the destination compartment.
6. Click **Move Resource**.

After you move the target to the new compartment, inherent policies apply immediately and affect access to the target through the Console. For more information, see Managing Compartments.

### Deleting a Target
Use the Console to delete a target.

Deleting a target does not delete the compute instances in the target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Delete**.
5. When prompted for confirmation, click **Delete**.

### Using the CLI
For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list all host scan targets in a compartment:

```
oci vulnerability-scanning host scan target list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host scan target list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```
To view the details of a specific host scan target:

```
oci vulnerability-scanning host scan target get --host-scan-target-id <target_ocid>
```

For example:

```
oci vulnerability-scanning host scan target get --host-scan-target-id ocid1.vsshostscantarget.oc1..exampleuniqueID
```

To create a host scan target:

```
oci vulnerability-scanning host scan target create --display-name <name> --description "<description>" --compartment-id <create_in_compartment_ocid> --host-scan-recipe-id <recipe_ocid> --target-compartment-id <target_compartment_ocid> --instance-ids <compute_instance_ocids>
```

For example, to scan all compute instances in a compartment:

```
oci vulnerability-scanning host scan target create --display-name MyTarget --description "All instances in compartment ABC" --compartment-id ocid1.compartment.oc1..exampleuniqueID1 --host-scan-recipe-id ocid1.vsshostscanrecipe.oc1..exampleuniqueID --target-compartment-id ocid1.compartment.oc1..exampleuniqueID2
```

**Using the API**

For information about using the API and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see SDKs and the CLI.

Use the following operations to manage host scan targets:

- ListHostScanTargets
- GetHostScanTarget
- CreateHostScanTarget
- UpdateHostScanTarget
- ChangeHostScanTargetCompartment
- DeleteHostScanTarget

**Host Scans**

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. Use host scans to identify security vulnerabilities in your compute instances like open ports, critical OS patches, and failed benchmark tests.

At least one host target must exist before any host scans are created. See Managing Host Targets on page 5740.

The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyInstance are in CompartmentB.

The Scanning service categorizes problems by these risk levels.
Vulnerability Scanning

- **Critical** - the most serious problems detected, which should be your highest priority to resolve.
- **High** - the next most serious problems.
- **Medium** - problems that are a bit less serious.
- **Low** - problems that are still less serious.
- **Minor** - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

Allow group SecurityAdmins to manage vss-family in compartment SalesApps

See Scanning IAM Policies on page 5763.

**Viewing Host Scans**

Use the Console to browse and search for host scans.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. (Optional) Click the table columns to sort the host scans by:
   - **Type**
   - **Risk Level**
   - **Issues Found**
   - **Operating System**
   - **Scan Completed date**

   All reports in the Scanning service are type **Compute**.

4. To view the host scan’s details, click its name.

A host scan includes metrics, open ports, vulnerabilities, and benchmarks for a specific compute instance.

**Viewing Metrics for a Host Scan**

Use the Console to view the metrics for a specific compute instance that was scanned.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. Click the name of the host scan.
4. Click **Metrics** if not already selected.

   The **Vulnerabilities** panel shows the number of security vulnerabilities of each risk level that were detected during the most recent scan of this compute instance.

**Viewing Open Ports in a Host Scan**

Use the Console to view details about the open ports that were detected on a specific compute instance that was scanned.

Ports that are unintentionally left open might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. Click the name of the host scan.
4. Click Open Ports.
   • The first panel shows the number of open ports that were detected on each Virtual Network Interface Card (VNIC) in this compute instance.

   A VNIC (virtual network interface card) enables a compute instance to connect to a specific VCN (virtual cloud network). You can mouseover the name of a VNIC to view its details.

   • The second panel shows the specific port numbers that were detected in this compute instance.
5. (Optional) Select one or more VNIC(s) to show only those ports that were detected on the selected VNICs.

Viewing Vulnerabilities in a Host Scan

Use the Console to view details about potential OS vulnerabilities that were detected on a specific compute instance.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

2. Select the Compartment in which you created the target.
3. Click the name of the host scan.
4. Click Vulnerabilities.

   The following details are shown for each issue that was detected in this compute instance:
   • Issue ID
   • Risk Level
   • Issue Title
   • Last Detected
   • First Detected
   • Hosts Impacted
5. Click an Issue ID to view more details about a specific vulnerability.

Because Oracle Linux and other enterprise Linux distributions back ports security fixes to the version that is included in a given major release, the Scanning service can incorrectly report vulnerabilities on OS packages that have already been fixed. Additionally, the Scanning service can incorrectly report Oracle Linux vulnerabilities that have been fixed by Ksplice. See Troubleshooting the Scanning Service on page 5759.

You can use vulnerabilities reports to browse all vulnerabilities that the Scanning service detected.

Viewing CIS Benchmarks in a Host Scan

Use the Console to view the results of CIS benchmark testing on a specific compute instance.

The Center for Internet Security (CIS) publishes best practices for devices and operating systems, which result from the collaboration of cybersecurity professionals and subject matter experts. The Scanning service checks hosts for compliance with the section 5 (Access, Authentication, and Authorization) benchmarks defined for Distribution Independent Linux.

2. Select the Compartment in which you created the target.
3. Click the name of the host scan.

   Locate the number of CIS Benchmarks Passed.
4. Click **CIS Benchmarks**.

   The following details are shown for each CIS benchmark that the Scanning service tested on this compute instance:

   - **Benchmark ID**
   - **Result** - pass or fail
   - **Summary**

5. You can learn more about a specific benchmark by downloading the document for **Distribution Independent Linux**.

**Exporting a Host Scan**

Use the Console to export all host scans as a file in comma-separated value (CSV) format for offline analysis.

Example output:

```plaintext
resultId,instanceId,compartmentId,highestProblemSeverity,operatingSystem,startDate,endDate,problemCount
ocid1.vsshostscanresult.example123,ocid1.instance.example123,ocid1.compartment.example123,MEDIUM,linux,2020-12-21T17:44:58Z,2020-12-21T17:44:59Z,2
```

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. Click **Export**.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see **CLI Help**.

To list all host scans (agent scans, port scans, and CIS benchmark scans) in a compartment:

```plaintext
oci vulnerability-scanning host scan result agent list --compartment-id <compartment_ocid>
oci vulnerability-scanning host scan result port list --compartment-id <compartment_ocid>
oci vulnerability-scanning host scan result cis-benchmark list --compartment-id <compartment_ocid>
```

For example:

```plaintext
oci vulnerability-scanning host scan result agent list --compartment-id ocid1.compartment.oc1..exampleuniqueID
oci vulnerability-scanning host scan result port list --compartment-id ocid1.compartment.oc1..exampleuniqueID
oci vulnerability-scanning host scan result cis-benchmark list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific host agent scan:

```plaintext
oci vulnerability-scanning host scan result agent get --host-agent-scan-result-id <agent_scan_ocid>
```

For example:

```plaintext
oci vulnerability-scanning host scan result agent get --host-agent-scan-result-id ocid1.vsshostscanresult.oc1..exampleuniqueID
```

**Using the API**

For information about using the API and signing requests, see **REST APIs** and **Security Credentials**.

For information about SDKs, see **SDKs and the CLI**.
Use the following operations to view host scans, port scans, and CIS benchmark scans:

- ListHostAgentScanResults
- GetHostAgentScanResult
- ExportHostAgentScanResultCsv
- ListHostPortScanResults
- GetHostPortScanResult
- ListHostCisBenchmarkScanResults
- GetHostCisBenchmarkScanResult

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The HostEndpointProtectionScanResult APIs have no effect and are reserved for future use.</td>
</tr>
</tbody>
</table>

### Port Scans

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. This service helps identify ports in your compute instances that are unintentionally left open and might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.

The Scanning service performs port scans only if all of the following are true:

- At least one host target exists. See Managing Host Targets on page 5740.
- At least one host target is associated with a scan recipe that enables port scanning. See Updating a Host Scan Recipe on page 5738.

The Scanning service offers two types of port scanning:

- A network mapper searches your public IP addresses for open ports.
- If agent-based scanning is enabled in the scan recipe, then the agent also checks for open ports that are not accessible from public IP addresses.

The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyInstance are in CompartmentB.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

```
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
```

See Scanning IAM Policies on page 5763.
**Viewing Port Scans**

Use the Console to view details about the open ports that were detected on a specific compute instance that was scanned.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Port Scans**.
2. Select the **Compartment** in which you created the target.
3. (Optional) Click the table columns to sort the port scans by:
   - Name
   - Number of Open Ports
   - Scan Completed date
4. To view the details of a port scan, click its name.
   - The first panel shows the number of open ports that were detected on each **Virtual Network Interface Card (VNIC)** in this compute instance.
     A **VNIC (virtual network interface card)** enables a compute instance to connect to a specific **VCN (virtual cloud network)**. You can mouseover the name of a VNIC to view its details.
   - The second panel shows the following details for each port number that was detected in this compute instance.
     - Protocol (TCP or UDP)
     - Typical service that uses this port
     - VNIC
     - Public or private IP address that the port is listening on
5. (Optional) Select one or more **VNIC(s)** to show only those ports that were detected on the selected VNICS.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see **CLI Help**.

To list all port scans in a compartment:

```
oci vulnerability-scanning host scan result port list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host scan result port list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific port scan:

```
oci vulnerability-scanning host scan result port get --host-port-scan-result-id <port_scan_ocid>
```

For example:

```
oci vulnerability-scanning host scan result port get --host-port-scan-result-id ocid1.vssportscanresult.oc1..exampleuniqueID
```

**Using the API**

For information about using the API and signing requests, see **REST APIs** and **Security Credentials**.

For information about SDKs, see **SDKs and the CLI**.

Use the following operations to view port scans:

- **ListHostPortScanResults**
**Vulnerability Scanning**

- **GetHostPortScanResult**

**Ports that are Scanned**
Lists the top 100 and top 1000 ports that Vulnerability Scanning scans.

Host Vulnerabilities Reports

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. Use vulnerabilities reports to identify security issues in your compute instances like critical OS patches.

At least one host target must exist before any vulnerabilities reports are created. See Managing Host Targets on page 5740.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

• The compute instance MyInstance is in CompartmentA.
• MyInstance is specified in Target1.
• Target1 is in CompartmentB.
• All reports related to MyInstance are in CompartmentB.

The Scanning service categorizes problems by these risk levels.

• Critical - the most serious problems detected, which should be your highest priority to resolve.
• High - the next most serious problems.
• Medium - problems that are a bit less serious.
• Low - problems that are still less serious.
• Minor - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

Allow group SecurityAdmins to manage vss-family in compartment SalesApps

See Scanning IAM Policies on page 5763.

Viewing Host Vulnerabilities Reports

Use the Console to browse and search for vulnerabilities reports.

1. Open the navigation menu and click Identity & Security. Under Scanning, click Vulnerability Reports.
2. Select the Compartment in which you created the target.
3. (Optional) Click the table columns to sort the reports by:
   • Risk Level
   • Issue Title
   • Last Detected
   • First Detected
   • Hosts Impacted
4. To view details about a vulnerability, click a report's CVE ID.

A vulnerabilities report includes details about the affected hosts and CVEs.
Vulnerability Scanning

Viewing the Affected Hosts in a Vulnerabilities Report
Use the Console to view details about the compute instances on which a specific vulnerability was detected.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.
2. Select the **Compartment** in which you created the target.
3. To view details about a vulnerability, click a report's **CVE ID**.

   The **Hosts** section lists the compute instances that are affected by the selected vulnerability.
   
   • To view more details about an affected compute instance, click the instance's name.
   • To view more details about the scanning results for an instance, click the name of a host scan report.

   The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

A host scan includes **metrics**, **open ports**, and **benchmarks** for a specific compute instance.

Viewing the CVE in a Vulnerabilities Report
Use the Console to learn more information about a specific vulnerability, such as the affected OS packages.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.
2. Select the **Compartment** in which you created the target.
3. To view details about a vulnerability, click a report's **CVE ID**.
4. From the report's details, click the **CVE ID** or **Related CVE ID**.

Exporting a Vulnerabilities Report
Use the Console to export all vulnerabilities reports as a file in comma-separated value (CSV) format for offline analysis.

Example output:

```
resultId,compartmentId,cveId,severity,state,title,lastDetected,firstDetected,hostCount
```

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.
2. Select the **Compartment** in which you created the target.
3. Click **Export**.

Using the CLI
For information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/usingapi.htm). For a complete list of flags and options available for CLI commands, see [CLI Help](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/usingapi.htm).

To list all vulnerabilities reports in a compartment:

```
oci vulnerability-scanning host vulnerability list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host vulnerability list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific vulnerability report:

```
oci vulnerability-scanning host vulnerability get --host-vulnerability-id <vulnerability_ocid>
```
Vulnerability Scanning

For example:

```
oci vulnerability-scanning host vulnerability get --host-vulnerability-id ocid1.vsshostvulnerability.oc1..exampleuniqueID
```

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) and [Security Credentials](#).

For information about SDKs, see [SDKs and the CLI](#).

Use the following operations to view reports:

- ListVulnerabilities
- GetVulnerability
- ListVulnerabilityImpactedHosts
- ExportHostVulnerabilityCsv

**Note:**

ListVulnerabilities includes vulnerabilities detected in both hosts and container images. To list only host vulnerabilities, use ListHostVulnerabilities.

**Scanning Images**

Use Oracle Vulnerability Scanning Service to create recipes and targets that scan images in Oracle Cloud Infrastructure Registry for potential security vulnerabilities.

**Note:**

You can configure image scanning and view results using:

- The Container Registry Console - see [Using Oracle Cloud Infrastructure Registry to Scan Images](#) on page 5755
- The Scanning API or CLI

Oracle Cloud Infrastructure Registry makes it easy to share and manage development artifacts like Docker images by storing them in repositories. A repository is a named collection of related images that are grouped for convenience. During the deployment of an application to a Kubernetes cluster, one or more images can be pulled from a repository to start containers on the cluster.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

The results of an image scan include the specific vulnerabilities in the CVE database that were detected in the image repository.

The Scanning service saves the results for an image repository in the same compartment as the repository's Scanning target.

Consider the following example.

- The repository MyRepo in Container Registry is in CompartmentA.
- MyRepo is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyRepo are in CompartmentB.
**Vulnerability Scanning**

**Required IAM Policy**
To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

```plaintext
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
```

See Scanning IAM Policies on page 5763.

**Required IAM Policy for Image Scanning**
You must give the Scanning service permission to pull images from Oracle Cloud Infrastructure Registry.

To grant this permission for all images in the entire tenancy:

```plaintext
allow service vulnerability-scanning-service to read repos in tenancy
allow service vulnerability-scanning-service to read compartments in tenancy
```

To grant this permission for all images in a specific compartment:

```plaintext
allow service vulnerability-scanning-service to read repos in compartment <compartment-name>
allow service vulnerability-scanning-service to read compartments in compartment <compartment_name>
```

**Using Oracle Cloud Infrastructure Registry to Scan Images**
Use Oracle Cloud Infrastructure Registry to quickly configure image scanning for your repositories.

When you create a new repository, image scanning is enabled by default on the repository. Every time an image is pushed to the repository, it is scanned for security vulnerabilities in the CVE database. Oracle Cloud Infrastructure Registry automatically rescans any images in the repository that have changed since the previous scan. You can also disable image scanning on a particular repository.

See Scanning Images for Vulnerabilities.

**Using the CLI**
Use the Scanning CLI to scan container images in Oracle Cloud Infrastructure Registry.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

1. Create a container scan recipe.

   ```plaintext
   oci vulnerability-scanning container scan recipe create --display-name <name> --compartment-id <compartment_ocid> --scan-settings "{"scanLevel": "STANDARD"}"
   ```
   
   Example:

   ```plaintext
   oci vulnerability-scanning container scan recipe create --display-name MyRecipe --compartment-id ocid1.compartment.oc1..exampleuniqueID --scan-settings "{"scanLevel": "STANDARD"}"
   ```
2. Create a container scan target.

```
oci vulnerability-scanning container scan target create --display-name <name> --compartment-id <create_in_compartment_ocid> --container-scan-recipe-id <recipe_ocid> --target-registry '{"type": "OCIR", "url": "https://<region_key>.ocir.io", "compartmentId": "<repository_compartment_ocid>", "repositories": ["<repository_name>"]}'
```

<region_key> is the key for the Oracle Cloud Infrastructure Registry region you're using. See Availability by Region.

For repositories, you can provide a list of repository names. If repositories is not specified, then all repositories in the compartment are scanned.

Example:

```
oci vulnerability-scanning container scan target create --display-name "MyTarget" --compartment-id ocid1.compartment.oc1..exampleuniqueID --container-scan-recipe-id ocid1.vsscontainerscanrecipe.oc1..exampleuniqueID --target-registry '{"type": "OCIR", "url": "https://syd.ocir.io", "compartmentId": "ocid1.compartment.oc1..exampleuniqueID", "repositories": ["myrepo"]}'
```

3. View a list of all container scan results in a target compartment.

```
oci vulnerability-scanning container scan result list --compartment-id <compartment_ocid>
```

Example:

```
oci vulnerability-scanning container scan result list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

4. View the details of a specific container scan result.

```
oci vulnerability-scanning container scan result get --container-scan-result-id <container_scan_ocid>
```

Example:

```
oci vulnerability-scanning container scan result get --container-scan-result-id ocid1.vsscontainerscanresult.oc1..exampleuniqueID
```

Using the API

Use the Scanning API to scan container images in Oracle Cloud Infrastructure Registry.

For information about using the API and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see SDKs and the CLI.

1. Create a container scan recipe.

```
POST /20210215/containerScanRecipes
Host: <host>
<authorization and other headers>
{
    "displayName": "<recipe_name>",
    "compartmentId": "<recipe_compartment_ocid>",
    "scanSettings": {
        "scanLevel": "STANDARD"
    }
}
```
2. Create a container scan target.

```
POST 20210215/containerScanTargets
Host: <host>
<authorization and other headers>
{
  "displayName": "<target_name>",
  "description": "<target_description>",
  "compartmentId": "<target_compartment_ocid>",
  "containerScanRecipeId": "<recipe_ocid>",
  "targetRegistry": {
    "type": "OCIR",
    "url": "https://<region_key>.ocir.io"
  }
}
```

<region_key> is the key for the Oracle Cloud Infrastructure Registry region you're using. See Availability by Region.

If repositories is not specified, all repositories in the compartment are scanned.

3. View container scan results.

```
GET 20210215/containerScanResults?
compartmentId=<target_compartment_ocid>&repository=<repository_name>
Host: <host>
<authorization and other headers>
```

For more information about these operations, refer to the Scanning API.

**Scanning with Cloud Guard**

Use Cloud Guard to detect and respond to security vulnerabilities identified by Oracle Vulnerability Scanning Service.

Cloud Guard is an Oracle Cloud Infrastructure service that provides a central dashboard to monitor all of your cloud resources for security weaknesses in configuration, metrics, and logs. When it detects a problem, it can suggest, assist, or take corrective actions, based on your Cloud Guard configuration.

**Cloud Guard Concepts**

Compare the concepts and features of the Scanning service with Cloud Guard.

Like the Scanning service, Cloud Guard supports recipes and targets.

- A Cloud Guard recipe defines the types of resources and problems that you want to monitor
- A Cloud Guard target defines one or more compartments that you want to monitor, and is associated with a Cloud Guard recipe.

A configuration detector recipe consists of detector rules. The default Cloud Guard configuration detector recipe includes rules that check for vulnerabilities and open ports found in reports created by Vulnerability Scanning. You can use this Oracle-managed configuration detector recipe or clone it to create a custom recipe.

You can also modify the default settings for the Scanning detector rules.

- Disallowed port numbers that Cloud Guard reports as a problem
- Allowed port numbers that Cloud Guard ignores
- Vulnerability risk levels (Low, Medium, High, Critical) that Cloud Guard reports as a problem
Using the Cloud Guard Scanning Detector Rules
Configure and use Cloud Guard to monitor security problems detected in Vulnerability Scanning.

Enable Cloud Guard and create at least one Cloud Guard target, if the service is not already enabled. See Getting Started with Cloud Guard and Managing Targets.

Before using Cloud Guard, at least one Scanning target must exist before the Scanning service creates any reports. These reports are used by the Cloud Guard detector. See Managing Host Targets on page 5740.

Note:
Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

To view Scanning problems in Cloud Guard:

1. If you created a custom configuration detector recipe in Cloud Guard, verify that the Vulnerability Scanning detector rules are enabled in your recipe.
   All detector rules are automatically enabled in Oracle-managed recipes like OCI Configuration Detector Recipe, and can't be disabled.
   a) From the Cloud Guard console, click Detector Recipes.
   b) Click your custom configuration detector recipe.
   c) Under Detector Rules, in the Filter by detector rule field, enter scan.
   d) Select the check boxes for the Vulnerability Scanning rules.
      • Scanned host has vulnerabilities
      • Scanned host has open ports
   e) If these rules are not already enabled, click Enable.
   For more information, see Modifying a Detector Recipe.

2. From the Cloud Guard console, click Problems.

3. Click the name of a Vulnerability Scanning problem to view its details.
   • Scanned host has vulnerabilities
   • Scanned host has open ports

   Tip:
   To filter the list of problems, scroll down and locate the Labels field. Enter "VSS" (case-sensitive) and click Apply Filters.

Vulnerability Scanning problems include links to the corresponding Host Scans on page 5744 and Port Scans on page 5748.

If no Vulnerability Scanning problems are displayed in Cloud Guard, then consider the following scenarios.

• The Vulnerability Scanning service did not create any reports yet. The schedule (daily/weekly) is configured in the Scanning target.
• You recently enabled Cloud Guard or the Vulnerability Scanning detector rules and Cloud Guard has not run them yet.

For more information, see Processing Reported Problems and Troubleshooting the Scanning Service on page 5759.
**Updating the Scanning Detector Rules**
In Cloud Guard recipes, you can modify the default settings for the Vulnerability Scanning detector rules. These settings control which vulnerabilities are reported as problems in Cloud Guard.

For example, you can configure which vulnerability risk levels are problems, or configure which TCP or UDP open ports are problems.

You can modify some rule settings in an Oracle-managed detector recipe like **OCI Configuration Detector Recipe**, and you can modify all rule settings in a custom recipe. You can't disable rules in Oracle-managed recipes.

1. From the Cloud Guard console, click **Detector Recipes**.
2. Click your configuration detector recipe.
3. Under **Detector Rules**, in the **Filter by detector rule** field, enter **scan**.
4. Click the **Actions** icon for the rule **Scanned host has vulnerabilities**, and then select **Edit**.
5. After updating the rule's settings, click **Save**.
6. Repeat this step on the rule **Scanned host has open ports**.

For more information, see **Modifying Rule Settings in a Detector Recipe**.

**Troubleshooting the Scanning Service**
Identify the causes and fixes for common problems with Oracle Vulnerability Scanning Service.

**No Scanning Results**
Fix general problems that prevent you from seeing any type of Scanning report.

**Target was Created Less Than 24 Hours Ago**
After you create a target, the Scanning service does not immediately scan the specified target resources (compute instances).

After creating a target that's associated with your recipe, it can take up to 24 hours for the Scanning service to perform the first scan of the target resources. This delay occurs if you configured your recipe with a **Daily** schedule or a **Weekly** schedule.

**Missing IAM Policy**
To view any type of Scanning report, you must be given the required type of access in a **policy (IAM)** written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

For example, to allow users in the group **SecurityAuditors** to view all Scanning resources in the compartment **SalesApps**:

```
Allow group SecurityAuditors to read vss-family in compartment SalesApps
```

See **Scanning IAM Policies** on page 5763.

**Wrong Compartment is Specified**
Within the Console, be sure to choose the **Compartment** that contains the Scanning results for the targets (compute instances) that you want to view.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

• The compute instance **MyInstance** is in **CompartmentA**.
• **MyInstance** is specified in **Target1**.
• **Target1** is in **CompartmentB**.
Vulnerability Scanning

- All reports related to MyInstance are in CompartmentB.

**All Features in the Recipe are Disabled**
If you created a recipe in the Scanning service, but you disabled all scanning options in the recipe, then the Scanning service doesn't scan any targets assigned to this recipe.

See [Updating a Host Scan Recipe](#) on page 5738.

**No Host Scans**
Fix problems that prevent you from seeing the results of host scans.

See [No Scanning Results](#) on page 5759 for other common issues.

**Agent-Based Scanning is not Enabled**
To create host scans, the Scanning service uses the Oracle Cloud Agent, which runs on the target compute instances. By default, Agent Based Scanning is enabled in a recipe. If you disabled this option in your recipe, then the Scanning service does not create host scans for the targets that are associated with your recipe.

See [Updating a Host Scan Recipe](#) on page 5738.

**Scanning Plugin is Disabled on the Agent**
The Oracle Cloud Agent process manages plugins running on the compute instance. The Scanning plugin is used to detect vulnerabilities and to test CIS benchmarks. By default, the Scanning plugin is enabled on all instances running the agent, but the plugin can be disabled.

If you manually disabled the Scanning plugin on the target compute instances, you must enable it. See [Managing Plugins with Oracle Cloud Agent](#).

**Missing IAM Policy to Deploy the Agent**
If the target compute instances are not running the Oracle Cloud Agent, the Scanning service automatically deploys the agent to the instances. However, an administrator must give the Scanning service permission to update your target compute instances.

See [Required IAM Policy for Host Scanning](#) on page 5736.

**Instance is Not Running the Latest Agent**
If the target compute instance is running Oracle Cloud Agent version 1.11.0, it might not automatically update itself to the latest version.

Manually update Oracle Cloud Agent on the instance. See:

- [Updating the Oracle Cloud Agent Software](#)
- [Oracle Cloud Agent version 1.11.0 does not update automatically](#)

**Missing Service Gateway for Hosts with no Public IP Address**
A compute instance is associated with a VCN (virtual cloud network) and a subnet. If a compute instance in your target is on a private subnet or has no public IP address, the VCN must include a service gateway and a route rule for the service gateway. See [Access to Oracle Services: Service Gateway](#).

If the VCN is not configured correctly, the Scanning service is not able to communicate with compute instances on the private subnet and perform a host scan.
Can't Export Scanning Results
Fix problems that prevent you from exporting scan reports or vulnerability reports to your local machine.

Missing IAM Policies
To export a Scanning report, you must be given the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

Your administrator might have given you read permissions for scan reports and vulnerability reports, but not export permissions. If you can't view the scan results either, see No Scanning Results on page 5759.

For example, to allow users in the group SecurityAuditors to view all Scanning resources in the compartment SalesApps and to export the results:

Allow group SecurityAuditors to read vss-family in compartment SalesApps
Allow group SecurityAuditors to manage host-agent-scan-results in compartment SalesApps where request.operation = 'ExportHostAgentScanResultCsv'
Allow group SecurityAuditors to manage host-vulnerabilities in compartment SalesApps where request.operation = 'ExportHostVulnerabilityCsv'

Note:
The export operation is available for the host-vulnerabilities resource type, not the vss-vulnerabilities resource type.

See Scanning IAM Policies on page 5763.

Reported CVE is Already Fixed in Host (False Positive)
Fix problems that cause host scans to report vulnerabilities that were already fixed.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

During a host scan, the Scanning service compares the version of OS packages on the host with the fixed version of the packages in the open source CVE database.

If you're using the OS Management service to update the target hosts, then the following scenario often indicates a false positive:
• The Scanning service report says that a specific CVE number is not fixed in a target host.
• The OS Management service says that there are no security updates to install on the same target host.

CVE Database Inaccuracies
Oracle Vulnerability Scanning Service is continually working to improve scan results by using the latest Oracle Linux and open source databases, but there can be inaccuracies in these databases, or in the method used by the service to detect the CVE. For example, the Scanning service can report a security issue in a Linux instance even though:
• The issue was recently fixed in the latest Linux distribution
• The issue was fixed in the latest Linux distribution but recently backported to older versions

If you are concerned that a vulnerability detected by the Scanning service might be a false positive, then you can use a CVE number to verify whether the vulnerability is already fixed in your compute instance.

For example, to verify a CVE for Oracle Linux:
1. From Unbreakable Linux Network CVE Summary, search for the CVE number.
2. From the Errata Information in the CVE details, identify the Release Date for the version of Oracle Linux running on the compute instance.
   If the version has a release date, then the CVE is fixed in that version.
3. Connect to the compute instance using SSH.
4. Search the package change log for the CVE number.

```
rpm -q --changelog package | grep <CVE>
```

**CVE Fixed Using Ksplice**

Oracle Ksplice allows you to update Oracle Linux hosts with important security patches without needing to reboot. If you fixed a CVE using Ksplice and did not reboot the host, the Scanning service might continue to report it as a vulnerability. You can use the CVE number to verify whether the vulnerability is already fixed in your compute instance.

Oracle Autonomous Linux is a self-patching operating system image based on Oracle Linux. It automatically applies patches daily using Oracle Ksplice. Because Oracle Autonomous Linux updates the kernel without rebooting the host, the Scanning service might continue to report a vulnerability even though it was fixed.

**Old Kernel or Package Files**

If old, unused kernel or package files are present on your host's file system, the Scanning service might report these old files as a vulnerability. This scenario can occur if you created backup copies of these files, or the files were not cleaned up properly during an update or uninstall.

Refer to the detected CVE description to identify the list of files associated with the vulnerability. Search your target host for any copies of these files and delete them.

**No Cloud Guard Results**

Fix problems that prevent you from seeing any Scanning problems in Cloud Guard.

Cloud Guard analyzes the results of the Scanning service and reports the following types of problems:

- **Scanned host has vulnerabilities**
- **Scanned host has open ports**

Before troubleshooting Cloud Guard, be sure you're able to view host scans and port scans in the Scanning service. If not, see No Scanning Results on page 5759.

For more information about common Cloud Guard problems, see Troubleshooting Cloud Guard.

**The Cloud Guard Targets Do Not Include Target Hosts**

Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

Consider this scenario.

- **CompartmentA** and **CompartmentB** are siblings (one is not a subcompartment of the other).
- The compute instance **MyInstance** is in CompartmentA.
- The Scanning target **ScanTarget1** is set to CompartmentA.
- The Cloud Guard target **CGTarget1** is set to CompartmentB.

In this example, Cloud Guard does not show problems for vulnerabilities detected in **MyInstance**. Inspect your target settings in Cloud Guard and the Scanning service. If the Cloud Guard target is set to the root compartment for your tenancy, then no change is needed.

To address this issue, create a Cloud Guard target that includes the compartments in your Scanning targets. See Managing Targets.
The Scanning Rules are Disabled

In an Oracle-managed detector recipe like OCI Configuration Detector Recipe, all detector rules are enabled. However, if you created a custom detector recipe and did not enable the Scanning detector rules, Cloud Guard does not report any Scanning problems.

See Using the Cloud Guard Scanning Detector Rules on page 5758.

The Scanning Rule Settings Exclude Your Vulnerabilities

In Cloud Guard detector recipes, the settings for the Scanning detector rules control which vulnerabilities are reported as problems in Cloud Guard.

- Disallowed port numbers that Cloud Guard reports as a problem
- Allowed port numbers that Cloud Guard ignores
- Vulnerability risk levels (Low, Medium, High, Critical) that Cloud Guard reports as a problem

Consider the following examples.

- A port scan in the Scanning service identifies the open ports 111 and 123, but the Scanning detector rules in Cloud Guard are configured to allow ports 111 and 123.
- A host scan in the Scanning service identifies vulnerabilities with the risk level Medium, but the Scanning detector rules in Cloud Guard are configured only to report vulnerabilities that are High or Critical.

Verify the settings for the Scanning detector rules in your configuration detector recipe. See Updating the Scanning Detector Rules on page 5759.

Scanning IAM Policies

Create IAM policies to control who has access to Oracle Vulnerability Scanning Service resources, and to control the type of access for each group of users.

By default, only users in the Administrators group have access to all Scanning resources. If you are new to IAM policies, see Getting Started with Policies.

For a complete list of all policies in Oracle Cloud Infrastructure, see the Policy Reference.

Resource-Types

The following resource types are related to Vulnerability Scanning.

To assign permissions to all Scanning resources, use the aggregate type:

- vss-family

To assign permissions to individual resource types:

- container-scan-recipes
- container-scan-results
- container-scan-targets
- host-agent-scan-results
- host-cis-benchmark-scan-results
- host-port-scan-results
- host-scan-recipes
- host-scan-targets
- host-vulnerabilities
- vss-vulnerabilities
- vss-work-requests

A policy that uses <verb> vss-family is equivalent to writing a policy with a separate <verb> <resource-type> statement for each of the individual resource types.
**Supported Variables**
Scanning IAM policies support all the general policy variables.

See [General Variables for All Requests](#).

**Details for Verb + Resource-Type Combinations**
Identify the permissions and API operations covered by each verb for Scanning resources.

The level of access is cumulative as you go from `inspect` to `read` to `use` to `manage`.

A plus sign (+) in a table cell indicates incremental access when compared to the preceding cell, whereas **no extra** indicates no incremental access.

### Policy Examples
Learn about Scanning IAM policies using examples.

#### Basic Policy Examples
- Allow users in the group SecurityAdmins to create, update, and delete all Scanning resources in the entire tenancy:
  
  ```
  Allow group SecurityAdmins to manage vss-family in tenancy
  ```
- Allow users in the group SecurityAdmins to create, update, and delete all Scanning resources in the compartment SalesApps:
  
  ```
  Allow group SecurityAdmins to manage vss-family in compartment SalesApps
  ```
- Allow users in the group SecurityAuditors to view all Scanning resources in the compartment SalesApps:
  
  ```
  Allow group SecurityAuditors to read vss-family in compartment SalesApps
  ```
Vulnerability Scanning

- Allow users in the group SecurityAuditors to view all Scanning resources in the compartment SalesApps and to export the results:

```
Allow group SecurityAuditors to read vss-family in compartment SalesApps
Allow group SecurityAuditors to manage host-agent-scan-results in compartment SalesApps where request.operation = 'ExportHostAgentScanResultCsv'
Allow group SecurityAuditors to manage host-vulnerabilities in compartment SalesApps where request.operation = 'ExportHostVulnerabilityCsv'
```

**Note:**
The export operation is available for the host-vulnerabilities resource type, not the vss-vulnerabilities resource type.

- Allow users in the group SecurityAdmins to create, update, and delete host scan recipes in the entire tenancy:

```
Allow group SecurityAdmins to manage host-scan-recipes in tenancy
```

- Allow users in the group SecurityAuditors to view all host scanning results in the compartment SalesApps:

```
Allow group SecurityAuditors to read host-agent-scan-results in compartment SalesApps
Allow group SecurityAuditors to read host-port-scan-results in compartment SalesApps
Allow group SecurityAuditors to read host-cis-benchmark-scan-results in compartment SalesApps
Allow group SecurityAuditors to read container-scan-results in compartment SalesApps
Allow group SecurityAuditors to read vss-vulnerabilities in compartment SalesApps
```

**Host Scanning Policy Examples**

To use agent-based host scanning, then you must also:

- Grant the Scanning service permission to deploy the Oracle Cloud Agent to your target compute instances.
- Grant the Scanning service permission to read the VNIC (virtual network interface card) on your target compute instances.
- Grant users permission to manage the target compute instances.

Examples:

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning in the entire tenancy:

```
Allow group SecurityAdmins to manage vss-family in tenancy
Allow group SecurityAdmins to manage instances in tenancy
Allow service vulnerability-scanning-service to manage instances in tenancy
Allow service vulnerability-scanning-service to read compartments in tenancy
Allow service vulnerability-scanning-service to read vnics in tenancy
Allow service vulnerability-scanning-service to read vnic-attachments in tenancy
```

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning on instances in the compartment SalesApps:

```
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
Allow group SecurityAdmins to manage instances in compartment SalesApps
```
Vulnerability Scanning

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning on instances in the compartment SalesApps. The VNICS of these instances are in the compartment SalesNetwork:

  Allow service vulnerability-scanning-service to manage instances in compartment SalesApps
  Allow service vulnerability-scanning-service to read compartments in compartment SalesApps
  Allow service vulnerability-scanning-service to read vnics in compartment SalesApps
  Allow service vulnerability-scanning-service to read vnic-attachments in compartment SalesApps

For more information about compute and network policies, see Policy Details for the Core Services.

**Scanning Metrics**

You monitor the health, capacity, and performance of Oracle Vulnerability Scanning Service by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_vss`.

**Overview**

Metrics help you monitor the vulnerabilities that the Vulnerability Scanning service detects in your cloud resources.

**Namespace**

A namespace is a container for metrics. The namespace identifies the service sending the metrics. The namespace for the Scanning service is `oci_vss`.

**Metrics**

Metrics are the fundamental concept in telemetry and monitoring. Metrics define a time-series set of datapoints. Each metric has a namespace, metric name, compartment identifier, one or more dimensions, and a unit of measure. Each datapoint has a timestamp, value, and count associated with it.

**Dimensions**

A dimension is a key-value pair that defines the characteristics associated with the metric. For example, `resourceId` is the OCID of the resource that was scanned.

**Statistics**

Statistics are metric data aggregations over specified periods of time. Aggregations are done using the namespace, metric name, dimensions, and the data point unit of measure within the time period specified.

**Alarms**

Alarms are used to automate operations monitoring and performance. An alarm tracks changes that occur over a specific time period and performs one or more defined actions, based on the rules defined for the metric.
Required IAM Policy
To monitor resources in Oracle Cloud Infrastructure, you must be given the required type of access in a policy (IAM) written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.

The policy must give you access to the monitoring services and the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics
Scanning metrics include the following dimensions:

- **resourceId**: The OCID of the cloud resource that was scanned, such as a compute instance (Compute).
- **resultId**: The OCID of the host scan in the Scanning service.
- **riskLevel**: The risk level of the cloud resource that was scanned.

The Scanning service categorizes problems by these risk levels.

- **Critical** - the most serious problems detected, which should be your highest priority to resolve.
- **High** - the next most serious problems.
- **Medium** - problems that are a bit less serious.
- **Low** - problems that are still less serious.
- **Minor** - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SecurityVulnerability</td>
<td>Security Vulnerability</td>
<td>count</td>
<td>Total number of vulnerabilities found in a scan of a cloud resource.</td>
</tr>
</tbody>
</table>

Using the Console
View the metric charts for the Scanning service.

1. Open the navigation menu and click **Observability & Management**, Under **Monitoring**, click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the **Scanning target** that you're interested in.
3. For **Metric Namespace**, select **oci_vss**.

The **Service Metrics** page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

Using the API
Use the following APIs for monitoring.

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

For information about using the API and signing requests, see **REST APIs** and **Security Credentials**.

For information about SDKs, see **SDKs and the CLI**.

Scanning Events
Oracle Cloud Infrastructure Events allows your development teams to automatically respond when a resource changes its state. Oracle Vulnerability Scanning Service resources emit the following events.

See **Getting Started with Events**.
## Host Scan Recipe Event Types

These are the event types that host scan recipes emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostScanRecipe - Create</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - Update Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscanrecipe.begin</td>
</tr>
<tr>
<td>HostScanRecipe - Update End</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscanrecipe.end</td>
</tr>
<tr>
<td>HostScanRecipe - Delete</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changehostscanrecipe</td>
</tr>
</tbody>
</table>

This is a reference event for host scan recipes.

```json
{
  "eventType":"com.oraclecloud.vulnerabilityscanning.createhostscanrecipe",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
  "source":"vulnerabilityScanning",
  "eventID":"<unique_ID>",
  "eventTime":"2020-12-02T00:08:27.770Z",
  "contentType":"application/json",
  "data": {
    "eventGroupingId":"<unique_ID>",
    "eventName":"CreateHostScanRecipe",
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
    "compartmentName":"compartment-name",

    "freeformTags": {},
    "definedTags": {},
    "additionalDetails": {}
  }
}
```
Host Scan Target Event Types
These are the event types that host scan targets emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostScanTarget - Create Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Create End</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostscantarget</td>
</tr>
<tr>
<td>HostScanTarget - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostscantarget</td>
</tr>
<tr>
<td>HostScanTarget - Update Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Update End</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - Delete Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Delete End</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changepartmentcompartment</td>
</tr>
</tbody>
</table>

This is a reference event for host scan targets.

```json
{
  "eventType":"com.oraclecloud.vulnerabilityscanning.createhostscantarget.begin",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
  "source":"vulnerabilityScanning",
  "eventID": "<unique_ID>",
  "eventTime": "2020-12-02T00:08:27.770Z",

    "eventName": "CreateHostScanTarget",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "compartment-name",
    "resourceName": "target-name",
    "resourceId": "ocid1.vsshostscantarget.oc1..<unique_ID>",
    "availabilityDomain": "AD3",
    "freeformTags": {},
    "definedTags": {},
    "additionalDetails": {}
  }
}
```
# Host Agent Scan Result Event Types

These are the event types that host agent scan results emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostAgentScanResult - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostagentscanresult</td>
</tr>
<tr>
<td>HostAgentScanResult - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostagentscanresult</td>
</tr>
<tr>
<td>HostAgentScanResult - Export</td>
<td>com.oraclecloud.vulnerabilityscanning.exporthostagentscanresultcsv</td>
</tr>
<tr>
<td>HostAgentScanResult - Delete</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostagentscanresult</td>
</tr>
<tr>
<td>HostAgentScanResult - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changehostagentscanresult</td>
</tr>
</tbody>
</table>

This is a reference event for host agent scan results.

```json
{
    "eventType": "com.oraclecloud.vulnerabilityscanning.exporthostagentscanresultcsv",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "vulnerabilityScanning",
    "eventID": "<unique_ID>",
    "eventTime": "2020-12-02T00:08:27.770Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "ExportHostAgentScanResultCsv",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment-name",
        "resourceName": "",
        "resourceId": "ocid1.vsshostagentscanresult.oc1..<unique_ID>",
        "availabilityDomain": "AD3",
        "additionalDetails": {}
    }
}
```
Host Port Scan Result Event Types
These are the event types that host port scan results emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostPortScanResult - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostportscanresult</td>
</tr>
<tr>
<td>HostPortScanResult - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostportscanresult</td>
</tr>
<tr>
<td>HostPortScanResult- Delete</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostportscanresult</td>
</tr>
<tr>
<td>HostPortScanResult - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changehostportscanresult</td>
</tr>
</tbody>
</table>

This is a reference event for host port scan results.

```
{
  "eventType": "com.oraclecloud.vulnerabilityscanning.changehostportscanresultcompartment",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "vulnerabilityScanning",
  "eventID": "<unique_ID>",

    "compartmentName": "compartment-name",
    "resourceName": "",
    "resourceId": "ocid1.vsshostportscanresult.oc1..<unique_ID>",
    "availabilityDomain": "AD3",
    "additionalDetails": {}  
  }
}
```

Host CIS Benchmark Scan Result Event Types
These are the event types that CIS (Center for Internet Security) benchmark scan results emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostCisBenchmarkScanResult - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostcibenchmarkscanresult</td>
</tr>
<tr>
<td>HostCisBenchmarkScanResult - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostcibenchmarkscanresult</td>
</tr>
<tr>
<td>HostCisBenchmarkScanResult- Delete</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostcibenchmarkscanresult</td>
</tr>
<tr>
<td>HostCisBenchmarkScanResult - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changehostcibenchmarkscanresult</td>
</tr>
</tbody>
</table>
This is a reference event for host CIS benchmark scan results.

```
{
    "eventType": "com.oraclecloud.vulnerabilityscanning.changehostcisbenchmarkscanresultcompartment",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "vulnerabilityScanning",
    "eventID": "<unique_ID>",
    "eventTime": "2020-12-02T00:08:27.770Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "ChangeHostCisBenchmarkScanResultCompartment",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment-name",
        "resourceName": "",
        "resourceId": "ocid1.vsscisbenchmarkscanresult.oc1..<unique_ID>",
        "availabilityDomain": "AD3",
        "additionalDetails": {}  
    }  
}
```

### Host Vulnerability Event Types
These are the event types that host vulnerabilities emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostVulnerability - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostvulnerability</td>
</tr>
<tr>
<td>HostVulnerability - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostvulnerability</td>
</tr>
<tr>
<td>HostVulnerabilityCsv - Export</td>
<td>com.oraclecloud.vulnerabilityscanning.exporthostvulnerabilitycsv</td>
</tr>
</tbody>
</table>

This is a reference event for host vulnerability.

```
{
    "eventType": "com.oraclecloud.vulnerabilityscanning.exporthostvulnerabilitycsv",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "vulnerabilityScanning",
    "eventID": "<unique_ID>",
    "eventTime": "2020-12-02T00:08:27.770Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "ExportHostVulnerabilityCsv",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment-name",
        "resourceName": "",
        "resourceId": "ocid1.vsshostvulnerability.oc1..<unique_ID>",
        "availabilityDomain": "AD3",
        "additionalDetails": {}  
    }  
}
```
Chapter 51

Web Application Firewall

This chapter explains how to make your endpoints more secure by monitoring and filtering out potentially malicious traffic.

Overview of Web Application Firewall

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a regional-based and edge enforcement service that is attached to an enforcement point, such as a load balancer or a web application domain name. WAF protects applications from malicious and unwanted internet traffic. WAF can protect any internet facing endpoint, providing consistent rule enforcement across a customer’s application.

If you want to use WAF for edge enforcement, see Edge Policies on page 5890 for more information.

WAF provides you with the ability to create and manage rules for internet threats including Cross-Site Scripting (XSS), SQL Injection, and other OWASP-defined vulnerabilities. Access rules can limit based on geography or the signature of the request.
Before You Begin

Refer to Required IAM Service Policy on page 5780 for important concepts about WAF.

To begin using the WAF service, you must have the following available:

- Ensure that you have the Required IAM Service Policy on page 5780 permissions.
- We recommended that you use a separate compartment for your WAF policy so that management is easier and more secure. See Managing Compartments for more information.
- A load balancer with an HTTP listener.

WAF Concepts

Describes concepts associated with a web application firewall (WAF).

Access Control

Access control encompasses request and response controls.

Action

Actions are objects that represent one of the following:

- **Allow**: An action, which upon matching rule, skips all remaining rules in the current module.
- **Check**: An action which does not stop the execution of rules in current module. Instead it generates a log message documenting result of rule execution.
- **Return HTTP response**: An action which returns a defined HTTP response.

Condition

Each rule accepts a JMESPath expression as the condition. HTTP requests or HTTP responses (depending on the type of rule) trigger WAF rules.

Firewall

The Firewall resource is a logical link between a WAF policy and an enforcement point, such as a load balancer.

Network Address List

Network address lists are collections of individual public IP addresses and CIDR IP ranges or private IP addresses used by WAF policies.

Origin

Your web application's origin host server.

Protection Rule

Protection rules are sets of protection capabilities that are used to determine if traffic should be logged, allowed, or blocked. The WAF will observe traffic to your web application. To view a list of available WAF rules, see Protection Rules on page 5829.

Rate Limiting

Rate limiting allows inspection of HTTP connection properties and limits the frequency of requests for a given key.

Request Control

Request control allows inspection of HTTP request properties and to return a defined HTTP response.

Request Protection Rules

Request protection rules enable the checking of HTTP requests for malicious content and to return a defined HTTP response.
Web Application Firewall

Response Control
Response control allows inspection of HTTP response properties and to return a defined HTTP response.

Web Application Firewall (WAF)
WAF is a Payment Card Industry (PCI) compliant, global security service that protects applications from malicious and unwanted internet traffic.

Ways to Access the WAF Service
You can access Oracle Cloud Infrastructure using the Console (a browser-based interface), command line interface (CLI), or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization
Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. These policies control who can create users, create and manage the cloud network, launch instances, create buckets, download objects, and similar tasks. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

WAF Service Capabilities and Limits
The WAF service has the following limits:

- WAF policies: 50 per tenant.
- Network address lists: 100 per tenant.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

The WAF service allows a total run time of 10 minutes for upload and download processes through the WAF.

Required IAM Service Policy
To use Oracle Cloud Infrastructure, you must be given access in a policy for waas-policy. If you try to perform an action and get a message that you do not have permission or are unauthorized, confirm with your administrator the type of access you have been granted and which compartment you should work in.

Policy examples:

- To allow a specific user group to manage web application firewalls in your tenancy:
  
  Allow group-id to manage web-app-firewall in tenancy

- To allow a specific user group to inspect web application firewall policies in a specific compartment:

  Allow group-id to inspect waf-policy in compartment-id

- To allow a specific user group to use web application firewall network address lists in your tenancy:

  Allow group-id to use waf-network-address-list in tenancy
If you are new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2638.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Understanding Conditions

Describes how to understand and compose conditions for rules associated with WAF policies.

WAF uses a subset of the JMESPath language as a rule condition language. JMESPath is a query language for JSON (documentation: https://jmespath.org/specification.html) that you can use to write JMESPath expressions, where each expression takes a JSON document as an input (the input document) and returns a transformed or new JSON document (the output document).

In WAF, each rule accepts a JMESPath expression as the condition. HTTP requests or HTTP responses (depending on the type of rule) trigger WAF rules. When evaluating a rule, the WAF service evaluates the JMESPath expression (the condition) of the rule and provides an input JSON document, which includes the details of the HTTP request or HTTP response that triggered the evaluation. Then, the result of the evaluated JMESPath expression is used to determine whether to run the action specified in rule or not.

Thus, JMESPath expressions in WAF rules are used to inspect HTTP requests and HTTP responses to determine if the action in a WAF rule needs to be run or not. All JMESPath expressions used in WAF must return a boolean value, either true or false, where true means that the action of a rule is run and false means that the action is not run.

The following sections describe JMESPath functions specific to WAF:

Examples

URL path conditions:

```plaintext
# URL path equals
http.request.url.path == '/example/path'

# URL path does not equal
http.request.url.path != '/example/path'

# URL path contains
contains(http.request.url.path, 'example')

# URL path does not contain
!contains(http.request.url.path, 'example')

# URL path starts with
starts_with(http.request.url.path, '/example/path')

# URL path ends with
ends_with(http.request.url.path, '.png')
```

HTTP request method conditions

```plaintext
# HTTP request method is one of
contains(('GET', 'POST'), http.request.method)
```
HTTP request header conditions

# HTTP request header exists
contains(keys(http.request.headers), 'example-header')

# HTTP request header has specific value
http.request.headers."example-header"[0] == 'specific-value'

# One of the HTTP request headers with the same name has a specific value
contains(http.request.headers."example-header", 'specific-value')

Multiple conditions

# HTTP request method is GET and URL path starts with /example/path
http.request.method == 'GET' && starts_with(http.request.url.path, '/example/path')

# URL path starts with /example/path_one or /example/path_two
starts_with(http.request.url.path, '/example/path_one') ||
starts_with(http.request.url.path, '/example/path_two')

# HTTP request method is POST and URL is either /example/path_one or /example/path_two
http.request.method == 'POST' && (http.request.url.path == '/example/path_one' ||
http.request.url.path == '/example/path_two')

Supported JMESPath Subset

The WAF service does not support all JMESPath features, it supports a subset that can still be used to write complex conditions.

Restrictions on the full JMESPath feature set:

- JMESPath conditions in WAF rules must be either:
  - A comparison that returns a boolean result.
  - Multiple such comparisons, combined with logical operators &&, ||.
- A small subset of built-in JMESPath functions is supported:
  - contains
  - ends_with
  - keys
  - length
  - starts_with

A comparison is a JMESPath expression that compares two values. Either a JMESPath comparison operator (==, !_, >, >=, <, <=) or a comparison function (contains, ends_with, starts_with, all custom WAF functions) can be used to write a comparison expression.

The compared values can be one of:

- A literal JSON value:
  - Raw string literal: [https://jmespath.org/specification.html#raw-string-literals](https://jmespath.org/specification.html#raw-string-literals)
  - JSON literal: [https://jmespath.org/specification.html#literal-expressions](https://jmespath.org/specification.html#literal-expressions). Only number, boolean, and null literals are supported.
- A MultiSelect List: [https://jmespath.org/specification.html#multiselect-list](https://jmespath.org/specification.html#multiselect-list). Items in the list must be either string or number literals and all items in a list must have the same type.
- A JMESPath expression referencing a value from the input JSON document (a variable). Only object property access and array index access are supported in these expressions.
Input JSON Document Structure

When evaluating JMESPath expressions, WAF provides an input JSON document, which includes the details of the HTTP request or HTTP response that triggered the evaluation. The input JSON document is always a JSON object.

Example

For an HTTP request with the following details:

- Source IP address and port: 129.146.10.1:48152
- Country code that the source IP address belongs to: US
- ASN that the source IP address belongs to: 31898
- Destination IP address and port: 205.147.88.0:80
- Destination host: example.com
- Protocol: HTTP/1.1

```
GET /test/path/img.jpg?param1=a&m2=b HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Connection: keep-alive
Cookie: cookie1=A; cookie2=B; cookie3=3C; cookie3=3D
Host: example.com
User-Agent: HTTPie/2.4.0
```

The following JSON input document is generated and passed to JMESPath expressions:

```
{
  "connection": {
    "source": {
      "address": "129.146.10.1",
      "port": 49152,
      "geo": {
        "countryCode": "US"
      },
      "routing": {
        "asn": 31898
      }
    },
    "destination": {
      "address": "205.147.88.0",
      "port": 80
    },
    "protocol": "http"
  },
  "http": {
    "request": {
      "host": "www.example.com",
      "method": "GET",
      "version": "1.1",
      "url": {
        "path": "/test/path/img.jpg",
        "query": "param1=a&param2=b",
        "queryParameters": {
          "param1": ["a"],
          "param2": ["b"]
        },
        "queryPrefix": "?"
      },
      "headers": {
        "accept": ["/*/*"],
        "accept-encoding": ["gzip, deflate"],
        "connection": ["keep-alive"],
        "cookie": ["cookie1=A; cookie2=B; cookie3=3C; cookie3=3D"
```
**connection.source.address**

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>

<tr>
<td></td>
<td>• Key: name of the cookie.</td>
</tr>
<tr>
<td></td>
<td>• Value: list of cookie values with the &quot;key&quot; as their name.</td>
</tr>
<tr>
<td>Available in</td>
<td>requestAccessControl, requestRateLimiting, requestProtection, responseAccessControl, responseProtection</td>
</tr>
</tbody>
</table>

### Example values

<table>
<thead>
<tr>
<th>Value of the HTTP request header &quot;Cookie&quot;</th>
<th>Parsed object structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>cookie1=A; cookie2=B; cookie3=3C; cookie3=3D</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;cookie1&quot;: [&quot;A&quot;],</td>
</tr>
<tr>
<td></td>
<td>&quot;cookie2&quot;: [&quot;B&quot;],</td>
</tr>
<tr>
<td></td>
<td>&quot;cookie3&quot;: [&quot;3C&quot;, &quot;3D&quot;]</td>
</tr>
</tbody>
</table>
### http.response.code

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>number</td>
</tr>
<tr>
<td>Description</td>
<td>HTTP response code</td>
</tr>
<tr>
<td>Available in</td>
<td>responseAccessControl, responseProtection</td>
</tr>
<tr>
<td>Example values</td>
<td>200</td>
</tr>
</tbody>
</table>

### http.response.headers

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>object</td>
</tr>
</tbody>
</table>
| Description | The HTTP response headers parsed into an object structure, where:  
  • Key: lowercased name of the header.  
  • Value: list of header values with the "key" as their name. |
| Available in | responseAccessControl, responseProtection |
| Example values | Raw HTTP response headers | Parsed object structure |
|              | Cache-Control: no-cache | { "cache-control": ["no-cache", "must-revalidate"],  
|              | Cache-Control: must-revalidate |  
|              | Connection: keep-alive |  
|              | Content-Encoding: gzip |  
|              | Content-Type: text/html;charset=UTF-8 |  
|              | { "connection": ["keep-alive"],  
|              | "content-encoding": ["gzip"],  
|              | "content-type": ["text/html;charset=UTF-8"] } |

### Case-Insensitive String Matching

In addition to string matching functions supported by default in JMESPath, WAF adds support for four functions that can match strings case-insensitively:

- **i_equals** (case-insensitive variant of the == operator);
- **i_contains** (case-insensitive variant of the contains function);
- **i_starts_with** (case-insensitive variant of the starts_with function);
- **i_ends_with** (case-insensitive variant of the ends_with function).

### IP Address Matching

WAF adds support for multiple functions that can match an IP address against a list of CIDR ranges or WAF Network Address List resources:

- **address_in** (matches an IP address against a list of CIDR ranges);
- address_in_network_address_list (matches an IP address against a WAF Network Address List resource);
- vcn_address_in_network_address_list (matches an IP address with a VCN ID against a WAF Network Address List resource).

### Keys Function

The Keys function returns an array containing the keys of the provided object. Because JSON hashes are inherently unordered, the keys associated with the provided object "$obj" are inherently unordered.

```php
array keys(object $obj)
```

#### Keys Function

<table>
<thead>
<tr>
<th>Given</th>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>{}</td>
<td>keys(@)</td>
<td>[]</td>
</tr>
<tr>
<td>&quot;foo&quot;: &quot;baz&quot;, &quot;bar&quot;: &quot;bam&quot;</td>
<td>keys(@)</td>
<td>[&quot;foo&quot;, &quot;bar&quot;]</td>
</tr>
<tr>
<td>false</td>
<td>keys(@)</td>
<td>&lt;error: invalid-type&gt;</td>
</tr>
<tr>
<td>[b, a, c]</td>
<td>keys(@)</td>
<td>&lt;error: invalid-type&gt;</td>
</tr>
</tbody>
</table>

In WAF, keys() is only supported to check if `http.request.headers`, `http.response.headers`, `http.request.url.query` or `http.request.cookies` contains a specific key. See the following examples:

```php
contains(keys(http.request.headers), 'x-forwarded-for')
contains(keys(http.request.url.query), 'my_test_param')
contains(keys(http.request.cookies), 'MyTestCookie')
contains(keys(http.response.headers), 'set-cookie')
```

### Length Function

Returns the number of elements in the given array.

```php
number length(array $subject)
```

#### Length Function

<table>
<thead>
<tr>
<th>Given</th>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>[&quot;a&quot;, &quot;b&quot;, &quot;c&quot;]</td>
<td>length(@)</td>
<td>3</td>
</tr>
<tr>
<td>[]</td>
<td>length(@)</td>
<td>0</td>
</tr>
</tbody>
</table>

In WAF, length() only works with values of these variables: `http.request.headers`, `http.response.headers`, `http.request.url.query` or `http.request.cookies`. See the following examples:

```php
length(http.request.headers."x-forwarded-for")
length(http.request.url.query."my_test_param")
length(http.request.cookies.MyTestCookie)
length(http.response.headers."set-cookie")
```
WAF Policy Management

Provides an overview of web application firewall (WAF) policies, including their creation, updating, and deletion.

WAF policies encompass the overall configuration of your WAF service, including access rules, rate limiting rules, and protection rules.

You can manage your WAF policies, including their creation, editing, deletion, and moving to another compartment. You also view all your WAF policies in a specified compartment collectively, or get the details of a specific policy.

Creating WAF Policies

Describes the different methods to create a WAF policy.

Use one of the following methods to create a WAF policy.

To create a WAF policy using the Console

Describes how to create a WAF policy using the OCI Console.

2. Choose a Compartment you have permission to work in under List Scope.
3. Click Create WAF Policy.

The Create WAF Policy dialog box appears. Creating a WAF policy consists of the following sections:

- Basic Information
- Access Control
- Rate Limiting
- Protections
- Select Enforcement Point
- Review and Create

By default, the Basic Information page appears first.
4. Run each of the following workflows in order. You can return to a previous page by clicking Previous

Step 1 - Basic Information

Complete the following:

- **Name**: Enter the name of the WAF policy.
- **WAF Policy Compartment**: Select the compartment that contains the WAF policy you are creating.
- **Actions**: Click to display the Actions list displaying those actions available for adding to your WAF policy. By default, the following pre-configured actions are associated with your WAF policy:
  - **Pre-configured Check Action**: Skips all remaining rules in the current module.
  - **Pre-configured Allow Action**: Does not stop the execution of rules. Instead, it generates a log message documenting the result of the running of the rule.
  - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

See Actions Management on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

Click **Add Action**: Click to display the Add Action dialog box where can create and add more actions to the WAF policy. See Actions Management on page 5878 for information on how to add an action.

- **Show Tagging Options**: Click to display the tagging option fields for the WAF policy. See Tagging Resources on page 5781 for more information.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the link at the bottom of the page to display the Edge Policy dialog box. This dialog box is the start of the legacy WAF creation workflow. See Edge Policies on page 5890 for more information.</td>
</tr>
</tbody>
</table>

Step 2 - Access Control

The Access Control option allows you to define explicit actions not only for requests, but also for responses that meet various conditions.

Complete the following:

- **Enable Access Control**: Click to display the Request Control section and the Access Rules list. See Request Control Management on page 5809 for more information about how to use request control rules with your WAF policy.

  The Access Rules list contains those access rules currently associated with the request control in tabular format. Check an existing access control rule and click **Change Action** to edit it, or **Delete** to remove it from the list.

- **Add Access Rules**: Click to display the Add Access Rule dialog box.

  Complete the following:
  
  - **Name**: Enter the name of the access rule.
  - **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur. See Understanding Conditions on page 5781 for more information on how to author the conditions for your access rule.
  
  - **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one.
    
    - **Pre-configured Check Action**: Skips all remaining rules in the current module.
    - **Pre-configured Allow Action**: Does not stop the execution of rules. Instead, it generates a log message documenting the result of the running of the rule.
Pre-configured 401 Response Code Action: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

Click Show Header Details to display the HTTP response headers specified in the selected Return HTTP response action.

Click Show Response Page Body Details to display the HTTP response body specified in the selected "Return HTTP response" action.

See Actions Management on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

Click Add Access Rule. The Add Access Rule dialog box closes.

- **Change Option**: Check one or more entries in the Access Control list and click Change Action.
- **Delete**: Check one or more entries in the Access Control list and click Delete to remove them.
- **Default Action**: Select the action to be followed from the Action Name list when requests do not match any rule group that is defined for the policy.
- **Show Response Control Options**: Click to display the Response Control section and the Access Rules list. The list contains those access rules currently associated with the response control in tabular format. See
Response Control Management on page 5814 for more information about how to use response control rules with your WAF policy.

Add and manage access rules and actions for response controls the same as for request controls described earlier in this step.

- Click Next.

**Step - 3 Rate Limiting**

The Rate Limiting option allows you to configure a threshold for the number of requests from a unique IP address for a given period. See Rate Limiting Management on page 5819 for more information about how to use rate limiting with your WAF policy.

Complete the following:

- **Enable Rate Limiting**: Click to display the Rate Limiting Rules list. The list contains those rate limiting rules in tabular format. Check an existing rate limiting rule and click Change Action to edit it, or Delete to remove it from the list.

**Add Rate Limit Rule**: Click to display the Add Access Rule dialog box.

Complete the following:

- **Name**: Enter the name of the rate limit rule.
- **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur. See Understanding Conditions on page 5781 for more information on how to author the conditions for your access rule.
- **Rate Limit Configuration**: Configure the maximum number of requests that can be made from a unique IP address and how long the request can be.
  - **Request Limit**: Enter the maximum number of requests that a unique IP address can make during the time value allocated in the Period in Seconds box.
  - **Period in Seconds**: Enter the number of seconds during which the maximum number of requests that can be made from each unique IP address as specified in the Request Limit box.
  - **Action Duration in Seconds**: Enter the duration in seconds that the action is applied for when the request limit is reached.

Click +Another Rate Limit to display another rate limit configuration row to complete. Click X to delete the associated rate limit configuration row.

- **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select Create New Action to add one.
  - **Pre-configured Check Action**: Skips all remaining rules in the current module.
  - **Pre-configured Allow Action**: Does not stop the execution of rules. Instead, it generates a log message documenting the result of the running of the rule.
  - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

Click Show Header Details to display the HTTP response headers specified in the selected Return HTTP response action.

Click Show Response Page Body Details to display the HTTP response body specified in the selected Return HTTP response action.

See Actions Management on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

Click Add Rate Limit Rule. The Add Rate Limit Rule dialog box closes.

- Click Next.

**Step 4 - Protections**
The Protections option lets you apply Oracle-managed request protection capabilities to catch malicious traffic. See Protections Management on page 5824 for more information about how to use request protections with your WAF policy.

Complete the following:

- **Enable Protections**: Click to display the Request Protection Rules list. The list contains those request protections rules in tabular format. Check an existing request protection rule and click **Delete** to remove it from the list.

**Add Request Protection Rule**: Click to display the Add Request Protection Rule dialog box. Complete the following:

  - **Name**: Enter the name of the request protection rule.
  - **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur. See Understanding Conditions on page 5781 for more information on how to author the conditions for your access rule.
  - **Action Name**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one.
    - **Pre-configured Check Action**: Skips all remaining rules in the current module.
    - **Pre-configured Allow Action**: Does not stop the execution of rules. Instead, it generates a log message documenting the result of the running of the rule.
    - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

      (Return HTTP Response actions only) Click **Show Header Details** to display the HTTP response headers specified in the selected Return HTTP response action.

      (Return HTTP Response actions only) Click **Show Response Page Body Details** to display the HTTP response body specified in the selected Return HTTP response action.

  - The Protection Capabilities list contains those request protection capabilities rules in tabular format. Check an existing rate limiting rule and click **Change Action** to edit it, or **Delete** to remove it from the list.

- **Show Response Protection Rules**: Click to display the Response Protection Rules list. The list contains those response protections rules in tabular format. Check an existing request protection rule and click **Delete** to remove it from the list.

**Add Response Protection Rule**: Click to display the Add Response Protection Rule dialog box.

Add and manage access rules and actions for response protections the same as for request protections described earlier in this step.

- **Click Next**.

**Step 5 - Select Enforcement Point**

The Select Enforcement Point option allows you to enforce web application firewall security on your load balancer. See Firewall Management on page 5801 for more information about how to use firewalls with your WAF policy.

Complete the following:

- **Add Firewalls**: Select a load balancer contained in your current compartment from the list. Click **Change Compartment** to select load balancers from a different compartment.

  The load balancer you select has the firewall security applied.

  Click **Additional Firewall** to display another firewall row where you can select another load balancer that the firewall is applied. Click **X** to delete the associated header row.

- **Click Next**.
Step 6 - Review and Create

The Review and Create step allows you to review all your WAF policy settings together before you complete the creation process. Each section on the page corresponds to one of the earlier steps you completed.

Review each section for accuracy and completion. Click Edit in any section you want to make changes.

Click Create WAF Policy.

The Create WAF Policy dialog box closes and you are returned to the WAF Policy page. The WAF policy you created is listed with the other policies.

To create a WAF policy using the CLI

Describes how to create a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall-policy create --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall-policy create --help
```

See `oci waf web-app-firewall-policy create` for a complete description of the command.

To create a WAF policy using the API

Describes how to create a WAF policy using the API.

Run the `CreateWebAppFirewallPolicy` method to create a WAF policy. See `CreateWebAppFirewallPolicy` for a complete description.

Listing WAF Policies

Describes the different methods to display a list of WAF policies.

Use one of the following methods to display a list of WAF policies.

To list the WAF policies using the Console

Describes how to display a list of WAF policies using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.

   The list of WAF policies displayed shows the Name, Policy Type (WAF Policy or Edge Policy), Status, and Created (UTC date timestamp) information for each entry.

To list the WAF policies using the CLI

Describes how to display a list of WAF policies using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall-policy list --compartment-id compartment-id
```

Oracle Cloud Infrastructure User Guide
To list the WAF policies using the API
Describes how to display a list of WAF policies using the API.
Run the ListWebAppFirewallPolicies method to list the WAF policies. See ListWebAppFirewallPolicies for a complete description.

Getting WAF Policy Details
Describes the different methods to get the details of a WAF policy.
Use one of the following methods to get the details of a WAF policy.

To get the details of a WAF policy using the Console
Describes how to get the details of a WAF policy using the Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select WAF Policy.
4. Select the WAF policy whose details you want to get.
   The WAF Policy Details dialog box appears.

The Details page contains information about the WAF policy, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the WAF policy's configuration.

To get the details of a WAF policy using the CLI
Describes how to get the details of a WAF Policy using the CLI.
Enter the following command and required parameters:

```
oci waf web-app-firewall-policy get --web-app-firewall-policy-id web-app-firewall-policy-id
```
See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall-policy get --help
```
See oci waf web-app-firewall-policy get for a complete description of the command.

To get the details of a WAF policy using the API
Describes how to get the details of a WAF Policy using the API.
Run the GetWebAppFirewallPolicy method to get the details of a WAF policy. See GetWebAppFirewallPolicy for a complete description.

Editing WAF Policies
Describes the different methods to edit a WAF policy.
Use one of the following methods to edit a WAF policy.
Web Application Firewall

**Note:**
You can only edit the name of a WAF policy when using the Console.

**To rename a WAF policy using the Console**
Describes how to rename a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy you want to rename.
   The WAF Policy Details dialog box appears.
5. Click **Rename**.
   Alternatively, click the **Actions** icon (하겠습니다) for the WAF policy and click **Rename**.
   The Rename Policy dialog box appears.
6. Edit the **Name** of the WAF policy.
7. Click **Save Changes**.
   The Rename Policy dialog box closes. The updated name of the WAF policy appears in the Details page and the list of WAF policies.

**To edit a WAF policy using the CLI**
Describes how to edit a WAF Policy using the CLI.

Enter the following command and required parameters:

```bash
oci waf web-app-firewall-policy update --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf web-app-firewall-policy update --help
```

**To edit a WAF policy using the API**
Describes how to edit a WAF Policy using the API.

**Deleting WAF Policies**
Describes the different methods to delete a WAF policy.

Use one of the following methods to delete a WAF policy.
**To delete a WAF policy using the Console**

Describes how to delete a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy you want to delete.

   The WAF Policy Details dialog box appears.

5. Click **Edit**.

   Alternatively, click the **Actions** icon (⋮) for the WAF policy and click **Delete**.

6. Confirm the deletion when prompted.

   The list of WAF policies reappears without the WAF policy you deleted.

**To delete a WAF policy using the CLI**

Describes how to delete a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall-policy delete --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall-policy delete --help
```

See **oci waf web-app-firewall-policy delete** for a complete description of the command.

**To delete a WAF policy using the API**

Describes how to delete a WAF policy using the API.

Run the **DeleteWebAppFirewallPolicy** method to delete a WAF policy. See **DeleteWebAppFirewallPolicy** for a complete description.

**Moving WAF Policies Between Compartments**

Describes the different methods to move a WAF policy between compartments.

Use one of the following methods to move a WAF policy between compartments.

**To move a WAF policy between compartments using the Console**

Describes how to move a WAF policy between compartments using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.
4. Select the WAF policy you want to move.
   The WAF Policy Details dialog box appears.
5. Click Move Resource.
   Alternatively, click the Actions icon for the WAF policy and click Move ???.
6. Select the compartment to which you want to move your WAF policy from the Choose New Compartment list.
7. Click Move Resource.
   The WAF policy now appears in the compartment you moved it to.

To move a WAF policy between compartments using the CLI
Describes how to move a WAF policy between compartments using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall-policy change-compartment --compartment-id compartment-id --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall-policy change-compartment --help
```

See `oci waf web-app-firewall-policy change-compartment` for a complete description of the command.

To move a WAF policy between compartments using the API
Describes how to move a WAF policy between compartments using the API.

Run the ChangeWebAppFirewallPolicyCompartment method to move a WAF Policy between compartments. See `ChangeWebAppFirewallPolicyCompartment` for a complete description.

Firewall Management
Provides an overview of firewalls associated with Web application firewall (WAF) policies, including their creation, updating, and deletion.

You can manage the firewalls associated with your WAF policies, including their creation, editing, deletion, and moving to another compartment. You also view all the firewalls associated with a specified WAF policy, or get the details of a specific firewall.

Adding Firewalls
Describes the different methods to add a firewall to a WAF policy.

Use one of the following methods to add a firewall to a WAF policy.

To add a firewall using the Console
Describes how to add a firewall to a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.
4. Select the WAF policy to which you want to add a firewall.
   The WAF Policy Details dialog box appears.
5. Click Firewalls under Resources.
   The Firewalls list appears.
6. Click Add Firewalls.
   The Add Firewalls dialog box appears.
7. Complete the following:
   - Firewall Name: Enter the name of the firewall.
   - Create in Compartment: Select the compartment that contains the firewall you are creating.
   - Load Balancer:
   - Check Enable WAF Logs to generate logs containing web application firewall security events.

   **Note:**
   WAF logging is an optional feature with associated fees. See ??? for more information.
8. (Optional) WAF Logs: Apply the following optional configurations to all WAF logs you enabled. You can later update these settings for individual log files in the log details. See Managing Logs and Log Groups on page 3911 for general information on logs.
   - Compartment: Select the compartment where the WAF logs reside from the list.
   - Log Group: Select the log group from the list.
   - Log Retention: Select the length of time log entries are retained in the log file from the list.
9. Click Add Firewalls.
   The Add Firewalls dialog box closes. The firewall you created is included in the Firewalls list.

**To add a firewall using the CLI**
Describes how to add a firewall to a WAF policy using the CLI.

Enter the following command and required parameters:

```bash
oci waf web-app-firewall create-for-load-balancer --compartment-id compartment-id --load-balancer-id load-balancer-id --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf web-app-firewall create-for-load-balancer --help
```

See `oci waf web-app-firewall create-for-load-balancer` for a complete description of the command.

**To add a firewall using the API**
Describes how to add a firewall to a WAF policy using the API.

Run the `CreateWebAppFirewall` method to create a firewall. See `CreateWebAppFirewall` for a complete description.

**Listing Firewalls**
Describes the different methods to display a list of firewalls contained in a WAF policy.

Use one of the following methods to display a list of firewalls contained in a WAF policy.
To list the firewalls using the Console
Describes how to display a list of firewall contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.
4. Select the WAF policy containing the firewalls you want to list.
   The WAF Policy Details dialog box appears.
5. Click Firewalls under Resources.
   The Firewalls list appears.
   The Firewalls list displayed shows the firewalls associated with the WAF policy.

To list the firewalls using the CLI
Describes how to display a list of firewall contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall list --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall list --help
```

See oci waf web-app-firewall list for a complete description of the command.

To list the firewalls using the API
Describes how to display a list of firewall contained within a WAF policy using the API.

Run the ListWebAppFirewalls method to list the firewalls. See ListWebAppFirewalls for a complete description.

Getting Firewall Details
Describes the different methods to get the details of a firewall contained within a WAF policy.

Use one of the following methods to get the details of a firewall contained within a WAF policy.

To get the details of a firewall using the Console
Describes how to get the details of a firewall contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select WAF Policy.

4. Select the WAF policy to whose firewall details which you want to get.
   The WAF Policy Details dialog box appears.

5. Click **Firewalls** under **Resources**.
   The Firewalls list appears.

6. Select the firewall whose details you want to get.
   The Firewall Details dialog box appears.

The Details page contains information about the firewall, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the firewall configuration.

**To get the details of a firewall using the CLI**

Describes how to get the details of a firewall contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall get --web-app-firewall-id web-app-firewall-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall get --help
```

See `oci waf web-app-firewall get` for a complete description of the command.

**To get the details of a firewall using the API**

Describes how to get the details of a firewall contained within a WAF policy using the API.

Run the `GetWebAppFirewall` method to get the details of a firewall. See `GetWebAppFirewall` for a complete description.

**Editing Firewalls**

Describes the different methods to edit a firewall contained within a WAF policy.

Use one of the following methods to edit a firewall contained within a WAF policy.

**To edit a firewall using the Console**

Describes how to edit a firewall contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select WAF Policy.

4. Select the WAF policy to whose firewall you want to edit.
   The WAF Policy Details dialog box appears.
5. Click **Firewalls** under **Resources**.
   The Firewalls list appears.
6. Select the firewall you want to edit.
   The Firewall Details dialog box appears.
7. Click **Edit**.
   Alternatively, click the **Actions** icon (asion) for the firewall and click **Edit**.
   The Edit Firewall dialog box appears.
8. Edit the firewall settings. See Adding Firewalls on page 5801 for descriptions of each setting.
9. Click **Save Changes**.
   The Edit Firewall dialog box closes. The updates you made are present in the details of the firewall.

**To edit a firewall using the CLI**
Describes how to edit a firewall contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall update-for-load-balancer --web-app-firewall-id web-app-firewall-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall update-for-load-balancer --help
```

See [oci waf web-app-firewall update-for-load-balancer](#) for a complete description of the command.

**To edit a firewall using the API**
Describes how to edit a firewall contained within a WAF policy using the API.

Run the `UpdateWebAppFirewall` method to edit a firewall. See [UpdateWebAppFirewall](#) for a complete description.

**Deleting Firewalls**
Describes the different methods to delete from a WAF policy.

Use one of the following methods to delete a firewall from a WAF policy.

**To delete a firewall using the Console**
Describes how to delete a firewall from a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   * **State**
   * **Name**
   * **Policy Type**: Select WAF Policy.
4. Select the WAF policy whose firewall you want to delete.
   The WAF Policy Details dialog box appears.
5. Click **Firewalls** under **Resources**.
   The Firewalls list appears.
Web Application Firewall

6. Select the firewall to delete.
   The Firewall Details dialog box appears.

7. Click Delete.
   Alternatively, click the Actions icon ( ⚙️ ) for the firewall and click Delete.

8. Confirm the deletion when prompted.

The list of firewalls reappears without the firewall you deleted.

**To delete a firewall using the CLI**
Describes how to delete a firewall from a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall delete --web-app-firewall-id web-app-firewall-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall delete --help
```

See `oci waf web-app-firewall delete` for a complete description of the command.

**To delete a firewall using the API**
Describes how to delete a firewall from a WAF policy using API.

Run the `DeleteWebAppFirewall` method to delete a firewall. See `DeleteWebAppFirewall` for a complete description.

Viewing Firewall Metrics
Describes how to view metrics for a firewall contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.

2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select WAF Policy.

4. Select the WAF policy to whose firewall metric which you want to view.
   The WAF Policy Details dialog box appears.

5. Click Firewalls under Resources.
   The Firewalls list appears.

6. Select the firewall whose details you want to get.
   The Firewall Details dialog box appears.

7. Click Metrics under Resources.
8. Specify the date-time group range covered by the metrics by completing the following:
   • Start time
   • End time

   Alternatively, select one of the time spans from the Quick Selects list. The time spans available range from
   the previous hour to 90 days in the future from that moment.

   The Metrics list appears. The list consists of panels displaying metric information on areas such as blocked requests,
   detected requests, traffic, and response code groups. For each panel, you can select commands from the Options list.
   These commands include viewing the query in the Metric Explorer, copying the chart URL, copying the query, and
   viewing the metric information in table view. You can also specify the Interval and Statistic for each chart.

   See Monitoring on page 4024 for more information on monitoring and the Metric Explorer. Use the oci_waf
   namespace when prompted to provide a monitoring namespace.

**Listing Firewall Logs**

Describes how to view logging information for a firewall contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.

2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select WAF Policy.

4. Select the WAF policy to whose firewall logs you want to list.
   The WAF Policy Details dialog box appears.

5. Click Firewalls under Resources.
   The Firewalls list appears.

6. Select the firewall whose logs you want to list.
   The Firewall Details dialog box appears.

7. Click Logs under Resources.
   The list of logs is displayed in tabular form. Each log entry includes the log status, links to display the individual
   log file and the log group to which it belongs. You can also enable or disable the log in each entry. See Logging
   Overview on page 3909 for general information on logging, including how to name log files and create log groups.

**Moving Firewalls Between Compartments**

Describes the different methods to move a firewall contained within a WAF policy between compartments.

Use one of the following methods to move a firewall contained within a WAF policy between compartments.

**To move a firewall between compartments using the Console**

Describes how to move a firewall contained within a WAF policy between compartments using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.

2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - Name
   - Policy Type
   - Status

4. Select the WAF policy to whose firewall you want to move.
   The WAF Policy Details dialog box appears.

5. Click **Firewalls** under **Resources**.
   The Firewalls list appears.

6. Select the firewall you want to move.
   The Firewall Details dialog box appears.

7. Click **Move Resource**.
   Alternatively, click the **Actions** icon ( Modiﬁcation button ) for the firewall and click **Move Resource**.
   The Move Resource to a Different Compartment dialog box appears.

8. Select the compartment to which you want to move your firewall from the **Choose New Compartment** list.

9. Click **Move Resource**.
   The firewall now appears in the compartment you moved it to.

**To move a firewall between compartments using the CLI**

Describes how to move a firewall contained within a WAF policy between compartments using the CLI.

Enter the following command and required parameters:

```bash
oci waf web-app-firewall change-compartment --compartment-id compartment-id --web-app-firewall-id web-app-firewall-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf web-app-firewall change-compartment --help
```

See **oci waf web-app-firewall change-compartment** for a complete description of the command.

**To move a firewall between compartments using the API**

Describes how to move a firewall contained within a WAF policy between compartments using the API.

Run the **ChangeWebAppFirewallCompartment** method to move a firewall between compartments. See **ChangeWebAppFirewallCompartment** for a complete description.

**Access Control Management**

Provides an overview of access controls associated with Web application firewall (WAF) policies, including their creation, updating, and deletion.

WAF access control consists of creating and managing access rules for the following controls:

- Request controls: Rules controlling the inspection of HTTP request properties and the return a defined HTTP response. See **Request Control Management** on page 5809 for more information.
- Response controls: Rules controlling the inspection of HTTP response properties and the return a defined HTTP response. See **Response Control Management** on page 5814 for more information.
Access Rules
Describes the conditions for an access rule used with a WAF policy.

As a WAF administrator, you can define explicit actions for requests that meet various conditions. Conditions use various operations. A rule action can be set to allow, check, and return HTTP response for all matched requests. See Actions Management on page 5878 for more information on actions.

If a WAF policy resource has multiple access rules configured, the rules are run in order. You can reorder these rules as needed.

The available conditions for an access rule are listed and described in Understanding Conditions on page 5781.

Access rules are distinct for request control and response control of a WAF policy. The same access rule cannot be shared between the two types of controls. Management of access rules, such as adding, editing, and deleting an access rule, is described in the Request Control Management on page 5809 and Response Control Management on page 5814 sections.

Request Control Management
Describes the request control for a WAF policy. The topic also describes how to manage its features and functionality.

The request control manages the inspection of HTTP request properties and the return a defined HTTP response.

Manage the request control through the Access Control resource of the WAF policy. Here you can do the following request control tasks:

- View access rules and their properties.
- View the default action for requests that do not match any rule defined in the WAF policy.
- Add and manage access rules, including editing, reordering, and deleting them.
- Specify the default action to be taken when request action rules are met.

Adding Access Rules to Request Controls
Describes how to add an access rule to a request control contained within a WAF policy.

To add an access rule to a request control using the Console

Describes how to add an access rule to a request control contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:

   - State
   - Name
   - Policy Type: Select WAF Policy.

4. Select the WAF policy to which you want to add an access rule to a request control.

   The WAF Policy Details dialog box appears.

5. Click Access Control under Resources.

   The Access Control list appears.

6. Select the Request Control tab.

7. Click Manage Request Control.

   The Manage Request Control dialog box appears.
8. Click **Add Access Rule**.

The Add Access Rule dialog box appears.

Complete the following:

- **Name**: Enter the name of the access rule.
- **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur.
- **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one.
  - **Pre-configured Check Action**: Allows the running of rules and generates a log message documenting the result.
  - **Pre-configured Allow Action**: Skips all remaining rules in the current module.
  - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

Click **Show Header Details** to display the HTTP response headers specified in the selected Return HTTP response action.

Click **Show Response Page Body Details** to display the HTTP response body specified in the selected "Return HTTP response" action.

See **Actions Management** on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

The access rule you created is added to the list of rules and is available for use.

9. Click **Add Access Rule**.

The Add Access Rule dialog box closes.

10. Click **Save Changes** in the Manage Request Control dialog box.

The rule you created appears in the list of access rules for the request control and is available for use.

**Listing Access Rules for Request Controls**

Describes how to display a list of access rules for a request control contained within a WAF policy.

*To list the access rules for a request control rules using the Console*

Describes how to display a list of access rules for a request control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select WAF Policy.

4. Select the WAF policy to which you want to add a firewall.

   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.

   The Access Control list appears.

6. Select the **Request Control** tab.

   Alternatively, click **Manage Request Control** to open the Manage Request Control dialog box.
The Request Control tab and Manage Request Control dialog box both display the list of access control rules contained within the WAF policy.

**Getting Access Rule Details for Request Controls**
Describes how to get the details of an access rule for a request control contained within a WAF policy.

**To view default action settings using the Console**
Describes how to display the default action settings for a request control contained within a WAF policy using the OCI Console.

View the default action settings of the request control to specify how access rules handle requests that do not match any rule defined in the WAF policy.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose default action settings you want to view.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Request Control** tab.

7. Click **Default Action Settings**.
   The Default Action Settings dialog box appears.

The Default Action Settings dialog box displays information regarding the default action. These details include the action name and type, block response code, header information, and the response page body code. The response page body code determines the message returned to users with an access request that cannot be met.

**To get the details of an access rule for a request control using the Console**
Describes how to get the details of an access rule for a request control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy request control access rules details you want to get.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.
6. Select the **Request Control** tab.
   A list of access rules is displayed.

7. Click the "down arrow" next to the access rule whose details you want to get.
   Alternatively, click **Manage Request Control** to display the Manage Request Control dialog box. Click the
   "down arrow" next to the access rule whose details you want to get.

   Alternatively, click **Manage Request Control** to display the Manage Request Control dialog box. Click the
   "down arrow" next to the access rule whose details you want to get.

The details for the request control access rule you selected are displayed, including conditions and action information.

**Editing Access Rules for Request Controls**
Describes how to edit an access rule for a request control contained within a WAF policy.

To edit an access rule for a request control using the Console
Describes how to edit an access rule for a request control contained within a WAF Policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   • **State**
   • **Name**
   • Policy Type: Select WAF Policy.

4. Select the WAF policy whose access rule you want to edit.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Request Control** tab.

7. Click **Manage Request Control**.
   The Manage Request Control dialog box appears.

8. Click **Edit** next to the access rule you want to edit.
   The Edit Access Rule dialog box appears.

9. Edit the access rule settings. See Adding Access Rules to Request Controls on page 5809 for descriptions of
   each setting.

10. Click **Save Changes**.
    The Edit Access Rule dialog box closes.

11. Click **Save Changes** in the Manage Request Control dialog box.

The updates you made are present in the details of the access rule.

**Changing Actions for Request Control Access Rules**
Describes how to change the action for one or more selected access rules for the WAF policy's request control.

To change the actions for request control access rules using the Console
Describes how to change the action for one or more selected access rules for the WAF policy's request control using
the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose request control access rule actions you want to change.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Request Control** tab.

7. Click **Manage Request Control**.
   The Manage Request Control dialog box appears.

8. Check one or more entries in the **Access Rules** list whose actions you want to change.

   **Note:**
   Select at least one access rule entry in the list to use this command.

9. Click **Change Action**.
   The Change Action dialog box appears.

10. Select the action you want to update the selected access rules to use from the list. See **Actions Management** on page 5878 for more information.

11. Click **Change Action**.
    The Change Action dialog box closes.

12. Click **Save Changes** in the Manage Request Control dialog box.
    Those access rules you selected are updated to use the action you specified.

**Reordering Request Control Access Rules**
Describes how to reorder the access rules for a WAF policy's request control.

*To reorder the access rules for a request control using the Console*

Describes how to reorder the access rules for a WAF policy's request control using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose request control access rules you want to reorder.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Request Control** tab.
7. Click **Manage Request Control**.
   
   The Manage Request Control dialog box appears.
   
   If there are multiple access rules listed, each has a **Reorder** menu included under **Change Order**.

8. Click the **Reorder** menu and select the appropriate command, such as **Move Up** or **Move to Bottom**, to reorder the access rule. Repeat this step for each access rule you want to reorder. The access rules run in the order they appear in this list.

9. Click **Save Changes** in the Manage Request Control dialog box.

   The access rules you reordered are updated in the WAF policy's request control.

**Deleting Access Rule from Request Controls**

Describes how to delete an access rule from the request control contained within a WAF policy.

To delete an access rule from a request control using the Console

Describes how to delete an access rule from the request control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose access rule for a request control you want to delete.
   
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   
   The Access Control list appears.

6. Select the **Request Control** tab.

7. Click **Manage Request Control**.
   
   The Manage Request Control dialog box appears.

8. Check one or more access rules that you want to delete and click **Delete**.

9. Confirm the deletion when prompted.

10. Click **Save Changes** in the Manage Request Control dialog box.

    The list of access rules reappears without the access rules you deleted.

**Response Control Management**

Describes response control for a WAF policy. The topic also describes how to manage its features and functionality.

The response control manages the inspection of HTTP response properties and the return a defined HTTP response.

Manage the response control through the Access Control resource of the WAF policy. Here you can do the following response control tasks:

- View access rules and their properties.
- Add and manage access rules, including editing, reordering, and deleting them.
**Adding Access Rules to Response Controls**

Describes how to add an access rule to a response control contained in a WAF policy.

*To add an access rule to a response control using the Console*

Describes how to add an access rule to a response control contained in a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy to which you want to add an access rule to a response control.
   
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   
   The Access Control list appears.

6. Select the **Response Control** tab.
    
   The Manage Response Control dialog box appears.

8. Click **Add Access Rule**.
   
   The Add Access Rule dialog box appears.
   
   Complete the following:
   
   - **Name**: Enter the name of the access rule.
   - **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur.
   - **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one.
   - **Pre-configured Check Action**: Allows the running of rules and generates a log message documenting the result.
   - **Pre-configured Allow Action**: Skips all remaining rules in the current module.
   - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

   Click **Show Header Details** to display the HTTP response headers specified in the selected Return HTTP response action.

   Click **Show Response Page Body Details** to display the HTTP response body specified in the selected "Return HTTP response" action.

   See **Actions Management** on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

   The access rule you created is added to the list of rules and is available for use.

9. Click **Add Access Rule**.
   
   The Add Access Rule dialog box closes.

10. Click **Save Changes** in the Manage Response Control dialog box.
    
   The rule you created appears in the list of access rules for the response control and is available for use.
Listing Access Rules for Response Controls
Describes how to display a list of response control rules contained within a WAF policy.

To list the access rules for a response control using the Console
Describes how to display a list of response control rules contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy to which you want to add a firewall.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Response Control** tab.
   Alternatively, click **Manage Response Control** to open the Manage Response Control dialog box.
   The Response Control tab and Manage Response Control dialog box both display the list of response control rules contained within the WAF policy.

Getting Access Rule Details for Response Controls
Describes how to get the details of an access rule for a response control contained within a WAF policy.

To get the details of an access rule for a response control using the Console
Describes how to get the details of an access rule for a response control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose response control access rule you want to get.
   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.
   The Access Control list appears.

6. Select the **Response Control** tab.
   A list of access rules is displayed.

7. Click the "down arrow" next to the access rule whose details you want to get.
   Alternatively, click **Manage Response Control** to display the Manage Response Control dialog box. Click the "down arrow" next to the action whose details you want to get.
The details for the response control access rule you selected are displayed, including conditions and action information.

**Editing Access Rules for Response Controls**

Describes how to edit an access rule for a response control contained within a WAF policy using the OCI Console.

*To edit an access rule for a response control using the Console*

Describes how to edit an access rule for a response control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy whose access rule for a response control you want to edit.
   
   The WAF Policy Details dialog box appears.
5. Click **Access Control** under **Resources**.
   
   The Access Control list appears.
6. Select the **Response Control** tab.
7. Click **Manage Response Control**.
   
   The Manage Response Control dialog box appears.
8. Click **Edit** next to the access rule you want to edit.
   
   The Edit Access Rule dialog box appears.
9. Edit the access rule settings. See **Adding Access Rules to Response Controls** on page 5815 for descriptions of each setting.
10. Click **Save Changes**.
    
    The Edit Access Rule dialog box closes.
11. Click **Save Changes** in the Manage Request Control dialog box.
   
    The updates you made are present in the details of the access rule.

**Changing Actions for Response Control Access Rules**

Describes how to change the action for one or more selected access rules for the WAF policy's response control.

*To change the actions for response control access rules using the Console*

Describes how to change the action for one or more selected access rules for the WAF policy's response control using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose response control access rule actions you want to change. The WAF Policy Details dialog box appears.
5. Click **Access Control** under **Resources**. The Access Control list appears.
6. Select the **Response Control** tab.
7. Click **Manage Response Control**. The Manage Response Control dialog box appears.
8. Check one or more entries in the **Access Rules** list whose actions you want to change.

   **Note:**
   You must select at least one access rule entry in the list to use this command.

9. Click **Change Action**. The Change Action dialog box appears.
10. Select the action you want to update the selected access rules to use from the list. See **Actions Management** on page 5878 for more information.
11. Click **Change Action**. The Change Action dialog box closes.
12. Click **Save Changes** in the Manage Request Control dialog box.
Those access rules you selected are updated to use the action you specified.

**Reordering Response Control Access Rules**
Describes how to reorder the access rules for a WAF policy's response control.

*To reorder the access rules for a response control using the Console*

Describes how to reorder the access rules for the WAF policy's response control using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**. Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**. The WAF Policies page appears.
2. Select the **Compartment** from the list. All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy whose response control access rules you want to reorder. The WAF Policy Details dialog box appears.
5. Click **Access Control** under **Resources**. The Access Control list appears.
6. Select the **Response Control** tab.
7. Click **Manage Response Control**.

   The Manage Response Control dialog box appears.

   If there are multiple access rules listed, each has a **Reorder** menu included under **Change Order**.

8. Click the **Reorder** menu and select the appropriate command, such as **Move Up** or **Move to Bottom**, to reorder the access rule. Repeat this step for each access rule you want to reorder. The access rules run in the order they appear in this list.

9. Click **Save Changes** in the Manage Response Control dialog box.

   The access rules you reordered are updated in the WAF policy's response control.

**Deleting Access Rules from Response Controls**

Describes how to delete an access rule from the response control contained within a WAF policy.

To delete an access rule from a response control using the Console

Describes how to delete an access rule from the response control contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:

   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose access rule for a response control you want to delete.

   The WAF Policy Details dialog box appears.

5. Click **Access Control** under **Resources**.

   The Access Control list appears.

6. Select the **Response Control** tab.

7. Click **Manage Response Control**.

   The Manage Response Control dialog box appears.

8. Check one or more access rules that you want to delete and click **Delete**.

9. Confirm the deletion when prompted.

10. Click **Save Changes** in the Manage Request Control dialog box.

    The list of access rules reappears without the access rules you deleted.

**Rate Limiting Management**

Provides an overview of rate limiting rules associated with Web application firewall (WAF) policies, including their creation, updating, and deletion.

Rate limiting allows inspection of HTTP request properties and limits the frequency of requests for each unique client IP address.
**Adding Rate Limiting Rules**
Describes how to add a rate limiting rule to a WAF policy.

**To add a rate limiting rule using the Console**
Describes how to add a rate limiting rule to a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select WAF Policy.
4. Select the WAF policy to which you want to add a rate limiting rule.
   The WAF Policy Details dialog box appears.
5. Click **Rate Limiting** under **Resources**.
   The Rate Limiting list appears.
6. Click **Manage Rate Limiting**.
   The Manage Rate Limiting dialog box appears.
7. Click **Add Rate Limiting Rule**.
   The Add Rate Limiting Rule dialog box appears.
   Complete the following:
   - **Name**: Enter the name of the rate limit rule.
   - **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur. The parameters displayed can vary depending on the **Condition Type** and **Operator** values you select.
+ **Another Condition** to add another condition linked to the first one using AND. Click X to delete the associated condition row.

(optional) Click **Show Advance Controls** if you want to specify a condition in the box using the condition syntax. See **Understanding Conditions** on page 5781 for more information on how to author the conditions for your rate limiting rule.

- **Rate Limiting Configuration**: Enter the following conditions that are required to be met before the conditions apply.
  - **Request Limit**: Enter the maximum number of requests made.
  - **Period in Seconds**: Enter the number of seconds passed.
  - **Action Duration in Seconds**: Enter the duration of the action in seconds.

Click + **Another Rate Limit** to display another rate limit configuration row to complete. Click X to delete the associated rate limit configuration row.

- **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one.
  - **Pre-configured Check Action**: Allows the running of rules and generates a log message documenting the result.
  - **Pre-configured Allow Action**: Skips all remaining rules in the current module.
  - **Pre-configured 401 Response Code Action**: Returns a defined HTTP response. The response code configuration (headers and response page body) determines the HTTP response that is returned when this action is run.

  Click **Show Header Details** to display the HTTP response headers specified in the selected Return HTTP response action.

  Click **Show Response Page Body Details** to display the HTTP response body specified in the selected "Return HTTP response" action.

See **Actions Management** on page 5878 for a complete description and explanation of how to use actions in a WAF policy.

8. Click **Add Rate Limiting Rule**.

   The Add Rate Limiting Rule dialog box closes.

9. Click **Save Changes** in the Manage Rate Limiting dialog box.

   The rate limiting rule you created is included in the Rate Limiting Rule list.

**Listing Rate Limiting Rules**

Describes how to display a list of rate limiting rules contained within a WAF policy.

**To list the rate limiting rules using the Console**

Describes how to display a list of rate limiting rules contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
  - **State**
  - **Name**
  - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose rate limiting rules you want to list.

   The WAF Policy Details dialog box appears.
5. Click **Rate Limiting** under **Resources**.
   The Rate Limiting list appears.
   Alternatively, click **Manage Rate Limiting** to open the Manage Rate Limiting dialog box.

The Rate Limiting list displayed shows the name, number of configurations using the rule, and action name associated with the rate limiting rule.

**Getting Rate Limiting Rule Details**
Describes how to get the details of a rate limiting rule contained within a WAF policy.

**To get the details of a rate limiting rule using the Console**
Describes how to get the details of a rate limiting rule contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy whose rate limiting details you want to get.
   The WAF Policy Details dialog box appears.
5. Click **Rate Limiting** under **Resources**.
   The Rate Limiting list appears.
6. Click the "down arrow" next to the rule whose details you want to get.
   Alternatively, click **Manage Request Control** to display the Manage Request Control dialog box. Click the "down arrow" next to the action whose details you want to get.

The details for the rate limiting rule you selected are displayed, including conditions and action information.

**Editing Rate Limiting Rules**
Describes how to edit a rate limiting rule contained within a WAF policy using the OCI Console.

**To edit a rate limiting rule using the Console**
Describes how to edit a rate limiting rule contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy whose rate limiting rule you want to edit.
   The WAF Policy Details dialog box appears.
5. Click **Rate Limiting** under **Resources**.

   The Rate Limiting list appears.

6. Click **Manage Rate Limiting**.

   The Manage Rate Limiting dialog box appears.

7. Click **Edit** next to the rate limiting rule you want to edit.

   The Edit Rate Limiting Rule dialog box appears.

8. Edit the rate limiting rule settings. See **Adding Rate Limiting Rules** on page 5820 for descriptions of each setting.

9. Click **Save Changes**.

   The Edit Rate Limiting Rules dialog box closes.

10. Click **Save Changes** in the Manage Rate Limiting dialog box.

    The updates you made are present in the details of the rate limiting rule.

**Changing Actions for Rate Limiting Rules**

Describes how to change the action for one or more selected rate limiting rules for the WAF policy.

**To change the actions for rate limiting rules using the Console**

Describes how to change the action for one or more selected rate limiting rules for the WAF policy.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:

   • **State**
   • **Name**
   • **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose rate limiting rule actions you want to change in bulk.

   The WAF Policy Details dialog box appears.

5. Click **Rate Limiting** under **Resources**.

   The Rate Limiting list appears.

6. Click **Manage Rate Limiting**.

   The Manage Rate Limiting dialog box appears.

7. Check each rate limiting rule whose action you want to change and click **Change Action**.

   The Change Action dialog box appears.

8. Select the action you want to update the selected access rules to use from the list. See **Actions Management** on page 5878 for more information.

9. Click **Change Action**.

   The Change Action dialog box closes.

10. Click **Save Changes** in the Manage Rate Limiting dialog box.

    The action rule is updated to the one you selected for the checked rate limiting rules.
Deleting Rate Limiting Rules
Describes how to delete a rate limiting rule from WAF policy using the OCI Console.

To delete a rate limiting rule using the Console
Describes how to delete a rate limiting rule from WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select **WAF Policy**.

4. Select the WAF policy whose rate limiting rule you want to delete.
   The WAF Policy Details dialog box appears.

5. Click **Rate Limiting** under **Resources**.
   The Rate Limiting list appears.

6. Click **Manage Rate Limiting**.
   The Manage Rate Limiting dialog box appears.

7. Check one or more rate limit rules that you want to delete and click **Delete**.

8. Confirm the deletion when prompted.

9. Click **Save Changes** in the Rate Limiting dialog box.
   The list of rate limiting rules reappears without the access rate limiting rules you deleted.

Protections Management
Provides an overview of protection rules associated with Web application firewall (WAF) policies, including their creation, updating, and deletion.

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met.

Exclusions
Sometimes a protection rule can trigger a false positive. You can configure an exception if the request(s) generating the false positive have a particular argument or cookie that can be used to identify that request be excluded from the action normally taken on the rule. You can create exclusions using the OCI Console or through the API. Use the following exclusion parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQUEST_COOKIES</td>
<td>Cookie Value</td>
</tr>
<tr>
<td>ARGS</td>
<td>Argument (Query Parameter or POST/PUT data)</td>
</tr>
</tbody>
</table>

Protection Capabilities Tuning
This basic WAF tuning guide outlines the fundamentals of rule tuning, log inspection, and setting up capability exclusions. Tuning a WAF policy can be beneficial for the following reasons:
- Reduces the chance of blocking a legitimate request.
- Protects against standard web application attacks.
Web Application Firewall

- Protects against specific web application attacks.
- Reduces the amount of scanning, which leads to better performance.

The following table shows protection capabilities terms and definitions.

**Protection Capabilities Definitions**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuning</td>
<td>The process in which the customer's engineer or analyst modifies protection capabilities and actions to allow the application server to be protected but remain functional. There exists a balance between locking down the application server and allowing the application server to perform its duties. The best tuning takes an intimate knowledge of the application server being protected and protection capabilities available to protect that application server.</td>
</tr>
<tr>
<td>False positive</td>
<td>A false positive occurs when a protection capability is matched against an HTTP transaction and the HTTP transaction is a legitimate (non-malicious) transaction.</td>
</tr>
<tr>
<td>Exclusion</td>
<td>A modification to a protection capability that allows the value or value name of a cookie or HTTP argument to be ignored.</td>
</tr>
</tbody>
</table>

**Overview of Protection Rules**

WAF protects your web applications against threats. WAF is a regional-based service that is attached to an enforcement point. WAF supports 454 rule sets, and rule sets for the Open Web Application Security Project (OWASP). Use these rules to protect your critical web applications against malicious cyberattacks. These rules are compared against incoming requests to determine if the request contains an attack payload. If it determines that the request is an attack, WAF blocks or alerts you to that request. These attacks are varied and include threats such as SQL injection, cross-site scripting, and HTML injection—all of which the WAF rule sets can detect and block.

WAF protection is a toolkit designed for web application monitoring, logging, and access control. The toolkit lets you decide how you want to take advantage of all the protection rules available instead. This flexibility is a core element of WAF protection rules, as we are constantly pushing updates to increase the security scope of our rules.

The core principles of WAF protection rules are:

- Passiveness: You decide which rules are required, therefore you have full control.
- Flexibility: The Oracle WAF security team has curated a list of protection rules that address both OWASP top 10 and critical CVE's for lots of popular web applications.
- Quality not quantity: WAF protection rules are a dedicated module designed to inspect HTTP traffic that works with the other WAF features (for example, access control).
- Predictability: Having full control of the WAF protection rules allows you to control the results expected. You can define and tune your protection rules and leave the setup unattended, knowing that it keeps working as it was configured.

**Setting Up Logging**

WAF uses the OCI Logging service for all logging needs. See Logging Overview on page 3909 for more information.
More Information on Protection Rules

Individual Protection Rules Versus Collaborative Protection Rules
To limit false positives, special protection rules that are tagged as "collaborative" exist. These rule groups operate differently than the rest of the protection rules, as they use a scoring and threshold system to evaluate traffic. Individual rules work by matching elements of the HTTP transaction against the rule signature. If a match is made, the rule performs its action (for example, detecting or blocking). Each of the collaborative protection rules uses a group of individual rules. The collaborative protection rules require multiple matches of elements of the HTTP transaction against individual rules to perform its action (for example, detecting or blocking). For a collaborative rule to perform its action, elements of the HTTP transaction must match against the individual rules in the collaborative group, related to the weight vs thresholds being set on the collaborative rules. After the exclusion is added within the collaborative protection rule group, it will apply to all the rules within it. The following is a list of the collaborative protection rule IDs.

Collaborative Protection Rule IDs

- 9300000 - Local File Inclusion (LFI) Collaborative Group - LFI Filter Categories
- 9320000 - Remote Code Execution (RCE) Collaborative Group - UNIX RCE Filter Categories
- 9330000 - PHP Injection Attacks Collaborative Group - PHP Filters Categories
- 9410000 - Cross-Site Scripting (XSS) Collaborative Group - XSS Filters Categories
- 9420000 - SQL Injection (SQLi) Collaborative Group - SQLi Filters Categories

Other Protection Rules
The following is a list of protection rules that are "noisy," with some descriptions and recommendations which help you understand what the rule is trying to match. Exclusions cannot be applied to some of these rules.

<table>
<thead>
<tr>
<th>Rule ID</th>
<th>Rule Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>920310</td>
<td>Missing Accept Header</td>
<td>Even when requests without accept headers do not mean a violation of the HTTP protocol, requests without accept headers are most often not genuine requests. The rule might be alerting for API or custom application requests. To avoid scanning API or custom application requests, collect a list of the well-known applications that send traffic through and request custom rules. For more information, see RFC 7231, section-5.3.2.</td>
</tr>
<tr>
<td>920311</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>----------</td>
<td>----------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920280</td>
<td>Missing Host Header</td>
<td>As described in RFC 7230, section-5.4 &quot;A server must respond with a 400 (Bad Request) status code to any HTTP/1.1 request message that lacks a Host header field and to any request message that contains more than one Host header field or a Host header field with an invalid field-value.&quot; This is an essential method of protection and at the same time ensures that WAF servers properly identify which WAF policy the request is intended for. Since WAF requires a host header to pass traffic to the proper origin, this rule might cause a high rate of false positives.</td>
</tr>
<tr>
<td>920320</td>
<td>Missing User-Agent Header</td>
<td>This rule prevents unidentified users from accessing your web application. User-Agent is one of the request headers defined in various RFCs that provides user information. Even when a request contains a user agent, it does not imply it comes from a real human. This rule works as a first level of mitigation for &quot;dummy&quot; attacks that originate from possible bots or &quot;non-RFC compliant&quot; applications. Note: Some APIs might not include the User-Agent header. If API requests are expected, ensure you add the API IP address to the allowlist or have a custom WAF rule that excludes this traffic from being inspected. For more information, see RFC 7231, section-5.5.3. This rule is an indicator of bad or malicious traffic, but it is possible legitimate applications do not have a User-Agent. Ask application owners to use User-Agents when applicable.</td>
</tr>
<tr>
<td>920330</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>-------</td>
</tr>
<tr>
<td>920170</td>
<td>GET/HEAD Requests Validation</td>
<td>As described in RFC 7231, section-4.3.1 and section-4.3.2, HEAD and GET are HTTP methods intended to retrieve information from the origin server. Even when not forbidden by the RFC, sending body or payload through these types of methods is not a common practice. Usually it is caused by improperly defined applications not following the best practices of the RFC and can be used by malicious users as a bypass technique. It is also defined in RFC 2616, section-4.3 &quot;if the request method does not include defined semantics for an entity-body, then the message-body should be ignored when handling the request.&quot;</td>
</tr>
<tr>
<td>920171</td>
<td>Missing Content-Type Header</td>
<td>As defined under RFC 2616, section-7.2.1, &quot;Any HTTP/1.1 message containing an entity-body should include a Content-Type header field defining the media type of that body.&quot; If this best practice is not followed, it could lead to MIME-type sniffing attacks.</td>
</tr>
<tr>
<td>920180</td>
<td>Allowed HTTP methods</td>
<td>The default allowed HTTP methods are GET, HEAD, POST, and OPTIONS. OPTIONS is known as an insecure method because it is highly used by attackers to gather up information from the origin server. This method is also required by some applications to work properly. If this method is not required, create a service request with My Oracle Support to disable it. Other methods can also be added as required with a service request.</td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>----------</td>
<td>----------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920380</td>
<td>Max amount of arguments</td>
<td>RFC does not enforce the number of arguments that a request must have, but using many arguments could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum number of ARGs allowed per request. The default value is 255.</td>
</tr>
<tr>
<td>920370</td>
<td>Max length of an argument</td>
<td>RFC does not enforce the length per argument that a request must have, but using large argument length could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum length of ARGs allowed per request. The default value is 400.</td>
</tr>
<tr>
<td>920390</td>
<td>Max total argument length</td>
<td>RFC does not enforce the total (combined) argument size that a request must have, but large combined argument values could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum combined argument value allowed per request. The default value is 64000.</td>
</tr>
<tr>
<td>920350</td>
<td>Host Header Is IP Address</td>
<td>This rule does not usually trigger, as WAF needs a host header to send traffic to the origin.</td>
</tr>
<tr>
<td>941120</td>
<td>Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 2</td>
<td>This rule takes a long time to process if there is a large payload. For example, a payload with 64,005 bytes takes around 32 seconds to process.</td>
</tr>
</tbody>
</table>

**Protection Rules**

The following table list those protection rules supported by WAF.
<table>

### Listing Protection Capabilities

Describes the different methods to display a list of protection capabilities.

Use one of the following methods to display a list of protection capabilities.

**To list the protection capabilities using the Console**

Describes how to display a list of protection capabilities using the Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy to which you want to add a request production rule.

   The WAF Policy Details dialog box appears.

5. Click **Protections** under **Resources**.

   The Protections list appears.

6. Click **Manage Request Protection Rules**.

   Manage Response Protection Rules dialog box appears.

7. Click **Add Request Protection Rule**.

   The Add Request Protection Rule dialog box appears.

8. Click **Choose Protection Capabilities**.

   The Choose Protection Capabilities dialog box appears.

   The Protection Capabilities list displays all the protections capabilities that are available for request protection and response protection rules.

**To list the protection capabilities using the CLI**

Describes how to display a list of protection capabilities using the CLI.

Enter the following command and required parameters:

```bash
oci waf protection-capability list --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf protection-capability list --help
```

See **oci waf protection-capability list** for a complete description of the command.

</table>
To list the protection capabilities using the API
Describes how to display a list of protection capabilities using the API.

Run the ListProtectionCapabilities method to display a list of protection capabilities. See ListProtectionCapabilities for a complete description.

Listing Tags for Filtering Protection Capabilities
Describes the different methods to display a list tags used to filter the list of protection capabilities contained within a WAF policy.

Use one of the following methods to display a list of tags used to filter the list of protection capabilities.

To list the tags for filtering protection capabilities using the Console
Describes how to display a list of tags used for filtering protection capabilities contained within a WAF policy using the Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select WAF Policy.
4. Select the WAF policy to which you want to add a request production rule.
   The WAF Policy Details dialog box appears.
5. Click Protections under Resources.
   The Protections list appears.
6. Click Manage Request Protection Rules.
   Manage Response Protection Rules dialog box appears.
7. Click Add Request Protection Rule.
   The Add Request Protection Rule dialog box appears.
8. Click Choose Protection Capabilities.
   The Choose Protection Capabilities dialog box appears.
9. Click the Filter by Tags box.
   The Filter by Tags list displays all the tags that are available for filtering the list of protection rules.

To list the tags for filtering protection capabilities using the CLI
Describes how to display a list of tags used for filtering protection capabilities contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf protection-capability list-protection-capability-group-tags --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waf protection-capability list-protection-capability-group-tags --help
```

See oci waf protection-capability list-protection-capability-group-tags for a complete description of the command.
To list the tags for filtering protection capabilities using the API
Describes how to display a list of tags used for filtering protection capabilities contained within a WAF policy using the API.

Run the ListProtectionCapabilityGroupTags method to display a list of protection capabilities. See ListProtectionCapabilityGroupTags for a complete description.

Request Protection Rules Management
Provides an overview of the request protection rules for a Web application firewall (WAF) policy, including their creation, updating, and deletion.

Request protection rules enable the checking of HTTP requests for malicious content and to return a defined HTTP response.

Adding Request Protection Rules
Describes how to add a request protection rule to a WAF policy.

To add a request protection rule using the Console
Describes how to add a request protection rule to a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:

   • State
   • Name
   • Policy Type: Select WAF Policy.

4. Select the WAF policy to which you want to add a request protection rule.

   The WAF Policy Details dialog box appears.

5. Click Protections under Resources.

   The Protections list appears.

7. Click Manage Request Protection Rules.

   The Manage Request Protection Rules dialog box appears.
8. Click **Add Request Protection Rule**.

The Add Request Protection Rule dialog box appears.

Complete the following:

- **Name**: Enter the name of the request protection rule.
- **Conditions**: Specify the prerequisite conditions that need to be met for the rule action to occur. See Understanding Conditions on page 5781 for more information on how to author the conditions for your access rule.
- **Rule Action**: Select an existing rule to be followed when the preceding conditions are met, or select **Create New Action** to add one. See Actions Management on page 5878 for more information.
- **Protection Capabilities** list: Displays all protection capabilities associated with the protection rule and their information. This information includes the key number, the capability name, collaborative status, any applied tags, and the action used.

  **Note**: Protection capabilities are not necessarily run in the order they are listed here.

Click **Choose Protection Capabilities** to open the Choose Protection Capabilities dialog box. Complete the following:

- **Filter by Tags**: Select one or more filters to limit the protection capabilities displayed.
- **Filter by Version**: Select one or more versions to limit the protection capabilities displayed.
- **Reset All Filters**: Click to remove all user-inputted filters.
- **Protections** list: Check each protection that you want to apply to the rule.

Click **Choose Protection Capabilities** to apply the protections you selected to the rule. The Choose Protection Capabilities dialog box closes.

Click the **Actions** icon ( ) for a protection capability entry and select any of the following commands:

- **View and Edit Protection Capability Settings**: Click to open the View and Edit Protection Capability Settings dialog box. Here you can view setting information such as allowed HTTP methods, header information, and argument information.

  Click **Edit** to update the following settings:

  - **Allowed HTTP Methods**: Select the HTTP methods allowed by the protection capability 911100: Restrict HTTP Request Methods.
  - **Maximum HTTP Request Header Length**: Enter the maximum header length allowed in an HTTP request by the protection capability 9200024: Limit length of request header size.
  - **Maximum HTTP Request Headers**: Enter the maximum number of headers allowed in an HTTP request by the protection capability 9200014: Limit Number of Request Headers.
  - **Maximum Number of Arguments**: Enter the maximum number of arguments allowed by the protection capability 920380: Number of Arguments Limits.
  - **Maximum Single Argument Length**: Enter the maximum argument length allowed by the protection capability 920370: Limit argument value length.
  - **Maximum Total Argument Length**: Enter the maximum total combined length of all arguments allowed by the protection capability 920390: Limit arguments total length.

Click **Save Changes**. The View and Edit Protection Capabilities Settings dialog box is closed and your updates saved.

- **Change Action**: Check one or more protections from the list and click **Change Action** to open the Change Action dialog box. Here you can select a different action for the protection capabilities you selected. See Actions Management on page 5878 for more information.
- **Delete**: Check one or more protections from the list and click **Delete**. Confirm the deletions when prompted. All the protections you checked are now deleted.
For each entry in the Protection Capabilities list, you can select the following from the Actions icon (⋮):

- **View Details**: Opens the Capability Details dialog box. Here you can view the name, description, version, and collaborative status of the protection capability.
- **Change Action**: Opens the Change Action dialog box. Here you can select a different action for the protection capability. See Actions Management on page 5878 for more information.
- **Exclusions**: Opens the Exclusions dialog box. Here you can specify the types of request that the protection rules bypass. If a request matches any of the set exclusions, the protection rules are run for that request. Select the type and corresponding value for each exclusion entry. Click +Additional Exclusion to add another exclusion to the protection capability. Click X to delete an exclusion. Click Save Changes when done.
- **Override Weight and Threshold**: Opens the Override Weight and Threshold dialog box. Here you can view the Default Collaborative Capability Weight and Default Collaborative Capability Threshold information. Check Override weights and threshold to override any of the default values. Click Save Changes.

9. Click Add Request Protection Rule.
   The Add Request Protection Rule dialog box closes and the request protection rule you added is included in the Request Protection Rules list.

10. Click Save Changes in the Manage Request Protection Rules dialog box.
    The rule you created appears in the list of request protection rules and is available for use.

**Listing Request Protection Rules**
Describes how to display a list of request protection rules contained with a WAF policy.

'To list the request protection rules using the Console'
Describes how to display a list of request protection rules contained with a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**. Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - State
   - Name
   - **Policy Type**: Select WAF Policy.

4. Select the WAF policy to which you want to add a request protection rule.
   The WAF Policy Details dialog box appears.

5. Click **Protections** under **Resources**.
   The Protections list appears.

6. Select the **Request Protection Rules** tab.
   Alternatively, click **Manage Request Protection Rules** to open the Manage Request Protection Rules dialog box.
   The list of request protection rules is displayed.

The list of request protection rules displayed shows the name, number of configurations using the rule, and action name associated with the request protection rule.
**Getting Request Protection Rule Details**
Describes how to get the details of a request protection rule contained within a WAF policy.

*To get the details of a request protection rule using the Console*
Describes how to get the details of a request protection rule contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy to which you want to add a request protection rule.
   The WAF Policy Details dialog box appears.
5. Click **Protections** under **Resources**.
   The Protections list appears.
6. Select the **Request Protection Rules** tab.
   Alternatively, click **Manage Request Control** to display the Manage Request Control dialog box.
   A list of request protection rules is displayed.
7. Click the "down arrow" next to the request protection rule whose details you want to get.
   The details for the request protection rule you selected are displayed, including conditions and action information.

**Editing Request Protection Rules**
Describes how to edit a request protection rule contained within a WAF policy using the OCI Console.

*To edit a request protection rule using the Console*
Describes how to edit a request protection rule contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.
4. Select the WAF policy whose request protection rule you want to edit.
   The WAF Policy Details dialog box appears.
5. Click **Protections** under **Resources**.
   The Protections list appears.
6. Select the **Request Protection Rules** tab.
7. Click **Manage Request Protection Rules**.
   The Manage Request Protection Rules dialog box appears.
8. Click **Edit** next to the request protection rule you want to edit.

   The Edit Request Protection Rule dialog box appears.

9. Edit the request protection rule settings. See *Adding Request Protection Rules* on page 5874 for descriptions of each setting.

10. Click **Save Changes**.

    The Edit Request Protection Rules dialog box closes.

11. Click **Save Changes** in the Manage Request Protection Rules dialog box.

    The updates you made are present in the details of the request protection rule.

**Deleting Request Protection Rules**

Describes how to delete a request protection rule from a WAF policy.

*To delete a request protection rule using the Console*

Describes how to delete a request protection rule from a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **WAF Policy**.

4. Select the WAF policy whose request protection rule you want to delete.

   The WAF Policy Details dialog box appears.

5. Click **Protections** under **Resources**.

   The Protections list appears.

6. Select the **Request Protection Rules** tab.

7. Click **Manage Request Protection Rules**.

   The Manage Request Protection Rules dialog box appears.

8. Check one or more request protection rules that you want to delete and click **Delete**.

9. Confirm the deletion when prompted.

10. Click **Save Changes** in the Manage Request Protection Rules dialog box.

    The list of request protections reappears without the request protection rules you deleted.

**Actions Management**

Describes how actions are added and managed with the WAF policy.

Actions are objects that represent one of the following:

- **Allow**: An action, which upon matching rule, skips all remaining rules in the current module.
- **Check**: An action which does not stop the execution of rules in current module. Instead it generates a log message documenting result of rule execution.
- **Return HTTP response**: An action which terminates all further processing of an HTTP request or HTTP response and returns a predefined HTTP response that can be configured in the action definition.

When this action is run in an HTTP request rule, it prevents the HTTP request from being forwarded to a backend. Instead of returning the HTTP response from the backend, the HTTP response that was defined in the action is returned. This action is typically used to block HTTP requests matching specific criteria. When this action is run
in an HTTP response rule, it prevents the original HTTP response from the backend from being sent back to the client. Instead, the HTTP response is replaced by the one defined in the action.

Access the Actions list in the WAF Policies page under Resources. Here you can view all the existing actions and their type and how frequently they are employed as part of a rule. The Actions list contains the Manage Action function that allows you to add and delete actions.

**Adding Actions**

Describes how to add an action to a WAF policy.

**To add an action using the Console**

Describes how to add an action to a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select WAF Policy.
4. Select the WAF policy for which you want to add an action.
   The WAF Policy Details dialog box appears.
5. Click Actions under Resources.
   The Actions list appears.
6. Click Manage Actions.
   The Manage Actions dialog box appears.
7. Click Add Action.
   The Add Action dialog box appears.
8. Complete the following:
   • Action Name: Enter the name of the action.
   • Action Type: Specify the action type:
     • Allow: Skips all remaining rules in the current module.
     • Check: Does not stop the execution of rules. Instead it generates a log message documenting the result of the rule.
     • Return HTTP Response: Returns a defined HTTP response.
       Select the Response Code from the list.
   • Headers: Complete the following:
     • Header Name: Enter the name of the header.
     • Header Value: Enter the associated value of the header.
     • Click + Another Header to display another header row where you can enter a header name and value pair. Click X to delete the associated header row.
   • Response Page Body: Enter the HTTP response body, for example a JSON error response:

```json
{"code":"403","message":"Forbidden"}
```
9. Click **Add Action**.
   The Add Action dialog box closes.

10. Click **Save Changes** in the Manage Actions dialog box.
    The action you created is included in the Action list.

**Listing Actions**
Describes how to display a list of actions contained within a WAF policy.

**To list the actions using the Console**
Describes how to display a list of actions contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - State
   - Name
   - **Policy Type**: Select WAF Policy.
4. Select the WAF policy containing the actions you want to list.
   The WAF Policy Details dialog box appears.
5. Click **Actions** under **Resources**.
   The Actions list appears.
   The Actions list displayed shows the name, action type (Allow, Check, Return HTTP Response), and rule usage (attached load balancer name).

**Getting Action Details**
Describes how to get the details of an action contained within a WAF policy.

**To get the details of an action using the Console**
Describes how to get the details of an action contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - State
   - Name
   - **Policy Type**: Select WAF Policy.
4. Select the WAF policy containing the action for which you want to get details.
   The WAF Policy Details dialog box appears.
5. Click **Actions** under **Resources**.
   The **Actions** list appears.
6. Click the "down arrow" next to the action whose details you want to get.
Alternatively, click Manage Actions to display the Manage Actions dialog box. Click the "down arrow" next to the action whose details you want to get.

The Actions details appear under the displayed shows the Name, Action Type (Allow, Check, Return HTTP Response), and Rule Usage (attached load balancer name).

**Editing Actions**

Describes how to edit an action contained within a WAF policy.

**To edit an action using the Console**

Describes how to edit an action contained within a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.

4. Select the WAF policy containing the action for which you want to edit.

   The WAF Policy Details dialog box appears.

5. Click Actions under Resources.

   The Actions list appears.

6. Click Manage Actions.

   The Manage Actions dialog box appears.

7. Click Edit.

   The Edit Action dialog box appears.

8. Edit the action settings. See Adding Actions on page 5879 for descriptions of each setting.

9. Click Save Changes.

   The Edit Action dialog box closes.

10. Click Save Changes in the Manage Actions dialog box.

   The updates you made are present in the details of the action.

**Deleting Actions**

Describes how to delete an action from a WAF policy.

**To delete an action using the Console**

Describes how to delete an action from a WAF policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   - State
   - Name
   - Policy Type: Select WAF Policy.

4. Select the WAF policy containing the action for which you want to edit.
   The WAF Policy Details dialog box appears.

5. Click Actions under Resources.
   The Actions list appears.

6. Click Manage Actions.
   The Manage Actions dialog box appears.

7. Check one or more actions from the list that you want to delete.

8. Click Delete.

9. Confirm the deletions when prompted.

10. Click Save Changes in the Manage Actions dialog box.
    The list of actions reappears without the actions you deleted.

Network Address List Management

Provides an overview of the network address lists for a web application firewall (WAF) policy, including their creation, updating, and deletion.

Network address lists are collections of individual public IP addresses and CIDR IP ranges or private IP addresses used by WAF policies.

Creating Network Address Lists

Describes the different methods to create a network address list for a WAF policy.

Use one of the following methods to create a network address list for a WAF policy.

To create a network address list using the Console
Describes how to create a network address list for a WAF policy using the OCI Console.

1. Open the navigation menu and click Identity & Security. Under Web Application Firewall, click Network Address List.
   Alternatively, open the Web Application Firewall page and click Network Address List under Resources.
   The WAF Network Address List page appears.

2. Choose a Compartment you have permission to work in under List Scope.

3. Click Create WAF Network Address List.
   The Create WAF Network Address List dialog box appears.
4. Complete the following:
   • **Name**: Enter the name of the network address list.
   • **Create in Compartment**: Select the compartment that contains the network address list you are creating.
   • **Address Type**: Specify the address type and its associated requirements:
     • **Addresses**: Use this type of network address list to match traffic coming from the internet or traffic coming from the same VCN where the associated load balancer is hosted.
     • **IP Addresses**: Enter each IP address and CIDR IP range on a separate line within the box.
     • **VCN Addresses**: Use this type of network address list to match traffic coming from other VCNs through service gateways or private endpoints.
     • **Virtual Cloud Network**: Select the VCN associated with your list of private IP addresses. Click **Change Compartment** to choose a VCN in a different compartment.
     • **VCN IP Addresses**: Enter each IP address and CIDR IP range on a separate line within the box.
     • **Show Tagging Options**: Click to display the tagging option fields for the WAF policy. See **Tagging Resources** on page 5781 for more information.

5. Click **Create**.

The Create WAF Network Address List dialog box closes. The network address list you created is included with the other lists in the WAF Network Address List page.

**To create a network address list using the CLI**

Describes how to create a network address list for a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list create-addresses-list --compartment-id compartment-id --addresses addresses
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list create-addresses-list --help
```

See **oci waf network-address-list create-addresses-list** for a complete description of the command.

**To create a VCN network address list using the CLI**

Describes how to create a VCN network address list for a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list create-vcn-addresses-list --compartment-id compartment-id --vcn-addresses vcn-addresses
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list create-vcn-addresses-list --help
```

See **oci waf network-address-list create-vcn-addresses-list** for a complete description of the command.

**To create a network address list using the API**

Describes how to create a network address list for a WAF policy using the API.

Run the **CreateNetworkAddressList** method to create a network address list. See **CreateNetworkAddressList** for a complete description.
**Listing Network Address Lists**
Describes the different methods to display a list of network address lists contained within a WAF policy.

Use one of the following methods to display a list of network address lists contained within a WAF policy.

**To list the network addresses using the Console**
Describes how to display a list of network address lists contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Network Address List**.
   
   Alternatively, open the Web Application Firewall page and click **Network Address List** under **Resources**.
   
   The WAF Network Address List page appears.
2. Select the **Compartment** from the list.
   
   All the WAF network address lists in that compartment are displayed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the network address lists displayed:
   - State
   - Name
   
   The network address lists displayed show the **Name**, **Address Type** (Public or Private), **Status**, and **Created** (UTC date timestamp) information for each entry.

**To list the network addresses using the CLI**
Describes how to display a list of network address lists contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```bash
oci waf network-address-list list --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf network-address-list list --help
```

See [oci waf network-address-list list](oci waf network-address-list list) for a complete description of the command.

**To list the network addresses using the API**
Describes how to display a list of network address lists contained within a WAF policy using the API.

Run the **ListNetworkAddressLists** method to list the network addresses. See [ListNetworkAddressLists](ListNetworkAddressLists) for a complete description.

**Getting Network Address List Details**
Describes the different methods to get the details of a network address list contained within a WAF policy.

Use one of the following methods to get the details of a network address list contained within a WAF policy.

**To get the details of a network address list using the Console**
Describes how to get the details of a network address list contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Network Address List**.
   
   Alternatively, open the Web Application Firewall page and click **Network Address List** under **Resources**.
   
   The WAF Network Address List page appears.
2. Select the **Compartment** from the list.
   
   All the WAF network address lists in that compartment are displayed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the network address lists displayed:
   - State
   - Name
4. Select the network address list whose details you want to get.

The Public Addresses or Private Addresses Details dialog box appears.

The Details page contains information about the WAF public or private network address list, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the WAF network address list configuration.

**To get the details of a network address list using the CLI**

Describes how to get the details of a network address list contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list get --network-address-list-id network-address-list-id
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list get --help
```

See `oci waf network-address-list get` for a complete description of the command.

**To get the details of a network address list using the API**

Describes how to get the details of a network address list contained within a WAF policy using the API.

Run the `GetNetworkAddressList` method to get the details of a network address list. See `GetNetworkAddressList` for a complete description.

**Editing Network Address Lists**

Describes the different methods to edit a network address list contained within a WAF policy.

Use one of the following methods to edit a network address list contained within a WAF policy.

**To edit a network address list using the Console**

Describes how to edit a network address list contained within a WAF policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Network Address List**.
   
   Alternatively, open the Web Application Firewall page and click **Network Address List** under **Resources**.
   
   The WAF Network Address List page appears.
2. Select the **Compartment** from the list.
   
   All the WAF network address lists in that compartment are displayed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the network address lists displayed:
   
   • **State**
   • **Name**
4. Select the network address list you want to edit.
   
   The Public Addresses or Private Addresses Details dialog box appears.
5. Click **Edit**.
   
   Alternatively, click the **Actions** icon (⋮) for the WAF policy and click **Edit**.
   
   The Edit WAF Network Address List dialog box appears.
6. Edit the network address list settings. See **Creating Network Address Lists** on page 5882 for descriptions of each setting.
7. Click **Save Changes**.
   
   The Edit WAF Network Address List dialog box closes. The updates you made are present in the details of the network address list.
To edit a network address list using the CLI
Describes how to edit a network address list contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list update-addresses-list --network-address-list-id network-address-list-id
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list update-addresses-list --help
```

See `oci waf network-address-list update-addresses-list` for a complete description of the command.

To edit a VCN network address list using the CLI
Describes how to edit a VCN network address list contained within a WAF policy using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list update-vcn-addresses-list --network-address-list-id network-address-list-id
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list update-vcn-addresses-list --help
```

See `oci waf network-address-list update-vcn-addresses-list` for a complete description of the command.

To edit a network address list using the API
Describes how to edit a network address list contained within a WAF policy using the API.

Run the `UpdateNetworkAddressList` method to edit a network address list. See `UpdateNetworkAddressList` for a complete description.

Deleting Network Address Lists
Describes the different methods to delete a network address list from a WAF policy.

Use one of the following methods to delete a network address list from a WAF policy.

To delete a network address list using the Console
Describes how to delete a network address list from a WAF policy from the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Network Address List**.
   Alternatively, open the Web Application Firewall page and click **Network Address List** under **Resources**.
   The WAF Network Address List page appears.
2. Select the **Compartment** from the list.
   All the WAF network address lists in that compartment are displayed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the network address lists displayed:
   • **State**
   • **Name**
4. Select the network address list you want to delete.
   The Public Addresses or Private Addresses Details dialog box appears.
5. Click **Delete**.
   Alternatively, click the **Actions** icon ( ) for the WAF policy and click **Delete**.
6. Confirm the deletion when prompted.
The list of WAF network address lists reappears without the WAF network address list you deleted.

**To delete a network address list using the CLI**
Describes how to delete a network address list from a WAF policy from the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list delete --network-address-list-id network-address-list-id
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list delete --help
```

See `oci waf network-address-list delete` for a complete description of the command.

**To delete a network address list using the API**
Describes how to delete a network address list from a WAF policy from the API.

Run the `DeleteNetworkAddressList` method to delete a network address list. See `DeleteNetworkAddressList` for a complete description.

**Moving Network Address Lists Between Compartments**
Describes the different methods to move a network address list contained within a WAF policy between compartments.

Use one of the following methods to move a network address list between compartments.

**To move a network address list between compartments using the Console**
Describes how to move a network address list contained within a WAF policy between compartments using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Network Address List**.
   
   Alternatively, open the Web Application Firewall page and click **Network Address List** under **Resources**.
   
   The WAF Network Address List page appears.

2. Select the **Compartment** from the list.
   
   All the WAF network address lists in that compartment are displayed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the network address lists displayed:
   
   • State
   
   • Name

4. Select the network address list you want to move.
   
   The Public Addresses or Private Addresses Details dialog box appears.

5. Click **Move**.
   
   Alternatively, click the **Actions** icon (_growth) for the WAF policy and click **Move Resource**.
   
   The Move Resource to a Different Compartment dialog box appears.

6. Select the compartment to which you want to move your network load balancer from the **Choose New Compartment** list.

7. Click **Move Resource**.
   
   The WAF network address list now appears in the compartment you moved it to.
**To move a network address list between compartments using the CLI**
Describes how to move a network address list contained within a WAF policy between compartments using the CLI.

Enter the following command and required parameters:

```
oci waf network-address-list change-compartment --compartment-id compartment-id --network-address-list-id network-address-list-id
```

See the CLI online help for a list of optional parameters:

```
oci waf network-address-list change-compartment --help
```

**To move a network address list between compartments using the API**
Describes how to move a network address list contained within a WAF policy between compartments using the API.

Run the `ChangeNetworkAddressListCompartment` method to move a network address list between compartments. See `ChangeNetworkAddressListCompartment` for a complete description.

**WAF Work Request Management**
Describes how to access information on work requests associated with web application firewalls.

Work requests are associated with all WAF top-level resources: policies, firewalls, and network address lists. A single work request is associated with one of these resources, either a policy, a firewall or a network address list. All changes to these resources are asynchronous and return a work request.

Access the following work request information using the CLI or API:

- Display a paginated list of work requests.
- Display details of a specified work request.
- Display a paginated list of errors for a specified work request.
- Display a paginated list of logs for a specified work request.

**Listing WAF Work Requests**
Describes the different methods to display a list of work requests.

Use one of the following methods to display a list of work requests.

**To list the WAF work requests using the CLI**
Describes how to display a list of work requests using the CLI.

Enter the following command and required parameters:

```
oci waf work-request list --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waf work-request list --help
```

**To list the WAF work requests using the API**
Describes how to display a list of work requests using the API.

Run the `ListWorkRequests` method to get the details of a work request. See `ListWorkRequests` for a complete description.

**Getting WAF Work Request Details**
Describes the different methods to get the details of a work request.

Use one of the following methods to get the details of a work request.
To get the details of a WAF work request using the CLI
Describes how to get the details of a WAF work request using the CLI.
Enter the following command and required parameters:

```
oci waf work-request get --work-request-id work-request-id
```

See the CLI online help for a list of optional parameters:

```
oci waf work-request get --help
```

See `oci waf work-request get` for a complete description of the command.

To get the details of a WAF work request using the API
Describes how to get the details of a WAF work request using the API.
Run the `GetWorkRequest` method to get the details of a work request. See `GetWorkRequest` for a complete description.

Listing WAF Work Request Errors
Describes the different methods to display a list of work request errors.
Use one of the following methods to display a list of work request errors.

To list the WAF work request errors using the CLI
Describes how to display a list of work request errors using the CLI.
Enter the following command and required parameters:

```
oci waf work-request-error list --work-request-id work-request-id
```

See the CLI online help for a list of optional parameters:

```
oci waf work-request-error list --help
```

See `oci waf work-request-error list` for a complete description of the command.

To list the WAF work request errors using the API
Describes how to display a list of work request errors using the API.
Run the `ListWorkRequestErrors` method to display a list of work request errors. See `ListWorkRequestErrors` for a complete description.

Listing WAF Work Request Logs
Describes the different methods to display a list of work request logs.
Use one of the following methods to display a list of work request logs.

To list the WAF work request logs using the CLI
Describes how to display a list of work request logs using the CLI.
Enter the following command and required parameters:

```
oci waf work-request-log list --work-request-id work-request-id
```

See the CLI online help for a list of optional parameters:

```
oci waf work-request-log list --help
```

See `oci waf work-request-log list` for a complete description of the command.
To list the WAF work request logs using the API
Describes how to display a list of work request logs using the API.

Run the `ListWorkRequestLogs` method to display a list of work request logs. See `ListWorkRequestLogs` for a complete description.

Edge Policies

Edge policies are the renamed WAF policies associated of the earlier version of the Web Application Service.

Getting Started with Edge Policies

Follow the instructions in this section to get started with edge policies.

Before You Begin

Refer to the Overview of Web Application Firewall on page 5778 for important concepts about WAF.

To begin using the WAF service, you must have the following available:

- Ensure that you have the Required IAM Service Policy on page 5780 permissions.
- We recommended that you use a separate compartment for your WAF policy so that management is easier and more secure.
- A main webapp domain.
- IP address of the LBaaS or other public facing endpoint of the application.
- Ability to update DNS records for the domain.
- The WAF service only supports traffic on ports 80/443. Ensure that your application is not running on other ports.

Also, if you plan to run your site on HTTPS/443, you will need:

- Public certificate for the fully qualified domain name (FQDN) of the application.
- Corresponding private key for the site.
- Certificate in PEM format.
- Full chain certificate (that is, Root, Intermediate, Origin Server)

Note:
SSL certificates can only be applied to the main application of the policy.

Initial Setup of Your WAF Policy

1. Create an Edge Policy to Route Traffic Through the WAF

To begin, create an edge policy to route traffic through the WAF without rules enabled. Creating a policy without rules enabled ensures that there are no regressions by having a reverse proxy in front of the application.

To create an edge policy

1. Select the region and compartment where the policy should be maintained (there is no constraint around the WAF co-existing with Load Balancing or other application resources in Oracle Cloud Infrastructure.
3. Click Create WAF Policy.
4. Look at the bottom of the Basic Information page for the following:
   - Use legacy workflow here if you need to secure your non-OCI web applications.
4. Click the link to display the Create Edge Policy dialog box.
6. Complete the following:

- **Name:** A unique name for the policy. Avoid entering confidential information.
- **Domains:**
  - **Primary Domain:** The fully qualified domain name (FQDN) of the application where the policy will be applied.
  - **Additional Domains:** (Optional) Subdomains where the policy will be applied.

  **Note:**
  Wildcard domains are accepted, however, only as additional domains and only through the API and CLI.

- **WAF Origin:** The host or IP address of the public internet facing application that is being protected by the application.
- **Origin Name:** A unique name for the origin.
- **URI:** Enter the public facing endpoint (IPv4 or FQDN) of the application.
- **HTTPS Port:** The port used for secure HTTP connection. The default port is 443.
- **HTTP Port:** The HTTP port the origin listens on. The default port is 80.
- **Headers:** (Optional)
  - **Header Name:** The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
  - **Header Value:** Specifies the data requested by the header.
- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create WAF Policy.** The WAF Policy overview appears. Expect the policy to become active within 15 minutes of creation.

   See [Managing Edge Policies](#) on page 5900 for more information.

2. **Update Origin Keep Alive Timeout**

   The edge policy requires that your origin's (load balancer or web server) keep alive timeouts are maintained for 301 seconds or more, as our upstream timeout value is 300 seconds. The additional second is to ensure that the connection has enough time to renegotiate when our nodes create connections and avoid connectivity issues. This applies to API calls, as we use our OCI Network Multiplexing technology that helps to reduce network bottlenecks and improve performance by optimizing TCP protocol.

   **To test the upstream keep alive timeout**

   **HTTP check:**

   1. Make the request against the origin or upstream server. Run the following command:

      ```
      time telnet www-origin.example.com 80
      ```

      Example output:

      ```
      Trying 12.34.56.78...
      Connected to lb65-soc-191485947.us-east-1.elb.amazonaws.com.
      Escape character is '^]'.
      ```

   2. Make a GET request by entering the following HTTP headers:

      ```
      GET / HTTP/1.1
      Host: www.example.com
      ```
3. Press ENTER twice and wait for the session to close or disconnect.

HTTPS check:

1. Initiate the request against the Origin or Upstream Server. Run the following command:

```plaintext
time openssl s_client -connect www-origin.example.com:443
```

2. Make a GET request by entering the following HTTP headers:

```plaintext
GET / HTTP/1.1
Host: www.example.com
Connection: keep-Alive
```

3. Press ENTER twice and wait for the session to close or disconnect.

You will receive the following output. In this example, the real section shows the actual time the session was alive (5.1 minutes (301 seconds)):

```
HTTP/1.1 200 OK
Content-Type: text/html; charset=UTF-8
...
<!DOCTYPE html>
<html>
...
</html>
Connection closed by foreign host.
real 5m1.962s
user 0m0.011s
sys 0m0.009s
```

See [Origin Management](#) for more information.

3. **Upload Your Certificate and Key**

This step assumes that your site runs on HTTPS/443.

To upload your certificate and key

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**. Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**. The WAF Policies page appears.

2. Select the **Compartment** from the list. All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Select the edge policy for which you want to upload the certificate and key. The Edge Policy Details dialog box appears.

5. Click **Settings** under **WAF Policy**. The Settings list appears.

6. Select **General Settings**.
7. Click **Edit**.
   The Edit Settings dialog box appears.

8. Complete the following:

   - **Enable HTTPS Support**: Click this check box to enable all communications between the browser and web application to be encrypted.
   
   - **Certificate Source**: Choose one of the following methods:
     
     - **Choose Certificate**: Select an existing certificate from the drop-down menu. Click **Change Compartment** to select a certificate from another compartment.
     
     - **Upload or Paste Certificate and Private Key**
       
       Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

       ```
       -----BEGIN CERTIFICATE-----
       <Base64_encoded_certificate>
       -----END CERTIFICATE-----
       -----BEGIN CERTIFICATE-----
       <Intermediate_Base64_encoded_certificate>
       -----END CERTIFICATE-----
       
       -----BEGIN PRIVATE KEY-----
       <Base64_encoded_private_key>
       -----END PRIVATE KEY-----
       ```

     - **Private Key**: Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

       ```
       -----BEGIN PRIVATE KEY-----
       <Base64_encoded_private_key>
       -----END PRIVATE KEY-----
       ```

   - **Self Signed Certificate**: Enable this field when using a self-signed certificate to show an SSL warning in the browser.
   
   - **HTTP to HTTPS Redirect**: When enabled, all HTTP traffic is automatically redirected to HTTPS.
   
   - **TLS Protocols Support**: Select a TLS protocol from the drop-down list.

     | Caution: |
     | --- |
     | TLS versions 1 and 1.1 have been deprecated and cannot be used in policy configurations. If you use these versions, a validation error might occur. Use versions 1.2 or 1.3 instead. |

   - **Enable SNI**: Server Name Indication (SNI) is an extension of the TLS protocol, which allows multiple secure hostnames to be served from a single IP address.
   
   - **Advanced Options**
     
     - **Enable Response Buffering**: Enable or disable buffering of the response from the origin.
     
     - **Cache Control Respected**: Enable or disable automatic content caching based on the response cache-control header.
     
     - **Behind CDN**: Enable this to allow the collection of IP addresses from the client request if WAF is connected to a CDN.

9. Click **Save Changes**.

   You must publish your changes for them to take effect. See **Publishing Changes** on page 6024.

4. **Test Your Application (Before Deploying it to Production)**

   In this step, you ensure that requests are being routed to the WAF and that your application continues to function normally with a reverse proxy in the topology.

   Test your application through a terminal command
1. Open a terminal.

Run the following command for HTTP:

```
curl -lvk http://<OCI_WAF_CNAME> -H "Host: <WEBAPP_DOMAIN>" -so /dev/null
```

Run the following command for HTTPS:

```
curl -lvk https://<OCI_WAF_CNAME> -H "Host: <WEBAPP_DOMAIN>" -so /dev/null
```

2. You can also run a DNS query against the <OCI_WAF_CNAME> for your WAF policy and copy one of the IP addresses from the resulting output.

   - To run a DNS query you can use one of the following commands:

     ```
     dig <OCI_WAF_CNAME>
     ```

     ```
     nslookup <OCI_WAF_CNAME>
     ```

   - Copy any of the IP addresses from the output.

3. Run the following command. Replace <WEBAPP_DOMAIN> with your WAF policy domain. Use port 80 or 443. Replace <OCI_NODE_IP> with the IP address from OCI_WAF_CNAME.

```
Query curl -vso /dev/null --resolve <WEBAPP_DOMAIN>:<PORT_80_OR_443>:<OCI_NODE_IP>
https://<WEBAPP_DOMAIN>
```

A 200, 301, 302, or any other expected HTTP response code is returned.

**Note:**

If you receive a 5XX HTTP error, ensure that you have updated your firewall setting to allow our IP addresses. If you are still experiencing an issue, open a service request with My Oracle Support. In the support request, provide your compartment OCID, policy OCID, explanation about the issue you are experiencing, a HAR file, and a time when the issue started.

Test your application through a web browser

To test your application using a hosts file, you need an IP address where you could point your application. Under the policy, you should see the CNAME which is assigned to you. You can get the IP address where you can point your application.

1. Open a terminal.

2. Run a DNS query using any of the following commands:

```
 dig <OCI_WAF_CNAME>
```

```
 nslookup <OCI_WAF_CNAME>
```

3. Copy one of three IP addresses from a dig command output Answer section and paste it to a hosts file with your domain name.

4. After you save your hosts file, open your application in a browser and verify it is working as expected.

A 200, 301, 302, or any other expected HTTP response code is returned.

**Note:**

If you receive a 5XX HTTP error, ensure that you have updated your firewall setting to allow our IP addresses. If you are still experiencing
Test your SSL

The following useful command line tools can be used to validate certificates on a given web application:

```
  echo | openssl s_client -servername <Domain> -connect <Domain>:443 2>/dev/null | openssl x509 -inform pem -noout -text
```

Pay special attention to the certificate validity dates and expiration dates that might cause connection issues:

```
Signature Algorithm: sha256WithRSAEncryption
Issuer: C = US, O = Let's Encrypt, CN = Let's Encrypt Authority X3
Validity
   Not Before: Jun 5 03:15:10 2020 GMT
   Not After : Sep 3 03:15:10 2020 GMT
Subject: CN = www.example.com
Subject Public Key Info:
```

You can also check the certificate from third-party websites such as SSL Shopper or SSL labs and perform the validation there.

5. Update DNS to Enable WAF

After confirming your web application works flawless through WAF, you can now proceed to update the DNS globally.

In this step, you update the CNAME for your zone to route requests from internet clients to WAF. Use the following instructions to make this DNS change in the Console. If your DNS setup resides with another provider, refer to their documentation for instructions.

To update the CNAME for your zone

1. In the Policy Information tab of the WAF Policy overview, select the CNAME Target.
2. Copy the CNAME target to your clipboard.
3. Open the navigation menu and click Networking. Under DNS Management, click Overview.
4. Click the Zone Name of the primary domain where you want to update the record. Zone details and a list of records appear.
5. Select the check box for the CNAME record and select Edit from the Actions drop-down menu.
6. In the Edit Record dialog box, update the Target field with the CNAME Target from your clipboard.
7. Click Submit.
8. Click Publish Changes.
9. In the confirmation dialog box, click Publish Changes.

6. Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges.

**CIDR Ranges**

- 129.146.12.128/25
- 129.146.13.128/25
- 129.146.14.128/25
- 129.148.156.0/22
- 129.213.0.128/25
• 129.213.2.128/25
• 129.213.4.128/25
• 130.35.0.0/20
• 130.35.112.0/22
• 130.35.116.0/25
• 130.35.120.0/21
• 130.35.128.0/20
• 130.35.144.0/20
• 130.35.16.0/20
• 130.35.176.0/20
• 130.35.192.0/19
• 130.35.224.0/22
• 130.35.232.0/21
• 130.35.240.0/20
• 130.35.48.0/20
• 130.35.64.0/19
• 130.35.96.0/20
• 130.35.228.0/22
• 132.145.0.128/25
• 132.145.2.128/25
• 132.145.4.128/25
• 134.70.16.0/22
• 134.70.24.0/21
• 134.70.32.0/22
• 134.70.56.0/21
• 134.70.64.0/22
• 134.70.72.0/22
• 134.70.76.0/22
• 134.70.8.0/21
• 134.70.80.0/22
• 134.70.84.0/22
• 134.70.88.0/22
• 134.70.92.0/22
• 134.70.96.0/22
• 138.1.0.0/20
• 138.1.104.0/22
• 138.1.128.0/19
• 138.1.16.0/20
• 138.1.160.0/19
• 138.1.192.0/20
• 138.1.208.0/20
• 138.1.224.0/19
• 138.1.32.0/21
• 138.1.40.0/21
• 138.1.48.0/21
• 138.1.64.0/20
• 138.1.80.0/20
• 138.1.96.0/21
• 138.1.112.0/20
• 140.204.0.128/25
• 140.204.12.128/25
• 140.204.16.128/25
• 140.204.20.128/25
• 140.204.24.128/25
• 140.204.4.128/25
• 140.204.8.128/25
• 140.91.10.0/23
• 140.91.12.0/22
• 140.91.22.0/23
• 140.91.24.0/22
• 140.91.28.0/23
• 140.91.30.0/23
• 140.91.32.0/23
• 140.91.34.0/23
• 140.91.36.0/23
• 140.91.38.0/23
• 140.91.4.0/22
• 140.91.40.0/23
• 140.91.8.0/23
• 147.154.0.0/18
• 147.154.128.0/18
• 147.154.192.0/20
• 147.154.208.0/21
• 147.154.224.0/19
• 147.154.64.0/20
• 147.154.80.0/21
• 147.154.96.0/19
• 192.157.18.0/24
• 192.157.19.0/24
• 192.29.0.0/20
• 192.29.128.0/21
• 192.29.138.0/23
• 192.29.144.0/21
• 192.29.152.0/22
• 192.29.16.0/20
• 192.29.160.0/21
• 192.29.168.0/22
• 192.29.172.0/25
• 192.29.178.0/25
• 192.29.180.0/22
• 192.29.32.0/21
• 192.29.40.0/22
• 192.29.44.0/25
• 192.29.48.0/21
• 192.29.56.0/21
• 192.29.60.0/23
• 192.29.64.0/20
• 192.29.96.0/20
• 192.29.140.0/22
• 192.69.118.0/23
Enable WAF to Passively Detect Rules

WAF protection rules add extra CPU cycles to each transaction, therefore, we recommended enabling only the rules designed for your web application topology. WAF offers a set of recommended rules that will not harm your site performance and work with most of the web application. The WAF bot protection feature makes your web application fully secured to threats.

If you need help with setting up WAF, you can open a service request with My Oracle Support requesting OCI WAF tuning help. An expert will guide you through the process.

To view Protection Rule Recommendations

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to view protection rule recommendations for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab. This list is generated based on the traffic the WAF detects flowing through the WAF. If nothing appears in this list, keep testing the FQDN of your application and check back later.
5. Select the protection rules with a **Detect** recommended action and then click **Accept Recommendations**.

Tip:

You can use the **Recommended Action** filter to locate a recommendation by **Detect**.

To enable WAF Protection Rules to detect mode

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Use the **Protection Rules table** to locate the rules you want to detect.
5. Enter the Rule IDs you located from the table into the **Rule ID** filter. For this example, enter **941140** (Cross-Site Scripting) in the **Rule ID** filter.
6. Select **Detect** from the **Actions** drop-down menu for the protection rules you filtered.

See WAF Protection Rules on page 5926 for more information.

To enable WAF Access Rules to detect mode

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure access rules for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Click **Add Access Rule**.
5. In the Add Access Rule dialog box, enter the following:
   a. **Name**: DetectRequestsFromMySpecificBrowser
   b. **Rule Action**: Select **Detect Only**.
   c. **Conditions**: Select IP Address is from the menu and enter the IP address you copied to your clipboard while testing your application in the IP Address field.
   d. Click **Add Additional Condition**.
   e. **Condition**: Select User Agent is from the menu and enter the agent value you copied to your clipboard while testing your application in the User Agent Header field.

   **Note:**
   Both the IP Address and the User Agent in the preceding example must match for the rule to be triggered. If a different User Agent is used to test your application, the request will not be detected.

6. Click **Add Access Rule**.
7. Click **Unpublished Changes**.
8. Click **Publish All**.

See **Access Control** on page 6006 for more information.

**To enable WAF BOT rules to detect mode (JavaScript Challenge)**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click **Edit JavaScript Challenge**.
5. In the JavaScript Challenge dialog box, select the **Enable JavaScript Challenge** check box.
6. In the JavaScript Challenge Action section, select **Detect Only**.
7. Enter the following information:
   - **Enable Conditions**: When enabled, conditions must match for a set action to be taken. See **Access Control** on page 6006 for more information about conditions and rules.
   - **Action Threshold (number of requests)**: Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - **Action Expire Time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Follow Redirects**: When enabled, redirect responses from the origin will also be challenged.
   - **Enable NAT Support**: When enabled, the user is identified not only by the IP address but also by a unique additional hash, which prevents blocking visitors with shared IP addresses. It is recommended that this NAT support is disabled for high-load apps (200+RPS).
8. Click **Save Changes**.

The JavaScript Challenge is added to the list of changes to be published.

See **Bot Management** on page 5910 for more information.

**To enable WAF BOT rules to detect mode (Human Interaction Challenge)**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Human Interaction Challenge** tab.
5. Click **Edit Human Interaction Challenge**.
6. In the Edit Human Interaction Challenge dialog box, select the **Enable Human Interaction Challenge** check box.
7. In the Human Interaction Action section, select **Detect Only**.
8. Enter the following information:
   - **Action Threshold (number of requests)**: Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basicajax usage, and 100 for apps with heavyajax usage.
   - **Threshold Expiry Period (seconds)**: The number of seconds before the threshold expires.
   - **Action Expire Time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of the client IP address changes, it is recommended that the expire time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Interaction Threshold (number of interactions)**: Number of interactions before the threshold expires.
   - **Recording Period (seconds)**: The period of time to record the user's events.
   - **NAT Support**: When enabled, the user is identified not only by the IP address but also by an unique additional hash, which prevents blocking visitors with shared IP addresses. It's recommended to disable the support for the high-load apps (200+ RPS).
9. Click **Save Changes**.

The Human Interaction Challenge is added to the list of changes to be published.

See **Bot Management** on page 5910 for more information.

See **Managing Edge Policies** on page 5900 for the order of processing of WAF.

**Test the Rules**

When the policy is active, you can test that your rules are detected by WAF.

*To initiate requests*

1. Use the same browser you used when you tested your application to do the following:
   - Request the FQDN of your application with the following query parameter appended:
     
     ```
     ?id=<script>alert("TEST");</script>
     ```
   2. Use a different browser on the same machine and repeat the preceding requests. All requests should go through the application.

*To verify that WAF is detecting requests*

To verify that WAF is detecting requests identified as a risk:

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click **Logs**. Logs for the WAF policy appear.
4. Select the **Detect** check box from the **Actions** filter.
5. Verify that there are two entries for the protection rule triggered by the Cross-Site Scripting request and one entry for detecting the User Agent and IP Address.

**Managing Edge Policies**

The Oracle Cloud Infrastructure WAF service enables you to create an edge policy and origin.

**Order of Processing**

The order in which rules and handlers are processed is:

1. IP Whitelists/Blacklists/Good Bot Whitelists
2. Threat Intelligence
3. Access Rules
Using the Console

Create and Manage WAF Policies

To create an edge policy

2. Click Create WAF Policy.
3. Look at the bottom of the Basic Information page for the following:
   - Use legacy workflow here if you need to secure your non-OCI web applications.
4. Click the link to display the Create Edge Policy dialog box.
5. Complete the following:
   - **Name**: A unique name for the policy. Avoid entering confidential information.
   - **Domains**:
     - **Primary Domain**: The fully qualified domain name (FQDN) of the application where the policy will be applied.
     - **Additional Domains**: (Optional) Subdomains where the policy will be applied.
       - **Note**: Wildcard domains are accepted, however, only as additional domains and only through the API and CLI.
   - **WAF Origin**: The host or IP address of the public internet facing application that is being protected by the application.
     - **Origin Name**: A unique name for the origin.
     - **URI**: Enter the public facing endpoint (IPv4 or FQDN) of the application.
     - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
     - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
     - **Headers**: (Optional)
       - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
       - **Header Value**: Specifies the data requested by the header.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click Create WAF Policy. The WAF Policy overview appears. Expect the policy to become active within 15 minutes of creation.

See Managing Edge Policies on page 5900 for more information.

To update an edge policy

2. Apply one or more of the following Filters to limit the edge policies displayed:
   - State
   - Name
   - Policy Type: Select Edge Policy.
3. Click the name of the edge policy you want to update. The Details page for the edge policy you selected appears.

   Tip:
   You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

4. Click Edit.
5. In the Edit Edge Policy dialog box, make the needed changes and then click Save Changes.

To delete an edge policy
2. Apply one or more of the following Filters to limit the edge policies displayed:
   - State
   - Name
   - Policy Type: Select Edge Policy.
3. Select the check box for the policy you want to delete.

   Tip:
   You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

4. Click Delete.
5. In the confirmation dialog box, click Delete.

   The status of the policy changes from Active to Deleting. Deleted policies are maintained for a short time before they are unavailable in the Console.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click Unpublished Changes.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click Publish All.
4. In the Publish Changes dialog box, click Publish All.

To manage tags for a edge policy
2. Click the name of the edge policy you want to view. The Details page for the edge policy you selected appears.
3. Click the Tags tab to view or edit existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 239.

To move a edge policy to a different compartment
2. Apply one or more of the following Filters to limit the edge policies displayed:
   - State
   - Name
   - Policy Type: Select Edge Policy.
3. Find the WAF policy in the list, click the Actions icon (three dots), and then click **Move Resource to a Different Compartment**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**Using the CLI**

Open a command prompt and run the following command to get the details of a WAAS policy:

```
oci waas waas-policy get --waas-policy-id <policy_ocid>
```

This can be useful in retrieving the necessary information when opening a ticket with Oracle Cloud Infrastructure support. For more information about how to access and use the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en-us/iaas/tools/python-sdk-examples/development/waas/get_waas_policy.py).

**Using the API**

For information about using the API and signing requests, see [REST APIs](https://docs.oracle.com/en-us/iaas/tools/python-sdk-examples/development/waas/get_waas_policy.py) on page 6275 and [Security Credentials](https://docs.oracle.com/en-us/iaas/tools/python-sdk-examples/development/waas/get_waas_policy.py) on page 205. For information about SDKs, see [Software Development Kits and Command Line Interface](https://docs.oracle.com/en-us/iaas/tools/python-sdk-examples/development/waas/get_waas_policy.py) on page 6094.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy
- DeleteWaasPolicy
- ChangeWaasPolicyCompartment

**Origin Management**

An origin is an endpoint (typically an IP address) of the application protected by the WAF. An origin can be an Oracle Cloud Infrastructure load balancer public IP address which can be used for high availability to an origin. When you create a WAF policy, you define a default origin and optional HTTP headers. An origin must be defined in your WAF policy to set up protection rules or other features. The details for the origin can be modified later in the Settings of the WAF policy. In the Origin Settings, you can modify or set up HTTP headers for outbound traffic from the WAF to the origin server. These name-value pairs are then available to the application.

**Origin Groups**

Multiple origins can be defined for a WAF policy using Origin Groups. When at least two origins are configured, load balancing is enabled. You can group multiple origins in an origin group. An origin group can include origin servers and their weights. The weight of each origin in the origin group determines the priority when load balancing across origins in this group. Origins with higher weights receive larger proportions of client requests. Under origin groups, all origins are active. The grouping is for visual purposes only.

**Securing Your WAF**

Describes how to secure your web application firewall servers.

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following [CIDR ranges](https://docs.oracle.com/en-us/iaas/tools/python-sdk-examples/development/waas/check_cidr_ranges.py).

**Adding Origins and Origin Groups**

Describes how to add an origin or an origin group to an edge policy.

Use one of the following methods to add origin and origin groups to an edge policy.

**To add an origin or origin group using the Console**

Describes how to add an origin or an origin group to an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.
2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:

   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy to which you want to add an origin.

   The Details page of the edge policy you selected appears.

5. Click **Settings** under **WAF Policies**.

   The Settings list appears.

6. Select the **Origin Groups** tab.

   If more than one origin for the edge policy exists, the origins and its group appear.

7. Click **Edit**.

   The Origin Groups dialog box appears. If only one origin defined for the edge policy exists, the origin belongs to a default origin group.

   Optionally, you can edit the name of the existing default group or add another group to group multiple origins. You can use origin groups to specify the default origin that is used in your edge policy.

8. Click **+ Additional Origin** below the origin group where you want to add an origin.

9. Complete the following:

   - **Name**: Accept the existing Default Group name, or enter a new origin group name. The origin you create resides under this origin group.
   - **Default Origin**: If multiple origins are listed, click which one you want to be the default origin.
   - **Name**: Enter the name of the origin.
   - **URI**: Enter the IPv4 address or FQDN of the origin.
   - **HTTP Port**: Enter the HTTP port on the origin that the web application listens on. The default port is 443.
   - **HTTPS Port**: The HTTPS port on the origin that the web application listens on. The default port is 80.
   - **Weight**: The weight of the origin within the group is used for load balancing purposes. Origins with higher weights receive larger proportions of client requests.

   Click **+ Additional Origin** to add another origin row for you to complete. Click **X** to remove an associated origin.

10. (optional) Click **+ Additional Group** to add another origin group.

    Enter a name for the origin group and add at least one origin using the same method as described earlier. Indicate which origin is the default if your origin group has multiple origins.

11. Click **Save Changes**.

    Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To add an origin or origin group using the CLI Describes how to add an origin or an origin group to an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waf web-app-firewall-policy create --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waf web-app-firewall-policy create --help
```

Adding origin and origin groups are configured as optional parameters. See **oci waf web-app-firewall-policy create** for a complete description of the command.
To add an origin or origin group using the API
Describes how to add an origin or an origin group to an edge policy using the API.

Use the CreateWaasPolicy method to add an origin using the API. Adding origin and origin groups are configured as optional parameters.

See CreateWaasPolicy in the Oracle Cloud Infrastructure documentation for a complete description.

Editing Origins and Groups
Describes how to edit an origin or an origin group for an edge policy.

To edit an origin or origin group using the Console
Describes how to edit an origin or an origin group for an edge policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.

   The WAF Policies page appears.

2. Select the Compartment from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following Filters to limit the edge policies displayed:
   - State
   - Name
   - Policy Type: Select Edge Policy.

4. Click the name of the edge policy whose origin you want to edit. Details page of the edge policy you selected appears.

5. Click Settings under WAF Policy.

   The Settings list appears.

6. Select the Origin Groups tab. If more than one origin for the edge policy exists, the origins and its group appear.

7. Click Edit. If only one origin is defined for the WAF policy, the origin belongs to a default origin group.

8. Edit the name of the existing default group or add another group to group multiple origins. You can use origin groups to specify the default origin that is used in your edge policy.

9. Click Save Changes

   Publish your changes for them to take effect. See Publishing Changes on page 6024.

To edit an origin or origin group using the CLI
Describes how to edit an origin or an origin group for an edge policy using the CLI.

Enter the following command and required parameters:

```bash
oci waf web-app-firewall-policy update --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf web-app-firewall-policy update --help
```

Editing origins and origin groups are configured as an optional parameter. See oci waf-web-app-firewall-policy update for a complete description of the command.

To edit an origin and origin group using the API
Describes how to edit an origin or an origin group for an edge policy using the API.

Use the UpdateWaasPolicy method to edit an origin using the API. Editing origin and origin groups are configured as optional parameters.
Web Application Firewall

See `UpdateWaasPolicy` in the Oracle Cloud Infrastructure documentation for a complete description.

**Deleting Origins and Groups**

Describes how to delete an origin or an origin group from an edge policy.

Use one of the following methods to delete origin and origin groups for an edge policy.

**To delete an origin or origin group using the Console**

Describes how to delete an origin or an origin group from an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:

   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy whose origin you want to edit. Details page of the edge policy you selected appears.

5. Click **Settings** under **WAF Policy**.

   The Settings list appears.

6. Select the **Origin Groups** tab. If more than one origin for the edge policy exists, the origins and its group appear.

7. Click **Edit**. If only one origin is defined for the WAF policy, the origin belongs to a default origin group.

8. Click the **X** next to any origin or origin group you want to delete.

   If you delete an origin group, all the origins assigned to that group are deleted.

9. Click **Save Changes**

   Publish your changes for them to take effect. See Publishing Changes on page 6024.

**To delete an origin or origin group using the CLI**

Describes how to edit an origin or an origin group to an edge policy using the CLI.

Enter the following command and required parameters:

```bash
oci waf web-app-firewall-policy update --web-app-firewall-policy-id web-app-firewall-policy-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waf web-app-firewall-policy update --help
```

Deleting origins and origin groups are configured as an optional parameter. See `oci waf web-app-firewall-policy update` for a complete description of the command.

**To delete an origin or origin group using the API**

Describes how to edit an origin or an origin group to an edge policy using the API.

Use the `UpdateWaasPolicy` method to edit an origin using the API. Deleting origin and origin groups are configured as optional parameters.

See `UpdateWaasPolicy` in the Oracle Cloud Infrastructure documentation for a complete description.

**Health Checks**

Describes how to health checks for an edge policy.

Health checks can be enabled when multiple origins are specified.
Default Settings

- Check URL: / (root/home page)
- Interval: 10 seconds (how often the check is performed)
- Timeout: 5 seconds (timeout after which the check is marked as failed)
- Fail count: 2 (number of failed checks for the origin to be considered down)
- Rise count: 2 (number of successful checks for the origin to be considered up)
- Successful responses: 2xx, 3xx, 4xx, 5xx

Custom health checks can also be configured. The following options are available:

- Enable response text checking (health checks are looking for the text entered under "Expected response text").
- Specify a host header.

To configure health checks using the Console

Describes how to health checks for an edge policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the edge policies displayed:
   - State
   - Name
   - Policy Type: Select Edge Policy.
4. Click the name of the edge policy whose health checks you want to configure. The Details page of the edge policy you selected appears.
5. Click Settings under WAF Policy.
   The Settings list appears.
6. Select the Origin Settings tab.
7. Click Edit.
   The Origin Management Settings dialog box appears.
8. Check Enable health checks.
9. Complete the following:
   • **Request**: Select the type of health check request:
     - GET
     - HEAD
     - POST
   • **URL**: Enter the URL to visit on the origin when performing the health check.
   • **Host header**: Enter the value of the host header in the HTTP health check request. If this field is left blank, the policy domain is used instead.
   • **User agent**: Enter the value of the user agent header in the HTTP health check request.
   • **Expected response code group**: Select the HTTP response codes that signify the health state from the list. You can select multiple codes.
   • **Check interval (seconds)**: Enter the interval (in seconds) between health checks to the origin.
   • **Response timeout (seconds)**: Enter the time to wait for a reply before marking the health check as failed.
   • **Healthy threshold (number of times)**: Enter the number of successful health checks after which the origin server is marked up.
   • **Unhealthy threshold (number of times)**: Enter the number of failed health checks after which the origin server is marked down.
   • **Enable response text checking**: (optional) Check to check for predefined text in addition to the response code.
     Enter the **Expected response text** in the accompanying box. Health checks search for the given text in a case-sensitive manner within the response body and fail if the text is not found.

10. Click **Save Changes**.

Publish your changes for them to take effect. See Publishing Changes on page 6024.

**Load Balancing**

Describes how to configure load balancing for multiple origins for an edge policy.

Configure load balancing when you have multiple origins associated with an edge policy.

*To configure load balancing for multiple origins using the Console*

Describes how to configure load balancing for multiple origins for an edge policy using the OCI Console.

Load balancing is only enabled when at least two origins have been defined. To define more origins, see Adding Origins and Origin Groups on page 5903.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**

4. Click the name of the edge policy where you want to configure the load balancers for the origins. The Details page of the edge policy you selected appears.

5. Click **Settings** under **WAF Policy**.

   The Settings list appears.

6. Click the **Origin Settings** tab.

7. Click **Edit**.

   The Origin Management Settings dialog box appears.
8. Complete the following:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>
The section on health checks is described in Health Checks on page 5906. Ignore that functionality for configuring load balancers for multiple origins.

- Select one of the following load balancing methods:
  - **IP_HASH**: All incoming requests from the same client IP address go to the same content origination server. IP_HASH load balancing method uses origin weights when choosing which origin to which the hash is initially assigned.
  - **ROUND_ROBIN**: Forwards requests sequentially to the available origin servers. The first request is to the first origin server, the second request is to the next origin server, and so on. After it sends a request to the last origin server, it starts again with the first origin server. When using weights on origins, Weighted Round Robin assigns more requests to origins with a greater weight. Over time, origins receive requests in proportion to their weight.
  - **STICKY_COOKIE**: Adds a session cookie to the first response from the origin server and identifies the server that sent the response. The client's next request contains the cookie value, and NGINX routes the request to the origin server that responded to the first request. STICKY_COOKIE load balancing method falls back to Round Robin for the first request.
  - **Enable Origin Compression**: (optional) Check to enable GZIP compression of origin responses.

9. Click **Save Changes**.

Publish your changes for them to take effect. See Publishing Changes on page 6024.

### Custom Headers

Describes how to configure custom headers for the origins for an edge policy.

Use custom headers to help validate that the requests made to your origin were sent from the edge. Custom headers let you configure your origin to only allow requests that contain the custom header values that you specify.

**To configure custom headers using the Console**

Describes how to configure custom headers for the origins for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:

   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy where you want to configure custom headers for the origins. The Details page of the edge policy you selected appears.

5. Click **Settings** under **WAF Policy**.

   The Settings list appears.

6. Click the **Origin Settings** tab.

7. Click **Edit**.

   The Origin Management Settings dialog box appears.

8. Scroll to the bottom of the dialog box and click **Show Advanced Options**.

   The Custom Headers section appears.
9. Enter the **Header Name** and **Header Value**. Click + **Additional Header** to add another custom header row for you to complete. Click X to remove an associated header row.  

10. Click **Save Changes**. Publish your changes for them to take effect. See Publishing Changes on page 6024.

**Bot Management**

Bot Management enables you to mitigate undesired bot traffic from your site using CAPTCHA and JavaScript detection tools while enabling known published bot providers to bypass these controls.

Non-human traffic makes up most of the traffic to sites. Bot Manager is designed to detect and block, or otherwise direct, non-human traffic that can interfere with site operations. The Bot Manager features mitigate bots that conduct content and price scraping, vulnerability scanning, comment spam, brute force attacks, and application-layer DDoS attacks. You can also manage the good bot whitelist.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you enable Bot Management, you incur a higher rate on requests to the WAF.</td>
</tr>
</tbody>
</table>

See these topics for more information about Bot Management:

- [JavaScript Challenge](#) on page 5910
- [Human Interaction Challenge](#) on page 5914
- [Device Fingerprint Challenge](#) on page 5917
- [CAPTCHA Challenge](#) on page 5920
- [Good Bot Allowlist](#) on page 5924
- [Address Rate Limiting](#) on page 5925

**JavaScript Challenge**

Describes the use and management of the JavaScript challenge for an edge policy.

JavaScript challenge validates that the client can accept JavaScript with a binary decision. JavaScript challenge is generally the first level of bot mitigation, but not sufficient with more advanced bot tools, which require more advanced challenges. More functionality, like detecting Network Address Translation (NAT) traffic, can mitigate the risk of blocking legitimate user traffic from users behind a shared IP address.

The Action Threshold parameter defines the number of requests that fail the challenge before the action is taken. The requests that fail under this threshold are not logged. For example, if you set the JavaScript challenge action to Block and the Action Threshold to 10, and a client that does not accept JavaScript makes 11 requests within the Action Expire Time, the first 10 requests are allowed through to origin (assuming no other rules exist). Logs show one Block entry action taken for the JavaScript challenge.

Enabling and Editing the JavaScript Challenge

Describes how to enable and edit the JavaScript challenge for an edge policy.

Use one of the following methods to enable and update the settings of a JavaScript challenge for an edge policy.

To enable and edit the JavaScript challenge using the Console

1. Open the navigation menu and click **Identity & Security.** Under **Web Application Firewall,** click **Policies.** Alternatively, open the Web Application Firewall page and click **Policies** under **Resources.** The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy for which you want to edit and enable the JavaScript challenge.
   The Details page of the edge policy you selected appears.

5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.

6. Select the **JavaScript Challenge** tab.

7. Click **Edit JavaScript Challenge**.
   The Edit JavaScript Challenge dialog box appears.

8. Check the **Enable JavaScript Challenge** box.

9. Complete the following:
   - **JavaScript Challenge Action** section: Choose one of the following options:
     - **Detect Only**: Select this option if you want to be alerted for every matched request.
       Complete the following:
       - **Enable Conditions**: Check to enable conditions. The JavaScript Challenge is applied only for the requests that match all the listed conditions.
         Select the condition and corresponding action from the lists. Click **+ Another Condition** to display another condition row where you can enter a condition and action pair. Click **X** to delete the associated condition row.
         See [Access Control](#) on page 6006 for more information about conditions and rules.
     - **Set header for failed request**: Check to add an HTTP header to requests that fail the challenge.
       Under **Additional Header**, enter the **Header name** (the name displayed in the HTTP request header) and the **Header value** (the data requested by the header) in the corresponding boxes.
     - **Block**: Select this option to block requests by returning a response code, error page, or CAPTCHA.
       Complete the following:
       - **Enable Conditions**: Check to enable conditions. The JavaScript Challenge is applied only for the requests that match all the listed conditions. Select the condition and corresponding action from the
lists. Click + Another Condition to display another condition row where you can enter a condition and action pair. Click X to delete the associated condition row.

See Access Control on page 6006 for more information about conditions and rules.

- **Block Action**: Select one of the following actions that are taken when a matching request is blocked.
  - **Set Response Code**:
    Complete the following:
    - **Block response code**: Select a status code to return in response to blocked requests.
  - **Show Error Page**:
    Complete the following:
    - **Block response code**: Select a status code to return in response to blocked requests.
    - **Block error page message**: Enter the message that defines the error or error code.
    - **Block error page description**: Enter more details about the error, including the cause and further instructions.
    - **Block Error Page Code**: Enter the error code that is displayed with the error.
  - **Show CAPTCHA**:
    Complete the following:
    - **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
    - **CAPTCHA Header**: Enter the text that appears before the CAPTCHA image (for example, "I am not a robot").
    - **CAPTCHA Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
    - **CAPTCHA submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
    - **Preview CAPTCHA**: Click to view the CAPTCHA as users would see it. Click Edit CAPTCHA to return.

- **Action threshold (number of requests)**: Specify the number of failed requests before the action occurs. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic Ajax usage, and 100 for apps with heavy Ajax usage.
- **Action expire time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
- **Follow Redirects** box: (optional) Check to enable. When enabled, redirect responses from the origin are also challenged.
- **Enable NAT Support** box: (optional) Check to enable. When enabled, the user is identified by the IP address and also by a unique hash. This checking prevents blocking visitors with shared IP addresses. Oracle recommends that you disable this NAT support for high-load apps (200+RPS).

10. Click **Save Changes**.

Publish your changes for them to take effect. See Publishing Changes on page 6024.

To enable and edit the JavaScript challenge using the CLI

Describes how to enable and edit the JavaScript challenge using the CLI.

Enter the following command and required parameters:

```
oci waas js-challenge update --is-enabled true --waas-policy-id waas_policy_id
```

See the CLI online help for a list of optional parameters:

```
oci waas js-challenge update --help
```
Web Application Firewall

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas js-challenge update` command.

To enable and edit the JavaScript challenge using the API
Describes how to enable and edit the JavaScript challenge using the API.

Use the `UpdateJsChallenge` method to enable and edit the JavaScript challenge using the API.
See `UpdateJsChallenge` in the Oracle Cloud Infrastructure documentation for a complete description.

**Getting JavaScript Challenge Details**
Describes how to get the details of the JavaScript challenge for an edge policy.

Use one of the following methods to get the details of the JavaScript challenge for an edge policy.

To get the details of the JavaScript challenge using the Console
Describes how to get the details of the JavaScript challenge for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy whose JavaScript challenge details you want to get.
   The Details page for the policy you select appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the **JavaScript Challenge** tab.
   The tab indicates whether the JavaScript challenge is enabled or not.
7. Click **Edit JavaScript Challenge**.
   The Edit JavaScript Challenge dialog box appears.
   View the settings of the JavaScript challenge. See **Enabling and Editing the JavaScript Challenge** on page 5910 for more information on these settings.

To get the details of the JavaScript challenge using the CLI
Describes how to get the details of the JavaScript challenge for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas js-challenge get --waas-policy-id waas_policy_id
```

See the CLI online help for a list of optional parameters:

```
oci waas js-challenge get --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas js-challenge get` command.

To get the details of the JavaScript challenge using the API
Describes how to get the details of the JavaScript challenge for an edge policy using the API.

Use the `GetJsChallenge` method to get the details of the JavaScript challenge using the API.
See GetJsChallenge in the Oracle Cloud Infrastructure documentation for a complete description.

**Human Interaction Challenge**

Describes the use and management of the human interaction challenge for an edge policy.

The human interaction challenge is an advanced countermeasure that looks for natural human interactions such as mouse movements, time on site, and page scrolling to identify bots. When an edge server receives requests from a client, instead of instantly reporting with the requested content, the human interaction challenge checks various event listeners in the user's browser to determine if a human user is making the request.

**Enabling and Editing the Human Interaction Challenge**

Describes how to enable and edit the human interaction challenge for an edge policy.

Use one of the following methods to enable and update the settings of the human interaction challenge for an edge policy.

To enable and edit the human interaction challenge using the Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy for which you want to edit and enable the human interaction challenge.

   The Details page of the edge policy you selected appears.

5. Click **Bot Management** under **WAF Policy**.

   The Bot Management list appears.

6. Select the **Human Interaction Challenge** tab.

7. Click **Edit Human Interaction Challenge**.

   The Edit Human Interaction Challenge dialog box appears.

8. Check the **Enable Human Interaction Challenge** box.

9. Complete the following:
   - **Human Interaction Challenge Action** section: Choose one of the following options:
     - **Detect Only**: Select this option if you want to be alerted for every matched request.
       
       Complete the following:
       - **Set header for failed request**: Check to add an HTTP header to requests that fail the challenge.
         
         Under **Additional Header**, enter the **Header name** (the name displayed in the HTTP request header) and the **Header value** (the data requested by the header) in the corresponding boxes.
       - **Block**: Select this option to block requests by returning a response code, error page, or CAPTCHA.
         
         Complete the following:
         - **Enable Conditions**: Check to enable conditions. The JavaScript Challenge is applied only for the requests that match all the listed conditions. Select the condition and corresponding action from the
lists. Click + **Another Condition** to display another condition row where you can enter a condition and action pair. Click X to delete the associated condition row.

See **Access Control** on page 6006 for more information about conditions and rules.

- **Block Action**: Select one of the following actions that is taken when a matching request is blocked.
  - **Set Response Code**:
    
    Complete the following:
    
    - Block **response code**: Select a status code to return in response to blocked requests.
  - **Show Error Page**:
    
    Complete the following:
    
    - Block **response code**: Select a status code to return in response to blocked requests.
    - Block **error page message**: Enter the message that defines the error or error code.
    - Block **error page description**: Enter more details about the error, including the cause and further instructions.
    - Block **Error Page Code**: Enter the error code that is displayed with the error.
  - **Show CAPTCHA**:
    
    Complete the following:
    
    - CAPTCHA **Title**: Enter the text for the CAPTCHA page title.
    - CAPTCHA **Header**: Enter the text that appears before the CAPTCHA image (for example, "I am not a robot").
    - CAPTCHA **Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
    - CAPTCHA **submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
    - Preview **CAPTCHA**: Click to view the CAPTCHA as users would see it. Click **Edit CAPTCHA** to return.

10. Complete the following:

   - **Action threshold (number of requests)**: Specify the number of failed requests before the action occurs. Because of the asynchronous request from the browser during page loading, Oracle recommends that you set a threshold of 10 for web applications with basic Ajax usage, and 100 for apps with heavy Ajax usage.
   - **Threshold expiry period (seconds)**: Enter the number of seconds before the threshold expires.
   - **Action expire time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, Oracle recommends that you set the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Interaction threshold (number of interactions)**: Enter the number of interactions before the threshold expires.
   - **Recording period (seconds)**: Enter the number of seconds to record the user's events.
   - **Enable NAT Support** box. (optional) Check to enable. When enabled, the user is identified by the IP address and also by a unique hash. This checking prevents blocking visitors with shared IP addresses. Oracle recommends that you disable this NAT support for high-load apps (200+RPS).

Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To enable and edit the human interaction challenge using the CLI

Describes how to enable and edit the human interaction challenge for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas human-interaction-challenge update --is-enabled true --waas-policy-id waas_policy_id [OPTIONS]
```

Enter the following command and required parameters:
Web Application Firewall

See the CLI online help for a list of optional parameters:

```
oci waas human-interaction-challenge update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas human-interaction-challenge update` command.

To enable and edit the human interaction challenge using the API
Describes how to enable and edit the human interaction challenge for an edge policy using the API.

Use the `UpdateHumanInteractionChallenge` method to enable and edit the human interaction challenge using the API.

See `UpdateHumanInteractionChallenge` in the Oracle Cloud Infrastructure documentation for a complete description.

**Getting Human Interaction Challenge Details**
Describes how to get details of the human interaction challenge for an edge policy

Use one of the following methods to get the details of the human interaction challenge for an edge policy.

To get the details of the human interaction challenge using the Console
Describe how to get the details of the human interaction challenge using the OCI Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy for which you want to edit and enable the human interaction challenge.
   The Details page of the edge policy you selected appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the **Human Interaction Challenge** tab.
   The tab indicates whether the Human Interaction challenge is enabled or not.
7. Click **Edit Human Interaction Challenge**.
   The Edit Human Interaction Challenge dialog box appears.
8. View the settings of the Human Interaction challenge.
   See **Enabling and Editing the Human Interaction Challenge** on page 5914 for more information on these settings.

To get the details of the human interaction challenge using the CLI
Describes how to get the details of the human interaction challenge using the CLI.

Enter the following command and required parameters:

```
oci waas human-interaction-challenge get --waas-policy-id waas_policy_id
```

See the CLI online help for a list of optional parameters:

```
oci waas human-interaction-challenge get --help
```
Web Application Firewall

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas human-interaction-challenge get` command.

To get the details of the human interaction challenge using the API
Describes how to get the details of the human interaction challenge using the API.
Use the `GetHumanInteractionChallenge` method to get the details of the human interaction challenge using the API.

See `GetHumanInteractionChallenge` in the Oracle Cloud Infrastructure documentation for a complete description.

Device Fingerprint Challenge
Describes the use and management of the device fingerprint challenge for an edge policy.

The device fingerprint challenge generates hashed signatures of both virtual and real browsers to identify and block malicious bots.

**Enabling and Editing the Device Fingerprint Challenge**
Describes how to enable and edit the device fingerprint challenge for an edge policy.

Use one of the following methods to enable and update the settings of the device fingerprint challenge for an edge policy.

To enable and edit the device fingerprint challenge using the Console
Describes how to enable and edit the device fingerprint challenge for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**. Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy for which you want to edit and enable the device fingerprint challenge.
   The Details page of the edge policy you selected appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the **Device Fingerprint Challenge** tab.
7. Click **Edit Device Fingerprint Challenge**.
   The Device Fingerprint Challenge dialog box appears.
8. Check the **Enable Device Fingerprint Challenge** box.
9. Complete the following:

   • **Device Fingerprint Challenge Action** section: Choose one of the following options:
     • **Detect Only**: Select this option if you want to be alerted for every matched request.
     • **Block**: Select this option to block requests by returning a response code, error page, or CAPTCHA.

   Complete the following:

   • **Block Action**: Select one of the following actions that is taken when a matching request is blocked.
     • **Set Response Code**:
       Complete the following:
       • **Block response code**: Select a status code to return in response to blocked requests.
     • **Show Error Page**:
       Complete the following:
       • **Block response code**: Select a status code to return in response to blocked requests.
       • **Block error page message**: Enter the message that defines the error or error code.
       • **Block error page description**: Enter more details about the error, including the cause and further instructions.
       • **Block Error Page Code**: Enter the error code that is displayed with the error.
     • **Show CAPTCHA**:
       Complete the following:
       • **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
       • **CAPTCHA Header**: Enter the text that appears before the CAPTCHA image (for example, "I am not a robot").
       • **CAPTCHA Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
       • **CAPTCHA submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
       • **Preview CAPTCHA**: Click to view the CAPTCHA as users would see it. Click **Edit CAPTCHA** to return.

10. Complete the following:

   a. Complete the following information:

      • **Action threshold (number of requests)**: Specify the number of failed requests before the action occurs. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic Ajax usage, and 100 for apps with heavy Ajax usage.
      • **Threshold expiry period (seconds)**: The number of seconds before the threshold expires.
      • **Action expire time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
      • **Max address count (IP addresses)**: The maximum number of IP addresses that are added to the list before the specified action is taken.
      • **Max address count expiration (seconds)**: The number of seconds an IP address is kept in the list before it is removed.

   b. Click **Save Changes**.

   Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To enable and edit the device fingerprint challenge using the CLI
Describes how to enable and edit the device fingerprint challenge for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas device-fingerprint-challenge update --is-enabled true --action DETECT --waas-policy-id waas_policy_id [OPTIONS]
```

See the CLI online help for a list of optional parameters:

```
oci waas device-fingerprint-challenge update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas device-fingerprint-challenge update` command.

To enable and edit the device fingerprint challenge using the API

Describes how to enable and edit the device fingerprint challenge for an edge policy using the API.

Use the `UpdateDeviceFingerprintChallenge` method to enable and edit the device fingerprint challenge using the API.

See `UpdateDeviceFingerprintChallenge` in the Oracle Cloud Infrastructure documentation for a complete description.

**Getting Device Fingerprint Challenge Details**

Describes how to get the details of the device fingerprint challenge for an edge policy.

Use one of the following methods to get the details of the device fingerprint challenge for an edge policy.

To get the details of the device fingerprint challenge using the Console

Describes how to get the details of the device fingerprint challenge for an edge policy using the OCI Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**. Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy for which you want to edit and enable the device fingerprint challenge.

   The Details page of the edge policy you selected appears.

5. Click **Bot Management** under **WAF Policy**.

   The Bot Management list appears.

6. Select the **Device Fingerprint Challenge** tab.

   The tab indicates whether the device fingerprint challenge is enabled or not.

7. Click **Edit Device Fingerprint Challenge**.

   The Edit Device Fingerprint Challenge dialog box appears.

8. View the settings of the device fingerprint challenge.

   See **Enabling and Editing the Device Fingerprint Challenge** on page 5917 for more information on these settings.

To get the details of the device fingerprint challenge using the CLI
Describes how to get the details of the device fingerprint challenge for an edge policy using the CLI.

Enter the following command and required parameters:

```bash
oci waas device-fingerprint-challenge get --waas-policy-id waas_policy_id
[OPTIONS]
```

See the CLI online help for a list of optional parameters:

```bash
oci waas device-fingerprint-challenge get --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas device-fingerprint-challenge get` command.

To get the details of the device fingerprint challenge using the API

Describes how to get the details of the device fingerprint challenge for an edge policy using the API.

Use the `GetDeviceFingerprintChallenge` method to get the details of the device fingerprint challenge using the API.

See `GetDeviceFingerprintChallenge` in the Oracle Cloud Infrastructure documentation for a complete description.

**CAPTCHA Challenge**

Describes the use and management of the CAPTCHA challenge for an edge policy.

If a specific URL should be accessed only by a human, you can control it with CAPTCHA protection. You can customize the comments for the CAPTCHA challenge for each URL. Bots are kept from accessing protected web application functionality using CAPTCHA images designed to be out of reach of computer vision and OCR technologies.

**Adding CAPTCHA Challenges**

Describes how to add a CAPTCHA challenge to an edge policy.

Use one of the following methods to add a CAPTCHA challenge to an edge policy.

To add a CAPTCHA challenge using the Console

Describes how to add a CAPTCHA challenge to an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy for which you want to edit and enable the CAPTCHA challenge.

   The Details page of the edge policy you selected appears.

5. Click **Bot Management** under **WAF Policy**.

   The Bot Management list appears.

6. Select the **CAPTCHA Challenge** tab.

7. Click **Add CAPTCHA Challenge**.

   The Add CAPTCHA Challenge dialog box appears.
8. Complete the following:
   - **Title**: Enter the text for the CAPTCHA page title.
   - **URL Path**: Enter the URL path challenged by CAPTCHA.
   - **Session Duration (seconds)**: Enter the number of seconds after which the CAPTCHA challenge cannot be resubmitted to the same user.
   - **Header**: Enter the text that appears before the CAPTCHA image (for example, "I am not a robot").
   - **Footer**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
   - **Incorrect CAPTCHA Text**: Enter the text that appears when incorrect text is entered (for example, "The CAPTCHA was incorrect. Please try again.").
   - **Submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
   - **Preview CAPTCHA**: Click to view the CAPTCHA as users would see it. Click **Edit CAPTCHA** to return.

9. Click **Add**.

   The CAPTCHA challenge is added to the list.

   Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To add a CAPTCHA challenge using the CLI
Describes how to add a CAPTCHA challenge to an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas captcha update --captchas captchas --waas-policy-id waas_policy_id
```

The `captchas` value is a list of CAPTCHA details. This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

See the CLI online help for a list of optional parameters:

```
oci waas captcha update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas captcha update` command.

To add a CAPTCHA challenge using the API
Describes how to add a CAPTCHA challenge to an edge policy using the API.

Use the `UpdateCaptchas` method to add a CAPTCHA challenge using the API.

See `UpdateCaptchas` in the Oracle Cloud Infrastructure documentation for a complete description.

**Listing the CAPTCHA Challenges**
Describes how to list the CAPTCHA challenges for an edge policy

Use one of the following methods to enable and update the settings of the CAPTCHA challenge for an edge policy.

To list the CAPTCHA challenges using the Console
Describes how to list the CAPTCHA challenges for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy for which you want to edit and enable the CAPTCHA challenge.
   The Details page of the edge policy you selected appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the **CAPTCHA Challenge** tab.
   The CAPTCHA Challenge tab lists all the available CAPTCHA challenges.

**To list the CAPTCHA challenges using the CLI**
Describes how to list the CAPTCHA challenges for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas captcha list --waas-policy-id waas_policy_id [OPTIONS]
```

See the CLI online help for a list of optional parameters:

```
oci waas captcha list --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas captcha list` command.

**To list the CAPTCHA challenges using the API**
Describes how to list the CAPTCHA challenges for an edge policy using the API.

Use the `ListCaptchas` method to get the details of the CAPTCHA challenge using the API.

See `ListCaptchas` in the Oracle Cloud Infrastructure documentation for a complete description.

**Editing the CAPTCHA Challenge**
Describes how to edit a CAPTCHA challenge for an edge policy

Use one of the following methods to edit the settings of the CAPTCHA challenge for an edge policy.

**To edit a CAPTCHA challenge using the Console**
Describes how to edit a CAPTCHA challenge for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy for which you want to edit and enable the CAPTCHA challenge.
   The Details page of the edge policy you selected appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the CAPTCHA Challenge tab.
   The CAPTCHA Challenge tab lists all the available CAPTCHA challenges.

7. Click the Actions icon (²) for the CAPTCHA challenge you want to edit and click Edit.
   The Edit CAPTCHA Challenge dialog box appears.

8. Edit the CAPTCHA challenge settings.
   See Adding CAPTCHA Challenges on page 5920 for more information on these settings.

9. Click Save Changes.
   Publish your changes for them to take effect. See Publishing Changes on page 6024.

To edit a CAPTCHA challenge using the CLI
Describes how to edit a CAPTCHA challenge for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas captcha update --captchas captchas --waas-policy-id waas_policy_id
[OPTIONS]
```

The `captchas` value is a list of CAPTCHA details. This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

See the CLI online help for a list of optional parameters:

```
oci waas captcha update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas captcha update` command.

To edit a CAPTCHA challenge using the API
Describes how to edit a CAPTCHA challenge for an edge policy using the API.

Use the UpdateCaptchas method to edit a CAPTCHA challenge using the API.

See UpdateCaptchas in the Oracle Cloud Infrastructure documentation for a complete description.

Deleting CAPTCHA Challenges
Describes how to delete a CAPTCHA challenge from an edge policy

Use one of the following methods to delete the settings of the CAPTCHA challenge from an edge policy.

To delete a CAPTCHA challenge using the Console
Describes how to delete a CAPTCHA challenge from an edge policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the edge policies displayed:
   • State
   • Name
   • Policy Type: Select Edge Policy.
4. Click the name of the edge policy for which you want to edit and enable the CAPTCHA challenge.
   The Details page of the edge policy you selected appears.
5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.
6. Select the **CAPTCHA Challenge** tab.
   The CAPTCHA Challenge tab lists all the available CAPTCHA challenges.
7. Click the **Actions** icon ( ⚙️ ) for the CAPTCHA challenge you want to edit and click **Delete**.
8. Confirm the deletion.
9. Click **Save Changes**.
   The CAPTCHA challenge you deleted is removed from the list of CAPTCHAs.

Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To delete a CAPTCHA challenge using the CLI

Describes how to delete a CAPTCHA challenge from an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas captcha update --captchas captchas --waas-policy-id waas_policy_id
```

The `captchas` value is a list of CAPTCHA details. This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

See the CLI online help for a list of optional parameters:

```
oci waas captcha update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas captcha update` command.

To delete a CAPTCHA challenge using the API

Describes how to delete a CAPTCHA challenge from an edge policy using the API.

Use the `UpdateCaptchas` method to delete a CAPTCHA challenge using the API.

See `UpdateCaptchas` in the Oracle Cloud Infrastructure documentation for a complete description.

**Good Bot Allowlist**

Describes the use and management of the good bot allowlist for an edge policy.

Good bots provides the list of bots managed by known providers, such as Baidu or Google. You can allow the access from a specific good bot, or block the bot if they serve no business purpose. Allowed good bots from this section are allowlisted.

Allowlisted bots are flagged with a Bypass action in the edge policy logs. You can select the Bypass check box from the Action filter in Logs to search for the traffic allowed from these rules. Logged good bot events are categorized as a Threat Intelligence Leads log type, however, they are not a threat when the action taken is to Bypass.

The list of good bots on this menu is managed and continuously updated. Other good bots can be added as a new access control rule in Access Control.

Use one of the following methods to manage the good bot allowlist for an edge policy.

**To manage the good bot whitelist using the Console**

Describes how to manage the good bot whitelist for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy for which you want to edit and enable the JavaScript challenge.
   The Details page of the edge policy you selected appears.

5. Click **Bot Management** under **WAF Policy**.
   The Bot Management list appears.

6. Select the **Good Bot Whitelist** tab.
   The Good Bot Whitelist tab lists the bots managed by known providers that you can add to a whitelist. Enabling a good bot lets it bypass all challenges.

7. Check each bot that you want to designate as a good bot. You can also check the **Disable All** or **Enable All** buttons.

**To manage the good bot whitelist using the CLI**

Describes how to manage the good bot whitelist for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas good-bot update --good-bots good-bots --waas-policy-id waas_policy_id [OPTIONS]
```

The **good-bots** value is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

See the CLI online help for a list of optional parameters:

```
oci waas good-bot update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas good-bot update` command.

**To manage the good bot whitelist using the API**

Describes how to manage the good bot whitelist for an edge policy using the API.

Use the `UpdateGoodBots` method to manage your good bot whitelist using the API.

See `UpdateGoodBots` in the Oracle Cloud Infrastructure documentation for a complete description.

**Address Rate Limiting**

Describes the use and management of the allow rate limiting for an edge policy.

The address rate limiting configuration defines the number of allowed requests from a unique IP address and the resulting block response code when that threshold is exceeded.

**Enabling and Editing Address Rate Limiting**

Describes how to enable and edit address rate limiting for an edge policy.

Use one of the following methods to enable and edit address rate limiting for an edge policy.

To enable and edit address rate limiting using the CLI
Web Application Firewall

Describes how to enable and edit address rate limiting for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas address-rate-limiting update-waf --good-bots good-bots --waas-policy-id waas_policy_id [OPTIONS]
```

The `good-bots` value is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

See the CLI online help for a list of optional parameters:

```
oci waas address-rate-limiting update-waf --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas good-bot update` command.

To enable and edit address rate limiting using the API

Describes how to enable and edit address rate limiting for an edge policy using the API.

Use the `UpdateWafAddressRateLimiting` method to edit and enable address rate limiting using the API.

See `UpdateWafAddressRateLimiting` in the Oracle Cloud Infrastructure documentation for a complete description.

**Getting Address Rate Limiting Details**

Describes how to get the details of the address rate limiting for an edge policy.

Use one of the following methods to get the details of the address rate limiting for an edge policy.

To get the details of the address rate limiting using the CLI

Describes how to get the details of the address rate limiting for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas address-rate-limiting get-waf --waas-policy-id waas_policy_id [OPTIONS]
```

See the CLI online help for a list of optional parameters:

```
oci waas address-rate-limiting get-waf --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas good-bot update` command.

To get the details of the address rate limiting using the API

Describes how to get the details of the address rate limiting for an edge policy using the API.

Use the `GetWafAddressRateLimiting` method to edit and enable the address rate limiting using the API.

See `GetWafAddressRateLimiting` in the Oracle Cloud Infrastructure documentation for a complete description.

**WAF Protection Rules**

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met. Protection Rule Settings allow you to define the parameters for enforcement any time a protection rule is matched. Recommendations aid in the optimization of your WAF security profile. The Security Operations team proactively monitors all events to provide recommendations about the action of a specific ruleset. See Supported Protection Rules on page 5938 for additional information.
Using the Console
To apply an action to a protection rule
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Rules tab.
5. Find the protection rule you want to apply an action to.

Tip:
You can use the Rule ID or Rule Action filters to locate a protection rule.

6. Click the Actions icon (three dots) and select one of the following options:
   • **Detect**: Matching requests generate an alert and the request is proxied.
   • **Block**: Matching requests are blocked.
   • **Off**: The rule is disabled.
   • **Exclusions**: Exclusions are set to specify the types of request that are to be bypassed by the protection rule(s). If a request matches any of the set exclusions, the protection rule(s) will not be executed for that request.
      a. In the Exclusions dialog box, enter the following criteria:
         • **Exclusion**: Select request cookie values, request cookie names, request parameters, or request parameter names.
         • **Value**: Enter the value for the selected exclusion.
      b. Click Save Changes.

The protection rule action is added to the list to be published.

To edit rule settings
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Settings tab.
5. Click Edit Rule Settings.
6. In the Edit Rule Settings dialog box, enter the following:
   • **Block Action**: The action taken on malicious requests blocked by WAF.
   • **Block Response Code**: Provides information indicating why the request was blocked.
   • **Max Number of Arguments**: The maximum number of arguments allowed in the request. The recommended setting is 255.
   • **Max Length of Argument**: The maximum argument length allowed in the request. The recommended setting is 400.
   • **Max Total Argument Length**: The maximum argument length for all arguments in the request. The recommended setting is 64000.
   • **Recommendations Period**: The period in days to analyze for recommended actions.
   • **Allowed HTTP Methods**: The list of allowed HTTP protocol methods.
7. Click Save Changes.

The accepted protection rules are added to the list to be published.

To accept recommendations
Recommendations will begin appearing once sufficient traffic has gone through the WAF to profile the right security posture.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the **Recommendations** tab.
5. Select the protection rules you want to accept.

| Tip: |
| You can use the **Recommended Action** filter to locate a recommendation by **Detect** or **Block**. |

6. Click **Accept Recommendations**.

The accepted protection rules are added to the list to be published.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6275 and Security Credentials on page 205. For information about SDKs, see Software Development Kits and Command Line Interface on page 6094.

- **GetProtectionRule**
- **ListProtectionRules**
- **UpdateProtectionRules**
- **GetProtectionSettings**
- **UpdateProtectionSettings**
- **ListRecommendations**
- **AcceptRecommendations**

**Listing and Accepting Protection Rule Recommendations**

Use the following operations to get the list of recommended rules:

- **ListRecommendations**

```json
{  
  "name": "SQL authentication bypass attempts",  
  "action": "OFF",  
  "description": "Detects basic SQL authentication bypass attempts.",  
  "exclusions": [],  
  "key": "981244",  
  "tags": "SQL Injections, Recommended"  
}
```
Using the key values from the output of the GET call above, you can accept one or more of the recommendations using the following operation passing an array of the keys:

- **AcceptRecommendations**

Body:

```json
[
  "981244",
  "950001"
]
```

### Protection Rule Specific Settings

Several protection rule settings are settings for specific protection rules.

<table>
<thead>
<tr>
<th>Setting</th>

</tbody>
</table>

The term "Arguments" refers to either query parameters or body parameters in a PUT/POST request. For instance, if the Max Number of Arguments is 2 and RuleID 960335 is set to BLOCK, any of the following requests would be blocked:

- GET /myapp/path?query=one&query=two&query=three
- POST /myapp/path with Body {"arg1":"one","arg2":"two","arg3":"three"}
- POST /myapp/path?query=one&query=two with Body {"arg1":"one"}

**Max Length of Argument** is the length of either a name or the value of the argument. **Total Argument Length** refers to the sum of the name and value length.

### Exclusions

Sometimes a protection rule can trigger a false positive. You can configure an exception if the request(s) generating the false positive have a particular argument or cookie that can be used to identify that request be excluded from the action normally taken on the rule. The following exclusion parameters can be used:
Exclusion Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request Parameters</td>
<td>List of parameter values (by parameter name) from form-urlencoded, XML, JSON, AMP, or POST payloads to exclude from inspecting.</td>
</tr>
<tr>
<td>Request Cookies</td>
<td>List of HTTP request cookie values (by cookie name) to exclude from inspecting.</td>
</tr>
</tbody>
</table>

Protection Rules Tuning

This basic WAF tuning guide outlines the fundamentals of rule tuning, log inspection, and setting up rule exclusions. Tuning a WAF policy can be beneficial for the following reasons:

- Reduces the chance of blocking a legitimate request.
- Protects against standard web application attacks.
- Protects against specific web application attacks.
- Reduces the amount of scanning, which leads to better performance.

The following table shows production rules terms and definitions.

Protection Rules Definitions

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuning</td>
<td>The process in which an engineer or analyst modifies protection rules and actions to allow the application server to be protected but remain functional. There is a balance between locking down the application server and allowing the application server to perform its duties. The best tuning takes an intimate knowledge of the application server being protected and protection rules available to protect that application server.</td>
</tr>
<tr>
<td>False positive</td>
<td>A false positive occurs when a protection rule is matched against an HTTP transaction and the HTTP transaction is a legitimate (non-malicious) transaction.</td>
</tr>
<tr>
<td>Exclusion</td>
<td>A modification to a protection rule that allows the value or value name of a cookie or HTTP argument to be ignored.</td>
</tr>
<tr>
<td>Oracle Recommendation Engine (ORE)</td>
<td>The ORE aids in the optimization of your WAF security profile by letting you enable all rules that do not trigger during an initial recommendation period.</td>
</tr>
</tbody>
</table>

Overview of WAF Protection Rules

WAF protects your web applications against threats. WAF is cloud-based and supports over 500 rule sets, and rule sets for the Open Web Application Security Project (OWASP). Use these rules to protect your critical web applications against malicious cyberattacks. These rules are compared against incoming requests to determine if the request contains an attack payload. If it determines that the request is an attack, WAF blocks or alerts you to that request. These attacks are varied and include threats such as SQL injection, cross-site scripting, and HTML injection—all of which can be detected and blocked by the WAF rule sets.
WAF protection is a toolkit designed for real-time web application monitoring, logging, and access control. The toolkit lets you decide how you want to take advantage of all the protection rules available instead. This flexibility is a core element of WAF protection rules, as we are constantly pushing updates to increase the security scope of our rules.

To identify and defend web applications against attacks, WAF protection rules run checks on any request to the webserver and all associated responses from the server against the set of rules. After the checks succeed, the HTTP request is sent to the website to retrieve the relevant content. If checks fail instead, the appropriate predefined actions are initiated.

The core principles of WAF protection rules are as follows:

- **Passiveness:** You decide which rules are required, therefore you have full control.
- **Flexibility:** WAF protection rules were created by a security expert who provided over 250 rules and the capacity to introduce custom protection rules.
- **Quality not quantity:** WAF protection rules are a dedicated module designed to inspect HTTP traffic that works with the other WAF features (for example, access control and bot management).
- **Predictability:** Having full control of the WAF protection rules allows you to control the results expected. You can define and tune your protection rules and leave the setup unattended, knowing that it keeps working as it was configured.

**Onboarding and Initial Tuning**

First, you need to have some knowledge about the web application for the tuning process. Otherwise, you might enable Linux-specific rules for your Windows server or origin and rules unnecessarily scan your traffic causing performance degradation. The ORE helps you by providing a solid and secure set of protection rules. The recommendation period is a configurable setting with a default of 10 days. We recommend increasing this value to 15 days to get a large sample of logs for normal traffic on the web application. Approximately twenty-four hours after your WAF policy is created, protection rule recommendations will appear in the recommendations tab. The recommendations are rules picked by WAF experts to cover the OWASP Top Ten. These recommended rules have been selected because they typically produce the least number of false positives and still provide good protection.

**Changing the Recommendation Period and Accepting the Recommendations**

By following the steps below, you enable the recommended rules in detect mode. After the rules are in detect mode, we advise waiting 15 days before changing them to block mode.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>During the assessment period, all the rules are in detect mode. Detect mode means that there will not be any blocking by protection rules. We recommend performing user acceptance testing and normal application use to help with the tuning process by generating logs. Review logs and check for false positives while the rules are in detect mode. By checking logs that trigger for protection rules, it gives you an idea of what traffic would cause a block when the rules are turned to block mode. During the assessment period, the application should receive as close to normal or production-like traffic as possible. Normal traffic shows you which rules trigger through logs, and false positives can be filtered out.</td>
</tr>
</tbody>
</table>

**To change the recommendations period**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Settings** tab.
5. Click **Edit Rule Settings**.
6. In the Edit Rule Settings dialog box, increased the **Recommendations Period** from 10 to 15 days.
7. Click **Save Changes**.
To accept the recommendations
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab.
5. Click **Accept Recommendations**.
6. Click **Unpublished Changes**.
7. Click **Publish All**.
8. In the Publish Changes dialog box, click **Publish All**.

**Using the API to Query for Specific Logs**
The API provides the most options for filtering rules. The following are examples of how to use the CLI to filter logs.

- To filter logs by protection rule ID:
  
  ```bash
  oci waas waf-log list --waas-policy-id <WASS Policy OCID> --protection-rule-key <protection rule id number>
  ```

- To filter logs by rule type (for example, protection or access rule types):
  
  ```bash
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --log-type PROTECTION_RULES
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --log-type ACCESS
  ```

- To filter logs by request URL:
  
  ```bash
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --request-url <request url>
  ```

**Setting Up Logging Analytics**
Logging Analytics helps you to narrow down the protection rules that require attention. Use the following guides to set up the Logging Analytics service with WAF. See Security Insights for your web apps with OMC Log Analytics and How to send OCI WAF Logs to OCI Logging Analytics and get Security Insights for more information.

**Note:**
The Security Operations Center (SOC) team can provide you with an OCI Protection Rules tuning proposal based on your WAF policy traffic. The proposal is delivered within 15 days, depending on the complexity of the request.

**Creating Exclusions in Protection Rules**
Reviewing logs is a critical part of the tuning process. Logs show us which rule was matched and what part of the HTTP transaction it was matched against. Refer to the following table for samples of logs and how to use them to create an exclusion.

The `protectionRuleDetections` object in `WafLog` provides a map of protection rule keys to detection message details. The following table shows four possible exclusions that can be set up for a protection rule.

<table>
<thead>
<tr>
<th>Log value</th>
<th>Exclusion value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGS</td>
<td>Request parameters</td>
<td>Used for values of a specific argument.</td>
</tr>
<tr>
<td>ARGS_NAMES</td>
<td>Request parameters names</td>
<td>Used for the name of the argument.</td>
</tr>
<tr>
<td>Log value</td>
<td>Exclusion value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>REQUEST_COOKIE</td>
<td>Request cookie values</td>
<td>Used for values of a specific cookie.</td>
</tr>
<tr>
<td>REQUEST_COOKIE</td>
<td>Request cookie names</td>
<td>Used for the name of the cookie.</td>
</tr>
</tbody>
</table>

### Sample Exclusions with Logs

The following section provides raw log samples and examples of what the exclusion value should be for each rule.

**• Rule ID 9411000 - ARGS**

In this example, the **Matched Data** was found within the `ARGS:foo` argument. The exclusion is for rule id 9411000. The exclusion to create is for **Request Parameters** with a value of `foo`.

```json
"protection-rule-detections": {
  "9411000": {
    "Message": "detected XSS using libinjection.",
    "Message details": "Matched Data: found within ARGS:foo: <script>xss"
  },
```

**• Rule ID 9411000 - ARGS_NAMES**

In this example, the **Matched Data** was found within the `ARGS_NAMES` argument. The exclusion is for rule id 9411000. The exclusion to create is for **Request Parameters Names** with a value of `<script>xss`.

```json
"protection-rule-detections": {
  "9411000": {
    "Message": "detected XSS using libinjection.",
    "Message details": "Matched Data: found within ARGS_NAMES:<script>xss: <script>xss"
  },
```

**• Rule ID 9411100**

In this example, the **Matched Data** was found within the `REQUEST_COOKIES:a` argument. The exclusion is for rule id 9411100. The exclusion to create is for **Request Cookie Values** with a value of `a`.

```json
"protection-rule-detections": {
  "9411100": {
    "Message": "Pattern match "(?i)([<\xef\xbc\x9c]script[^>\xef\xbc\x9e]*[<\xef\xbc\x9e])[\\s\\S]*?)" at REQUEST_COOKIES:a.",
    "Message details": "Matched Data: <script> found within REQUEST_COOKIES:a: <script>xss"
  },
```

To create exclusions

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Rules** tab.
5. Find the protection rule you want to apply an action to.
6. Click the Actions icon (three dots) and select **Exclusions**. Include the exclusions using the information you obtain from the preceding Sample Exclusions with Logs section.
7. Click **Save Changes**.
8. Click **Unpublished Changes**.
9. Click **Publish All**.
10. In the Publish Changes dialog box, click **Publish All**.
More Information on Protection Rules

Individual Protection Rules Versus Collaborative Protection Rules
To limit false positives, there are special protection rules that are tagged as "collaborative". These rule groups operate differently than the rest of the protection rules, as they use a scoring and threshold system to evaluate traffic. Individual rules work by matching elements of the HTTP transaction against the rule signature. If a match is made, the rule performs its action (for example, detecting or blocking). Each of the collaborative protection rules uses a group of individual rules. The collaborative protection rules require multiple matches of elements of the HTTP transaction against individual rules to perform its action (for example, detecting or blocking). For a collaborative rule to perform its action, at least three elements of the HTTP transaction must match against the individual rules in the collaborative group. After the exclusion is added within the collaborative protection rule group, it will apply to all the rules within it. The following is a list of the collaborative protection rule IDs.

Collaborative Protection Rule IDs
- 9300000 - Local File Inclusion (LFI) Collaborative Group - LFI Filter Categories
- 9320000 - Remote Code Execution (RCE) Collaborative Group - UNIX RCE Filter Categories
- 9330000 - PHP Injection Attacks Collaborative Group - PHP Filters Categories
- 9410000 - Cross-Site Scripting (XSS) Collaborative Group - XSS Filters Categories
- 9420000 - SQL Injection (SQLi) Collaborative Group - SQLi Filters Categories

Request Body Inspection Rule IDs
The following rules require response body inspection to be enabled. Remember that response body inspection delays the transaction, as it scans all the information within it. Enable only the required rules.

| 970014, 90005, 120133, 970008, 970016, 981080, 920020, 920006, 920008, 920010, 920012, 920014, 920016, 920018, 90017, 90018, 90020, 90019, 90014, 90021, 90015, 90016, 920021, 920022, 920023, 90024, 90022, 90023, 970013, 970011, 981177, 981000, 981001, 981003, 970018, 970004, 970904, 970010, 970118, 2100090, 970012, 970903, 970009, 970902, 981005, 981004, 981007, 981006, 970003, 970002, 950110, 950921, 950922, 90002, 90025, 970021, 970007 |

No Exception Rules
The following rules create different raw log values than ARGS, ARGS_NAMES, REQUEST_COOKIE, and REQUEST_COOKIE_VALUE. Exclusions do not exist for these rules, since the rules are based on if the element is present or not. For example, if the content-type header is present, the only option to exclude this rule is to open a service request with My Oracle Support to ask for a custom WAF rule that excludes any of the following rules.

| 960020, 960015, 960009, 950103 |

These rules are easily spotted, as the log values are REQUEST_URI, REQUEST_PROTOCOL, and REQUEST_HEADERS.

Other Protection Rules
The following is a list of protection rules that are "noisy", with some descriptions and recommendations which help you understand what the rule is trying to match. Exclusions cannot be applied to some of these rules.
<table>
<thead>
<tr>
<th>Rule ID</th>
<th>Rule Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>981318</td>
<td>String Termination/Statement Ending</td>
<td>This rule is important, as it alerts for any escaping character detected within any input field and queryString [ARGS] or cookie. Review the validations taken at the application side and ensure it only allows the proper input characters, for example, letters and numbers. If another input value is required, an exclusion to the rule can be applied in the WAF and let it through.</td>
</tr>
<tr>
<td>960015</td>
<td>Missing Accept Header</td>
<td>Even when requests without accept headers do not mean a violation of the HTTP protocol, requests without accept headers are most often not genuine requests. The rule might be alerting for API or custom application requests. To avoid scanning API or custom application requests, collect a list of the well-known applications that send traffic through and request custom rules. For more information, see RFC 7231, section-5.3.2.</td>
</tr>
<tr>
<td>960021</td>
<td></td>
<td></td>
</tr>
<tr>
<td>960007</td>
<td>Missing Host Header</td>
<td>As described in RFC 7230, section-5.4 &quot;A server must respond with a 400 (Bad Request) status code to any HTTP/1.1 request message that lacks a Host header field and to any request message that contains more than one Host header field or a Host header field with an invalid field-value.&quot; This is an essential method of protection and at the same time ensures that WAF servers properly identify which WAF policy the request is intended for. Since WAF requires a host header to pass traffic to the proper origin, this rule might cause a high rate of false positives.</td>
</tr>
<tr>
<td>960008</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>---------</td>
<td>----------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>960009</td>
<td>Missing User-Agent Header</td>
<td>This rule prevents unidentified users from accessing your web application. User-Agent is one of the request headers defined in various RFCs that provides user information. Even when a request contains a user agent, it does not imply it comes from a real human. This rule works as a first level of mitigation for “dummy” attacks that originate from possible bots or “non-RFC compliant” applications.</td>
</tr>
<tr>
<td>960006</td>
<td></td>
<td><em>Note:</em> Some APIs might not include the User-Agent header. If API requests are expected, ensure you add the API IP address to the allowlist or have a custom WAF rule that excludes this traffic from being inspected. For more information, see RFC 7231, section-5.5.3. This rule is an indicator of bad or malicious traffic, but it is possible legitimate applications do not have a User-Agent. Ask application owners to use User-Agents when applicable.</td>
</tr>
<tr>
<td>960011</td>
<td>GET/HEAD Requests Validation</td>
<td>As described in RFC 7231, section-4.3.1 and section-4.3.2, HEAD and GET are HTTP methods intended to retrieve information from the origin server. Even when not forbidden by the RFC, sending body or payload through these types of methods is not a common practice. Usually it is caused by improperly defined applications not following the best practices of the RFC and can be used by malicious users as a bypass technique. It is also defined in RFC 2616, section-4.3 “if the request method does not include defined semantics for an entity-body, then the message-body should be ignored when handling the request.”</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 5936
<table>
<thead>
<tr>
<th>Rule ID</th>
<th>Rule Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>960904</td>
<td>Missing Content-Type Header</td>
<td>As defined under RFC 2616, section-7.2.1, &quot;Any HTTP/1.1 message containing an entity-body should include a Content-Type header field defining the media type of that body.&quot; If this best practice is not followed, it could lead to MIME-type sniffing attacks.</td>
</tr>
<tr>
<td>960032</td>
<td>Allowed HTTP methods</td>
<td>The default allowed HTTP methods are GET, HEAD, POST, and OPTIONS. OPTIONS is known as an insecure method because it is highly used by attackers to gather up information from the origin server. This method is also required by some applications to work properly. If this method is not required, create a service request with My Oracle Support to disable it. Other methods can also be added as required with a service request.</td>
</tr>
<tr>
<td>960335</td>
<td>Max amount of arguments</td>
<td>RFC does not enforce the number of arguments that a request must have, but using many arguments could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum number of ARGs allowed per request. The default value is 255.</td>
</tr>
<tr>
<td>960208</td>
<td>Max length of an argument</td>
<td>RFC does not enforce the length per argument that a request must have, but using large argument length could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum length of ARGs allowed per request. The default value is 400.</td>
</tr>
</tbody>
</table>
Web Application Firewall

**Rule ID** | **Rule Name** | **Notes**
---|---|---
960341 | Max total argument length | RFC does not enforce the total (combined) argument size that a request must have, but large combined argument values could be a method used by malicious users attempting to overflow a web application.
To protect against these types of attacks, we recommend limiting the maximum combined argument value allowed per request.
The default value is 64000.

92035032 | Host Header Is IP Address | This rule does not usually trigger, as WAF needs a host header to send traffic to the origin.

941120 | Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 2 | This rule takes a long time to process if there is a large payload.
For example, a payload with 64,005 bytes takes around 32 seconds to process.

**Supported Protection Rules**
The Oracle Cloud Infrastructure WAF service supports many protection rule types. The following list provides a brief explanation of the purpose of each protection rule type.

**Protection Rules**

<td>Session fixation</td>
<td>Session Fixation is an attack technique that forces a user’s session ID to an explicit value. Depending on the functionality of the target web site, a number of techniques can be utilized to &quot;fix&quot; the session ID value. These techniques range from Cross-site Scripting exploits to peppering the web site with previously made HTTP requests. After a user’s session ID has been fixed, the attacker will wait for that user to login. Once the user does so, the attacker uses the predefined session ID value to assume the same online identity.</td>

**Custom Protection Rules**

The WAF service allows you to define and apply custom protection rules from open source firewall modules to your WAF configurations, such as ModSecurity modules. This topic describes how to format, create, and implement custom protection rules in your WAF policies using the Console and WAAS API. For a list of protection rules already available in the service, see Supported Protection Rules on page 5938.

**Custom Protection Rule Syntax**

All custom protection rules are expressed in ModSecurity Rule Language. For more information about ModSecurity syntax, see Making Rules: The Basic Syntax.

Additionally, each rule must include two placeholder variables that are updated by the WAF service upon publication of the rule.

**id: {{id_1}}** - This field is updated with a unique rule ID generated by the WAF service which identifies a SecRule. More than one SecRule can be defined in the template field of a CreateCustomProtectionRule call. The value of the first SecRule must be id: {{id_1}} and the id field of each subsequent SecRule should increase by one, as shown in the example.

**ctl:ruleEngine={{mode}}** - The action to be taken when the criteria of the SecRule are met, either OFF, DETECT or BLOCK. This field is updated with the corresponding value of the action field of the CustomProtectionRuleSetting object when using the UpdateWafConfig operation.

**Example of a custom protection rule format:**

```
SecRule REQUEST_COOKIES "regex matching SQL injection - part 1/2" \
```
"phase:2,                                                             
msg:'Detects chained SQL injection attempts 1/2.',                  
id: {{id_1}},                                                       
ctl:ruleEngine={{mode}},                                           
deny"
SecRule REQUEST_COOKIES "regex matching SQL injection - part 2/2" 
"phase:2,                                                             
msg:'Detects chained SQL injection attempts 2/2.',                  
id: {{id_2}},                                                       
ctl:ruleEngine={{mode}},                                           
deny"

**Actions**

The WAF service can take an action on an HTTP request when the criteria of a custom protection rule are met.

- **DETECT** - Logs the request when the criteria of the custom protection are met.
- **BLOCK** - Blocks the request when the criteria of the custom protection rule are met.
- **OFF** - The custom protection rule is inactive and will take no action.

**Using the Console**

To create a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click **Create WAF Custom Protection Rule**.
4. In the Create a Custom Protection Rule dialog box, enter the following:
   - **Name**: A unique name for the protection rule. Avoid entering confidential information.
   - **Description**: Optional. A description of the custom protection rule.
   - **Template**: Enter the protection rule criteria in ModSecurity Rule Language. Each rule must include two placeholder variables: id: {{id_1}} and ctl:ruleEngine={{mode}}. For more information about ModSecurity syntax, see **Making Rules: The Basic Syntax**.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

To edit a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click the name of the custom protection rule you want to edit.
4. Click **Edit**.
5. Make the necessary changes and then click **Save Changes**.

To manage tags for a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click the name of the protection rule you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

To move a custom protection rule to another compartment

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Find the protection rule in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To delete a custom protection rule

2. Click Custom Protection Rules.
3. Select the check box for the protection rule you want to delete.
4. Click Delete.
5. In the confirmation dialog box, click Delete.

To add a custom protection rule to a WAF policy

2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Custom Rules tab.
5. Click Add from the Actions drop down menu.
6. In the Add Custom Rule dialog box, select a custom protection rule from the drop down menu. If the custom protection rule exists in another compartment, you can change the compartment where the rule exists.
7. Select one of the following actions to apply to the rule:
   - Detect: Matching requests generate an alert and the request is proxied.
   - Block: Matching requests are blocked.
8. Click Add.

To apply a new action to a custom protection rule in a WAF policy

2. Click the name of the WAF Policy where you want to edit a custom protection rule.
3. Click Protection Rules and then click the Custom Rules tab.
4. Select the check box for the custom rule you want to change the action for.
5. Select the action from the Actions drop down menu.

To delete a custom protection rule from a WAF policy

2. Click the name of the WAF Policy where you want to remove a custom protection rule. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Custom Rules tab.
5. Select the check box for the custom rule you want to delete.
6. Select delete from the Actions drop down menu.

Using the API

Custom protection rules can be created and added to a compartment using the CreateProtectionRule call in the WAAS API. Using ModSecurity Rule Language formatting, populate the template field with the criteria of the rule.

Example:

```
{
"compartmentId": "ocid1.compartment.region1..<unique_ID>",
"description": "The description text for the rule being created",
"displayName": "Custom Protection Rule Name",
"template": "SecRule REQUEST_URI /"phase:2, t:none, capture, msg:'Custom (XSS) Attack. Matched Data: %{TX.0} found within %{MATCHED_VAR_NAME}: %{MATCHED_VAR}, id:{id_1}), ctl:ruleEngine={"mode"}, tag:'Custom', severity:'2'"
}
```
Adding Custom Protection Rules to a WAF Configuration

Custom protection rules can be added to a WAF configuration using the `UpdateWafConfig` call in the WAAS API. Add the OCID and the desired action to take to the `CustomProtectionRuleSetting` object of the `UpdateWafConfig` schema.

Example:

```json
[
  {
    "action": "BLOCK",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaalxd4jrws4rbbnddz1notu3giuzo53kopbj74mbvarttr7vyy7ja"
  },
  {
    "action": "DETECT",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaamx5r72ntmmhwgeaspzpdqcwsgprpuvwsa7xoshnyol"
  }
]
```

To view a list of available custom protection rules in a compartment and their corresponding OCIDs, use the `ListCustomProtectionRules` call in the WAAS API.

Access Control

See these topics for more information about access control:

- Access Rules on page 6006
- IP Address Lists on page 6012
- IP Address Whitelist on page 6014

Access Rules

As a WAF administrator, you can define explicit actions for requests that meet various conditions. Conditions use various operations and regular expressions. A rule action can be set to log and allow, detect, block, redirect, bypass, or show a CAPTCHA for all matched requests.

The available conditions for an access rule are shown in the following table:

<table>
<thead>
<tr>
<th>Criteria Type</th>
<th>Criteria</th>
</tr>
</thead>
</table>
| URL           | Define one or more criteria based on:  
|               | • URL is  
|               | • URL is not  
|               | • URL starts with  
|               | • URL does not start with  
|               | • URL part ends with  
|               | • URL part does not end with  
|               | • URL part contains  
|               | • URL part does not contain  
|               | • URL regex  
|               | • URL does not match regex  

The URL regex matching uses Perl-compatible regular expressions.

### Adding Access Rules

Describes how to add access rules to an edge policy.

Use one of the following methods to add an access rule to an edge policy.

To add an access rule using the Console

Describes how to add access rules to an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   • State
   • Name
   • **Policy Type**: Select **Edge Policy**.
4. Click the name of the edge policy for which you want to add an access rule.
   
The Details page of the edge policy you selected appears.

5. Click Access Control under WAF Policy.
   
The Access Rules list appears.

6. Click Add Access Rule.
   
The Add Access Rules dialog box appears.

7. Complete the following:
   
   • **Name:** Enter the name of the access rule. Avoid entering confidential information.
   
   • **Action:** Select one of the following options to determine the response to a request when the rule is matched.
     
     • **Log and Allow:** A log is created for all matched requests and no further action is taken.
     
     • **Detect Only:** A detection alert is created for all matched requests and no further action is taken.
     
     • **Block:** All matched requests are blocked and a browser page for the selected response code is returned.
       
       • **Block Action:** Select the action that is taken when a matching request is blocked.
       
       • **Block Response Code:** Select a response code that is returned when the request has been blocked. The response code provides information indicating why the request was blocked. The default response code is 403 Forbidden.
     
   • **Redirect:** Complete the following:
     
     • **Redirect Status Code:** Select the status code returned in response to redirect requests from the list.
     
     • **Redirect URL:** Enter the URL address to redirect the request to.
     
   • **Bypass:** Select one or more challenges to bypass. If this section is not specified, all challenges are bypassed.
     
   • **Show CAPTCHA:** Select this option to show a CAPTCHA for all matched requests and take no further action. Enter the following:
     
     • **CAPTCHA Title:** Enter the text for the CAPTCHA page title.
     
     • **CAPTCHA Header:** Enter the text that appears before the CAPTCHA image (for example, "I am not a robot").
     
     • **CAPTCHA Footer Text:** Enter the text that will be shown after the CAPTCHA input box and before the submit button.
     
     • **CAPTCHA submit button:** Enter the text for the Submit button (for example, "Yes, I am human.").
     
   • **Conditions:** Select the condition that must be met before the rule is matched and specify the details of the condition. You can add other conditions in this section.
     
   • **Header Manipulation(s):** Complete the following:
     
     • **Action:** Select the action to apply to the request.
     
     • **Header Name:** Enter the HTTP header name of the request.
     
     • **Header Value:** Enter the HTTP header value of the request.

8. Click Add Access Rule.
   
The access rule is added to the access rule list.

Publish your changes for them to take effect. See Publishing Changes on page 6024.

To add an access rule using the CLI

Describes how to add an access rule to an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas access-rule update --waas-policy-id waas_policy_id --access-rules access_rules [OPTIONS]
```

The `access-rules` value is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.
Note:
This operation can create, delete, update, or reorder access rules depending on the structure of the request body.

See the CLI online help for a list of optional parameters:

```
oci waas access-rule update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas access-rule update` command.

To add an access rule using the API
Describes how to add access rules to an edge policy using the API.

Use the `UpdateAccessRules` method to add an address rule using the API.

See `UpdateAccessRules` in the Oracle Cloud Infrastructure documentation for a complete description.

Note:
This operation can create, delete, update, or reorder access rules depending on the structure of the request body.

Listing Access Rules
Describes how to list the access rules for an edge policy.

Use one of the following methods to list the access rules for an edge policy.

To list the access rules using the Console
Describes how to list the access rules for an edge policy using the OCI Console.

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the edge policies displayed:
   • State
   • Name
   • Policy Type: Select Edge Policy.
4. Click the name of the edge policy whose access rules you want to list.
   The Details page of the edge policy you selected appears.
5. Click Access Control under WAF Policy.
   The Access Rules list appears.
   All the access rules for the edge policy are listed.

To list the access rules using the CLI
Describes how to list the access rules for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas access-rule list --waas-policy-id waas_policy_id [OPTIONS]
```

See the CLI online help for a list of optional parameters:

```
oci waas access-rule list --help
```
Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas access-rule list` command.

To list the access rules using the API
Describes how to list the access rules for an edge policy using the API.
Use the `ListAccessRules` method to list the address rules using the API.
See `ListAccessRules` in the Oracle Cloud Infrastructure documentation for a complete description.

**Editing Access Rules**
Describes how to edit access rules for an edge policy.

Use one of the following methods to edit an access rule to an edge policy.

To edit an access rule using the Console
Describes how to edit access rules for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.

   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy whose access rule you want to edit.

   The Details page of the edge policy you selected appears.

5. Click **Access Control** under **WAF Policy**.

   The Access Rules list appears.

6. Select the check box for the access rule you want to update, and then click **Edit**.

   The Edit Access Rule dialog box appears.

7. Edit the access rule.

   See **Adding Access Rules** on page 6007 for a description of the access rule settings.

8. Click **Save**.

   The Edit Access Rule dialog box closes. The access rule you edited appears in the Access Rule list with the updates you made.

   Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To edit an access rule using the CLI
Describes how to edit an access rule for an edge policy using the CLI.

Enter the following command and required parameters:

```
oci waas access-rule update --waas-policy-id waas_policy_id --access-rules access_rules [OPTIONS]
```

The `access-rules` value is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.

**Note:**

This operation can create, delete, update, or reorder access rules depending on the structure of the request body.
See the CLI online help for a list of optional parameters:

```
oci waas access-rule update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas access-rule update` command.

To edit an access rule using the API

Describes how to edit an access rule for an edge policy using the API.

Use the `UpdateAccessRules` method to edit an access rule using the API.

See `UpdateAccessRules` in the Oracle Cloud Infrastructure documentation for a complete description.

**Note:**

This operation can create, delete, update, or reorder access rules depending on the structure of the request body.

**Deleting Access Rules**

Describes how to delete access rules from an edge policy.

Use one of the following methods to delete an access rule from an edge policy.

To delete an access rule using the Console

Describes how to delete an access rule using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.

2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the edge policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy whose access rule you want to delete.
   
   The Details page of the edge policy you selected appears.

5. Click **Access Control** under **WAF Policy**.
   
   The Access Rules list appears.

6. Select the check box for one or more access rules you want to delete, and then click **Delete**.

7. Confirm the deletion.
   
   The Access Rule list no longer includes those access rules you deleted.

Publish your changes for them to take effect. See **Publishing Changes** on page 6024.

To delete an access rule using the CLI

Describes how to delete an access rule using the CLI.

Enter the following command and required parameters:

```
oci waas access-rule update --waas-policy-id waas_policy_id --access-rules access_rules [OPTIONS]
```

The `access-rules` value is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the `file://path/to/file` syntax.
Web Application Firewall

**Note:**

This operation can create, delete, update, or reorder access rules depending on the structure of the request body.

See the CLI online help for a list of optional parameters:

```
oci waas access-rule update --help
```

Refer to the Oracle Cloud Infrastructure documentation for a complete description of the `oci waas access-rule update` command.

To delete an access rule using the API

Describes how to delete an access rule using the API.

Use the `UpdateAccessRules` method to edit an address rule using the API.

See `UpdateAccessRules` in the Oracle Cloud Infrastructure documentation for a complete description.

**Note:**

This operation can create, delete, update, or reorder access rules depending on the structure of the request body.

**IP Address Lists**

WAF IP Address Lists allow you to define a list of IP addresses to use in WAF policy configurations. An IP Address List can be used in multiple WAF policies. The IP addresses in the list can be a valid IPv4 address, a subset, or CIDR notations. You can use the IP address list to define the conditions for an access rule. Access rules allow you to specify explicit actions for requests that meet various conditions.

**Using the Console**

To add an IP address list

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **IP Address Lists**.
3. Click **Create WAF IP Address List**.
4. In the Create WAF IP Address List dialog box, enter the following:
   - **Name**: A user-friendly name for the IP address list. Avoid entering confidential information.
   - **IP Addresses**: Enter IP addresses or CIDR notations.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

To edit an IP address list

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **IP Address Lists**.
3. Click the name of the IP address list you want to update.
4. Click **Edit**.
5. In the Edit WAF IP Address List dialog box, update the Name or IP Addresses. Avoid entering confidential information.
6. Click **Save Changes**.

To delete an IP address list

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **IP Address Lists**.
3. Select the check box for the IP address list you want to delete.
4. Click **Delete**.
5. In the confirmation dialog box, click **Delete**.

To move an IP address list to another compartment

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. In the **List Scope** section, select a compartment.
3. Click **IP Address Lists**.
4. Find the IP address list in the list, click the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To manage tags for an IP address list

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **IP Address Lists**.
3. Click the name of the IP address list you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 6275 and **Security Credentials** on page 205. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 6094.

Use the following API operations to create and manage address lists that can be applied to access rules:

- **CreateAddressList**
- **ListAddressLists**
- **GetAddressLists**
- **UpdateAddressList**
- **DeleteAddressLists**

**Example**

To create an address list:

```
POST /addressLists
{
  "addresses": [ 
    "198.51.100.0",
```
IP Address Whitelist

You can use the IP Address Whitelist tab in Access Control to manage whitelists containing trusted IP addresses that bypass all rules and challenges. See Access Control on page 6006 for more information.

Using the Console

To add an IP address whitelist in a WAF policy

2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click Access Control.
4. Select the IP Whitelist tab.
5. Click Add IP Address Whitelist.
6. In the Add IP Address Whitelist dialog box, enter the following:
   - Whitelist Name: A name for the IP addresses used in the list.
   - IP Addresses: Select an IP address or enter an IP address and select it to add it. This field supports CIDR notation.
7. Click Add IP Address Whitelist.

The IP Address Whitelist is added to the list of changes to be published.

To edit an IP address whitelist in a WAF policy

2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click Access Control.
4. Select the IP Whitelist tab.
5. Select the check box for the IP Address Whitelist name you want to edit.
6. Click Edit.
7. In the Edit IP Address Whitelist dialog box, make the needed changes.
8. Click Save.

The IP Address Whitelist change is added to the list of changes to be published.

To delete an IP address whitelist in a policy

2. Click the name of the WAF Policy you want to view alerts for. The WAF Policy overview appears.
3. Click Access Control.
4. Select the IP Whitelist tab.
5. Select the check box for the IP Address Whitelist name you want to delete.
6. Click Delete.

The deleted IP Address Whitelist is added to the list of changes to be published.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.
1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

### To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

### Using the API

For information about using the API and signing requests, see REST APIs on page 6275 and Security Credentials on page 205. For information about SDKs, see Software Development Kits and Command Line Interface on page 6094.

- UpdateWhitelists
- ListWhitelists

### Logs

Logs displays log activity and the details of each logged event within a specified time frame. Logs enable you to understand what rules and countermeasures are triggered by requests and are used as a basis to move request handling into block mode. Logs can come from Access Control, Protection Rules, or Bot events.

**Note:**

If you have concerns over General Data Protection Regulation (GDPR) requirements, Logs can be disabled for the WAF service. You can use My Oracle Support to file a service request to disable Logs.

### Viewing Logs

Describes the different methods to view logs for an edge policy.

You can filter logs by the following log types:

- Access Rules
- CAPTCHA Challenge
- JavaScript Challenge
- Protection Rules
- Human Interaction Challenge
- Device Fingerprinting Challenge
- Threat Intelligence Feeds
- Address Rate Limiting
- Access

Use one of the following methods to view logs for an edge policy.

**To view logs using the Console**

Describes the different methods to view logs for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.

   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - Name
   - Policy Type
   - Status

4. Select the edge policy whose logs you want to view.
   The Edge Policy Details dialog box appears.

5. Click **Logs** under **Resources**.
   The Logs list appears.

6. (Optional) Complete one or more of the following **Filters** to limit the log information to the values you enter:
   - Start date
   - Start time
   - End date
   - End time
   - Request URL
   - Client IP address
   - Country name

7. (Optional) Check one or more of the following **Action** filters to limit the log information to the selected options:
   - Detect
   - Block
   - Bypass
   - Log
   - Redirected

8. (Optional) Check one or more of the following **Log type** filters to limit the log information to the selected options:
   - Access rules
   - CAPTCHA challenge
   - JavaScript challenge
   - Protection rules
   - Human interaction challenge
   - Device fingerprinting challenge
   - Threat intelligence feeds
   - Address rate limiting
   - Access

   Only log information containing the checked actions is displayed.

9. Click the plus sign next to the **Alert Type** you want to view.
   Log entries are displayed based on the options you chose.

*To view logs using the API*

Describes the different methods to view logs for an edge policy using the API.

Run the `ListWafLogs` method to view log activity. See `ListWafLogs` for a complete description.

You can filter logs by the following **logType** options:

- ACCESS_RULES
- CAPTCHA_CHALLENGE
- JAVASCRIPT_CHALLENGE
- PROTECTION_RULES
- HUMAN_INTERACTION_CHALLENGE
Logs can be filtered by logType by making the following request:

GET /20181116/waasPolicies/unique_ID/wafLogs?
logType=logType&timeObservedGreaterThanOrEqualTo=timestamp&timeObservedLessThan=timestamp&compartmentId=unique_ID

For example:

GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?
logType=PROTECTION_RULES&timeObservedGreaterThanOrEqualTo=2019-10-24T13:00:00+00:00&timeObservedLessThan=2019-10-24T13:47:00+00:00&compartmentId=ocid1.compartment.oc1..

The following response output for the filtered logs is returned:

```

Edge Policy Metrics

You can monitor the health, capacity, and performance of your edge policies by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_waf (the WAF service).

Overview of the WAF Service Metrics

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based global security service that protects applications from malicious and unwanted internet traffic. The WAF service metrics help you measure various levels of traffic encountering your WAF policies, including non-malicious traffic. For more information, see Overview of the Web Application Firewall Service.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
Permissions are required to allow monitoring, alarm, and notification (ONS) definition for users in a group for all compartments. The following policies must be configured in the root compartment:

- Allow group <WAFMonitors> to read metrics in compartment <CompartmentName>
- Allow group <WAFMonitors> to manage alarms in compartment <CompartmentName>
- Allow group <WAFmonitors> to manage ons-family in compartment <CompartmentName>

**Available Metrics: oci_waf**

The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have the policy properly set up with web traffic passing through it to make the oci_waf metric space available in the Metrics Explorer feature. Policies with no web traffic emit no metric data.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Requests</td>
<td>Requests</td>
<td>count</td>
<td>The total number of requests serviced by the WAF.</td>
<td>resourceID, primaryDomain, module, action, countryCode, responseCode, responseCodeGroup</td>
</tr>
<tr>
<td>Traffic</td>
<td>Traffic</td>
<td>byte</td>
<td>Data egress from the WAF (compressed by default) measured in one minute intervals.</td>
<td></td>
</tr>
<tr>
<td>Bandwidth</td>
<td>Bandwidth</td>
<td>B/s (byte per second)</td>
<td>Bandwidth rate calculated by dividing total data egress in a minute by 60.</td>
<td></td>
</tr>
</tbody>
</table>
### Available Dimensions

The following dimensions are available for WAF metrics:

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
<th>Sample Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td>The rule type that was triggered by the request.</td>
<td>• blocked</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• passed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• redirected</td>
</tr>
<tr>
<td><strong>Country</strong></td>
<td>Two-letter country code where the request originated.</td>
<td>• US</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• BZ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CN</td>
</tr>
<tr>
<td><strong>Module</strong></td>
<td>The rule type that was triggered by the request.</td>
<td>• access_rules</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• captcha</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• threat (threat intelligence)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• modsecurity (protection rule)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• origin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• fp_challenge (device fingerprint)</td>
</tr>
<tr>
<td><strong>PrimaryDomain</strong></td>
<td>Web domain of the WAF policy.</td>
<td><a href="http://www.mydomain.com">www.mydomain.com</a></td>
</tr>
<tr>
<td><strong>ResponseCode</strong></td>
<td>HTTP response.</td>
<td>• 200</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 403</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 404</td>
</tr>
<tr>
<td><strong>ResponseCodeGroup</strong></td>
<td>HTTP response status code series.</td>
<td>• 2XX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 4XX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 5XX</td>
</tr>
<tr>
<td><strong>ResourceId</strong></td>
<td>The OCID of the WAF policy.</td>
<td>ocid1.waaspol</td>
</tr>
</tbody>
</table>

Multiple dimensions can be combined and aggregated to form ad-hoc subset reports of telemetry.

### Viewing Metrics

Describes the different methods to view metrics for an edge policy.

Use one of the following methods to view logs for an edge policy.
To view metrics using the Console
Describes how to view metrics for an edge policy using the OCI Console.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
   
   Alternatively, open the Web Application Firewall page and click **Policies** under **Resources**.
   
   The WAF Policies page appears.
2. Select the **Compartment** from the list.
   
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   
   - **Name**
   - **Policy Type**
   - **Status**
4. Select the edge policy whose logs you want to view.
   
   The Edge Policy Details dialog box appears.
5. Click **Metrics** under **Resources**.
   
   The Metrics list appears. The list consists of panels displaying metric information on areas such as blocked requests, detected requests, traffic, and response code groups.
   
   For each panel, you can select commands from the **Options** list, such as viewing the query in the Metric Explorer, copying the chart URL, copying the query, and viewing the metric information in table view. You can also specify the **Interval** and **Statistic** for each chart.
   
   See **Monitoring** on page 4024 for more information on monitoring and the Metric Explorer. Use the oci_waf namespace when prompted to provide a monitoring namespace.
6. Specify the date-time group range covered by the metrics by completing the following:
   
   - **Start time**
   - **End time**
   
   Alternatively, select one of the time spans from the **Quick Selects** list. The time spans available range from the previous hour to 90 days in the future from that moment.

   The metrics for the edge policy are displayed according to your specifications.

**Caching Rules**

Caching rules allow you to selectively cache requested content on Oracle Cloud Infrastructure's edge servers, such as web pages or certain file types.

**Using the Console**

*To create a caching rule*

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to add a caching rule. The WAF Policy overview appears.
3. Click **Caching Rules**.
4. Click **Create Caching Rule**.
5. In the Create Caching Rule dialog box, enter the following:
   • **Name:** A unique name for the access rule. Avoid entering confidential information.
   • **Caching Rule Action:** Select one of the following options:
     • **Cache:** Cache the requested content when criteria of the rule is met.
     • **Caching Duration:** The duration to cache content for the caching rule.
     • **Time Unit:** The unit of time for the caching duration.
     • **Enable Client Caching:** Select this check box to specify the duration to cache content in the user’s browser.
     • **Bypass Cache:** Allow requests to bypass the cache and be directed to the origin when the criteria of the rule is met.
   • **Conditions:** Select the condition and URL address that must match for the action to be taken. At least one condition must match for the set action to be taken.

6. Click **Create**. The caching rule is added to the Caching Rules list.

**To edit a caching rule**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy you want to edit the Caching Rules for. The WAF policy overview appears.
3. Click **Caching Rules**.
4. Select the check box for the caching rule you want to update.
5. Select **Edit** from the Actions drop down menu.
6. In the Edit Caching Rule dialog box, make the necessary updates.
7. Click **Save Changes**.

**To delete a caching rule**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy where you want to delete a caching rule. The WAF policy overview appears.
3. Click **Caching Rules**.
4. Select the check box for the caching rule you want to delete.
5. Select **Delete** from the Actions drop down menu.
6. In the confirmation dialog box, click **Delete**.

**To purge the cache**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy where you want to purge the cache. The WAF Policy overview appears.
3. Click **Caching Rules**.
4. Select **Purge Cache** from the Actions dropdown menu.
5. In the Purge Cache dialog box, select the condition and URL address to purge and click **Purge**.

**Using the API**

Use the following API operations to create and manage caching rules that can be applied to your WAF configurations:

- **ListCachingRules**
- **UpdateCachingRules**
- **PurgeCache**

**Available Cache Rules Criteria**

The criteria of the caching rule determines if the requested content should be cached.

- **URL_IS** - Matches if the concatenation of requested URL path and query is identical to the contents of the value field. For example, if this rule is set to cache the content of `www.example.com/products`, only HTTP requests for `www.example.com/products` will cache.
• **URL_STARTS_WITH** - Matches if the concatenation of requested URL path and query starts with the contents of the value field. For example, if this rule is set to cache content from www.example.com/products, all HTTP requests requesting URLs starting with www.example.com/products will be cached and subsequent requests will receive content from the cache, including requests for www.example.com/products/new-product and www.example.com/products/old-product.

• **URL_PART_ENDS_WITH** - Matches if the concatenation of requested URL path and query ends with the contents of the value field. For example, if the rule is set to cache content from URLs that end with /product.jpg, HTTP requests for the URLs www.example.com/products/new-product/product-banner.jpg and www.example.com/products/old-product/product-banner.jpg will be cached and subsequent requests will receive content from the cache.

• **URL_PART_CONTAINS** - Matches if the concatenation of requested URL path and query contains the contents of the value field. If the rule is set to cache content from URLs that contain /product-banner, HTTP requests for the URLs www.example.com/products/new-product/product-banner/blue.jpg and www.example.com/products/new-product/product-banner/red.jpg will be cached and subsequent requests will receive content from the cache.

### Available Cache Rule Actions

A caching rule can be set to take one of two available actions when receiving a request:

• **CACHE** - Requests matching the criteria of the rule will be cached and subsequent requests will receive content from the cache.

• **BYPASS_CACHE** - Requests matching the criteria of the rule will bypass the cache and be directed to the origin.

### Cache Duration

Content can be cached for a specified period of time on Oracle Cloud Infrastructure's edge servers or cached locally by the client. The duration is set in the `cachingDuration` and `clientCachingDuration` fields, in ISO 8601 extended format.

### Example of a Caching Rule

```json
[
    {
        "action": "CACHE",
        "cachingDuration": "PT20M",
        "clientCachingDuration": "PT20M",
        "criteria": [
            {
                "condition": "URL_IS",
                "value": "/path/to-cache"
            }
        ],
        "isClientCachingEnabled": true,
        "name": "Caching Rule 1"
    },
    {
        "action": "BYPASS_CACHE",
        "criteria": [
            {
                "condition": "URL_PART_ENDS_WITH",
                "value": "urp-part-not-to-cache"
            }
        ],
        "isClientCachingEnabled": false,
        "name": "Do not cache"
    }
]
```
Best Practices

The order the caching rules is specified in are important. The rules are processed in the order they are specified in and the first matching rule will be used when processing a request. It is best to add rules that bypass cache to the top of the order and caching rules below any bypass rules.

Purge Caches

Caches can be purged using the PurgeCache operation. Caches can either be selectively purged by specifying the URL path of a resource or all caches can be purged for the WAF by not specifying any resources to pass to the API.

Examples

Purge the cache for specified resources:

```json
{
   "resources": [
      "/path/to-purge",
      "/multiple-paths"
   ]
}
```

Publishing Changes

Many of the actions you can take for an edge policy require publishing before they can take effect. Updates to your WAF policy appear in the list to be published using the Unpublished Changes feature under WAF Policy for the edge policy. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

To publish changes using the Console

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the Compartment from the list.
   All the WAF policies in that compartment are listed in tabular form.
3. (Optional) Apply one or more of the following Filters to limit the WAF policies displayed:
   • State
   • Name
   • Policy Type: Select Edge Policy.
4. Click the name of the edge policy whose unpublished changes you want to publish.
   The Details page of the edge policy you selected appears.
5. Click Unpublished Changes under WAF Policy.
   The Unpublished Changes list appears.
6. Click the arrow beside any unpublished change entry in the list to review the change.
7. Click Publish All.
8. Confirm the publish.

To discard changes using the Console

   Alternatively, open the Web Application Firewall page and click Policies under Resources.
   The WAF Policies page appears.
2. Select the **Compartment** from the list.

   All the WAF policies in that compartment are listed in tabular form.

3. (Optional) Apply one or more of the following **Filters** to limit the WAF policies displayed:
   - **State**
   - **Name**
   - **Policy Type**: Select **Edge Policy**.

4. Click the name of the edge policy whose unpublished changes you want to discard.

   The Details page of the edge policy you selected appears.

5. Click **Unpublished Changes** under **WAF Policy**.

   The Unpublished Changes list appears.

6. Click the arrow beside any unpublished change entry in the list to review the change.

7. Check the boxes for one or more unpublished change entries you want to discard.

8. Click **Discard**.

9. Confirm the discard.

**Threat Intelligence**

WAF has several sources of known IP address threats that are updated daily. The IP address threats are displayed in the following table:

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABUSE</td>
<td>(^{ch})</td>
</tr>
<tr>
<td>Bambenek Consulting</td>
<td>Active and non-sinkholed Command &amp; Control (C&amp;C) IP addresses.</td>
</tr>
<tr>
<td>BlockList.de</td>
<td>Includes IP addresses for hosting phishing sites and other kinds of fraud activities such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>BruteForceBlocker Project</td>
<td>The feed of known IP addresses from blocked SSH brute force attacks.</td>
</tr>
<tr>
<td>Proofpoint ET Labs</td>
<td>IP addresses involved in suspicious and malicious activity.</td>
</tr>
<tr>
<td>Feodo IP Blocklist</td>
<td>IP addresses used as C&amp;C communication channel by the Feodo Trojan.</td>
</tr>
<tr>
<td>Palevo</td>
<td>IP addresses which are being used as botnet C&amp;C for the Palevo crimeware.</td>
</tr>
<tr>
<td>TOR Nodes</td>
<td>List of IP addresses for known Tor nodes. The Tor network is a group of volunteer-operated servers that allows people to improve their privacy and security on the internet. Tor's users employ this network by connecting through a series of virtual tunnels rather than making a direct connection, thus allowing both organizations and individuals to share information over public networks without compromising their privacy.</td>
</tr>
<tr>
<td>Source</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Webroot BotNets</td>
<td>Botnet C&amp;C channels and infected zombie machines controlled by Botmaster.</td>
</tr>
<tr>
<td>Webroot Denial of</td>
<td>Service: includes DOS, DDOS, anomalous sync flood, and anomalous traffic</td>
</tr>
<tr>
<td>Webroot Mobile Threats</td>
<td>detection.</td>
</tr>
<tr>
<td>Webroot Phishing</td>
<td>IP addresses hosting phishing sites and other kinds of illicit activities</td>
</tr>
<tr>
<td>Webroot Proxy</td>
<td>such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>Webroot Reputation</td>
<td>IP addresses currently known to be infected with malware. This category</td>
</tr>
<tr>
<td>Webroot Scanners</td>
<td>also includes IP addresses with an average low Webroot Reputation Index</td>
</tr>
<tr>
<td>Webroot Spam Sources</td>
<td>score.</td>
</tr>
<tr>
<td>Webroot Tor Proxy</td>
<td>Includes IP addresses acting as exit nodes for the Tor Network. Exit nodes</td>
</tr>
<tr>
<td>Webroot Web Attacks</td>
<td>are the last point along the proxy chain and make a direct connection to</td>
</tr>
<tr>
<td>Webroot Windows Exploits</td>
<td>the originator’s intended destination.</td>
</tr>
<tr>
<td>ZeuS</td>
<td>IP blocklist including known C&amp;C servers/hosts.</td>
</tr>
</tbody>
</table>

### Using the CLI

You can use the CLI to enable threat intelligence sources to block.

Open a command prompt and run the following command to list the keys for all of the threat intelligence:

```bash
oci waas threat-feed list --waas-policy-id <policy_ocid>
```

Then parse the keys to block and add them to the JSON:

```bash
oci waas threat-feed update --threat-feeds '[]' --waas-policy-id <policy_ocid>
```

For example:

```bash
oci waas threat-feed update --threat-feeds '[]' --waas-policy-id ocid1.waaspolicy.oc1...
```

### Using the API

Enabling Threat Intelligence can only be performed by using the API at this time.
For information about using the API and signing requests, see REST APIs on page 6275 and Security Credentials on page 205. For information about SDKs, see Software Development Kits and Command Line Interface on page 6094.

To return a set of keys for the threat intelligence:

- **ListThreatFeeds**

  ```json
  { 
    "8d3f7f1b-673f-4e3a-ba49-08226f385df3": "OFF",
    "0ff7b308-6afe-4b83-91e0-e3ca04af6ed6": "OFF",
    "ea5d7c67-1326-43c9-ac31-1df034b9c063": "OFF",
    "87b420ca-5fbb-4ad4-aeba-1b02a9e60b30": "OFF",
    "2168fc70-2d05-466a-9db5-c13c0e32177d": "OFF",
    "7d080a4a-58ce-4370-a02c-f600b3a84e7b": "OFF",
    "a36c7c50-e99e-4b84-9140-5653fc68ce8d": "OFF",
    "5de7bbcc-313f-4995-9810-f6f77cfd30c9": "OFF",
    "fd2152cc-14f5-4471-a58b-d94cc8a61444": "OFF",
    "cfacd3d-65d9-43e8-93e0-62c906e7a748": "OFF",
    "6eb86368-01ea-4e94-ac1b-49bf0e551443": "OFF",
    "aab4d59-0d75-481d-9568-58ecad217e1e": "OFF",
    "3085ecc2-1d6d-428b-a03e-2a0fe77fbd46": "OFF",
    "c3452861-4910-4f3a-9872-22cf92d42eb": "OFF",
    "4cf31deb-11af-460a-a46a-ec1946a6688": "OFF",
    "eff34d63-6235-4081-976d-acd39248bdc3": "OFF",
    "1d1c94d9-038b-45eb-acd4-fb422e281f4c": "OFF",
    "687b5ff4-b1b6-4d12-8db3-3ea90b4536a1": "OFF",
    "65cf274d-991b-41f8-adda-6fe60ba2704f": "OFF"
  } 
  ```

  **Note:**
  Do not use the keys in the example below, as keys are unique across each policy.

To set all threats to DETECT:

- **UpdateThreatFeeds**

  ```json
  [ 
    {"action":"DETECT","key":"8d3f7f1b-673f-4e3a-ba49-08226f385df3"},
    {"action":"DETECT","key":"0ff7b308-6afe-4b83-91e0-e3ca04af6ed6"},
    {"action":"DETECT","key":"ea5d7c67-1326-43c9-ac31-1df034b9c063"},
    {"action":"DETECT","key":"87b420ca-5fbb-4ad4-aeba-1b02a9e60b30"},
    {"action":"DETECT","key":"2168fc70-2d05-466a-9db5-c13c0e32177d"},
    {"action":"DETECT","key":"7d080a4a-58ce-4370-a02c-f600b3a84e7b"},
    {"action":"DETECT","key":"a36c7c50-e99e-4b84-9140-5653fc68ce8d"},
    {"action":"DETECT","key":"5de7bbcc-313f-4995-9810-f6f77cfd30c9"},
    {"action":"DETECT","key":"fd2152cc-14f5-4471-a58b-d94cc8a61444"},
    {"action":"DETECT","key":"cfacd3d-65d9-43e8-93e0-62c906e7a748"},
    {"action":"DETECT","key":"6eb86368-01ea-4e94-ac1b-49bf0e551443"},
    {"action":"DETECT","key":"aab4d59-0d75-481d-9568-58ecad217e1e"},
    {"action":"DETECT","key":"3085ecc2-1d6d-428b-a03e-2a0fe77fbd46"},
    {"action":"DETECT","key":"c3452861-4910-4f3a-9872-22cf92d42eb"},
    {"action":"DETECT","key":"4cf31deb-11af-460a-a46a-ec1946a6688"},
    {"action":"DETECT","key":"eff34d63-6235-4081-976d-acd39248bdc3"},
    {"action":"DETECT","key":"1d1c94d9-038b-45eb-acd4-fb422e281f4c"},
    {"action":"DETECT","key":"687b5ff4-b1b6-4d12-8db3-3ea90b4536a1"},
    {"action":"DETECT","key":"65cf274d-991b-41f8-adda-6fe60ba2704f"}
  ]
  ```
This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

Layer 7 DDoS Mitigation

Distributed Denial of Service (DDoS) Overview

A DDoS attack is an often intentional attack that consumes an entity’s resources, usually using a large number of distributed sources. DDoS can be categorized into either Layer 7 or Layer 3/4 (L3/4), as defined by the Open Systems Interconnection (OSI) model. L3/4 DDoS attacks are DDoS attacks that occur at lower levels of the OSI stack than layer 7. Examples of such attacks include UDP, CharGen, and NTP Floods. L3/4 DDoS mitigation is inherently provided by Oracle Cloud Infrastructure.

A layer 7 DDoS attack is a DDoS attack that sends HTTP/S traffic to consume resources and hamper a website’s ability to delivery content or to harm the owner of the site. The Web Application Firewall (WAF) service can protect layer 7 HTTP-based resources from layer 7 DDoS and other web application attack vectors.

Layer 7 DDoS Mitigation Services

Oracle provides a Layer 7 DDoS Mitigation service to help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists are trained members of our Cloud Customer Support team who help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists help onboard you to WAF if you are not already using it. They must be granted access to your account to make changes to the WAF policy on your behalf. A DDoS attack report is generated after mitigation is complete. The report describes the type and parameters of the attack and what actions were taken to mitigate the attack. At the conclusion of the DDoS mitigation effort of a layer 7 DDoS attack, you may seek to receive credits for services that incurred additional Cloud Service fees. Details of this claim is available in the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Requesting Help

It is your responsibility to report an attack through My Oracle Support. You can use monitoring and alarm definitions based on telemetry to receive notifications of thresholds exceeded. For more information about setting up alarms, see Managing Alarms on page 4094. All changes will be audited in the Audit service.

To request help, go to My Oracle Support and select the WAF product and then DDoS. You will be invited to a web conference where you will interact with a DDoS Mitigation Specialist to review the issue. At this time, you can also participate in the WAF on-boarding and tuning process.

Required IAM Service Policy

In order for the Mitigation Specialist to manage rules to block the attack, you must provision an IAM user account with permissions.

To create an account with the correct permissions:

1. Create a user with the email address of the Mitigation Specialist. See Managing Users.
2. Create a group named "SOCMember". See Managing Groups.
3. Assign the user to the new group.
4. Grant group access to WAF, audit, and metrics in the compartment where the WAF policy resides.

Policy example:

- To allow the SOCMember group to manage WAF:

  ```plaintext
  Allow group SOCMember to manage waas-family in compartment <CompartmentName>
  ```
• To allow the SOCMember group to read audit events:

```plaintext
Allow group SOCMember to read audit-events in compartment <CompartmentName>
```

• To allow the SOCMember group to read metrics:

```plaintext
Allow group SOCMember to read metrics in compartment <CompartmentName>
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service.

The following scripts in the SDK for Python on page 6115 enable you to provision an IAM user account with the correct permissions.

• add_soc_user.py
• add_soc_group_policy.py

Python script example:

```bash
python add_soc_user.py -c ~/.oci/config -u 'ddos.mitigation.specialist@oracle.com' -g DDoSMitigationGroup -f ~/.oci/ddos_public_key.pem
```

Where:

• `-c` is the tenancy configuration file
• `-u` is the username to be created
• `-g` is the group name to be created
• `-f` is the path to the public certificate to be attached to the user in PEM format

Debug options:

• `-h` shows help
• `-d` turns on debug mode

```bash
python add_soc_group_policy.py -c ~/.oci/config -g DDoSMitigationGroup -o ocid1.compartment.oc1..<unique_ID>
```

Where:

• `-c` is the tenancy configuration file
• `-g` is the existing group name to be used in IAM policy
• `-o` is the compartment of the WAF policy and where the IAM policy will be created

**DDoS Attack Report**

A DDoS attack report will be sent to you within a few days of the attack. The report contains metrics on the resources consumed by the attack and include all WAF policy changes made during the mitigation effort. This report is used by Oracle Cloud Infrastructure to review what possible service credits are available.

**Price Insurance Program**

You may be eligible for credits due to excessive consumption due to a DDoS attack. Refer to the Oracle PaaS and IaaS Public Cloud Services Pillar documentation for details. Contact your customer success manager for details on how to apply for credits.

**Monitoring**

For future monitoring, you can create an alarm definition in the Monitoring service that will alert you of high activity levels of HTTP traffic that could indicate another layer 7 DDoS attack. For more information, see Managing Alarms.
on page 4094. Oracle Cloud Infrastructure automatically scrubs layer 3 and 4 attacks. If you suspect malicious activity that is not being properly remediated, go to My Oracle Support to open a service request to report your concerns.

**HTTP WAF Headers**

HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with X-, are common. The WAF service adds or modifies the following headers when it passes the requests to your servers or the response to the end users.

**X-Client-IP**

Contains the remote user IP address. If the webapp is using a CDN and has the feature "behind cdn" enabled, this IP is taken from one of the configured headers. While forwarding the request to the origin, WAF adds X-Client-IP.

**X-Country-Code**

Contains the geo location country code where the user's IP belongs to. While forwarding the request to the origin, WAF adds X-Country-Code.

**Zen-Host: ZENEDGE**

Identifies that the request was analyzed by a WAF node. While forwarding the request to the origin, WAF adds Zen-Host: ZENEDGE.

**Request-Id**

Identifies the request in the logs. While forwarding the request to the origin, WAF adds Request-Id.

**Connection**

If there is not a defined Connection value previously established (for example, "Upgrade" or "WebSocket"), WAF clears the Connection header by default. This header can be modified based on the available connection pool to "close" or "keep-alive". While forwarding the request to the origin, WAF modifies, adds, or removes Connection.

**Accept-Encoding**

In this header, WAF clears Accept-Encoding with an empty string. This means the header is not passed to the origin side as it comes from the user side. This header can be removed, based on WAF settings on response body inspection and caching. While forwarding the request to the origin, WAF modifies or adds or removes Accept-Encoding.

**X-Cdn: Served-By-Zenedge**

Our platform injects this header to say that we are handling the connection. While forwarding the response to the client, WAF adds X-Cdn: Served-By-Zenedge.

**X-Zen-Fury**

This header identifies the WAF node which processed the request via an encrypted token. While forwarding the response to the client, WAF adds X-Zen-Fury.

**X-Cache-Status**

WAF can act as a cache server. Based on the configuration, WAF can respect Cache-Control headers or cache based on the caching configuration rules. The status of the cache is reported via the X-Cache-Status response header. The value of the header can be one of the standard values: MISS, BYPASS, EXPIRED, STALE, UPDATING, REVALIDATED, or HIT. In addition, for never cache rules, a non-standard NOTCACHED value will be set.

**Cache-Control**

This header can be modified based on various user caching and Bot Management configurations. While forwarding the response to the client, WAF modifies or adds Cache-Control.
**Certificates Management**
Describes how certificates are added and managed with the WAF policy.

To use SSL with your WAF policy, you must add a certificate bundle. The certificate bundle you upload includes the public certificate and the corresponding private key. Self-signed certificates can be used for the internal communication within Oracle Cloud Infrastructure.

Oracle Cloud Infrastructure accepts third-party and self-signed certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

**Obtaining Third-Party SSL Certificates**
You can purchase an SSL certificate from a trusted Certificate Authority such as Symantec, Thawte, RapidSSL, or GeoTrust. The certificate issuer provides an SSL certificate that includes a certificate, intermediate certificate, and private key. Use this information, including the intermediate certificate, when adding an SSL certificate to Oracle Cloud Infrastructure.

**Converting to PEM Format**
If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format.

**Uploading Certificate Chains**
If you have multiple certificates that form a single certification chain, you must include all relevant certificates in one file before you upload them to the system. The following example of a certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

**Submitting Private Keys**
If your private key submission returns an error, the most common reasons are your private key is malformed or the system does not recognize the encryption method used for your key.

**Private Key Consistency**
If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.
Deciphering a Private key

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

Creating Certificates

Describes the different methods to create a certificate.

*To create a certificate using the Console*

   Alternatively, open the Web Application Firewall page and click Edge Policy Resources under Resources.

   The Edge Policy Resources page appears.

2. Select the Compartment from the list.

   The WAF Certificates page appears.

3. Click Certificate under Resources.

   All the certificates in that compartment are listed in tabular form.

4. Click Create WAF Certificate.

   The Create WAF Certificate dialog box appears.

5. Complete the following:

   - **Name**: Enter the name for the certificate. Avoid entering confidential information.
   - **SSL Certificate**: Drag and drop, select, or paste a valid SSL certificate in PEM format. Also include intermediate certificates (the website certificate must be first). The following is an example:

     ```
     -----BEGIN CERTIFICATE-----
     <Base64_encoded_certificate>
     -----END CERTIFICATE-----
     -----BEGIN CERTIFICATE-----
     <Intermediate_Base64_encoded_certificate>
     -----END CERTIFICATE-----
     ```

   - **Private Key**: Drag and drop, select, or paste a valid private key in PEM format in this field. The passphrase cannot protect the private key. The following is an example:

     ```
     -----BEGIN PRIVATE KEY-----
     <Base64_encoded_private_key>
     -----END PRIVATE KEY-----
     ```

   - **Self Signed Certificate**: Check this box when using a self-signed certificate to show an SSL warning in the browser.
   - **Show Advanced Options**: Click this link to display the following options:

     - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click Create.

   The Create WAF Certificate dialog box closes. The certificate you created is included in the WAF Certificates list.
To create a certificate using a CLI

Enter the following command and required parameters:

```
oci waas certificate create --certificate-data compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waas certificate create --help
```

See oci waas certificate create for a complete description of the command.

To create a certificate using an API

Run the `CreateCertificate` method to create a certificate. See CreateCertificate for a complete description.

Listing Certificates

Describes the different methods to display a list of certificates.

Use one of the following methods to display a list of certificates.

To list the certificates using the Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Edge Policy Resources**.

   Alternatively, open the Web Application Firewall page and click **Edge Policy Resources** under **Resources**.

   The Edge Policy Resources page appears.

2. Select the **Compartment** from the list.

   The WAF Certificates page appears.

3. Click **Certificate** under **Resources**.

   All the certificates in that compartment are listed in tabular form.

The WAF Certificates list displayed shows the **Name**, **Status**, **Expires On**, and **Created** dates (UTC date timestamp) information for each entry.

To list the certificates using the CLI

Enter the following command and required parameters:

```
oci waas certificate list --compartment-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waas certificate list --help
```

See oci waas certificate list for a complete description of the command.

To list the certificates using the API

Run the `ListCertificates` method to list the certificates. See ListCertificates for a complete description.

Getting Certificate Details

Describes the different methods to get the details of a certificate.

Use one of the following methods to get the details of a certificate.
To get the details of a certificate using the Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Edge Policy Resources**.
   
   Alternatively, open the Web Application Firewall page and click **Edge Policy Resources** under **Resources**.
   
   The Edge Policy Resources page appears.

2. Select the **Compartment** from the list.
   
   The WAF Certificates page appears.

3. Click **Certificate** under **Resources**.
   
   All the certificates in that compartment are listed in tabular form.

4. Click the certificate whose details you want to get.
   
   The WAF Certificate Details dialog box appears.

   The Details page contains information about the certificate, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the certificate configuration.

To get the details of a certificate using the CLI

Enter the following command and required parameters:

```bash
oci waas certificate get --certificate-id compartment-id
```

See the CLI online help for a list of optional parameters:

```bash
oci waas certificate get --help
```

See `oci waas certificate get` for a complete description of the command.

To get the details of a certificate using the API

Run the `GetCertificate` method to get the details of a certificate. See `GetCertificate` for a complete description.

Editing Certificates

Describes the different methods to edit a certificate.

Use one of the following methods to edit a certificate.

**Note:**

You can only edit the name of a certificate.

To edit a certificate using the Console

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Edge Policy Resources**.
   
   Alternatively, open the Web Application Firewall page and click **Edge Policy Resources** under **Resources**.
   
   The Edge Policy Resources page appears.

2. Select the **Compartment** from the list.
   
   The WAF Certificates page appears.

3. Click **Certificate** under **Resources**.
   
   All the certificates in that compartment are listed in tabular form.

4. Click the certificate you want to edit.
   
   The WAF Certificate Details dialog box appears.
5. Click Edit.
   
   Alternatively, click the Actions icon (ɔ) for the certificate and click Edit.
   
   The Edit WAF Certificate dialog box appears.

6. Update the Name of the certificate.

7. Click Save Changes.

   The Edit WAF Certificate dialog box closes. The updated name of the certificate appears in the Details page and the list of WAF certificates.

To edit a certificate using the CLI

Enter the following command and required parameters:

```
oci waas certificate update --certificate-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waas certificate update --help
```

See oci waas certificate update for a complete description of the command.

To edit a certificate using the API

Run the UpdateCertificate method to edit a certificate. See UpdateCertificate for a complete description.

Deleting Certificates

Describes the different methods to delete a certificate.

To delete a certificate using the Console

   Alternatively, open the Web Application Firewall page and click Edge Policy Resources under Resources.

   The Edge Policy Resources page appears.

2. Select the Compartment from the list.

   The WAF Certificates page appears.

3. Click Certificate under Resources.

   All the certificates in that compartment are listed in tabular form.

4. Click the certificate you want to delete.

   The WAF Certificate Details dialog box appears.

5. Click Delete.

   Alternatively, click the Actions icon (ɔ) for the certificate and click Delete.

6. Confirm the deletion when prompted.

   The list of certificates reappears without the certificate you deleted.

To delete a certificate using the CLI

Enter the following certificate command and required parameters:

```
oci waas certificate delete --certificate-id compartment-id
```
Web Application Firewall

See the CLI online help for a list of optional parameters:

```
oci waas certificate delete --help
```

See `oci waas certificate delete` for a complete description of the command.

**To delete a certificate using the API**

Run the `DeleteCertificate` method to delete a certificate. See `DeleteCertificate` for a complete description.

**Moving Certificates Between Compartments**

Describes the different methods to move a certificate between compartments.

Use one of the following methods to move a certificate between compartments.

**To move a certificate between compartments using the Console**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Edge Policy Resources**.
   
   Alternatively, open the Web Application Firewall page and click **Edge Policy Resources** under **Resources**.
   
   The Edge Policy Resources page appears.

2. Select the **Compartment** from the list.
   
   The WAF Certificates page appears.

3. Click **Certificate** under **Resources**.
   
   All the certificates in that compartment are listed in tabular form.

4. Click the certificate you want to move.
   
   The WAF Certificate Details dialog box appears.

5. Click **Move Resource**.
   
   Alternatively, click the **Actions** icon ( ) for the certificate and click **Move**.
   
   The Move Resource to a Different Compartment dialog box appears.

6. Select the compartment to which you want to move your certificate from the **Choose New Compartment** list.

7. Click **Move Resource**.
   
   The certificate now appears in the compartment you moved it to.

**To move a certificate between compartments using the CLI**

Enter the following command and required parameters:

```
oci waas certificate change-compartment --certificate-id compartment-id
```

See the CLI online help for a list of optional parameters:

```
oci waas certificate change-compartment --help
```

See `oci waas certificate change-compartment` for a complete description of the command.

**To move a certificate between compartments using the API**

Run the `ChangeCertificateCompartment` method to delete a certificate. See `ChangeCertificateCompartment` for a complete description.

**Frequently Asked Questions**

Questions often asked about WAF.
Web Application Firewall

General

General questions about WAF.

What is the order in which rules and handlers are processed inside OCI WAF?

1. IP Whitelists/Blacklists/Good Bot Whitelists
2. Threat Intelligence
3. Access Rules
4. Rate Limiting (available in the API)
5. JavaScript Challenge
6. Device Fingerprint Challenge
7. Human Interaction Challenge
8. CAPTCHA Challenge
9. Protection Rules
10. Caching Rules

What ports are available to use with WAF?

WAF supports ports 80 (for HTTP) and 443 (for HTTPS), however, after requests reach WAF on ports 80/443, we are able to send the requests to your origin server on any port necessary. The following is an example:

End User # Port 80/443 # WAF # Port 443/8000/555/*** # Origin Server

Can WAF be used to restrict specific IP addresses and CIDR ranges from within Oracle (instead of non-Oracle external IPs) from reaching the load balancer?

Yes, the WAF Access Rules feature can be used to restrict specific IP addresses and CIDR ranges. If you have many prefixes, you can use address lists.

Does WAF support other compression methods besides Gzip compression?

No, all other compression methods that come to the infrastructure are forwarded unaltered to the origin.

How long it takes for changes to propagate?

• Changes usually take 10–30 minutes to propagate, depending on the change. It takes that long to propagate because we have hundreds of nodes where your new configurations are pushed to.
• The following is a list of feature changes which propagate within 10–15 minutes:
  • Bots policies
  • Human Interaction Challenge (HIC)
  • Device Fingerprint Challenge
  • Javascript Challenge
  • CAPTCHA Challenge
  • Good Bot Whitelist
  • Access Rules
  • Thread Intelligence
  • IP Lists
  • IP Whitelist

Is IPv6 supported?

No, IPv6 is not supported currently.

Does WAF inspect the response body?

Yes, WAF inspects, but doesn't alter the response body.

Can you use WAF for traffic like SSH, FTP, or SMTP?

No, WAF only allows HTTP traffic on ports 80 and 443. All other traffic and all other ports are blocked.

What is the caching limit?
The caching limit is 1 GB per policy.

**Is there a limit for "Additional Domains" that can be added to a WAF policy?**

No, limits do not exist on the number of domains that can be added.

Questions about file size upload limitations.

**Is there a maximum upload file size limitation for WAF?**

Yes, the limit is 1 GB.

**Does the limit effect certain file types (images, videos, binaries, and so on)?**

No, it doesn't depend on the type of upload.

**Does the Content-Type header effect the limit?**

No, only different protection rules are applied based on the Content-Type header.

**Does the limit affect only chunked uploads or stream uploads?**

Usually, uploads using chunked or streams do not affect the limit. In buffering mode, the limit is 1 GB for uploads and downloads. However, there are some other modes including streaming the response body, which disregards the 1-GB limit.

**Are the upload processes interrupted because of the node reloads? What is the root cause for upload errors with large files?**

No, reloads do not cause connection interruptions. However, after the reload, the next step is "cleanup," which is only run if the request or response cycle takes too long. It terminates the connection. Connection terminations rarely happen, but users with large uploads and slow connections are sometimes affected.

**What information do I need to know about using WAF with content streaming services?**

Since our protection rules require buffering of the full HTML content before analysis, streaming services might be affected. Streaming services might be effected because the entire content needs to be buffered within our protection rules core engine which might lead to slow responses or events not displaying the streaming content.

### Access Rules

Questions about Access Rules.

**Is there a sequence of processing for "Access Rules" versus "IP Whitelist" tabs?**

Yes, IP whitelist is triggered first. If the IP address is not in the IP address allowlist, it then goes to access rules.

**Can I use wildcards for access rules specified in the “HTTP header contains” field?**

No, wildcards for this field are not currently supported.

**Which HTTP redirect response codes does WAF support?**

- **301 - Moved permanently:** Use this response code if your website was permanently moved to the redirection URL and you want search engines to index it.
- **302 - Temporary redirect:** Use this response code if a certain URL has been changed to a different address for a short amount of time.

**Is it possible to include CAPTCHA as an inline component in the website instead of an entry point?**

Currently, you can only have CAPTCHA as a full page. It is not possible to include it as an inline component.

**Can I reorder access rules?**

No, access rule reordering is not currently supported. We advise taking this into consideration when creating an access rule with the BLOCK action.

**Is the URL-based match in Access Rules the absolute URL (www.example.com/example.php) or relative URL (/example.php)?**
The URL-based matching is for a location on the same domain. For example, “/login.php”. To target a full absolute URL, you can use a combination of header matching (Host:www.example.com) and URL “/login.php”.

**For a URL-based match, is the scheme (http:// or https://) relevant, or is the FQDN enough?**

The URL-based matching is for a location on the same domain. For example, “/login.php”. To target a full absolute URL, you can use a combination of header matching (Host:www.example.com) and URL “/login.php”.

**How do you block everything except specific IP addresses?**

The easiest way to allow only specific IPs is to create a single access rule to BLOCK if “IP Address not in Address list”. This rule blocks all traffic other than the IP addresses you have in your IP address lists. If you have other security features enabled, they will still be active, even for your IP addresses in the address list. To bypass all security measures, you need to add your IP addresses to the IP address whitelist.

**Protection Rules**

Questions about protection rules.

**Do new WAF rule definitions get added or updated?**

WAF policies are kept up to date with CRS and CVEs releasing new and updated definitions on a quarterly basis. Rule definitions in use will never be updated since they could cause unexpected behavior. New definitions are always pushed in an off state.

**How can I exclude multiple cookies that end with the same string from inspection by WAF Protection Rules?**

For this example, we received alerts from WAF Protection from values under multiple cookies:

123_SessionID=bad_value1; 456_SessionID=bad_value2; 789_SessionID=bad_value3; ...

Instead of adding each cookie manually, you can group them all in a "Regex" format:

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Rules** tab.
5. Find the protection rule you want to apply the exclusion to.
6. Click the Actions icon (three dots) and select **Exclusions**.
7. In the Exclusions dialog box, enter the following criteria:
   - **Exclusion**: Select request cookie values.
   - **Value**: Enter /_SessionID$/. This value matches all cookies that end with _SessionID triggering WAF rules with "bad_values."
8. Click **Save Changes**.

**Is there any limit on the number of rules that can be enabled for a WAF policy?**

Yes, you can only enable a maximum of 100 rules per WAF policy.

**Why is my application slow when I have enabled all protection rules?**

Each WAF rule adds CPU cycles to each transaction. The more rules you enable, regardless of the action (DETECT or BLOCK), slows transaction, especially with large payload transactions. We recommend that you only enable the recommended WAF protection rules in DETECT mode and open a service request with My Oracle Support requesting OCI WAF tuning help before changing the rules to BLOCK. An expert will guide you through the process.

**Which protection rules require me to enable response body inspection?**

The following protection rule IDs require you to enable response body inspection:

- 90002
- 90005
- 90014
- 90015
IP Address List

Questions about IP address lists.

Does IP Whitelist bypass every security measure?

Yes, IP Whitelist bypasses everything, including caching rules.
While adding an IP address to the WAF IP Address List, I received the following error: "Authorization failed or requested resource not found". Why am I receiving this error?

This error can occur when you do not have the correct policies set up to create an address list. To create an address list, manage permissions are required for `waas-address-list`. If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service.

**Logs**

Questions about logs.

**What is the log retention policy in WAF?**

The log retention policy is seven days, however, you can request to set up an S3 bucket and have more logs delivered to it. The logs in your bucket can be kept as long as you want.

**Do you support log delivery to ELK?**

Log delivery is only supported to OCI and S3 buckets. Raw logs are sent to the buckets. From the buckets, you can implement them into elastic search.

**What type of OCI Object Storage bucket can I deliver logs to?**

Only "Standard" OCI buckets are supported. The "Archive" storage tier is not supported.

**Certificates**

Questions about certificates.

**Are there any limitations when adding SSL certificates?**

- Yes, each line except the last must contain exactly 64 printable characters. The final line must contain 64 or fewer printable characters. The text editor you use could save it differently and might have a different number of characters per line.
- To check how many characters there are per line, run following command: `awk '{ print length }' filename.pem`

**Can I add an SSL certificate for another domain?**

No, only one certificate per WAF policy is supported for the main domain. If you want to apply an SSL certificate for an extra domain, you need to create a separate WAF policy for it.

**What SSL cipher suites are supported?**

The following SSL cipher suites are supported:

```plaintext
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES256-GCM8
ECDHE-ECDSA-AES256-CCM
ECDHE-ECDSA-AES128-CCM8
ECDHE-ECDSA-AES128-CCM
DHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-CCM8
DHE-RSA-AES256-CCM
DHE-RSA-AES128-GCM-SHA256
DHE-RSA-AES128-CCM8
DHE-RSA-AES128-CCM
DHE-DSS-AES256-GCM-SHA384
DHE-DSS-AES128-GCM-SHA256
TLS_CHACHA20_POLY1305_SHA256
TLS_AES_256_GCM_SHA384
TLS_AES_128_GCM_SHA256
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES128-GCM-SHA256
```

Oracle Cloud Infrastructure User Guide 6041
**Troubleshooting and debugging**

Questions about troubleshooting and debugging WAF.

**What is the maximum upstream time to live (TTL) on the OCI WAF side? How can it be increased?**

The maximum upstream timeout for WAF can be increased up to 1,200 seconds (20 minutes). By default, the timeout is set to 300 seconds. If you need to increase it, you need to create a service request in My Oracle Support with the following information:

- Tenancy ID
- Policy ID
- Webapp domain
- Upstream timeout time
- The reason why you need us to increase it

**Note:**

WAF has an internal 100-second timeout value (which is not changeable) that drops the connection if the origin doesn't send any keep-alive, stating that origin is still working on a response, "please wait." If the origin is sending keep-alives, you won't reach this type of timeout, since it always resets with keep-alive.

**What do I do if my domain works by using an A record instead of the CNAME?**

It is recommended that your APEX domains point to the IP address based on your server location:

- US: 147.154.3.128
- EU: 147.154.225.212
- APAC: 192.29.50.64
- AUS: 192.29.152.173

**What value must I configure for the origin keep-alive timeout?**

WAF requires that your origin's (load balancer or web server) keep-alive timeouts are maintained for 301 seconds or more, as our upstream timeout value is 300 seconds. During this time, the connections are safely maintained while TCP is optimized. The network multiplexing methodology our nodes use to maintain connectivity with your origin ensure that the connections are safely maintained while TCP is optimized. For more information, see Getting Started with Edge Policies on page 5890.

**Is Palo Alto firewall supported?**

- OCI requires Palo Alto firewall to enable Jumbo frames as part of our PMTUd format and our MTU of 9000.
- Refer to Hanging Connection on page 4811 for troubleshooting information.
- Refer to Throughput troubleshooting with Palo Alto and OCI for Palo Alto's troubleshooting information.

**Why is my API application responding with a 5XX HTTP status code?**

Multiple factors can lead to a 5xx HTTP status code. Review the following information:

- The origin keep-alive timeout must be 301 seconds.
- Session persistency must be cookie-based.
- IP affinity is a best practice as our nodes work in a round robin scenario and every 10 minutes the node IP potentially changes within the same transaction.
- If you have multiple WAF rules enabled and the transaction includes a large payload, it causes the transaction to timeout on the origin. The request is still in the WAF buffer and has been parsed before responding to the origin.
- One or more nodes are not fully whitelisted on the ingress rules from the origin side.
- One specific node is failing. In this case, immediately escalate the issue to our support team.

**Why is my website timing out?**

- Refer to Why is my API application responding with a 5XX HTTP status code? for a list of checkpoints.
• The timeout can also be related to the Whitelist (Security Lists or NSG). Review the following information:
  • Did you add the security lists to allow the OCI WAF nodes?
  • Are the rules stateless?
  • If the rules are stateless, did you add the respective egress rules?

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you add a stateless security rule, you are allowing only one side of the traffic (ingress or egress). To allow the complete traffic flow, add another rule on the other side (egress or ingress). Adding a stateful rule (which means just keeping the stateless option unchecked) allows both sides of the traffic without the requirement of adding an egress rule.</td>
</tr>
</tbody>
</table>

Command Line Interface (CLI)

Questions about the CLI.

Where can I find information on setting up the CLI?

Refer to the following documentation for CLI-related topics:

• Getting started with the CLI
• Command Line Reference for Web Application Acceleration and Security Services
• Web Application Acceleration and Security (WAAS) API
• OCI Cloud Shell Reference

Can I create or restore WAF policy backups?

Yes, you can create or restore WAF policy backups with the OCI CLI. Extract the full JSON file of the web application and then re-create it in parts. We recommend that you re-create the main settings first and then the security challenges and features of the web application.

How do I enable WebSocket for a specific URL through the CLI?

To enable WebSocket for a specific URL, perform the following command:

```bash
oci waas policy-config update --waas-policy-id ocid1.waaspolicy.oc1...[WAAS POLICY OCID] --websocket-path-prefixes "[/url/url/websocket"]"
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSocket support prevents WAF processing in the specified paths, which means that if a WAF rule is enabled it doesn't analyze the requests going to the URL excluded in the configuration. However, other countermeasures such as Human Interaction Challenge and JavaScript Challenge can be enabled to provide an extra layer of security for WebSocket URL.</td>
</tr>
</tbody>
</table>

I generated a JSON sample file (``generate-full-command-json-input``) as input for my WAAS CLI commands through the PowerShell console, however, they are failing to load. Why am I getting a "Parameter 'from-json' must be in JSON format" error?

Ensure that the generated JSON file is saved with UTF-8 encoding. Older PowerShell versions might save JSON files with a different encoding.

Does the "key" in Threat Intelligence Feed remain the same for all WAF policies?

No, the "key" generated is different for each WAF policy.
Chapter 52

Developer Tools

This chapter includes general information about using the Oracle Cloud Infrastructure REST API and developer tools.

Developer Resources

This section provides reference documentation and tutorials for building applications that leverage Oracle Cloud Infrastructure.

- Developer Guide on page 6044
- Developer Tutorials
- API Reference

Developer Guide

Welcome to the Oracle Cloud Infrastructure Developer Guide.

This guide is intended to be a one-stop source for anyone interested in developing applications that leverage Oracle Cloud Infrastructure resources.

What's In This Guide

Here's an overview of what's in this guide:

- Introduction and overview (you are here)
- Quick-start walkthroughs that let you try out some of the SDKs using Cloud Shell
- How to setup SSH keys and configure the SDKs
- Working with Cloud Shell
- Working with the Command Line Interface (CLI)
- SDK references
- DevOps Tools and Plug-ins
- Other Tools
- Appendix and API Reference

Overview

Oracle Cloud Infrastructure provides kits, tools, and plug-ins to facilitate the development of apps and simplify the management of infrastructure.

- Cloud Shell Cloud Shell is a free-to-use browser-based terminal accessible from the Oracle Cloud Console that provides access to a Linux shell with pre-authenticated Oracle Cloud Infrastructure CLI and other useful developer tools. You can use the shell to interact with OCI resources, follow labs and tutorials, and quickly run OCI CLI commands.
- Command Line Interface (CLI) on page 6059 The CLI is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend the Console's functionality.
Developer Tools

• **Software Development Kits and Command Line Interface** on page 6094 Oracle Cloud Infrastructure provides Software Development Kits (SDKs) to enable the development of apps and custom solutions.

• **Other Tools** on page 6252 These tools can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery. Tools include Terraform Provider used with Resource Manager.

• **API Reference and Appendices** on page 6275 This general reference shows how to configure the SDKs and other developer tools to integrate with Oracle Cloud Infrastructure services.

• **REST APIs** on page 6275 This complete reference provides details on the Oracle Cloud Infrastructure REST APIs, including descriptions, syntax, endpoints, errors, and signatures.

Other Resources

You can also stay up-to-date on the latest news on Oracle Cloud Infrastructure developer tools with these other resources and communities.

• **Oracle GraalVM Enterprise** is a JDK distribution designed to accelerate the execution of applications written in Java and other JVM languages while also providing a high-performance runtime for JavaScript, Ruby, Python, and a number of other popular languages. For more information, see Getting Started with GraalVM Enterprise on OCI.

• **Oracle Cloud Infrastructure Forum** See the latest discussion threads tagged with Developer Tools

• Stack Overflow Ask and answer questions tagged with oracle-cloud-infrastructure

• Twitter Follow Oracle Developers @oracledevs and Oracle Cloud Infrastructure @OracleIaaS on Twitter

SDK Breaking Changes & Previous Version Support

Oracle Cloud Infrastructure will sometimes make a breaking change to an SDK. Breaking changes are documented in the changelog file included with each SDK distribution and on GitHub (for example, the Java SDK changelog is available here).

If you are unable to migrate to the next version of the SDK due to a breaking change, OCI will provide a patched version of any SDK version released within the past year if the next version introduces a breaking change. These patches are limited to high severity bugs in the SDK and security fixes, such as data corruption issues or upgrading a third-party package from a version with security vulnerabilities to a version where such vulnerabilities have been fixed.

To request a patched version of an SDK, contact support or file a ticket in the SDK's GitHub repository (for example, the GitHub issues page for the SDK for Java can be found here).

Setup and Prerequisites

This section covers how to set up the required SSH keys to work with the OCI SDKs and developer toolkits as well as how to configure your SDKs.

What's included:

• **Required Keys and OCIDs** on page 6045

• **SDK and CLI Configuration File** on page 6051

Required Keys and OCIDs

Whether you're using an Oracle client (see Software Development Kits and Command Line Interface on page 6094) or a client you built yourself, you need to do the following:

1. Create a user in IAM for the person or system who will be calling the API, and put that user in at least one IAM group with any desired permissions. See “Adding Users” in the Oracle Cloud Infrastructure Getting Started Guide. You can skip this if the user exists already.
2. Get these items:
   • RSA key pair in **PEM format** (minimum 2048 bits). See *How to Generate an API Signing Key* on page 6046.
   • Fingerprint of the public key. See *How to Get the Key's Fingerprint* on page 6050.
   • Tenancy's OCID and user's OCID. See *Where to Get the Tenancy's OCID and User's OCID* on page 6050.

3. Upload the public key from the key pair in the Console. See *How to Upload the Public Key* on page 6050.

4. If you're using one of the Oracle SDKs or tools, supply the required credentials listed above in either a configuration file or a config object in the code. See *SDK and CLI Configuration File* on page 6051. If you're instead building your own client, see *Request Signatures* on page 6295.

**Important:**

This key pair is **not** the SSH key that you use to access compute instances. See *Security Credentials* on page 205.

Both the private key and public key must be in PEM format (not SSH-RSA format). The public key in PEM format looks something like this:

```plaintext
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQE...
...
-----END PUBLIC KEY-----
```

*How to Generate an API Signing Key*

**Note:**

You can use the Console or command line tools available for Linux, Mac OS or Windows to generate an API signing key.

Generating an API Signing Key (Console)

You can use the Console to generate the private/public key pair for you. If you already have a key pair, you can choose to upload the public key. When you use the Console to add the key pair, the Console also generates a configuration file preview snippet for you.

The following procedures work for a regular user or an administrator. Administrators can manage API keys for either another user or themselves.

**About the Config File Snippet**

When you use the Console to add the API signing key pair, a configuration file preview snippet is generated with the following information:

- `user` - the OCID of the user for whom the key pair is being added.
- `fingerprint` - the fingerprint of the key that was just added.
- `tenancy` - your tenancy's OCID.
- `region` - the currently selected region in the Console.
- `key_file` - the path to your downloaded private key file. You must update this value to the path on your file system where you saved the private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

You can copy this snippet into your config file, to help you get started. If you don't already have a config file, see *SDK and CLI Configuration File* on page 6051 for details on how to create one. You can also retrieve the config file snippet later for an API signing key whenever you need it. See: To get the config file snippet for an API signing key.
**Prerequisite:** Before you generate a key pair, create the `.oci` directory in your home directory to store the credentials. See SDK and CLI Configuration File on page 6051 for more details.

1. View the user's details:
   
   • If you're adding an API key for **yourself**:
     
     Open the Profile menu and click User Settings.
   
   • If you're an administrator adding an API key for **another user**: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select Generate API Key Pair.

4. Click **Download Private Key** and save the key to your `.oci` directory. In most cases, you do not need to download the public key.

   **Note:** If your browser downloads the private key to a different directory, be sure to move it to your `.oci` directory.

5. Click **Add**.

   The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config` file. (If you have not yet created this file, see SDK and CLI Configuration File on page 6051 for details on how to create one.)

   After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:

   • Replace the existing profile and its contents.
   • Rename the existing profile.
   • Rename this profile to a different name after pasting it into the config file.

6. Update the permissions on your downloaded private key file so that only you can view it:

   a. Go to the `.oci` directory where you placed the private key file.
   b. Use the command `chmod go-rwx ~/.oci/<oci_api_keyfile>.pem` to set the permissions on the file.

To upload or paste an API key

**Prerequisite:** You have generated a public **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...

-----END PUBLIC KEY-----
```

1. View the user's details:

   • If you're adding an API key for **yourself**:
     
     Open the Profile menu and click User Settings.
   
   • If you're an administrator adding an API key for **another user**: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select Choose Public Key File to upload your file, or Paste Public Key, if you prefer to paste it into a text box.
4. Click Add.

The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 6051 for details on how to create one.)

After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

• Replace the existing profile and its contents.
• Rename the existing profile.
• Rename this profile to a different name after pasting it into the config file.

To get the config file snippet for an API signing key

The following procedure works for a regular user or an administrator.

1. View the user's details:
   • If you're getting an API key config file snippet for yourself:
     Open the Profile menu ( ) and click User Settings.
   • If you're an administrator getting an API key config file snippet for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click API Keys. The list of API key fingerprints is displayed.

3. Click the Actions menu for the fingerprint, and select View configuration file.

The Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 6051 for details on how to create one.) After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

• Replace the existing profile and its contents.
• Rename the existing profile.
• Rename this profile to a different name after pasting it into the config file.

Generating an API Signing Key (Linux and Mac OS X)

Use the following OpenSSL commands to generate the key pair in the required PEM format.

1. If you haven't already, create an .oci directory to store the credentials:

   mkdir ~/.oci
2. Generate the private key with one of the following commands.
   • To generate the key, encrypted with a passphrase you provide when prompted:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```
     **Note:** We recommend that you use a passphrase for your key.
   • To generate the key with no passphrase:
     ```bash
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Change the file permission to ensure that only you can read the private key file:
   ```bash
   chmod go-rwx ~/.oci/oci_api_key.pem
   ```

4. Generate the public key from your new private key:
   ```bash
   openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
   ```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:
   ```bash
   cat ~/.oci/oci_api_key_public.pem | pbcopy
   ```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

Generating an API Signing Key (Windows)

If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

1. If you haven't already, create a .oci directory to store the credentials. For example:
   ```bash
   mkdir %HOMEDRIVE%%HOMEPATH%\oci
   ```

2. Generate the private key with one of the following commands:
   • To generate the key that is encrypted with a passphrase you provide when prompted:
     ```bash
     openssl genrsa -out %HOMEDRIVE%HOMEPATH\oci\oci_api_key.pem -aes128 -passout stdin 2048
     ```
     **Note:** We recommend that you use a passphrase for your key.
   • To generate the key with no passphrase:
     ```bash
     openssl genrsa -out %HOMEDRIVE%HOMEPATH\oci\oci_api_key.pem 2048
     ```

Use the following OpenSSL commands to generate the key pair in the required PEM format.

---

**Note:**

Be sure to include the openssl binary in your Windows path. On default installations, the openssl.exe file can be found in C:\Program Files\Git\mingw64\bin.
3. Generate the public key from your new private key:

```bash
openssl rsa -pubout -in %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key_public.pem
```

4. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later). For example:

```bash
type \oci\oci_api_key_public.pem
```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

**How to Get the Key's Fingerprint**

You can get the key's fingerprint with the following OpenSSL command.

**For Linux and Mac OS X:**

```bash
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

**For Windows:**

```
Note:
If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.
```

```bash
openssl rsa -pubout -outform DER -in \oci\oci_api_key.pem | openssl md5 -c
```

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef

**Where to Get the Tenancy's OCID and User's OCID**

Both OCIDs are in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator. If you're not familiar with OCIDs, see Resource Identifiers.

**Tenancy's OCID**

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu ( ) and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

**User's OCID**

Get the user's OCID in the Console on the page showing the user's details. To get to that page:

- If you're signed in as the user:
  
  Open the Profile menu ( ) and click User Settings.
  - If you're an administrator doing this for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Select the user from the list.
  - The user OCID is shown under User Information. Click Copy to copy it to your clipboard.

**How to Upload the Public Key**

You can upload the PEM public key in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator.
1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
   - If you're signed in as the user:
     Open the Profile menu (ґ) and click User Settings.
     • If you're an administrator doing this for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Select the user from the list.
3. Click Add Public Key.
4. Paste the contents of the PEM public key in the dialog box and click Add.

Notice that after you've uploaded your first public key, you can also use the UploadApiKey API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

SDK and CLI Configuration File

Oracle Cloud Infrastructure SDKs and CLI require basic configuration information, like user credentials and tenancy OCID. You can provide this information by:

- Using a configuration file
- Declaring a configuration at runtime

**Note:**

You can use the Console to help generate a configuration file. For more information, see Generating an API Signing Key (Console) on page 6046.

The SDKs fully support both options. Refer to the documentation for each SDK for information about the config object and any exceptions when using a configuration file:

- Oracle Cloud Infrastructure SDK for Java Configuration
- Oracle Cloud Infrastructure SDK for Python Configuration
- Oracle Cloud Infrastructure SDK for Ruby Configuration
- Oracle Cloud Infrastructure SDK for Go Configuration
- Oracle Cloud Infrastructure SDK for TypeScript and JavaScript Configuration
- Oracle Cloud Infrastructure SDK for .NET Configuration

The CLI requires a configuration file, but also allows you to set environment variables to provide certain information. See CLI Environment Variables for more information.

**File Name and Location**

The default configuration file name and location is `~/.oci/config`.

**Note:**

On Windows, you can use PowerShell to create the folder with the following command: `mkdir %HOMEDRIVE%%HOMEPATH%\.oci`. File Explorer does not support creating folder names that start with a period.

**File Entries**

The following table lists the basic entries that are required for the configuration file, as well as where to get the required information.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the user calling the API. To get the value, see Required Keys and OCIDs on page 6045. Example: ocid1.user.oc1..&lt;unique_ID&gt;(shortened for brevity)</td>
</tr>
<tr>
<td>Entry</td>
<td>Description and Where to Get the Value</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the public key that was added to this user.</td>
</tr>
</tbody>
</table>
| key_file      | Full path and filename of the private key. **Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 6045.
|               | Example (Linux/Mac OS): `~/.oci/oci_api_key.pem`
|               | Example (Windows): `~/.oci/oci_api_key.pem`
|               | This corresponds to the file `%HOMEDRIVE%\%HOMEPATH%.oci\oci_api_key.pem` |
| pass_phrase   | Passphrase used for the key, if it is encrypted. |
| tenancy       | OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 6045.
|               | Example: `ocid1.tenancy.oc1..<unique_ID>` |
| region        | An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 206.
|               | Example: `us-ashburn-1` |

**Custom Values**

Some Oracle Cloud Infrastructure SDKs support defining custom values in the configuration file. Refer to the documentation for each SDK for more information.

**Profiles and Inheritance**

You can create multiple profiles with different values for these entries, then you can specify which profile to load.

Some Oracle Cloud Infrastructure SDKs require a DEFAULT profile and support profile inheritance. This means that any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile. Refer to the documentation for each SDK for more information.

**Example Configuration**

The following example (for Linux and Mac OS) shows key values in a configuration file and how to set profiles for a SDK that supports profile inheritance.

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
```
This example is for Windows:

```bash
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=~/oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=keys/admin_key.pem
pass_phrase=<your_passphrase>
```

### SDK Quick Starts with Cloud Shell

This section includes quick and easy no-setup walk-throughs that demonstrate how to use OCI developer tools and SDKs using Cloud Shell.

- [SDK for Python Cloud Shell Quick Start](#) on page 6053
- [SDK for Java Cloud Shell Quick Start](#) on page 6054
- [SDK for .NET Cloud Shell Quick Start](#) on page 6055
- [SDK for Go Cloud Shell Quick Start](#) on page 6056
- [SDK for TypeScript and JavaScript Cloud Shell Quick Start](#) on page 6057
- [SDK for Ruby Cloud Shell Quick Start](#) on page 6058
- [OCI Modules for PowerShell Cloud Shell Quick Start](#) on page 6059

#### SDK for Python Cloud Shell Quick Start

This section discusses how to quickly get started with the Oracle Cloud Infrastructure SDK for Python using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Run Python:

   ```bash
   user@cloudshell:oci (us-phoenix-1)$ python3
   Python 3.6.8 (default, Oct 1 2020, 20:32:44)
   [GCC 4.8.5 20150623 (Red Hat 4.8.5-44.0.3)] on linux
   Type "help", "copyright", "credits" or "license" for more information.
   >>>
   ```
4. Run the following code sample to see your current Object Storage namespace:

   ```python
   import oci
   object_storage_client =
   oci.object_storage.ObjectStorageClient(oci.config.from_file())
   result = object_storage_client.get_namespace()
   ```

---

Oracle Cloud Infrastructure User Guide 6053
print("Current object storage namespace: {}".format(result.data))

This will return output similar to the following:

Current object storage namespace: mynamespace

SDK for Java Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Java using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a working directory and move to it:

   mkdir java_demo
   cd java_demo

4. Copy a pre-installed example (also available from github) from the OCI Java SDK examples/ folder to your working directory:

   cp $OCI_JAVA_SDK_LOCATION/examples/ListDBVersionExample.java .

5. Compile the example:

   javac -cp .:$OCI_JAVA_SDK_FULL_JAR_LOCATION:$OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample.java

6. Run the example:

   java -cp .:$OCI_JAVA_SDK_FULL_JAR_LOCATION:$OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample $OCI_TENANCY BM.HighIO1.36

This will return output similar to the following:

SLF4J: Failed to load class "org.slf4j.impl.StaticLoggerBinder".
SLF4J: Defaulting to no-operation (NOP) logger implementation
SLF4J: See http://www.slf4j.org/codes.html#StaticLoggerBinder for further details.

DB Versions Fetched for Shape ocid1.tenancy.oc1..aaaaaaaayexample and compartment ocid: BM.HighIO1.36

SDK for .NET Cloud Shell Quick Start

This topic explains how to quickly get started with the Oracle Cloud Infrastructure SDK for .NET using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a working directory and move to it:

   ```bash
   mkdir DotnetDemo && cd DotnetDemo
   ```
4. Create a new .NET console application project:

   ```bash
   dotnet new console
   ```
5. Add the `OCI.DotNetSDK.Objectstorage` package to your project.

   ```bash
   dotnet add package OCI.DotNetSDK.Objectstorage --source /usr/lib/dotnet/NuPkgs/
   ```

   Optionally, you can include the `--source` parameter, which will fall back to retrieving the package from the pre-installed location (`/usr/lib/dotnet/NuPkgs/`) if it cannot be downloaded from nuget.org.

   **Note:** To bypass nuget.org and force usage of the pre-installed .NET SDK, you can use the `nuget.config` provided in step 2a of the instructions here.

6. Add the following code to the `Program.cs` file:

   ```csharp
   using System;
   using System.Collections.Generic;
   using System.Threading.Tasks;
   using Oci.ObjectstorageService;
   using Oci.ObjectstorageService.Requests;
   using Oci.ObjectstorageService.Responses;
   using Oci.Common.Auth;

   namespace DotnetDemo
   {
       public class Program
       {
           static void Main(string[] args)
           {
               var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
               var compartmentId = Environment.GetEnvironmentVariable("OCI_TENANCY");
               var objectStorageClient = new ObjectStorageClient(provider);

               Task<GetNamespaceResponse> getNamespaceResponse = objectStorageClient.GetNamespace(new GetNamespaceRequest());
               Console.WriteLine(getNamespaceResponse.Result.Value);
           }
   }
   ```
7. Run the example:

    dotnet run

**SDK for Go Cloud Shell Quick Start**

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Go using Cloud Shell. The OCI Go SDK is pre-installed in the Cloud Shell environment and included in your $GOPATH.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `main.go` with the following code, which will list the availability domains in your tenancy:

```go
package main

import (
    "context"
    "fmt"
    "github.com/oracle/oci-go-sdk/common"
    "github.com/oracle/oci-go-sdk/identity"
)

func main() {
    c, err := identity.NewIdentityClientWithConfigurationProvider(common.DefaultConfigProvider())
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    // The OCID of the tenancy containing the compartment.
    tenancyID, err := common.DefaultConfigProvider().TenancyOCID()
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    request := identity.ListAvailabilityDomainsRequest{
        CompartmentId: &tenancyID,
    }

    r, err := c.ListAvailabilityDomains(context.Background(), request)
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    fmt.Printf("List of available domains: %v", r.Items)
    return
}
```

4. Add the following environment variable:

    export GO111MODULE=auto
5. Run the example:

```go
run main.go
```

**SDK for TypeScript and JavaScript Cloud Shell Quick Start**

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript using Cloud Shell. The OCI SDK for TypeScript and JavaScript SDK is pre-installed globally through npm.

**JavaScript Example**

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `region_subscriptions_example.js` with the following example code, which lists the subscribed regions for your current tenancy:

```javascript
const identity = require("oci-sdk/node_modules/oci-identity");
const common = require("oci-sdk/node_modules/oci-common");
const provider = new common.ConfigFileAuthenticationDetailsProvider();
const compartmentId = provider.getTenantId() || ";

let identityClient;

async function getSubscriptionRegions(tenancyId) {
    const regions = await identityClient.listRegionSubscriptions(
        tenancyId: tenancyId
    );
    return regions.items.map(region => {
        return region.regionName;
    });
}

(async () => {
    identityClient = await new identity.IdentityClient({
        authenticationDetailsProvider: provider
    });
    const regions = await getSubscriptionRegions(compartmentId);
    console.log("Currently subscribed to the following region(s): ",
    regions)
})();
```

4. Run the example:

```node
node region_subscriptions_example.js
```

**TypeScript Example**

This TypeScript example will list the subscribed regions for the current tenancy.

1. Create an empty project named `ts_demo` and link the global installation of `oci-sdk` library using the following commands:

```bash
# create a new project folder and move into it
mkdir ts_demo
cd ts_demo
# initialize a new javascript/typescript project
npm init --y
```
# link the global installation of oci-sdk to the current project
npm link oci-sdk
npm link @types/node

2. Create a file named `region_subscriptions_example.ts` inside your `ts_demo` project with the following code:

```typescript
import * as identity from "oci-sdk/node_modules/oci-identity";
import common = require("oci-sdk/node_modules/oci-common");

const provider: common.ConfigFileAuthenticationDetailsProvider = new
  common.ConfigFileAuthenticationDetailsProvider();

const compartmentId = provider.getTenantId();

let identityClient: identity.IdentityClient;

export async function getSubscriptionRegions(tenancyId: string) {
  const listRegionSubscriptionsRequest:
    identity.requests.ListRegionSubscriptionsRequest = {
      tenancyId: tenancyId
    };

  const regions = await
    identityClient.listRegionSubscriptions(listRegionSubscriptionsRequest);
  return regions.items.map(region => {
    return region.regionName;
  });
}

(async () => {
  identityClient = await new
    identity.IdentityClient({ authenticationDetailsProvider: provider });
  const regions = await getSubscriptionRegions(compartmentId);
  console.log("Currently subscribed to the following region(s): ",
    regions)
})();
```

3. Compile the example:

```shell
# use the TypeScript compiler to compile the example
tsc region_subscriptions_example.ts
```

4. Run the example:

```shell
# run the example using node
node region_subscriptions_example.js
```

**SDK for Ruby Cloud Shell Quick Start**

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Ruby using Cloud Shell. The OCI SDK for Ruby is installed in the cloud shell environment and automatically added to your `GEM_PATH`.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `list_users_example.rb` with the following code, which lists the users in your tenancy:

```ruby
require 'oci'

api = OCI::Identity::IdentityClient.new()
response = api.list_users(OCI.config.tenancy)
```
**OCI Modules for PowerShell Cloud Shell Quick Start**

This topic discusses how to quickly get started with the Oracle Cloud Infrastructure Modules for PowerShell using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. From the Cloud Shell session's command prompt, start the PowerShell environment:

   ```
   user@cloudshell:oci (us-phoenix-1)$ pwsh
   ```

4. Run the following command to get the current object storage namespace:

   ```
   Get-OCIObjectstorageNamespace
   ```

**Command Line Interface (CLI)**

The CLI is a small-footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend Console functionality.

### Tip:

**Cloud Shell**: The CLI is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the CLI from within Cloud Shell, see Getting Started with Cloud Shell.

**Oracle Linux Cloud Developer image**: The CLI is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

This CLI and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

The CLI is built on the Oracle Cloud Infrastructure SDK for Python and runs on Mac, Windows, or Linux. The Python code makes calls to Oracle Cloud Infrastructure APIs to provide the functionality implemented for the various services. These are REST APIs that use HTTPS requests and responses. For more information, see About the API.

**Installation**: See Quickstart on page 6062.

**Reference**: For help with a specific command, you can enter `help <command>` on the command line or view the Command Line Reference. This reference is derived from the APIs and help text in the Python source code.

**Requirements**

To install and use the CLI, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This account user can be you, another person, or a system that calls the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of other typical Oracle Cloud Infrastructure policies, see Common Policies.
• A keypair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. See Configuring the CLI.

Note:
To use the CLI without a keypair, you can use token-based authentication. For more information, see Token-based Authentication for the CLI on page 6068.

• A supported version of Python on a supported operating system.
• If you require FIPS-compliance, see Using FIPS-validated Libraries on page 6075.

Supported Python Versions and Operating Systems
The CLI supports Python versions 3.6 and later running on MacOS, Windows, or supported Linux and UNIX-like operating systems:
• Oracle Linux 6.10, Oracle Linux 7.7 and 7.8, and Oracle Linux 8.0
• Oracle Autonomous Linux 7.8
• Oracle Linux Cloud Developer 8.x
• CentOS 7.0 and CentOS 8.x
• Ubuntu 16.04, Ubuntu 18.04, and Ubuntu 20.04

Note:
You need to upgrade to Python version 3.6 or later to continue receiving support from Oracle. OCI support for Python version 2.x is being deprecated. Versions of the OCI CLI released after August 1st, 2021, (version 3.x.x and later), will not work with Python version 2.7. Versions of the OCI CLI released before August 1st 2021, (version 2.x.x), will continue to work with Python versions 2.7 by setting the environment variable OCI_CLI_ALLOW_PYTHON2 to True.

Newer versions of Python may not be immediately supported. The CLI might work on unlisted operating systems, but we do not test them for compatibility.

If you use the CLI installer and do not have Python on your machine, the installer offers to automatically install Python for you. If you already have Python installed on your machine, you can use the python --version command to find out which version is installed.

Services Supported
• AI Anomaly Detection
• AI Language
• Analytics Cloud
• Announcements
• API Gateway
• Classic Migration Service
• Application Performance Monitoring
• Audit
• Autoscaling (Compute)
• Bastion
• Big Data
• Blockchain Platform
• Budgets
• Build
• Certificates
• Cloud Guard
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content Management
- Core Services (Networking, Compute, Block Volume)
- Database Migration
- Data Catalog
- Data Flow
- Data Labeling
- Data Integration
- Data Labeling
- Data Safe
- Data Science
- Data Transfer

Quickstart
Installing the CLI

Oracle Linux 8
If you're using Oracle Linux 8, you can use dnf to install the CLI.

```bash
Note:
We strongly recommend running `sudo dnf update` regularly to ensure your system is up-to-date by installing available updated RPMs.
```

To use dnf to install the CLI:

```
sudo dnf -y install oraclelinux-developer-release-el8
sudo dnf install python36-oci-cli
```

The CLI will be installed to the Python site packages:

- `/usr/lib/python3.6/site-packages/oci_cli`
- `/usr/lib/python3.6/site-packages/services`

Documentation and examples will be installed in the `/usr/share/doc/python36-oci-cli-<version>/` directory.
To uninstall the CLI:

```
sudo dnf remove python36-oci-cli
```

**Oracle Linux 7**

If you're using Oracle Linux 7, you can use yum to install the CLI.

To use yum to install the CLI:

```
sudo yum install python36-oci-cli
```

The CLI will be installed to the Python site packages:

- `/usr/lib/python3.6/site-packages/oci_cli`
- `/usr/lib/python3.6/site-packages/services`

Documentation and examples will be installed in the `/usr/share/doc/python36-oci-cli-<version>/` directory.

To uninstall the CLI:

```
sudo yum remove python36-oci-cli
```

**Mac OS X**

You can use Homebrew to install, upgrade, and uninstall the CLI on Mac OS.

To install the CLI on Mac OS X with Homebrew:

```
brew update && brew install oci-cli
```

To upgrade your CLI install on Mac OS X using Homebrew:

```
brew update && brew upgrade oci-cli
```

To uninstall the CLI on Mac OS X using Homebrew:

```
brew uninstall oci-cli
```

**Windows**

1. Open the PowerShell console using the Run as Administrator option.
2. The installer enables auto-complete by installing and running a script. To allow this script to run, you must enable the RemoteSigned execution policy.

   To configure the remote execution policy for PowerShell, run the following command.

   ```
   Set-ExecutionPolicy RemoteSigned
   ```

3. Force PowerShell to use TLS 1.2 for Windows 2012 and Windows 2016:

   ```
   ```

4. Download the installer script:

   ```
   ```
5. Run the installer script with or without prompts:

a. To run the installer script with prompts, run the following command:

```
```

...and respond to the Installation Script Prompts on page 6064.

b. To run the installer script without prompting the user, accepting the default settings, run the following command:

```
install.ps1 -AcceptAllDefaults
```

**Linux and Unix**

**Note:**
The installer script automatically installs the CLI and its dependencies, Python and virtualenv. Before running the installer, be sure you meet the requirements.

**Note:**
Oracle Linux 8 and Oracle Linux Cloud Developer 7 have the CLI pre-installed.

1. Open a terminal.
2. To run the installer script, run the following command:

```
```

**Note:**
To run a 'silent' install that accepts all default values with no prompts, use the `--accept-all-defaults` parameter.

3. Respond to the Installation Script Prompts on page 6064.

**Verifying the OCI CLI Installation**

1. From a command prompt, run the following command:

```
oci --version
```

**Installation Script Prompts**

The installation script prompts you for the following information.

- If you do not have a compatible version of Python installed:
  - Windows and Linux: You are prompted to provide a location for installing the binaries and executables. The script will install Python for you.
  - MacOS: You are notified that your version of Python is incompatible. You must upgrade before you can proceed with the installation. The script will not install Python for you.
- When prompted to upgrade the CLI to the newest version, respond with **Y** to overwrite an existing installation.
- When prompted to update your PATH, respond with **Y** to be able to invoke the CLI without providing the full path to the executable. This will add oci.exe to your PATH.
Setting up the Config File

Before using the CLI, you must create a config file that contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup dialog or manually using a text editor.

Use the Setup Dialog

To have the CLI walk you through the first-time setup process, use the `oci setup config` command. The command prompts you for the information required for the config file and the API public/private keys. The setup dialog generates an API key pair and creates the config file.

For more information about how to find the required information, see:
- Where to Get the Tenancy's OCID and User's OCID on page 6050
- Regions and Availability Domains on page 206

Manual Setup

If you want to set up the API public/private keys yourself and write your own config file, see SDK and Tool Configuration.

Tip:

Use the `oci setup keys` command to generate a key pair to include in the config file.

Next Steps

- Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.
- Using the CLI on page 6076 provides detailed examples of CLI usage.

Manual and Offline Installations

Instead of using the installer script as described in the Quickstart on page 6062, you can manually install the CLI and its dependencies. Before proceeding, be sure you meet the Requirements on page 6059.

Prior to manually installing the CLI:

- Make sure your python path is set correctly
- Run "python --version" or "python3 --version" and make sure you have the required version
- If installing on Oracle Linux or CentOS, have the following installed:
  - gcc
  - zlib-devel
  - python3-devel
  - the latest version of OpenSSL 1.1.1

You can also download the CLI installation files and perform an offline installation.

Step 1: Installing Python

Python installation instructions vary for each operating system that the CLI supports.

Note:

The CLI supports only the Python versions listed in the CLI Requirements.

Windows

Install a supported version of Python from the Python Windows downloads page. During installation, choose to add Python to the PATH and/or environment variables (depending on the prompt).

Oracle Linux
Some versions of Oracle Linux come with incompatible versions of Python, and might require additional components to install the CLI. Before installing the CLI, run the following commands on a new Oracle Linux image.

**Tip:**
Oracle Autonomous Linux 7 and Oracle Linux Cloud Developer 8 come with the CLI pre-installed.

### Oracle Linux 7 and Oracle Linux 8

```shell
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
./configure --enable-optimizations
sudo make altinstall
```

### Oracle Linux 6

```shell
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.6.3/Python-3.6.3.tgz
tar xvf Python-3.6.3.tgz
cd Python-3.6*/
./configure --enable-optimizations
sudo make altinstall
```

### CentOS

Before you install the CLI, run the following commands on a new CentOS image.

### CentOS 7, CentOS 8

```shell
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
./configure --enable-optimizations
sudo make altinstall
```

### Ubuntu

Before you install the CLI, run the following commands on a new Ubuntu image.

### Ubuntu 16, Ubuntu 18, and Ubuntu 20

```shell
sudo apt update
sudo apt install build-essential zlib1g-dev libncurses5-dev libgdbm-dev libnss3-dev libssl1-dev libreadline-dev libffi-dev libsqlite3-dev wget libbz2-dev
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar -xf Python-3.8.3.tgz
cd Python-3.8.3
./configure --enable-optimizations
sudo make altinstall
```
Mac OS X

Mac OS X comes with Python pre-installed.
To install the latest version of Python on Mac OS X, see the official Python documentation.

*Step 2: Creating and Configuring a Virtual Environment*

The *venv* Python module is a virtual environment builder that lets you create isolated Python environments. We recommend installing the CLI in a virtual environment.

**Installing and Activating your Virtual Environment**

After Python is installed, set up a virtual environment for your operating system using the following steps.

**Windows**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running the following command:

   ```bash
   python -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:

   ```bash
   oracle-cli/Scripts/activate
   ```

**Linux and Mac**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running one of the following commands, depending on the version of Python installed:

   ```bash
   python3.8 -m venv oracle-cli
   ```

   ```bash
   python3.6 -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:

   ```bash
   source oracle-cli/bin/activate
   ```

*Step 3: Installing the Command Line Interface*

You can download the CLI from GitHub or install the package from Python Package Index (PyPI).

To install using the GitHub download:

- Download and unzip *oci-cli.zip*.
- Run the following command.

  ```bash
  pip install oci_cli-*-py2.py3-none-any.whl
  ```

To install using PyPI, run the following command:

```bash
pip install oci-cli
```

For information on how to start a CLI session, see *Using the CLI* on page 6076.

**Installing Without a Virtual Environment**

We do not recommend installing the CLI in your system-wide Python and suggest that instead you install the CLI using the installer or virtual environment.
In cases where you are trying to install the CLI in your system-wide Python using the latest pip version, you might encounter conflicts with some `distutils` installed packages. Following is an example error message when this occurs:

```
sudo pip install oci-cli
...  
...  
Cannot uninstall 'requests'. It is a distutils installed project and thus we cannot accurately determine which files belong to it which would lead to only a partial uninstall.
```

Another option is to install the CLI for the user using the following command, although this approach is not supported:

```
pip install --user oci-cli
```

**Offline Installation**

If you have Python 3 installed, you can perform an offline installation of the OCI CLI.

**To perform an offline installation:**

1. Go to the [OCI CLI release page on GitHub](https://github.com/oracle/oci-cli/releases) and select the version of the CLI that you want to install.
2. Scroll down to the **Assets** section of the release page and click on the zip file to download it.
3. Copy the zip file to the target system.
4. Unzip the zip file.
5. Run the appropriate installer for the platform:
   a. On Unix and Linux, run `bash install.sh --offline-install`
   b. On Windows, run `install.ps1 -OfflineInstall`
6. Follow the installation prompts.

For troubleshooting offline installs, see [Common Issues](https://github.com/oracle/oci-cli/issues) or create an issue on GitHub.

**Token-based Authentication for the CLI**

Token-based authentication for the CLI allows customers to authenticate their session interactively, then use the CLI for a single session without an API signing key. This enables customers using an identity provider that is not SCIM-supported to use a federated user account with the CLI and SDKs.

**Requirements**

The requirements are the same as those listed for the CLI in [Requirements](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/sdkoverview.htm) on page 6059, except that instead of a SSH keypair, you need a web browser for the authentication process.

**Starting a Token-based CLI Session**

To use token-based authentication for the CLI on a computer with a web browser:

1. In the CLI, run the following command. This will launch a web browser.

   ```
   oci session authenticate
   ```

2. In the browser, enter your user credentials. This authentication information is saved to the `.config` file.

**Validating a Token**

To verify that a token is valid, run the following command:

```
oci session validate --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

You should receive a message showing the expiration date for the session. If you receive an error, check your profile settings.
**Refreshing a Token**

The default token TTL is set to 1 hour before it expires and can be refreshed within the validity period up to 24 hours.

To refresh the token, run the following command:

```
oci session refresh --profile <profile_name>
```

**Starting a Token-based CLI Session without a Browser**

To use token-based authentication for the CLI on a computer without a web browser, you must export a session from a web-enabled computer, then import it to the computer without a web browser.

**Exporting from Source Computer**

On the source computer with the browser:

1. In the CLI, run the following command:

   ```
   oci session authenticate
   ```

2. Enter the user credentials you wish to use on the target computer.

3. To export a zip file, run the following command:

   ```
   oci session export --profile <profile_name> --output-file <output_filename>
   ```

To verify the export, see Validating a Token on page 6068.

**Importing to Target Computer**

On the target computer without the browser, run the following command in the CLI:

```
oci session import --session-archive <path_to_exported_zip>
```

You can test the import by running the following:

```
oci iam region list --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

It should return a list of regions. Successful execution of this command verifies that the token authentication is working as expected.

**Running Scripts on a Computer without a Browser**

After importing the authentication to the target computer, you can run the CLI and SDKs by using the following settings.

**For CLI**

To run scripts on the CLI, append the following suffix:

```
--config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

**For SDKs**

To run SDKs on the target computer, you must read in the token file, then use it to initialize the SecurityTokenSigner.

After creating a token file as shown in Starting a Token-based CLI Session on page 6068, use the following process.
Note:
These code samples demonstrate how to accomplish this using the Oracle Cloud Infrastructure SDK for Python. For other SDKs, follow the same process, but adjust the syntax accordingly.

1. Read the token file from the security_token_file parameter of the .config file.

```python
config = oci.config.from_file(profile_name='TokenDemo')
token_file = config['security_token_file']
token = None
with open(token_file, 'r') as f:
    token = f.read()
```

2. Read the private key specified by the .config file.

```python
private_key = oci.signer.load_private_key_from_file(config['key_file'])
```

3. Create the initial SDK client which targets the user-specified region.

```python
signer = oci.auth.signers.SecurityTokenSigner(token, private_key)
client = oci.identity.IdentityClient({'region': region}, signer=signer)
```

4. Make the identity request.

```python
result = client.list_region_subscriptions(config['tenancy'])
```

Configuring the CLI
You can use these optional configurations to extend CLI functionality. The CLI supports using a file for CLI-specific configurations. You can:

- Specify a default profile.
- Set default values for command options so you don't have to type them into the command line.
- Define aliases for commands. For example, using "ls" as an alias for list.
- Define aliases for options. For example, using "--ad" as an alias for --availability-domain.
- Define named queries that are passed to the --query option instead of typing a JMESPath expression on the command line.

The CLI also supports the use of environment variables to specify defaults for some options. See CLI Environment Variables for more information.

CLI Configuration File
The default location and file name for the CLI-specific configuration file is ~/.oci/oci_cli_rc, but you can use the OCI_CLI_RC_FILE environment variable to modify where the CLI looks for a configuration file and its default values upon startup.

You can also explicitly specify a CLI configuration file with the --cli-rc-file option or with the legacy --defaults-file option. For example:

```bash
# Uses the file from ~/.oci/oci_cli_rc
# or OCI_CLI_RC_FILE environment variable
oci os bucket list

# Uses a custom file
oci os bucket list --cli-rc-file path/to/my/cli/rc/file
```

To set up an oci_cli_rc file, run the following command.

```
oci setup oci-cli-rc --file path/to/target/file
```
This command creates the file you specify that includes examples of default command aliases, parameter aliases, and named queries.

**Note:**
If you are using Windows, you should use backslash as the directory separator in pathnames, instead of the forward slash.

**Specifying a Default Profile**

Specify a default profile in the `OCI_CLI_SETTINGS` section of the CLI configuration file. The next example shows how to specify a default profile named IAD. The CLI looks for a profile named IAD in your `~/.oci/config` file, or any other file that you specify using the `--config-file` option or the `OCI_CLI_CONFIG_FILE` environment variable.

```ini
[OCI_CLI_SETTINGS]
default_profile=IAD
```

You can also specify a default profile by using the `--profile` option or by setting the `OCI_CLI_PROFILE` environment variable.

If a default profile value has been specified in multiple locations, the order of precedence is:

1. The value specified in the `--profile` option.
2. The value specified in the `OCI_CLI_PROFILE` environment variable.
3. The value specified in the `default_profile` field in the `OCI_CLI_SETTINGS` section of the CLI configuration file.

**Specifying Default Values**

The CLI supports using default values so that you don't have to keep typing every value into the command line. For example, instead of typing in a `--compartment-id` on each launch instance command or having to keep specifying the `--namespace` when using Object Storage commands. You can specify this information in a default values file.

Default values can be applied at different levels, from general to specific:

- Globally, across all the CLI commands.
- To a particular service, such as Compute or Object Storage.
- To a specific group, such as commands related to exporting images.
- To a specific command.

Default values are treated hierarchically, with specific values having a higher order of precedence than general values. For example, if there is a globally defined value for `compartment-id` and a specific `compartment-id` defined for the `compute instance launch` command, the CLI uses the value for the `compute instance launch` command instead of the global default.

**Command Value Priority**

If a value is provided on the command line also exists in `--cli-rc-file`, the value from the command line has priority. For a command with options that take multiple values, the values are taken entirely from the command line or from `--cli-rc-file`. The 2 sources aren't merged.

**Defaults Value File Syntax**

The `--cli-rc-file` file can be divided into different sections with one or more keys per section.
Sections

In the next example, the file has two sections, with a key in each section. To specify which section to use, you use the --profile option in the CLI.

```
[DEFAULT]
compartment-id = ocid1.compartment.oc1..<unique_ID_1>
[ANOTHER_SECTION]
compartment-id = ocid1.compartment.oc1..<unique_ID_2>
```

Keys

Keys are named after command line options, but do not use a leading double hyphen (--). For example, the key for --image-id is image-id. You can specify keys for single values, multiple values, and flags.

- Keys for Single Values. The next example shows how to specify key values at different levels, and with different scope.

```
# Defines a global default for bucket-name
bucket-name = my-global-default-bucket-name
# Defines a default for bucket-name, which applies to all 'compute'
# commands
compute.bucket-name = bucket-name-for-image-import-export
# Defines a default for bucket-name, which applies to all 'os object'
# commands (e.g., os object get)
os.object.bucket-name = bucket-name-for-object-commands
# Defines a default for bucket-name, for the 'os object multipart list'
# command
os.object.multipart.list.bucket-name = bucket-name-for-multipart-list
```

- Keys for Multiple Values. Some options, such as --include and --exclude on the oci os object bulk-upload command can be specified more than once. For example:

```
oci os object bulk-upload -ns my-namespace -bn my-bucket --src-dir my-directory --include *.txt --include *.png
```

The next example shows how you would enter the --include values in the --cli-rc-file file.

```
[DEFAULT]
os.object.bulk-upload.include =
  *.txt
  *.png
```

In the previous example, one value is given for each line and each line must be indented underneath its key. You can use tabs or spaces and the amount of indentation doesn't matter. You can also put a value on the same line as the key, add more values on the following lines, and use a path statement for a value. For example:
• Keys for Flags. Some command options are flags, like --force, which uses a Boolean value. To set a flag for the --force option, use the following command.

```
  os.object.delete.force=true
```

**Specifying Command Aliases**

Specify named queries in the OCI_CLI_COMMAND_ALIASES section of the CLI configuration file. There are two types of aliases, global aliases and command sequence aliases. The following example shows each type of alias.

```
[OCI_CLI_COMMAND_ALIASES]
  # This is a global alias that lets you use "ls" instead of "list" for any list command in the CLI.
  #
  ls = list

  # Command examples:
  # oci os object ls or oci os compute ls

  # This is a command sequence alias that lets you use "oci os object rm" instead of "oci os object delete".
  # <alias> = <dot-separated sequence of groups and sub-groups>.<command or group to alias>
  #
  rm = os.object.delete

  # Command example:
  # <alias> = rm, <sequence of groups and sub-groups> = os object, <command or group to alias> = delete
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have -ls as an alias for --list, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
  compute.instance.ls.compartment-id=ocid1.compartment.oc1..<unique_ID>
```

**Specifying Option Aliases**

Specify option aliases in the OCI_CLI_PARAM_ALIASES section of the CLI configuration file. Option aliases are applied globally. The following example shows some aliases for command options.

```
[OCI_CLI_PARAM_ALIASES]
  # Option aliases either start with a double hyphen (--) or are a single hyphen (-) followed by a # single letter. For example: --example-alias, -e
  #
  --ad = --availability-domain
  --dn = --display-name
  --egress-rules = --egress-security-rules
  --ingress-rules = --ingress-security-rules
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have -ad as an alias for --Availability-Domain, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
  compute.instance.list.ad=xyx:PHX-AD-1
```
**Specifying Named Queries**

If you use the `--query` parameter to filter or manipulate output, you can define named queries instead of using a JMESPath expression on the command line.

Specify named queries in the `OCI_CLI_CANNED_QUERIES` section of the CLI configuration file.

Examples of Named Queries

```
[OCI_CLI_CANNED_QUERIES]
# For list results, this gets the ID and display-name of each item in the list.
# Note that when the names of attributes have dashes in them they need to be surrounded
# with double quotes. This query knows to look for a list because of the 
[*] syntax
get_id_and_display_name_from_list=data[*].{id: id, "display-name": "display-name"}

get_id_and_display_name_from_single_result=data.{id: id, "display-name": "display-name"}

# Retrieves a comma separated string, for example:
# ocid1.instance.oc1.phx.xyz....,cli_test_instance_675195,RUNNING
# get_id_display_name_and_lifecycle_state_from_single_result_as_csv=data.[id, "display-name", "lifecycle-state"] | join(``,``, @)

# Retrieves comma separated strings from a list of results
# get_id_display_name_and_lifecycle_state_from_list_as_csv=data[*].[join(``,``, [id, "display-name", "lifecycle-state"])[]]

# Filters where the display name contains some text
# filter_by_display_name_contains_text=data[?contains("display-name", `your_text_here`)]

# Filters where the display name contains some text and pull out certain attributes(id and time-created)
# filter_by_display_name_contains_text_and_get_attributes=data[?contains("display-name", `your_text_here`)].{id: id, timeCreated: "time-created"}

# Get the top 5 results from a list operation
# get_top_5_results=data[:5]

# Get the last 2 results from a list operation
# get_last_2_results=data[-2:]
```

You can reference any of these queries using this syntax: `query://<query name>`. For example, to get id and display name from a list, run the following command.

```
oci compute instance list -c $C --query query://get_id_and_display_name_from_list
```

**Enabling Auto-complete**

If you used the CLI installer, you don’t have to configure auto-complete because it’s enabled automatically.
To enable auto-complete (tab completion) for a manual CLI installation, run the following command.

```
oci setup autocomplete
```

To enable auto-complete on a session by session basis, run the following command.

```
eval "$_OCI_COMPLETE=source oci"
```

**Note:**

Support for Auto-complete on Windows

Auto-complete on Windows is only supported if you're using PowerShell. A script runs to enable this feature. However, you must change the PowerShell execution policy to RemoteSigned. To configure this policy, run the following command at the PowerShell command line.

```
Set-ExecutionPolicy RemoteSigned
```

**Specifying a Proxy Server**

If your environment requires you to use a proxy server for outgoing HTTP requests, you can specify that in the configuration file.

To configure a proxy server, add a `proxy` entry to the configuration file. For example:

```
proxy=http://<add your proxy URL here>/
```

**Using FIPS-validated Libraries**

The CLI can be configured to use FIPS-validated libraries on Linux. The CLI is built on the Oracle Cloud Infrastructure SDK for Python and leverages operating system level cryptographic libraries.

**Configuring the Environment**

1. Verify the installed version of OpenSSL is FIPS-compliant. Run the following command:

   ```
   openssl version
   ```

   If "fips" is not part of the version name, you should upgrade OpenSSL to a FIPS-compliant version. You can download the latest versions of OpenSSL at: https://www.openssl.org/source/

2. Determine the location of the FIPS-compliant version of libcrypto:

   ```
   ls -l /usr/lib64/libcrypto*
   ```

3. Set the environment variable `OCI_CLI_FIPS_LIBCRYPTO_FILE` to the location of libcrypto:

   ```
   export OCI_CLI_FIPS_LIBCRYPTO_FILE=/path/to/libcrypto.x.x.x
   ```

   If you do not want to run this command at the start of every session, you can add it to your .bashrc or .bash_profile file.

   You can confirm that the environment variable is set properly with this command:

   ```
   set | grep OCI_CLI_FIPS_LIBCRYPTO_FILE
   ```

You can now proceed to the standard installation process outlined in Quickstart on page 6062.
**Verifying the Configuration**

To verify that the CLI is using the library that you specified during Configuring the CLI on page 6070, execute the following commands in Python. Be sure to do so in the same environment that the CLI uses.

```python
import ssl
ssl.FIPS_mode()
```

This should return 1, indicating that SSL is using the library specified by the OCI_CLI_FIPS_LIBCRYPTO_FILE environment variable.

**Using the CLI**

This topic describes how to use the CLI to access Oracle Cloud Infrastructure and carry out service-related tasks. This topic assumes that you have configured the CLI and are ready to start using it.

**Tip:**

Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.

**Command Line Syntax**

Most commands must specify a service, followed by a resource type and then an action. The basic command line syntax is:

```bash
oci <service> <type> <action> <options>
```

For example, this syntax is applied as follows:

- `compute` is the `<service>`
- `instance` is the resource `<type>`
- `launch` is the `<action>`, and
- the rest of the command string consists of `<options>`.

The following command to launch an instance shows a typical command line construct.

```bash
oci compute instance launch --availability-domain "EMIr:PHX-AD-1" -c ocid1.compartment.oc1..aaaaaaaal3gzijdlieqeyg35nz5zxil26astxxhqol2pgeyqdrqgnx7jnhwa --shape "VM.Standard1.1" --display-name "Instance 1 for sandbox" --image-id ocid1.image.oc1.phx.aaaaaaaaqutj4qjixihp14mboabsa27mrpusygv6gurp47kat5z7vljm3puq --subnet-id ocid1.subnet.oc1.phx.aaaaaaaaaypsr25bzjmjyn6xwkgcrkxd3dbhi61odzus3gafscirbhj5bpa
```

In the previous example, you can provide a friendly name for the instance using the `--display-name` option. Avoid entering confidential information.

**Basic Examples**

This section provides examples of basic operations using the CLI.

**Note:**

Using Environment Variables for OCIDs

Several of the CLI examples use environment variables for OCIDs, such as:

- `$T` for a tenancy OCID
- `$C` for a compartment OCID

For example:

```bash
T=ocid1.tenancy.oc1..aaaaaaaah2y3iv7j94eljve6z65sdr57kor2zaagpgkccswnbgh5j5789"%n"%7d"n"
```
To get a namespace, run the following command:

```shell
oci os ns get
```

To list compartments, run the following command:

```shell
oci iam compartment list -c $T
```

To get a list of buckets, run the following command:

```shell
oci os bucket list -ns mynamespace --compartment-id $C
```

To list users and limit the output, run the following command:

```shell
oci iam user list --compartment-id $T --limit 5
```

To add a user to a group, run the following command:

```shell
oci iam group add-user --user-id ocid1.user.oc1..aaabcaaaxkkhhtmghvqqq7rvgzvuj3drwmtlsgz6sbfo7y4uc5sprzli377q --group-id ocid1.group.oc1..aaabcaaa66plootq6uwwxhfdw2lsdqtgeb6l4pjsv5eeuenxraujuj35b7b
```

### Getting Help with Commands

You can get help for any command using `--help`, `-h`, or `?-`. For example:

```shell
oci --help
oci os bucket -h
oci os bucket create -?
```

### Viewing all the CLI Help

You can view the command line help.

### Determining the Installed Version of the CLI

To get the installed version of the CLI, run the following command:

```shell
oci --version
```

### Authenticating Using Instance Principals

*Instance principals* is an IAM service feature that enables instances to be authorized actors (or principals) that can perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

To enable instance principal authorization from the CLI, you can set the authorization option (`--auth`) for a command.

For example:

```shell
oci os ns get --auth instance_principal
```
You can also enable instance principle authorization by setting the `OCI_CLI_AUTH` environment variable. For example:

```
OCI_CLI_AUTH=instance_principal
```

**Note:**

The value set for `--auth` parameter takes precedence over the environment variable.

For more information on instance principals, see Calling Services from an Instance.

### Using a Proxy Server

The CLI uses HTTP requests to make calls to Oracle Cloud Infrastructure services. If you need to use a proxy server for outgoing HTTP requests in your environment, you can use one of the following methods:

**Use the `--proxy` parameter on the command line**

You can specify a proxy server on the command line by including the `--proxy` parameter when calling a CLI command.

For example:

```
oci os ns get --proxy https://<add your proxy URL here>/
```

**Add a proxy entry to the CLI configuration file**

For details, see Specifying a Proxy Server on page 6075.

**Use environment variables**

Set the `HTTP_PROXY` and `HTTPS_PROXY` environment variables to point to your proxy server.

For example, on Linux:

```
https_proxy=https://<add your proxy URL here>/
http_proxy=http://<add your proxy URL here>/
```

On Windows, using PowerShell:

```
$Env:http_proxy = "http://<add your proxy URL here>/"
```

### Using Dates and Times in CLI Commands

The CLI supports the following accepted date formats.

- UTC with milliseconds

  Format: `YYYY-MM-DDTHH:mm:ss.sssTZD`, Example: `2017-09-15T20:30:00.123Z`

- UTC without milliseconds

  Format: `YYYY-MM-DDTHH:mm:ssTZD`, Example: `2017-09-15T20:30:00Z`

- UTC with minute precision

  Format: `YYYY-MM-DDTHH:mmTZD`, Example: `2017-09-15T20:30Z`

- Timezone with milliseconds

  Format: `YYYY-MM-DDTHH:mm:ss.sssTZD`, Example: `2017-09-15T12:30:00.456-08:00`
Developer Tools

- Timezone without milliseconds
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T12:30:00-08:00
- Timezone with offset with minute precision
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T12:35-08:00
- Date Only (This date will be taken as midnight UTC of that day)
  Format: YYYY-MM-DD, Example: 2017-09-15
- Epoch seconds
  Example: 1412195400

Note:
In our datetime formats, the T can be replaced with a space.
For example, both "2017-09-15 20:30:00.123Z" and
2017-09-15T20:30:00.123 are acceptable. (Note that if you do not
include the T, you must wrap the value in quotes.) We also support time
zones with and without the colon. Both +10:00 and +1000 are acceptable.

Managing CLI Input and Output
The CLI provides several options for managing command input and output.

Passing Complex Input
Complex input, such as arrays and objects with more than one value, are passed in JSON format and can be provided
as a string at the command line, as a file, or as a command line string and as a file.

MacOS, Linux, or Unix
The following command shows how to pass two values for the --metadata object.

```
oci os bucket create -ns mynamespace --name mybucket --metadata '{"key1":"value1","key2":"value2"}' --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga
```

Windows
On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes.
Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.
The following command shows how to pass two values for the --metadata object on Windows.

```
oci os bucket create -ns mynamespace --name mybucket --metadata "{"key1":"value1","key2":"value2"}" --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5gq6rck6copzqck3ukc5f1drwpp2jojdcypxfga
```

Note:
JSON Errors
The error message "Parameter '<PARAMETER NAME>' must be in JSON format." indicates that the value you passed for the parameter with name
"PARAMETER NAME" was not valid JSON. This error is typically a result of the JSON string not being escaped correctly.
For more information about using JSON strings, see Advanced JSON Options

Format Output as a Table

By default, all responses to a command are returned in JSON format. For example, a response like the following is returned when you issue the command to get a list of regions.

```
{
    "data": [
    {
        "key": "FRA",
        "name": "eu-frankfurt-1"
    },
    {
        "key": "IAD",
        "name": "us-ashburn-1"
    },
    {
        "key": "ICN",
        "name": "ap-seoul-1"
    },
    {
        "key": "PHX",
        "name": "us-phoenix-1"
    },
    {
        "key": "LHR",
        "name": "uk-london-1"
    },
    {
        "key": "NRT",
        "name": "ap-tokyo-1"
    },
    {
        "key": "YYZ",
        "name": "ca-toronto-1"
    }
    ]
}
```

In some cases, readability can become an issue, which is easily resolved by formatting a response as a table. To get a response to a command formatted as a table, run the following command.

```
oci iam region list --output table
```

The following sample list of regions is returned as a two column table.

```
+-----+----------------+
| key | name           |
+-----+----------------+
| FRA | eu-frankfurt-1 |
| IAD | us-ashburn-1   |
| ICN | ap-seoul-1     |
| PHX | us-phoenix-1   |
| NRT | ap-tokyo-1     |
| LHR | uk-london-1    |
| YYZ | ca-toronto-1   |
+-----+----------------+
```
Filter Output

You can filter output using the JMESPath query option for JSON. Filtering is very useful when dealing with large amounts of output. For example, run the following command with the output table option to get a list of images.

```
oci compute image list -c
oci1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypqntfjrcieq7rrobo2u2zbe9sh3wlafsgthhqtea
--output table
```

The image information is returned in table format, but too much data is returned, which overflows the width of the terminal. In addition, you might not need all the information that's returned.

```
<table>
<thead>
<tr>
<th>base-image-id</th>
<th>compartment-id</th>
<th>create-image-allowed</th>
<th>display-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>lifecycle-state</td>
<td>operating-system</td>
<td>operating-system-version</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
<td>----------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>Windows-Server-2012-R2-Standard-Edition-VM-2017.04.03-0</td>
<td>None</td>
<td>None</td>
<td>True</td>
</tr>
<tr>
<td>Windows-Server-2012-R2-Standard-Edition-VM-2017.09.29-0</td>
<td>None</td>
<td>None</td>
<td>True</td>
</tr>
<tr>
<td>Windows-Server-2012-R2-Standard-Edition-VM-2017.08.25-0</td>
<td>None</td>
<td>None</td>
<td>True</td>
</tr>
</tbody>
</table>
```

You can limit the amount of data returned by combining the `--query` option with `--output table` to get the information you want from a command.
To get filtered image information returned in a table format, run the following command.

```
oci compute image list -c
ocid1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcie7rrob2u2zbesh3wlafsgthhqtea
--output table --query "data [*].{ImageName:"display-name", OCID:id}"
```

The previous command returns the following image information, formatted as a two column table.

<table>
<thead>
<tr>
<th>ImageName</th>
<th>OCID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows-Server-2012-R2-Standard-Edition-VM-2017.04.03-0</td>
<td>ocid1.image.oc1.phx.aaaaaaaa53cliaqvgmuf1lwqkafrbro2y4wjebci5szc4eus5byy2e2b7ua</td>
</tr>
<tr>
<td>Oracle-Linux-7.4-2017.09.29-0</td>

</tbody>
</table>
For more information about the JMESPath query language for JSON, see JMESPath.

**Advanced JSON Options**

You can get the correct JSON format for command options and commands.

- For a command option, use `--generate-param-json-input` and specify the command option that you want to get the JSON for. To generate the JSON for creating or updating a security rule, run the following command.

```bash
oci network security-list create --generate-param-json-input ingress-security-rules
```

- For an entire command, use `--generate-full-command-json-input`. To generate the JSON for launching an instance, run the following command.

```bash
oci compute instance launch --generate-full-command-json-input
```

**Order of Precedence for JSON Input**

The CLI supports combining arguments on the command line with file input. However, if the same values are provided in a file and on the command line, the command line takes precedence.

**Using a JSON File for Complex Input**

You can pass complex input from a file by referencing it from the command line. For Windows users, this removes the requirement of having to escape JSON text. You provide a path to the file using the `file://` prefix.

**Path Types**

Using `testfile.json` as an example, the following types of paths are supported.

- Relative paths from the same directory, for example: `file://testfile.json` and `file://relative/path/to/testfile.json`
- Absolute paths on Linux, MacOS or Unix, for example: `file:///absolute/path/to/testfile.json`
- Full file paths on Windows, for example: `file://C:\path\to\testfile.json`

**Note:**

File path expansions, such as `~/`, `.`, and `../`, are supported. On Windows, the `~/` expression expands to your user directory, which is stored in the `%USERPROFILE%` environment variable. Using environment variables in paths is also supported.

**File Locations**

The following file locations are supported.

- Your home directory.

```bash
oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga --metadata file://~/testfile.json
```
• The current directory.

```bash
oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file://testfile.json
```

• The /tmp directory (Linux, Unix, or MacOS).

```bash
oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file:///tmp/testfile.json
```

• The C:\temp directory (Windows).

```bash
oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file://C:\temp\testfile.json
```

**Examples of Using a JSON File as Input**

The examples in this section use JSON that’s generated for a command option and an entire command. The JSON is saved in a file, edited, and then used as command line input.

**Use File Input for a Command Option**

This end-to-end example shows how to generate the JSON for a security list id option used to create a subnet. The JSON is saved in a file, edited, and then used as command line input.

Response from the Command

```json
[
  {
    "icmpOptions": {
      "code": 0,
      "type": 0
    },
    "isStateless": true,
    "protocol": "string",
    "source": "string",
    "tcpOptions": {
      "destinationPortRange": {
        "max": 0,
        "min": 0
      },
      "sourcePortRange": {
        "max": 0,
        "min": 0
      }
    },
    "udpOptions": {
      "destinationPortRange": {
        "max": 0,
        "min": 0
      },
      "sourcePortRange": {
        "max": 0,
        "min": 0
      }
    }
  }
]```
"icmpOptions": {  
  "code": 0,  
  "type": 0  
},  
"isStateless": true,  
"protocol": "string",  
"source": "string",  
"tcpOptions": {  
  "destinationPortRange": {  
    "max": 0,  
    "min": 0  
  },  
  "sourcePortRange": {  
    "max": 0,  
    "min": 0  
  }  
},  
  
"udpOptions": {  
  "destinationPortRange": {  
    "max": 0,  
    "min": 0  
  },  
  "sourcePortRange": {  
    "max": 0,  
    "min": 0  
  }  
}  
}

Response from the Command

{
  "assignPublicIp": true,
  "availabilityDomain": "string",
  "compartmentId": "string",
  "displayName": "string",
  "extendedMetadata": {
    "string1": {
      "string1": "string",
      "string2": "string"
    },
    "string2": {
      "string1": "string",
      "string2": "string"
    }
  },
  "hostnameLabel": "string",
  "imageId": "string",
  "metadata": {
    "string1": "string",
    "string2": "string"
  },
  "privateIp": "string",
  "shape": "string",
  "skipSourceDestCheck": true,
  "subnetId": "string",
  "vnicDisplayName": "string"
}

Use a JSON File as Input for a Security List Option
1. To generate the JSON for the `security-list-ids` option, run the following command.

```bash
oci network subnet create --generate-param-json-input security-list-ids
```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```json
[
    "string",
    "string"
]
```

3. Edit the file and replace the "string" values with values, as shown in the following example.

```json
[
    "ocid1.securitylist.oc1.phx.anieldjy4k57c62lvnbh5v2iaqjfbkbh4sf75tjcf5dm6",
    "ocid1.securitylist.oc1.phx.anieldjy4k57c62lvnbh5v2iaqjfbkbh4sf75tjcf5dm6"
]
```

4. Save the file as "security-list.json".

5. To create the subnet using "security-list.json" as input, run the following command.

```bash
oci network subnet create --vcn-id ocid1.vcn.oc1.phx.anieldjy4k57c62lvnbh5v2iaqjfbkbh4sf75tjcf5dm6
   --compartment-id ocid1.compartment.oc1..anieldjy4k57c62lvnbh5v2iaqjfbkbh4sf75tjcf5dm6
   --availability-domain "EMIR:PHX-AD-1" --display-name TESTSUB --dns-label testinstances
   --cidr-block "10.0.0.0/16" --security-list-ids file://security-list.json
```

---

**Use File Input for an Entire Command**

This end-to-end example shows how to generate the JSON to create a virtual cloud network (VCN). The JSON is saved in a file, edited, and then used as command line input.

**Use a JSON File as Input to Create a VCN**

1. To generate the JSON needed to create a VCN, run the following command.

```bash
oci network vcn create --generate-full-command-json-input
```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```json
{
    "cidrBlock": "string",
    "compartmentId": "string",
    "displayName": "string",
    "dnsLabel": "string"
}
```

3. Edit the file and replace the "string" values with values, as shown in the following example.

```json
{
    "cidrBlock": "10.0.0.0/16",
    "compartmentId": "ocid1.compartment.oc1..anieldjy4k57c62lvnbh5v2iaqjfbkbh4sf75tjcf5dm6",
    "displayName": "TestVCN",
    "dnsLabel": "testdns"
}
```
4. Save the file and name it "create-vcn.json"
5. To create the VCN using "create-vcn.json" as input, run the following command.

```bash
oci network vcn create --from-json file://create-vcn.json
```

**Advanced Examples**

The following examples show how you can use the CLI to complete complex tasks in Oracle Cloud Infrastructure.

**Working with Object Storage**

You can use the CLI for several object operations with the Object Storage service.

**Uploading and Downloading Files**

Objects can be uploaded from a file or from the command line (STDIN), and can be downloaded to a file or to the command line (STDOUT).

Upload an object:

```bash
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt --metadata '{"key1":"value1","key2":"value2"}'
```

Upload object contents from the command line (STDIN):

```bash
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file <---'object content'
```

Download an object:

```bash
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt
```

Print object contents to the command line (STDOUT):

```bash
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file -
```

**Bulk Operations in Object Storage**

The CLI supports the following bulk operations in Object Storage:

- Uploading files in a directory and all its subdirectories to a bucket
  ```bash
  # Upload all the files in a directory.
  oci os object bulk-upload -ns mynamespace -bn mybucket --src-dir path/to/upload/directory
  
  # Download all the objects.
  oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory
  
  # Download all the objects that match the specified prefix.
  oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory --prefix myprefix
  
  # Deleting all objects, or all the objects that match a specified prefix, in a bucket
  ```
# Delete objects that match the specified prefix.
oci os object bulk-delete -ns mynamespace -bn mybucket --prefix myprefix

Bulk operations support several options that let you:

- Overwrite or skip files/objects using --overwrite or --no-overwrite. (**Note:** If you pass neither of these options you are prompted for confirmation every time there is something to overwrite.)
- Limit delete, upload, or download operations using --prefix and/or --delimiter
- Preview a bulk deletion with --dry-run

To get more information about the commands for bulk operations, run the following help commands:

```bash
# bulk-upload
oci os object bulk-upload -h

# bulk-download
oci os object bulk-download -h

# bulk-delete
oci os object bulk-delete -h
```

### Multipart Operations in Object Storage

Multipart operations for Object Storage include object uploads and downloads.

#### Multipart Uploads

Large files can be uploaded to Object Storage in multiple parts to speed up the upload. By default, files larger than 128 MiB are uploaded using multipart operations. You can override this default by using the --no-multipart option.

You can configure the following options for the `oci os object put` command:

- **--no-multipart** overrides an automatic multipart upload if the object is larger than 128 MiB. The object is uploaded as a single part, regardless of size.
- **--part-size** in MiB, to use in a multipart operation. The default part size is 128 MiB and a part size that you specify must be greater than 10 MiB. If the object is larger than the `--part-size`, it is uploaded in multiple parts.
- **--parallel-upload-count**, to specify the number of parallel operations to perform. You can use this value to balance resources and upload times. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The **--resume-put** command allows you to resume a large file upload in cases where the upload was interrupted.

**Note:**

Multipart Uploads from STDIN

Objects uploaded from STDIN are uploaded in multiple parts. If the object content is smaller than 10 MiB, the upload is only 1 part, and the MultipartUpload API is used for the upload. Specifying --no-multipart when uploading from STDIN will result in an error.

The following example shows the command for a multipart upload if the object is larger than 200 MiB.

```bash
oci os object put -ns my-namespace -bn my-bucket --file path/to/large/file --part-size 200
```

For more information about multipart uploads, see Using Multipart Uploads on page 4974.
Multipart Downloads

Large files can be downloaded from Object Storage in multiple parts to speed up the download.

You can configure the following options for the `oci os object get` command:

- `--multipart-download-threshold` lets you specify the size, in MiB at which an object should be downloaded in multiple parts. This size must be at least 128 MiB.
- `--part-size`, in MiB, to use for a download part. This gives you the flexibility to use more (smaller size) or fewer (larger size) parts as appropriate for your requirements. For example, compute power and network bandwidth. The default minimum part size is 120 MiB.
- `--parallel-download-count` lets you specify how many parts are downloaded at the same time. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The following example shows the command to download any object with a size greater than 500 MiB. The object is downloaded in 128 MiB parts.

```
oci os object get -ns my-namespace -bn my-bucket --name my-large-object --multipart-download-threshold 500 --part-size 128
```

Upgrading the CLI

If you installed the CLI manually, use one of the following commands to upgrade the CLI.

- To upgrade a standard installation, run the following command.
  ```
pip install oci-cli --upgrade
  ```
- To upgrade a standard virtualenv installation, run the following command.
  ```
cli-testing/bin/pip install oci-cli --upgrade
  ```

If you installed the CLI using the install script, use the following process to upgrade the CLI:

- Run the install script and specify the same install directory.
- When prompted, reply `Y` to remove the existing directory.

**Upgrading the CLI on Mac OS X with Homebrew**

Homebrew offers a convenient way to manage your CLI install on Mac OS.

To upgrade your CLI install using Homebrew:

```
brew update && brew upgrade oci-cli
```

Uninstalling the CLI

**For Manual Installations**

If you manually installed the CLI using pip, run the following command:

```
pip uninstall oci-cli
```

If you manually installed the CLI in a virtual environment, run the following command:

```
<path/to/virtualenv>/bin/pip uninstall oci-cli
```

**For Script Installations**

If you used the install script and the default installation location, you should delete the following directories.

On Windows:
• %USERPROFILE%/lib/oracle-cli
• %USERPROFILE%/bin/oci
• %USERPROFILE%/bin/oci-cli-scripts

On Mac:
• $HOME/lib/oracle-cli
• $HOME/bin/oci
• $HOME/bin/oci-cli-scripts

If you used the install script, but installed to a custom location, you should delete the directories at that location.

**Uninstalling Python**

The script also installs Python as a dependency if it was not already installed. In Windows 10, you can uninstall Python in Control Panel or at the command line.

**Using Control Panel**

To uninstall Python in Control Panel, select Programs and Features. Right-click Python and select Uninstall.

For more information, see Repair or remove programs in Windows 10.

**Using the Command Line**

To uninstall Python at the command line, run the following command:

```
msiexec /x python<version>.msi
```

If you do not have the MSI file, you can also use the package or product code. For more information, see Using the Windows Installer.

**Uninstalling the CLI on Mac OS X with Homebrew**

To uninstall the CLI from Mac OS X using Homebrew:

```
brew uninstall oci-cli
```

**Troubleshooting the CLI**

This topic describes how to resolve issues that you might encounter when installing Python or the CLI, or when using the CLI.

**Service Errors**

Any operation resulting in a service error causes an error of type "ServiceError" to be returned by the CLI. For information about common service errors that Oracle Cloud Infrastructure returns, see API Errors.

**Oracle Linux Permissions Issues**

On Oracle Linux 7.3, if you encounter permission issues when running `pip install`, you might need to use `sudo`.

**oci Command Not Found**

If the `oci` command isn't found, this can be caused by one of the following reasons:

- pip installed the package to a different virtual environment than your active one.
- You switched to a different active virtual environment after you installed the CLI.

To determine where the CLI is installed, run the `which pip` and `which oci` commands.

**Wheel File Won't Install**

If the wheel file won't install, verify that pip is up to date. To update pip, run the `pip install -U pip` command. Try to install the wheel again.
Windows Issues

If the oci command isn't found, make sure that the oci.exe location is in your path (for example, the Scripts directory in your Python installation).

No Matching Distribution Found

Error: No matching distribution found for oci-cli==3.x.x

This error occurs if you are attempting to install the CLI in a Python 2 environment. Support for Python 2 was deprecated as of August 1, 2021.

To resolve this issue, update your Python to version 3.6.5 or later. If you require Python 2, any CLI version starting with 2.x.x will still support Python 2.

Contact Information

If you want to contribute ideas, report a bug, get notified about updates, have questions, or want to give feedback, use one of the following links.

Contributions

Got a fix for a bug, or a new feature you’d like to contribute? The CLI is open source and accepting pull requests on GitHub.

Notifications

To be notified when a new version of the CLI is released, subscribe to the Atom feed.

Questions or Feedback

Ways to get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Use the oracle-cloud-infrastructure and oci-cli tags in your post.
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

CLI Environment Variables

The Oracle Cloud Infrastructure CLI supports the use of environment variables to specify default values for some options.

Environment Variables

The following table lists the available environment variables and their corresponding CLI options or ~/.oci/ config entries.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>CLI option</th>
<th>OCI config entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCI_CLI_PROFILE</td>
<td>--profile</td>
<td>Specified by [DEFAULT]</td>
<td>The profile in the OCI config file to load. This profile will also be used to locate any default parameter values which have been specified in the OCI CLI-specific configuration file.</td>
</tr>
<tr>
<td>Environment Variable</td>
<td>CLI option</td>
<td>OCI config entry</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------</td>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OCI_CLI_USER</td>
<td>n/a</td>
<td>user</td>
<td>The OCID of the user calling the API. To get the value, see Required Keys and OCIDs on page 6045. Example: ocid1.user.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>OCI_CLI_REGION</td>
<td>--region</td>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 206. Example: us-ashburn-1</td>
</tr>
<tr>
<td>OCI_CLI_FINGERPRINT</td>
<td>fingerprint</td>
<td></td>
<td>The fingerprint for the public key that was added to this user. To get the value, see Required Keys and OCIDs on page 6045. Example:</td>
</tr>
<tr>
<td>OCI_CLI_KEY_FILE</td>
<td>n/a</td>
<td>key_file</td>
<td>The full path and filename of the private key. Important: The key pair must be in PEM format. For instructions on generating a key pair in PEM</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>format, see Required Keys and OCIDs on page 6045. If you encrypted the key with a passphrase, you must also include the pass_phrase entry in</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>the config file. Example: ~/.oci/oci_api_key.pem</td>
</tr>
<tr>
<td>OCI_CLI_KEY_CONTENT</td>
<td>n/a</td>
<td></td>
<td>The full content of the private key enclosed in single quotes. Important: The key pair must be in PEM format. Example: $ export OCI_CLI_KEYCONTENT=&quot;$($&lt;path/to/oci_api_key.pem)&quot;</td>
</tr>
<tr>
<td>OCI_CLI_TENANCY</td>
<td>n/a</td>
<td>tenancy</td>
<td>The OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 6045. Example: ocid1.tenancy.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>Environment Variable</td>
<td>CLI option</td>
<td>OCI config entry</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>----------------</td>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OCI_CLI_ENDPOINT</td>
<td>--endpoint</td>
<td>OCICLI_ENDPOINT</td>
<td>The value to use as the service endpoint, including any required API version path. Example: <a href="https://iaas.us-phoenix-1.oracle.com/20160918">https://iaas.us-phoenix-1.oracle.com/20160918</a>. Note: The --region parameter is the recommended way of targeting different regions.</td>
</tr>
<tr>
<td>OCI_CLI_CONFIG_FILE</td>
<td>--config-file</td>
<td>n/a</td>
<td>The path to the OCI config file.</td>
</tr>
<tr>
<td>OCI_CLI_RC_FILE</td>
<td>--cli-rc-file</td>
<td>n/a</td>
<td>The path to the OCI CLI-specific configuration file, containing parameter default values and other configuration information such as command aliases and predefined queries. See Configuring the CLI on page 6070 for more information.</td>
</tr>
<tr>
<td>OCI_CLI_CERT_BUNDLE</td>
<td>--cert-bundle</td>
<td>n/a</td>
<td>The full path to a CA certificate bundle to be used for SSL verification.</td>
</tr>
<tr>
<td>OCI_CLI_AUTH</td>
<td>--auth</td>
<td>n/a</td>
<td>The type of auth to use for the API request. By default the API key in your config file will be used. Accepted values are: api_key, instance_obo_user, instance_principal, resource_principal, security_token</td>
</tr>
<tr>
<td>OCI_CLI_SECURITY_TOKEN_FILE</td>
<td>--token-file</td>
<td>Security_token_file</td>
<td>The location of the file used for token-based authentication for the CLI.</td>
</tr>
<tr>
<td>HTTP_PROXY</td>
<td>--proxy</td>
<td>n/a</td>
<td>The URL of the HTTP proxy server to use for outgoing CLI requests. See Specifying a Proxy Server on page 6075.</td>
</tr>
<tr>
<td>HTTPS_PROXY</td>
<td>--proxy</td>
<td>n/a</td>
<td>The URL of the HTTPS proxy server to use for outgoing CLI requests. See Specifying a Proxy Server on page 6075.</td>
</tr>
</tbody>
</table>

**Order of precedence**

The CLI respects and applies configurations specified by option, environment variable, or OCI config file entry in the following order of precedence:

1. The value specified in the command option.
2. The value specified in the environment variable.
3. The value specified in the OCI config file.

**Software Development Kits and Command Line Interface**

Oracle Cloud Infrastructure provides a number of Software Development Kits (SDKs) and a Command Line Interface (CLI) to facilitate development of custom solutions.

- **Software Development Kits (SDKs)** Build and deploy apps that integrate with Oracle Cloud Infrastructure services. Each SDK provides the tools you need to develop an app, including code samples and documentation to create, test, and troubleshoot. In addition, if you want to contribute to the development of the SDKs, they are all open source and available on GitHub.
  - SDK for Java
  - SDK for Python
  - SDK for TypeScript and JavaScript
  - SDK for .NET
  - SDK for Go
  - SDK for Ruby

- **Command Line Interface (CLI)** on page 6059 The CLI provides the same core capabilities as the Oracle Cloud Infrastructure Console and provides additional commands that can extend the Console’s functionality. The CLI is convenient for developers or anyone who prefers the command line to a GUI.

- **PL/SQL SDK** The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write code to manage Oracle Cloud Infrastructure resources. The latest version of the PL/SQL SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

**SDK for Java**

The Oracle Cloud Infrastructure SDK for Java enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** GitHub or Maven.

**Tip:**

Cloud Shell: The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see SDK for Java Cloud Shell Quick Start on page 6054.

Oracle Linux Cloud Developer image: The SDK for Java is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

**Requirements**

To use the SDK for Java, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 80. For a list of typical policies you may want to use, see Common Policies.
• A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Configuring the SDK on page 6098.
• Java 8 or Java 11 (see Java Support Notes).
• A TTL value of 60. For more information, see Configuring the SDK on page 6098.

Java Support Notes

Java 11 Support

• The OCI SDK for Java has been tested with Java version 11.
• Java 8 is required to build the OCI SDK for Java from source, but once it's built you can use the OCI SDK for Java with Java version 11.
• For OCI Java SDK versions before 1.27.0, you need to include the javax.bind and sun.bind dependencies, since Java 11 no longer includes Java EE and CORBA modules. For more information, see the JDK 11 Release Notes.

Services Supported

• AI Anomaly Detection
• AI Language
• Analytics Cloud
• Announcements
• API Gateway
• Classic Migration Service
• Application Performance Monitoring
• Audit
• Autoscaling (Compute)
• Bastion
• Big Data
• Blockchain Platform
• Budgets
• Build
• Certificates
• Cloud Guard
• Compute Instance Agent (Oracle Cloud Agent)
• Container Engine for Kubernetes
• Content Management
• Core Services (Networking, Compute, Block Volume)
• Data Catalog
• Data Flow
• Data Integration
• Data Labeling
• Data Science
• Data Safe
• Data Transfer

• Work Requests (Compute, Database)
Getting Started

This topic describes how to install and configure the Oracle Cloud Infrastructure SDK for Java.

Tip:

The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see SDK for Java Cloud Shell Quick Start on page 6054.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Java, along with other Oracle development tools.

Downloading the SDK from GitHub

You can download the SDK for Java as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples. For best compatibility and to avoid issues, use the version of the dependencies included in the archive. Some notable issues are:

- Bouncy Castle: The SDK bundles 1.60 (included in this distribution). If you need FIPS compliance, see Using BC-FIPS Instead of Bouncy Castle on page 6102.
- Jersey Core and Client: The SDK bundles 2.24.1, which is required to support large object uploads to Object Storage. Older versions will not support uploads greater than ~2.1 GB.
- Jax-RS API: The SDK bundles 2.0.1 of the spec. Older versions will cause issues.

Note:

The SDK for Java is bundled with Jersey (included in this distribution), but you can also use your own JAX-RS implementation. For details, see Using Your Own JAX-RS Implementation on page 6103.

Downloading the SDK from Maven or JCenter

Maven Central and JCenter.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Java.
For Oracle Linux 7:
```bash
sudo yum-config-manager --enable ol7_developer
sudo yum install java-oci-sdk
```

For Oracle Linux 8:
```bash
sudo yum-config-manager --enable ol8_developer
sudo yum install java-oci-sdk
```

The OCI jar file will be located in: `/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar`, and third-party libraries will be in `/usr/lib64/java-oci-sdk/third-party/lib`.

You can add the following entries to your classpath: `/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar:/usr/lib64/java-oci-sdk/third-party/lib/*` For example:
```bash
javac -cp "/usr/lib64/java-oci-sdk/third-party/lib/*:/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-1.8.2.jar" MyFile.java
```

### Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

#### Configuring Credentials

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 6051.

Next you need to set up the client to use the credentials. The credentials are abstracted through an `AuthenticationDetailsProvider` interface. Clients can implement this however you choose. We have included a simple POJO/builder class to help with this task (`SimpleAuthenticationDetailsProvider`).

- You can load a config with or without a profile:
  ```java
  ConfigFile config = ConfigFileReader.parse("~/.oci/config");
  ConfigFile configWithProfile = ConfigFileReader.parse("~/.oci/config", "DEFAULT");
  ```

- The private key supplier can be created with the file path directly, or using the config file:
  ```java
  Supplier<InputStream> privateKeySupplier = new SimplePrivateKeySupplier("~/oci/oci_api_key.pem");
  Supplier<InputStream> privateKeySupplierFromConfigEntry = new SimplePrivateKeySupplier(config.get("key_file"));
  ```

- To create an auth provider using the builder:
  ```java
  AuthenticationDetailsProvider provider = SimpleAuthenticationDetailsProvider.builder()
  .tenantId("myTenantId")
  .userId("myUserId")
  .fingerprint("myFingerprint")
  .privateKeySupplier(privateKeySupplier)
  .build();
  ```

- To create an auth provider using the builder with a config file:
  ```java
  AuthenticationDetailsProvider provider = SimpleAuthenticationDetailsProvider.builder()
  .tenantId(config.get("tenancy"))
  .userId(config.get("user"))
  ```
Finally, if you use standard config file keys and the standard config file location, you can simplify this further by using `ConfigFileAuthenticationDetailsProvider`:

```java
AuthenticationDetailsProvider provider = new ConfigFileAuthenticationDetailsProvider("ADMIN_USER");
```

### Configuring Client-side Options

Create a client-side configuration through the `ClientConfiguration` class. If you do not provide your own configuration, the SDK for Java uses a default configuration. To provide your own configuration, use the following:

```java
ClientConfiguration clientConfig = ClientConfiguration.builder() .connectionTimeoutMillis(3000) .readTimeoutMillis(60000) .build();
```

After you have both a credential configuration and the optional client configuration, you can start creating service instances.

### Configuring Custom Options

In the config file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file like so (highlighted in red italics):

```
[DEFAULT]
user=ocid1.user.oc1..aaaaaaaat5nvwcna5j6aqzjcmdy5eqbb6qt2jvpkanghtgdaqedqw3rynjq
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaaba3pv6wkr4jqa5f15p2bcmdyt2j6rx32uzr4h25vqstifsfsdq
custom_compartment_id=ocid1.compartment.oc1..aaaaaaaayzqeibduyox6iib3olcmdar3ugly4fmame
```

Then you can retrieve the value like so:

```java
ConfigFile config = ConfigFileReader.parse("~/oci/config");
String compartmentId = config.get("custom_compartment_id");
```

### Using the SDK for Java

To use the Oracle Cloud Infrastructure SDK for Java in your project, import the `oci-java-sdk-bom`, followed by your project dependencies. For example:

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.oracle.oci.sdk</groupId>
      <artifactId>oci-java-sdk-bom</artifactId>
      <version>1.5.2</version>
      <type>pom</type>
    </dependency>
  </dependencies>
</dependencyManagement>
```
<scope>import</scope>
  </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-audit</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-core</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-database</artifactId>
  </dependency>
</dependencies>
<!-- more dependencies if needed -->

**Configuration**

This topic provides details on compatibility, advanced configurations, and add-ons for the Oracle Cloud Infrastructure SDK for Java.

**Security Manager Permissions**

If your application needs to run inside the [Java Security Manager](https://docs.oracle.com/javase/7/docs/api/java/security/package-summary.html), you must grant additional permissions by updating a policy file, or by specifying an additional or a different policy file at runtime.

The SDK requires the following permissions:

- **Required by Jersey:**
  
  ```
  permission java.lang.RuntimePermission "getClassLoader";
  permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
  permission java.lang.RuntimePermission "accessDeclaredMembers";
  permission java.util.PropertyPermission "+", "read,write";
  permission java.lang.RuntimePermission "setFactory";
  ```

- **Required by the SDK to overwrite reserved headers:**
  
  ```
  permission java.util.PropertyPermission "sun.net.http.allowRestrictedHeaders", "write";
  ```

- **Required by the SDK to open socket connections:**
  
  ```
  permission java.net.SocketPermission "+", "connect";
  ```

To include another policy file, in addition to Java Runtime Environment's default policy file, launch the Java Virtual Machine with:

```java
java -Djava.security.manager -Djava.security.policy=</path/to/other_policy>
```

To replace the default policy file, launch the Java Virtual Machine with:

```java
java -Djava.security.manager -Djava.security.policy==</path/to/other_policy>
```

**Note:**

Use a single equals sign (=) when supplying an additional policy file. Use a double equals sign (==) only if you wish to replace the default policy file.
Java Virtual Machine TTL for DNS Name Lookups

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called *time-to-live* (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the `networkaddress.cache.ttl` property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, `-1`, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

  ```
  networkaddress.cache.ttl=60
  ```

- To set TTL only for your application, set the following in your application's initialization code:

  ```java
  java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
  ```

Using the Jersey Default HttpUrlConnectorProvider

Starting with version 2.0.0, the SDK for Java supports using the Jersey `ApacheConnectorProvider` instead of the Jersey default `HttpUrlConnectorProvider` to allow the Apache HttpClient to make OCI service calls.

**To change to the Jersey default connector at the client level**

- For clients that buffer requests into memory:

  ```java
  IdentityClient.builder().clientConfigurator(new JerseyDefaultConnectorConfigurator());
  ```

- For clients that do not buffer requests into memory:

  ```java
  IdentityClient.builder().clientConfigurator(new JerseyDefaultConnectorConfigurator.NonBuffering());
  ```

**Note:**

Overriding the `clientConfigurator` property of the client will revert back to the Jersey defaults. For configuring `clientConfigurator` with the use of Apache Connector, use `additionalClientConfigurator` or `additionalClientConfigurators`.

**To change to the Jersey default connector at the global level**

You can exclude the Apache HttpClient dependencies or use an environment variable.

**Excluding HttpClient Dependencies**

If you are managing dependencies yourself:

- Remove the `org.apache.httpcomponents.httpclient` and `org.glassfish.jersey.connectors.jersey-apache-connector` JARs from the classpath.

If you are using Maven to manage your dependencies:
• Add exclusions for the `org.apache.httpcomponents.httpclient` and
  `org.glassfish.jersey.connectors.jersey-apache-connector` dependencies:

```xml
<dependencies>
  ...
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-common</artifactId>
    <version>...</version>
    <exclusions>
      <exclusion>
        <groupId>org.glassfish.jersey.connectors</groupId>
        <artifactId>jersey-apache-connector</artifactId>
      </exclusion>
      <exclusion>
        <groupId>org.apache.httpcomponents</groupId>
        <artifactId>httpclient</artifactId>
      </exclusion>
    </exclusions>
  </dependency>
  ...
<dependencies>
```

Switching back via environment variable

The SDK for Java provides an environment variable to switch back to the old Jersey
Default Connector at the global level. Set the value of the environment variable :
`OCI_JAVASDK_JERSEY_CLIENT_DEFAULTCONNECTOR_ENABLED` to `true`. By default, this value is set to false.

Switching off auto-close of streams

For API calls that return binary/stream response, the SDK will auto-close the stream once the stream has been completely read. This is because the SDK for Java supports the Apache Connector for sending requests and managing connections to the service. By default, the Apache Connector supports connection pooling. In the cases where the stream from the response is not closed, the connections don't get released from the connection pool.

To disable the auto-close behavior, call
`ResponseHelper.shouldAutoCloseResponseInputStream(false)`.

Choosing connection closing strategies with the Apache Connector to optimize performance

The Apache Connector supports two connection closing strategies:
`ApacheConnectionClosingStrategy.GracefulClosingStrategy` and
`ApacheConnectionClosingStrategy.ImmediateClosingStrategy`.

When using `ApacheConnectionClosingStrategy.GracefulClosingStrategy`, streams returned from a response are read until the end of the stream when closing the stream. This can introduce additional time when closing the stream with a partial read, depending on how large the remaining stream is. To avoid this delay, consider using `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` for large files with partial reads. Note that `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` takes longer when using partial read for smaller stream size (streams smaller than 1MB).

Note:
If these Apache Connection closing strategies do not give you optimal results for your use cases, you can switch back to Jersey Default `HttpUrlConnectorProvider` using the method stated above.

For more information, see: https://github.com/oracle/oci-java-sdk/blob/master/ApacheConnector-README.md.

Using BC-FIPS Instead of Bouncy Castle
If you need FIPS compliance, you must download and use a FIPS-certified version. The SDK supports bc-fips 1.0.2 and bcpkix-fips 1.0.3. You can download them at: https://www.bouncycastle.org/fips-java/

For help installing and configuring Bouncy Castle FIPS, see "BC FIPS Documentation" in the User Guides and Security Policy of the Bouncy Castle Documentation.

Self-Managed Dependencies
If you are managing dependencies yourself:

1. Remove the non-FIPS Bouncy Castle jar files from the class path:
   a. bcprov-jdk15on-1.60.jar
   b. bcpkix-jdk15on-1.60.jar

2. Add the FIPS Bouncy Castle jar files to the class path instead:
   a. bc-fips-1.0.2.jar
   b. bcpkix-fips-1.0.3.jar

Maven-Managed Dependencies
If you are using Maven to manage your dependencies:

1. Add the correct versions of bc-fips and bcpkix-fips to your dependencies:

   <dependencies>
   ...
   <dependency>
     <groupId>bc-fips</groupId>
     <artifactId>bc-fips</artifactId>
     <version>1.0.2</version>
   </dependency>
   <dependency>
     <groupId>bcpkix-fips</groupId>
     <artifactId>bcpkix-fips</artifactId>
     <version>1.0.3</version>
   </dependency>
   ...
   </dependencies>

2. Since you are depending on an oci-java-sdk* package, you need to remove the non-FIPS Bouncy Castle dependencies:

   <dependencies>
   ...
   <dependency>
     <groupId>com.oracle.oci.sdk</groupId>
     <artifactId>oci-java-sdk-common</artifactId>
     <version>. . .</version>
     <exclusions>
       <exclusion>
         <groupId>org.bouncycastle</groupId>
         <artifactId>bcprov-jdk15on</artifactId>
       </exclusion>
       <exclusion>
         <groupId>org.bouncycastle</groupId>
         <artifactId>bcpkix-jdk15on</artifactId>
       </exclusion>
     </exclusions>
   </dependency>
   ...
   </dependencies>

Using Your Own JAX-RS Implementation
The SDK for Java is bundled with Jersey, but you can also use your own JAX-RS implementation.

**RESTEasy Client Configurator Add-On**

The `oci-java-sdk-addons-resteasy-client-configurator` is provided to demonstrate how to configure an alternate JAX-RS implementation. The add-on can be found in the `bmc-addons` directory of the SDK. For details on installation and configuration, see the Readme for the add-on.

For code samples that demonstrate how to configure the client, see:

- `ResteasyClientExample.java`
- `ResteasyClientWithObjectStorageExample.java`
- `InstancePrincipalsAuthenticationDetailsProviderWithResteasyClientExample.java`

Using SLF4J for Logging

Logging in the SDK is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following is an example that enables basic logging to standard out. More advanced logging options can be configured by using the log4j binding.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath (e.g., add it to the `/third-party/lib` directory of the SDK download)
3. Add the following VM arg to enable debug level logging (by default, info level is used):
   ```
   -Dorg.slf4j.simpleLogger.defaultLogLevel=debug
   ```

**Concepts**

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for Java.

**Synchronous Calls**

To make synchronous calls, create an instance of the synchronous client. The general pattern for synchronous clients is that for a service named Example, there will be an interface named ExampleService, and the synchronous client implementation will be called ExampleServiceClient. Here’s an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorage clientWithDefaultClientConfig = new
    ObjectStorageClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorage clientWithExplicitClientConfig = new
    ObjectStorageClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Synchronous calls will block until the response is available. All SDK APIs return a response object (regardless of whether or not the API sends any content back). The response object typically contains at least a request ID that you can use when contacting Oracle support for help on a particular request.

```java
ObjectStorage client = ...;
GetBucketResponse response = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
String requestId = response.getOpcRequestId();
Bucket bucket = response.getBucket();
System.out.println(requestId);
System.out.println(bucket.getName());
```

**Asynchronous Calls**
To make asynchronous calls, create an instance of the asynchronous client. The general pattern for asynchronous clients is that for a service named Example, there will be an interface named ExampleServiceAsync, and the asynchronous client implementation will be called ExampleServiceAsyncClient. Here's an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorageAsync clientWithDefaultClientConfig = new ObjectStorageAsyncClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorageAsync clientWithExplicitClientConfig = new ObjectStorageAsyncClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Asynchronous calls return immediately. You need to provide an AsyncHandler that will be invoked after the call completes either successfully or unsuccessfully:

```java
AsyncHandler<GetBucketRequest, GetBucketResponse> handler = new AsyncHandler<GetBucketRequest, GetBucketResponse>() {
    @Override
    public void onSuccess(GetBucketRequest request, GetBucketResponse response) {
        String requestId = response.getOpcRequestId();
        Bucket bucket = response.getBucket();
        System.out.println(requestId);
        System.out.println(bucket.getName());
    }

    @Override
    public void onError(GetBucketRequest request, Throwable error) {
        error.printStackTrace();
    }
};
```

Future<GetBucketResponse> future = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build(),
    handler);

Polling with Waiters

The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write into an easy-to-use single method call.

Waiters are obtained through the service client (client.getWaiters()). Both a Get<Resource>Request and the desired lifecycle state are passed in to the waiters.for<Resource> method. For example:

```java
public static Instance waitForInstanceProvisioningToComplete(ComputeClient computeClient, String instanceId) throws Exception {
    ComputeWaiters waiters = computeClient.getWaiters();
    GetInstanceResponse response = waiters.getInstance(
        GetInstanceRequest.builder().instanceId(instanceId).build(),
        Instance.LifecycleState.Running)
        .execute();

    return response.getInstance();
}
```
Each `waiters.for<Resource>` method has two versions:

- One version uses the default polling values. For example:
  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState)
  ```

- The other version gives you full control over how long to wait and how much time between polling attempts. For example:
  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState, TerminationStrategy, DelayStrategy)
  ```

### Threading Model

A client becomes thread-safe when it is initialized. After setting its endpoint, you can safely use a client in multiple threads and concurrently call methods on it.

You can reuse a client on multiple requests, both across concurrent threads or within a single thread. Unless the environment's resources are constrained, you should only close the client immediately before it goes out of scope.

**Note:**

This guarantee applies only to the default JAX-RS implementation, Jersey. When using an alternate implementation, you must manage thread safety yourself. For more information, see Configuring the SDK on page 6098.

### Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for Java supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the `UploadManager`, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The `UploadObject` example shows how to use the `UploadManager` to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

### Retries

You can configure the SDK for Java to retry SDK operations that fail. The SDK allows you to specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

**Note:**

Retries are not currently supported for asynchronous clients.

### Delay Strategy

The `delayStrategy` parameter determines how long to wait between each retry call. There are two options for this parameter:

- **FixedTimeDelayStrategy (milliseconds)** - Each retry is delayed by a specified number of milliseconds.

- **ExponentialBackoffDelayStrategy (milliseconds)** - The delay time for subsequent retry calls increases by an exponential factor of 2 until it reaches the defined maximum delay (in milliseconds), with a base value of one millisecond.

The default delay strategy is set to `ExponentialBackoffDelayStrategy` with 30 seconds (30000 milliseconds) of delay.
Developer Tools

Retry Condition
The retryCondition defines a function with an error argument that returns a boolean indicating whether to retry
or not. The operation will be retried if this function returns true.
Termination Strategy
The terminationStrategy parameter defines when to terminate the retry attempts. This parameter supports the
following options:
•
•

MaxTimeTerminationStrategy (milliseconds) - Defines total duration in milliseconds for which
the retry attempts.
MaxAttemptsTerminationStrategy (attempts) - Defines the total number of retry attempts.

Retry Examples
Java
This example shows how to configure and use retries with the SDK for Java:

String profile = "DEFAULT";
// Configuring the AuthenticationDetailsProvider. It's assuming
there is a default OCI config file
// "~/.oci/config", and a profile in that config with the name
"DEFAULT". Make changes to the following
// line if needed and use
ConfigFileReader.parse(configurationFilePath, profile);
final ConfigFileReader.ConfigFile configFile =
ConfigFileReader.parseDefault();

Oracle Cloud Infrastructure User Guide

6107


final AuthenticationDetailsProvider provider =
    new ConfigFileAuthenticationDetailsProvider(configFile);

    // Set the default retry strategy for all operations to set retry
    // attempts to 3
    Retiers.setDefaultRetryConfiguration(
        RetryConfiguration.builder()
            .terminationStrategy(new
                MaxAttemptsTerminationStrategy(3))
            .build());

    // Override the default retry strategy for the identity client and
    // update retry attempts to 4
    final Identity identityClient =
        new IdentityClient(
            provider,
            ClientConfiguration.builder()
                .retryConfiguration(
                    RetryConfiguration.builder()
                        .terminationStrategy(new
                            MaxAttemptsTerminationStrategy(4))
                        .build())
                .build());

    // Override the client's retry strategy for the list regions request
    // and wait for 5ms between retrying
    final ListRegionsRequest listRegionsRequest =
        ListRegionsRequest.builder()
            .retryConfiguration(
                RetryConfiguration.builder()
                    .terminationStrategy(new
                        MaxAttemptsTerminationStrategy(2))
                    .delayStrategy(new
                        FixedTimeDelayStrategy(5L))
                    .build())
            .build();

    final ListRegionsResponse listRegionsResponse =
        identityClient.listRegions(listRegionsRequest);

    System.out.println(listRegionsResponse.getItems());
}

Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client,
making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently
supported in the SDK. The SDK for Java exposes the DefaultRequestSigner class that you can use to create a
RequestSigner instance for non-standard requests.

The Raw Request example on GitHub shows how to:

• create an authentication provider and request signer
• integrate with an HTTP client (Jersey in this example) to authenticate requests

Setting the Endpoints

Service endpoints can be set in three ways.

• Call setEndpoint() on the service instance. This lets you specify a full host name (for example, https://
  www.example.com).
• Call `setRegion()` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for Java returns an error.

• Pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 6051.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

Forward Compatibility and enums

If you have conditional logic based on an enum, be sure that your code handles the `UnknownEnumValue` case to ensure forward compatibility. Some response fields are of type enum, but in the future, individual services may return values not covered by existing enums for that field. To address this possibility, every response field of type enum has an additional value named `UnknownEnumValue`. If a service returns a value that is not recognized by your version of the SDK, then the response field will be set to this value.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains on page 206.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.register` to register the new region, and then you can set the region by either using the configuration file or by calling the `setRegion` method.

**Note:**

Once a region is registered, the federation endpoint is no longer required while using instance principals. For an example, see [https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java](https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java).

oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the `Region` enum for your SDK version.

**Note:**

For the following code samples, be sure to supply the appropriate endpoints for your region.

If you are using version 1.2.34 or later of the SDK for Java, you can pass the new region name as a string using one of the following methods:

• To set the region on a previously created client:

```
client.setRegion("ca-toronto-1");
```

• To set a region when building a new client:

```
Identity identityClient = IdentityClient.builder()
    .region("ca-toronto-1")
    .build(provider);
```

• You can also pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 6051.
Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To specify the endpoint:

```java
AuthenticationDetailsProvider provider =
        new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);

IdentityClient client = IdentityClient.builder()
       .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
       .build(provider);
```

If you are authenticating via instance principals, you can set the endpoint and federationEndpoint via the following process:

```java
InstancePrincipalsAuthenticationDetailsProvider provider =
        InstancePrincipalsAuthenticationDetailsProvider.builder()
       .federationEndpoint("https://auth.ca-toronto-1.oraclecloud.com/v1/x509")
       .build();

IdentityClient identityClient = IdentityClient.builder()
       .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
       .build(provider);
```

Paginated Responses

Some APIs return paginated result sets, so you must check for additional items and if necessary, fetch the next page. You can do so manually or you can use an iterator.

Manually Fetching Pages

The Response objects contain a method to fetch the next page token. If the token is null, there are no more items. If it is not null, you can make an additional request, by setting the token on the Request object, to get the next page of responses.

**Note:**

Some APIs may return a token even if there are no additional results. Be sure to also check whether any items were returned and stop if there are none.

This example shows how to handle page tokens returned by the Object Storage API:

```java
ObjectStorage client = ...;

ListBucketsRequest.Builder builder =
        ListBucketsRequest.builder().namespaceName(namespace);
String nextPageToken = null;
do {
        builder.page(nextPageToken);
        ListBucketsResponse listResponse = client.listBuckets(builder.build());
        List<Bucket> buckets = listResponse.getItems();
        // handle buckets
        nextPageToken = listResponse.getOpcNextPage();
} while (nextPageToken != null);
```
Developer Tools

Using an Iterator

Instead of manually working with page tokens, you can use an iterator. Each service client exposes a `getPaginators()` method that returns a `Paginator` object. This object contains methods to return objects of type `Iterable`. We support two approaches to using `Iterable`:

- **Response Iterator**: You can iterate over the `Response` objects that are returned by the list operation. These are referred to as `ResponseIterators`, and their methods are suffixed with "ResponseIterator," for example, `listUsersResponseIterator`.

```java
Iterable<ListUsersResponse> responseIterator = identityClient.getPaginators().listUsersResponseIterator(request);
for (ListUsersResponse response : responseIterator) {
    for (User user : response.getItems()) {
        System.out.println(user);
    }
}
```

- **Record Iterator**: You can iterate over the resources/records that are listed. These are referred to as `RecordIterator`, and their methods are suffixed with "RecordIterator," for example, `listUsersRecordIterator`.

```java
Iterable<User> recordIterator = identityClient.getPaginators().listUsersRecordIterator(request);
for (User user : recordIterator) {
    System.out.println(user);
}
```

Client-Side Encryption

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the `CreateKey` or `ImportKey` operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

Java Prerequisites

The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171, and 6u16. For those versions and later the policy files are included but not enabled by default.

Current versions of the JDK do not require these policy files. They are provided here for use with older versions of the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.

Examples

The following code example shows how to encrypt a string:

```java
// String encryption example
final byte[] plainText = "Hello World".getBytes();
String masterKeyId = "OCID....";
Map<String, String> context = Collections.singletonMap("Example", "value");

OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
    Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(kmsMasterKey);
```
// Encrypt the data and embed the master key ID in the header
final OciCryptoResult encryptResult =
    ociCrypto.encryptData(kmsMasterKeyProvider, plainText, context);
final byte[] cipherText = encryptResult.getResult();

// Decrypt the data
final OciCryptoResult decryptResult =
    ociCrypto.decryptData(kmsMasterKeyProvider, cipherText);

The following example shows how to encrypt a file stream:

// Create Encryption file stream
FileInputStream in = new FileInputStream(srcFile);
OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
    Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(kmsMasterKey);
OciCryptoInputStream encryptingStream =
    ociCrypto.createEncryptingStream(kmsMasterKeyProvider, in);

// Write the encrypted data to file
FileOutputStream out = new FileOutputStream(srcFile + ".encrypted");
IOUtils.copy(encryptingStream, out);
encryptingStream.close();
out.close();

// For decryption, no need to pass key info
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(authenticationProvider);
// Create the Decryption file stream.
in = new FileInputStream(srcFile + ".encrypted");
OciCryptoInputStream decryptingStream =
    ociCrypto.createDecryptingStream(kmsMasterKeyProvider, in);

// Return the plaintext data
out = new FileOutputStream(srcFile + ".decrypted");
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
out.close();

Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as
the status code or timeout. You can also get the request ID when handling a BmcException by using the
getOpcRequestId method.

This example shows a try-catch block that handles a BmcException and prints the request ID.

ObjectStorage client = ...;
try {
    GetBucketResponse response = client.getBucket(
        GetBucketRequest.builder().namespaceName("myNamespace")
            .bucketName("myBucket")
            .build());
    String requestId = response.getOpcRequestId();
    System.out.println(requestId);
} catch (BmcException e) {
    String requestId = e.getOpcRequestId();
    System.out.println(requestId);
    e.printStackTrace();
Exceptions in the SDK for Java are runtime exceptions (unchecked), so they do not show up in method signatures. All APIs can throw a BmcException.

Examples

GitHub

Examples of SDK usage can be found on GitHub, including:

- Example: Synchronous Object Storage
- Example: Asynchronous Object Storage
- Example: Create an instance
- Example: Get an instance's public IP address

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

SDK Reference

In addition to the examples found on GitHub, the SDK for Java API reference contains code examples that you can copy and modify to run in your own environment.

Running Examples

1. Download the SDK to a directory named oci. See GitHub for the download.
2. Unzip the SDK into the oci directory. For example: $ tar -xf oci-java-sdk-dist.zip
3. Create your configuration file in your home directory (~/.oci/config). See Configuring the SDK on page 6098.
4. Use javac to compile one of the previous example classes from the examples directory, ex:

   ```
   javac -cp lib/oci-java-sdk-full-<version>.jar:third-party/lib/* examples/ObjectStorageSyncExample.java
   ```

5. You should now have a class file in the examples directory. Run the example:

   ```
   java -cp examples:lib/oci-java-sdk-full-<version>.jar:third-party/lib/* ObjectStorageSyncExample
   ```

Third-Party Dependencies and Shading

The SDK requires a number of third-party dependencies, which are available in the third-party/lib directory. To use the SDK library lib/oci-java-sdk-full-<version>.jar, all of the third-party dependencies in third-party/lib have to be on the class path.

The SDK also includes a second version of the SDK library, shaded/lib/oci-java-sdk-full-shaded-<version>.jar, which contains most of the third-party dependencies already. Only a few more third-party libraries in shaded/third-party/lib have to be on the class path when you use this version of the SDK library.

These two versions of the SDK library are functionally the same, however the second version, shaded/lib/oci-java-sdk-full-shaded-<version>.jar can simplify dealing with different versions of third-party dependencies. This is because all the dependencies that are included in shaded/lib/oci-java-sdk-full-shaded-<version>.jar were shaded, which means they will not interfere with other versions of themselves you may want to include along with this SDK.

To use the shaded version of the SDK, replace the `javac` commands in steps 4 and 5 with the following:

• **Step 4:**

```
```

• **Step 5:**

```
```

**Troubleshooting**

This section contains troubleshooting information for the Oracle Cloud Infrastructure SDK for Java.

**Program hangs for an indefinite time**

If a request to the server hangs for an indefinite time, it could be because the connection was not released from the connection pool.

The SDK for Java now supports the Apache Connector for sending requests and managing connections to the service. The Apache Connector supports connection pooling. If a stream is not closed, the connections do not get released from the connection pool, which can result in an indefinite wait time.

The SDK automatically closes the stream to release the connection from the connection pool, but only when the stream is read completely.

To avoid program hangs, be sure to close all streams returned from the response to release the connections from the connection pool to avoid indefinite wait times. For example:

```
GetObjectResponse getObjectResponse = client.getObject(getObjectRequest);
getObjectResponse.getInputStream().close(); // Close the stream OR use try-with-resources
try (final InputStream fileStream = getResponse.getInputStream()) {
} // try-with-resources automatically closes fileStream
```

You can also switch back to the Jersey default connector `HttpUrlConnector`. For more information, see Using the Jersey Default `HttpUrlConnectorProvider` on page 6101.

**Server drops Apache Client Library connection with no response**

In some cases, usually under heavy load, the server receives but does not process a request. This may cause the server to drop the connection to the client without giving any response. The Apache HttpClient throws a `NoHttpResponseException` when it encounters such a condition. In such cases, the underlying Apache HttpClient will retry requests to the server and emit INFO level logs about retries to the server. If the retries fail and the request fails to complete, you should switch back to the Jersey default connector `HttpUrlConnector`. For more information, see Using the Jersey Default `HttpUrlConnectorProvider` on page 6101.

**ObjectStorage client does not close connections when client is closed.**

Too many file descriptors are opened up, and it takes too long to close existing ones. An exception may look like this:

```
Caused by: java.io.FileNotFoundException: classes/caspertest.pem (Too many open files)
at java.io.FileInputStream.open0(Native Method)
at java.io.FileInputStream.open(FileInputStream.java:195)
at java.io.FileInputStream.<init>(InputStream.java:138)
```

Use one of the following workarounds to fix this issue.

• Make this call before creating a client: `System.setProperty("http.keepAlive", "false");`
• Use this command line argument when running Java: `-Dhttp.keepAlive=false`

**Serialization errors when making requests or handling responses**
An UnrecognizedPropertyException error when handling a response indicates that the version of the Jackson library does not support a feature that was injected at runtime from another dependency in your application’s class path. This happens even if the FAIL_ON_UNKNOWN_PROPERTIES deserialization property is set to false for the configured ObjectMapper.

Solution:
Determine which version of Jackson libraries are referenced in your application’s class path and, if necessary, upgrade to version 2.9.5. For a complete list of Jackson libraries that the SDK for Java depends on, please refer to the pom.xml file that is hosted on GitHub.

Note:
If you customize a client when instantiated in your application, ensure that you reference the preconfigured ObjectMapper from the RestClientFactory using the RestClientFactory#getObjectMapper() method.

An alternative solution is to use the shaded version of the SDK for Java jar file, which includes a bundled version of the Jackson libraries.

Encryption key size errors
By default, the SDK for Java can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256.

Use one of the following workarounds to fix this issue.

• Use a 128 bit key, such as AES128.
• Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Troubleshooting Service Errors
Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the SDK. For information about common service errors returned by OCI, see API Errors.

SDK for Python
The Oracle Cloud Infrastructure SDK for Python enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The SDK for Python is available on GitHub or the Python Package Index (PyPi).

Documentation: Available on docs.cloud.oracle.com and readthedocs.io.

Tip:
Cloud Shell: The SDK for Python is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Python from within Cloud Shell, see SDK for Python Cloud Shell Quick Start on page 6053.

Oracle Linux Cloud Developer image: The SDK for Python is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Python, along with other Oracle development tools.

**Installing with yum**

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Python.

The following example shows how to use yum to install the OCI SDK for Python 3.6:

```
sudo yum install python36-oci-sdk
```

This example shows how to use yum to install the OCI SDK for Python 2.7:

```
sudo yum install python-oci-sdk
```

**Client-Side Encryption**

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the CreateKey or ImportKey operations.
The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

Examples
The following code example shows how to encrypt a string:

```python
import oci

# user supplied vars
vault_id = TEST_VAULT OCID
master_key_id = TEST_MASTER_KEY ID
data_to_encrypt_bytes = b"This is a secret message"

config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id
)

kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

crypto_result = crypto.encrypt(kms_master_key_provider,
data_to_encrypt_bytes)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
prompt("unencrypted text: {}".format(crypto_result.get_data()))
```

The following example shows how to encrypt a file stream:

```python
import oci
import shutil

# user supplied vars
vault_id = TEST_VAULT OCID
master_key_id = TEST_MASTER_KEY ID
file_to_encrypt = "/file/to/encrypt/message.txt"
output_encrypted_file = "/tmp/message.txt.encrypted"
output_decrypted_file = "/tmp/message.txt.decrypted"

# setup OCI KMS keys
config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id
)

kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

# encrypt stream example
with open(output_encrypted_file, 'wb') as output_stream,
     open(file_to_encrypt, 'rb') as stream_to_encrypt:
    ciphertext = stream_to_encrypt.read()
with crypto.create_encryption_stream(
    kms_master_key_provider,
    stream_to_encrypt
) as encryption_stream:
    shutil.copyfileobj(encryption_stream, output_stream)

# decrypt stream example
with open(output_decrypted_file, 'wb') as output_stream,
    open(output_encrypted_file, 'rb') as stream_to_decrypt:
    with crypto.create_decryption_stream(
        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)

SDK for TypeScript and JavaScript
The Oracle Cloud Infrastructure SDK for TypeScript and JavaScript enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: GitHub or NPM.

Tip:
The SDK for TypeScript and JavaScript is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Requirements
To use the SDK for TypeScript and JavaScript, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 80. For a list of typical policies you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Getting Started on page 6122.

Versions Supported

The SDK for TypeScript and JavaScript currently supports NodeJS version 14.x and TypeScript version 4.x.

NodeJS & Browser Support

The SDK for TypeScript and JavaScript currently supports NodeJS but does not have browser support.

Questions or Feedback

- GitHub Issues: To file bugs and feature requests only
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-typescript-sdk tags in your post
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Getting Started

This topic describes how to install and configure the SDK for TypeScript and JavaScript.

To use the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript in your project, import any service from ./oci-typescript-sdk/index.ts. For example:

```typescript
// Container Engine
export import containerengine = require("oci-containerengine");

// Core
export import core = require("oci-core");

// Database
export import database = require("oci-database");
```

Downloading the SDK from GitHub

You can download the SDK for TypeScript and JavaScript as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for TypeScript and JavaScript.

For Oracle Linux 8:

```
sudo yum module enable nodejs:14
sudo yum install oci-typescript-sdk
```

For Oracle Linux 7:

```
sudo yum install oracle-nodejs-release-el7
sudo yum install --enablerepo=ol7_developer_nodejs14 --enablerepo=ol7_developer oci-typescript-sdk
```

The oci-typescript-sdk yum package will only work for Node version 10.X.X. The oci-sdk package will be installed into the global node_modules folder. To use the oci-sdk package in a project, link the oci-sdk global package to your local project.

For example:

```
# Assuming you are in your project's top level directory
npm link oci-sdk
# You should now see oci-sdk package in your local project's node_modules folder
```

Because the oci-sdk package is globally installed, you must update the import statements for oci-sdk's sub-packages when running the oci-typescript-sdk examples on GitHub.

For example:

```
import * as identity from "oci-identity"; // Change needed
```
Using the SDK for TypeScript and JavaScript with NPM

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 6051.

The default configuration location is `~/.oci/config` and "DEFAULT" profile is used. You can use `ConfigFileAuthenticationDetailsProvider` with or without specifying the configuration location and profile name:

```typescript
// TypeScript
import common = require("oci-common");
// Using default configuration
const provider: common.ConfigFileAuthenticationDetailsProvider = new common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const provider: common.ConfigFileAuthenticationDetailsProvider = new common.ConfigFileAuthenticationDetailsProvider(
  configurationFilePath,
  configProfile
);
```

```javascript
// JavaScript
const common = require("oci-common");
// Using default configurations
const provider = new common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const provider = new common.ConfigFileAuthenticationDetailsProvider(
  configurationFilePath,
  configProfile
);
```

**Configuring Custom Options**

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

```
[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>
```
Then you can retrieve the value:

```typescript
// TypeScript
import common = require("oci-common");
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile = config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";
```

```javascript
// JavaScript
import common = require("oci-common");
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile = config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";
```

**Concepts**

This topic explains some of the key concepts for using the SDK for TypeScript and JavaScript.

**Raw Requests**

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for TypeScript and JavaScript exposes the DefaultRequestSigner class that you can use to create an instance and call signHttpRequest.

The [Raw Request example on GitHub](#) shows how to create an instance of DefaultRequestSigner and call signHttpRequest.

**Uploading Large Objects**

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for TypeScript and JavaScript supports a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the UploadManager, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage. The UploadObject example shows how to use the UploadManager to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

**Retries**

Starting with version 2.0.0, the SDK for TypeScript and JavaScript is configured by default to retry SDK operations that fail using the default retry policy.

- **Note:**
  Default retry attempts for operations with binary or stream bodies (for example putObject or uploadPart) are only made if the backupBinaryBody property for the default retry configuration is set to true, or if you do not provide the content-length in the request.

If you have already implemented retry logic that does not use the default retry policy feature, this may result in looping retries. To opt-out of the new default retries feature, set the environment variable OCI_SDK_DEFAULT_RETRY_ENABLED to false.
Note:
The default retry configuration and the list of errors that can be retried can be seen on Github.

To change the global default retry configuration programmatically:

```javascript
let retryConfiguration : common.RetryConfiguration = {
    terminationStrategy : new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

Retry Behavior Precedence

- Any retry configuration that you explicitly define at the request level will override the client level retry configuration or the global level default retry configuration and the environment variable override for that specific request.
- Any retry configuration explicitly defined at the client level will override the global default retry configuration and the environment variable level override for the particular client.
- Default retry configuration set at the global level programmatically will override the environment variable level override.

Retry Strategies

You can specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

Delay Strategy

The `delayStrategy` parameter determines how long to wait between each retry call. There are two options for this parameter:

- `FixedTimeDelayStrategy (seconds)` - Each retry is delayed by a specified number of seconds.
- `ExponentialBackoffStrategy (seconds)` - The delay time for subsequent retry calls increases by an exponential factor of 2 until it reaches the defined maximum delay (in seconds), with a base value of one second.

The default delay strategy is set to `ExponentialBackoffDelayStrategy` with 30 seconds of delay.

Retry Condition

The `retryCondition` defines a function with an error argument that returns a boolean indicating whether to retry or not. The operation will be retried if this function returns `true`.

Note:
For all requests with binary/stream bodies, retries are only attempted if `RetryConfiguration.backupBinaryBody` is set to `true`, or if the original stream body is able to be retried. By default, stream bodies will be not be backed up. Stream bodies will only be backed up if `backupBinaryBody` is set to `true` or if you don't provide the content-length in the request.

Termination Strategy

The `terminationStrategy` parameter defines when to terminate the retry attempts. This parameter supports the following options:

- `MaxTimeTerminationStrategy (seconds)` - Defines total duration in seconds for which the retry attempts.
- `MaxAttemptsTerminationStrategy (attempts)` - Defines the total number of retry attempts.

Retry Examples
TypeScript

This example sets the retry configuration at the client level:

```javascript
identityClient.clientConfiguration = {
    retryConfiguration : {
        delayStrategy : new common.FixedTimeDelayStrategy(5),
        terminationStrategy : new common.MaxTimeTerminationStrategy(30),
        retryCondition : (error) => { return error.statusCode >= 500; }
    }
}
```

This example sets the retry configuration at the request level:

```javascript
const request: identity.requests.ListAvailabilityDomainsRequest = {
    compartmentId: tenancyId,
    retryConfiguration : {
        terminationStrategy : new common.MaxAttemptsTerminationStrategy(6),
    }
};
```

To change the default retry condition programmatically:

```javascript
let retryConfiguration : common.RetryConfiguration = {
    terminationStrategy : new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

JavaScript

This example sets the retry configuration at the client level:

```javascript
identityClient.clientConfiguration = {
    retryConfiguration : {
        delayStrategy : new common.FixedTimeDelayStrategy(5),
        terminationStrategy : new common.MaxTimeTerminationStrategy(30),
        retryCondition : (error) => { return error.statusCode >= 500; }
    }
}
```

This example sets the retry configuration at the request level:

```javascript
const request = {
    compartmentId: tenancyId,
    retryConfiguration : {
        terminationStrategy : new common.MaxAttemptsTerminationStrategy(6),
    }
};
```

To change the default retry condition programmatically:

```javascript
let retryConfiguration = {
    terminationStrategy : new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

Circuit Breakers

Starting with version 2.0.0, the SDK for Typescript and Javascript provides default support for circuit breakers. Circuit breakers help prevent the client from overwhelming the service by blocking the requests from being sent to
the service after a certain failure threshold is reached. For default circuit breakers, all errors that can be retried will be treated as failures for the circuit breakers.

**Note:**
The default circuit breaker configuration can be viewed on Github.

To opt out of the default circuit breaker feature, set the environment variable `OCI_SDK_DEFAULT_CIRCUITBREAKER_ENABLED` to `false`. You can also turn the default behavior off programmatically with:

```javascript
common.CircuitBreaker.EnableGlobalCircuitBreaker = false
```

To change the default circuit breaker configuration at the global level:

```javascript
let customDefaultCircuitBreakerConfig = {
  timeout: 10000, // If our function takes longer than 10 seconds, trigger a failure
  errorThresholdPercentage: 80, // When 80% of requests fail, trip the circuit
  resetTimeout: 30000, // After 30 seconds, try again.
  rollingCountTimeout: 120000, // the duration of the statistical rolling window, in milliseconds
  rollingCountBuckets: 120, // the number of buckets the rolling statistical window is divided into
  volumeThreshold: 10, // minimum number of failures in the circuit
  errorFilter: defaultErrorFilterFunction // defines the failure filter for the circuit
};
common.CircuitBreaker.defaultConfiguration = customDefaultCircuitBreakerConfig;
```

**Circuit Breaker Behavior Precedence**

Any circuit breaker configuration that you explicitly define at the client level will override the global default circuit breaker configuration and the environment level override for that client.

For additional information on circuit breakers and the default circuit breaker configuration, see this example on Github.

**Setting Endpoints**

Service endpoints can be set in three ways:

- Set `.endpoint = '<YOUR_ENDPOINT>'` on the service instance. This lets you specify a full host name (for example, `https://www.example.com`).
- Set `.region = '<YOUR_REGION_ID>'` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for TypeScript and JavaScript returns an error. You can refer to the list of regionIds in: ./oci-typescript-sdk/common/lib/region.ts
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

**New Region Support**

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains.
A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for xyz.abc.123.oraclecloud.com is oraclecloud.com.

You must first call Region.register to register the new region, and then you can set the region by either using the configuration file or by set .region = <Your_new_registered_region>.

oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the Region enum for your SDK version.

To set the region:

```javascript
identityClient = await new identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.region = 'us-phoenix-1'
```

Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the endpoint:

```javascript
// Instantiate an identity client
identityClient = await new
identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.endpoint = 'https://<your_endpoint>.com'
```

Paginated Responses

Sometimes it is better to lazy load a result. In order to retrieve more data from lazy load, you have to continue to make calls to the list operation, passing in the value of the most recent response's next token. The pagination module allows you:

- Eagerly load all possible results from a list call
- Lazily load results

For an example on how to use these functions, please check GitHub.

Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or timeout. You can also get the request ID when handling an exception by looking at the opcRequestId property of the error object.

```javascript
try {
    const response = await identityClient.listAllUsersResponses(listUserReq);
} catch (err) {
    console.log('requestId: ', err.opcRequestId);
}
```

Logging

The SDK for Typescript and JavaScript enables you to integrate your own logger. Logging in the SDK is done through the Logger interface. This interface is a logging abstraction that allows the use of a user-supplied logging library, such as log4js, bunyan, or winston.

For more information, see the logging example on GitHub.

To enable logging:

```typescript
// TypeScript
// Download the logger that you want to use with the SDK (like bunyan)
import { LOG } from "oci-sdk";
```
var bunyan = require("bunyan");

// Set the logger here
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;

// Javascript
import { LOG } from "oci-sdk";
var bunyan = require("bunyan");

// Set the logger here.
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;

Examples

GitHub
Examples of SDK usage can be found on GitHub, including:
- Example: Create an instance
- Example: Invoke Oracle Function
- Example: Move Compartment

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

SDK Reference
In addition to the examples found on GitHub, the SDK for TypeScript and JavaScript API reference contains code examples that you can copy and modify to run in your own environment.

Running Examples

Note:
If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

1. git clone the SDK for TypeScript and JavaScript
   git clone https://github.com/oracle/oci-typescript-sdk.git
2. Change to the directory where you installed the oci-typescript-sdk repository.
3. Run npm install
4. Run npm run build
5. If you do not have typescript globally installed, run:
   npm install -g typescript@4.1.3.
   Note: We've tested and support TypeScript version 4.1.3 with the OCI SDK for TypeScript and JavaScript. We cannot guarantee full support for other versions of TypeScript.
6. You can optionally install ts-node globally to make it easier to run examples:
   npm install -g ts-node
7. Create your configuration file in your home directory. See SDK and CLI Configuration File on page 6051 for more information.
8. Change directory into the TypeScript example folder to run TypeScript examples. For example:

```bash
cd ./oci-typescript-sdk/examples/typescript/
```

9. Run any of the examples.

For example, if you're running ts-node:

```bash
ts-node "./identity.ts"
```

If you're not running ts-node:

```bash
tsc ./identity.ts
tsc ./identity.js
```

10. Some examples are available in JavaScript. They are located in the `oci-typescript-sdk/examples/javascript` folder. To run the JavaScript equivalent of the above example:

```bash
node "./identity.js"
```

**SDK for .NET**

The Oracle Cloud Infrastructure SDK for .NET enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** [GitHub](#) or [Nuget](#).

**Requirements**

To use the SDK for .NET, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see **Adding Users** on page 80. For a list of typical policies you may want to use, see **Common Policies**.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see **SDK and CLI Configuration File** on page 6051.
- **.NET Standard version 2.0 or higher**

**Services Supported**

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Classic Migration Service
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data
- Blockchain Platform
- Budgets
- Build
• Certificates
• Compute Instance Agent (Oracle Cloud Agent)
• Container Engine for Kubernetes
• Content Management
• Core Services (Networking, Compute, Block Volume)
• Cloud Guard
• Data Catalog
• Data Flow
• Data Integration
• Data Labeling
• Data Safe
• Data Science
• Data Transfer
• Database
• Database Management
• Database Migration
• Database Tools
• DevOps
• Digital Assistant
• DNS
• Email Delivery
• Events
• File Storage
• Functions
• Generic Artifacts
• GoldenGate
• Health Checks
• IAM
• Integration
• Java Management
• Key Management (for the Vault service)
• Limits
• Load Balancing
• Logging
• Logging Analytics
• Logging Search
• Logging Ingestion
• Management Agent Cloud
• Management Dashboard
• Marketplace
• Monitoring
• Network Load Balancing
• Networking Topology
• Object Storage
• OCI Registry
• Operations Insights
• Operator Access Control
• Optimizer
• Organizations
• OS Management
• Quotas
• Resource Manager
• Roving Edge Infrastructure
• Search
• Secret Management (for the Vault)
• Service Catalog
• Service Connector Hub
• Source Code Management
• Streaming
• Support Management
• Usage
• VMWare Solution
• Vulnerability Scanning
• Web Application Acceleration and Security
• Work Requests (Compute, Database)

Getting Started
This topic describes how to install and configure the SDK for .NET.

To use a specific Oracle Cloud Infrastructure service in your project, you can use the dotnet add package command from the root directory of your project workspace that contains the project file. The syntax for the add package command is:

```
  dotnet add package <PACKAGE_ID> -v <DESIRED_VERSION>
```

If you do not specify a version number, the add package command will install the latest version.

This example installs the latest version of the Core Service package:

```
  dotnet add package OCI.DotNetSDK.Core
```

This example installs version 1.0.0 of the Identity Service package:

```
  dotnet add package OCI.DotNetSDK.Identity -v 1.0.0
```

Note:
To avoid dependency conflicts, you should use the same versions of all OCI.NET SDK Nuget packages within an application.
Downloading the SDK from GitHub

You can download the SDK for .NET as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

Installing the SDK with Yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for .NET.

1. To install the OCI SDK for .NET using yum:
   a. For Oracle Linux 7:
      
      ```
sudo yum-config-manager --enable ol7_developer
sudo yum install oci-dotnet-sdk
      ```
   b. For Oracle Linux 8:
      
      ```
sudo yum-config-manager --enable ol8_developer
sudo yum install oci-dotnet-sdk
      ```

   The OCI Dotnet SDK service packages and its dependencies are located in `/usr/lib/dotnet/NuPkgs/`.

2. So the dotnet CLI can find the installed packages, you must do one of the following:
   a. Create a file named `nuget.config` in the root of your .NET application project and add the following content:

      ```xml
      <?xml version="1.0" encoding="utf-8"?>
      <configuration>
      <packageSources>
      <!--To inherit the global NuGet package sources remove the <clear/> line below -->
      <clear />
      <add key="local" value="/usr/lib/dotnet/NuPkgs" />
      </packageSources>
      </configuration>
      ```
   
   ...or...

   b. Use the `--source` option with the dotnet CLI commands, passing in the directory `/usr/lib/dotnet/NuPkgs/`. For example:

      ```
dotnet build --source /usr/lib/dotnet/NuPkgs/
dotnet restore --source /usr/lib/dotnet/NuPkgs/
dotnet add package OCI.DotNetSDK.Common --source /usr/lib/dotnet/NuPkgs/
      ```

3. To get information about the installed package, run the following command:

   ```
rpm -qi oci-dotnet-sdk
   ```

4. Add the OCI Service packages to your project using the dotnet command line:

   ```
dotnet add package OCI.DotNetSDK.Common
dotnet add package OCI.DotNetSDK.Audit --version 4.3.0
dotnet add package OCI.DotNetSDK.Audit --version 4.3.0 --source /usr/lib/
dotnet/NuPkgs/
      ```

5. You can now import namespaces into your project. For example:

   ```
using Oci.AuditService;
using Oci.AuditService.Models;
using Oci.Common;
using Oci.Common.Auth;
   ```
Using the SDK for .NET with Nuget

**Nuget.**

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 6051.

Next, you need to set up the client to use the credentials. The credentials are abstracted through an IAuthenticationDetailsProvider interface that the client needs to implement.

These examples shows implementations of ConfigFileAuthenticationDetailsProvider and SimpleAuthenticationDetailsProvider.

**Using a Standard Configuration**

If you use standard config file keys and the standard config file location, you can use ConfigFileAuthenticationDetailsProvider:

```csharp
using Oci.Common.Auth;

// uses DEFAULT profile in default file location: i.e ~/.oci/config
var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
// uses custom configuration
var provider = new
    ConfigFileAuthenticationDetailsProvider("custom_file_location", "CUSTOM_PROFILE");
```

**Using a Custom Configuration**

If you are using custom key names in the config file, you can use SimpleAuthenticationDetailsProvider.

To load a config with or without a profile:

```csharp
using Oci.Common;

var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);
var configWithProfile = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH, "DEFAULT");

Next, create an Auth provider using SimpleAuthenticationDetailsProvider:

```csharp
using Oci.Common;
using Oci.Common.Auth;

var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);

// The private key supplier can be created with the file path, or using the config file
var provider = new SimpleAuthenticationDetailsProvider {
    TenantId = config.GetValue("tenancy"),
    UserId = config.GetValue("user"),
    Fingerprint = config.GetValue("fingerprint"),
    Region = Region.FromRegionId(config.GetValue("region")),
    PrivateKeySupplier = new
        FilePrivateKeySupplier(config.GetValue("key_file"),
        config.GetValue("pass_phrase"))
};
```
### Configuring Client-Side Options

Create a client-side configuration through the `ClientConfiguration` class. If you do not provide your own configuration, the SDK for .NET uses a default configuration.

The following example shows how to provide your own configuration:

```csharp
var clientConfiguration = new ClientConfiguration
{
    ClientUserAgent = "DotNet-SDK-Example",
    RetryConfiguration = new RetryConfiguration
    {
        // maximum number of attempts to retry the same request
        MaxAttempts = 5,
        // retries the request if the response status code is in the range
        // [400-499] or [500-599]
        RetryableStatusCodeFamilies = new List<int> { 4, 5 }
    }
};
```

### Configuring Custom Options

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

```
[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>
```

Then you can retrieve the value:

```csharp
using Oci.Common;
var config = ConfigFileReader.parse(ConfigFileReader.DEFAULT_FILE_PATH);
String compartmentId = config.GetValue("customCompartmentId");
```

### Enabling Logging

The OCI SDK for .NET uses the `NLog` package for logging. `NLog` is automatically installed with the .NET SDK, so no additional installation is required.

To enable logging in your project:

1. Add an `NLog.config` file at the project's root directory. You can find an example NLog.config file [here](#).
2. Add an `ItemGroup` section in the project file. For example:

   ```xml
   <ItemGroup>
   <Content Include="PATH TO NLog.config File" />
   <CopyToOutputDirectory>PreserveNewest</CopyToOutputDirectory>
   </Content>
   </ItemGroup>
   
3. To log from an application, create a `Logger` and use the `Info()` method. For example:

   ```csharp
   var logger = NLog.LogManager.GetCurrentClassLogger();
   logger.Info("Hello World");
   ```
**Note:**

Only SDK logging will be captured if you don't create a logger from an application.

**Concepts**

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for .NET.

**Raw Requests**

Raw requests can be useful, and in some cases necessary. Typical use cases include using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, or making a request to a OCI API that is not currently supported in the SDK. The SDK for .NET exposes the `OciHttpClientHandler` class that you can use to create a client handler which signs the request.

This raw request example on GitHub shows how to use the `OciHttpClientHandler`.

**Setting the Endpoints**

Service endpoints can be set in several ways:

- Call `SetEndpoint(<YOUR_ENDPOINT>)` on the service client instance. This lets you specify a full host name (for example, `https://www.example.com`).
- Call `SetRegion(<YOUR_REGION_ID>)` on the service client instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for .NET returns an error.
- Call `SetRegion(<Region>)` on the service client instance. For example, `SetRegion(Region.US_PHOENIX_1)`.
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 6051.

An example on setting endpoint can be found on GitHub.

Note that a service client instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service client instances.

**New Region Support**

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A *region* is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains on page 206.

A *realm* is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.Register()` to register the new region, and then you can set the region by either using the configuration file or by calling the `SetRegion` method.

An example on adding a new region can be found on GitHub.

**oraclecloud.com Realm**

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the `Region` enum for your SDK version.

To set the region:

```csharp
using Oci.IdentityService;

var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetRegion("US_NEWYORK_1");
```
Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the region:

```csharp
using Oci.IdentityService;

var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetEndpoint("https://<your_endpoint>.com");
```

Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for .NET supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the UploadManager, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The UploadObject example shows how to use the UploadManager to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

Retries

You can configure the SDK for .NET to retry SDK operations that fail. The SDK allows you to specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

Delay Strategy

You can define your own delay strategy with the GetNextDelayInSeconds property. The SDK for .NET provides two different Delay Strategies:

- GetFixedDelayInSeconds (seconds) - Each retry is delayed by a specified number of seconds.
- GetExponentialDelayInSeconds - The delay time for subsequent retry calls increases by an exponential factor of 2.

Termination Strategy

You can define a termination strategy with two properties:

- TotalElapsedTimeInSecs (seconds) - Defines total duration in seconds for which the retry attempts.
- MaxAttempts (attempts) - Defines the total number of retry attempts.

Retryable Status Code Families

You can specify a list of status codes to retry using the RetryableStatusCodeFamilies property. For example:

```csharp
// Retryable status code family - this will make the SDK retry for all 5xx status codes:
RetryableStatusCodeFamilies = new List<int>(new int[]{ 5 }),
```

Retryable Errors

This property is a collection of integer and string tuples containing status and error codes returned by a service error for which the SDK can retry. For example:

```csharp
// Retry on the following HTTP status and error codes:
RetryableErrors = new Collection<Tuple<int, string>>(new Tuple<int, string>[] {
    new Tuple<int, string>(409, "IncorrectState"),
});
```
Retry Examples

.NET

This example shows how to configure and use retries with the SDK for .NET:

```csharp
namespace Oci.Examples
{
    public class RetryExample
    {
        private static NLog.Logger logger = NLog.LogManager.GetCurrentClassLogger();
        const string OciConfigProfileName = "DEFAULT";

        public static async Task MainRetry()
        {
            string compartmentId = Environment.GetEnvironmentVariable("OCI_COMPARTMENT_ID");

            // Configuring the AuthenticationDetailsProvider. It's assumed there is a default OCI config file
            // "~/.oci/config", and a profile in that config with the name OciConfigProfileName . Make changes to the following
            // line if needed and use
            var provider = new ConfigFileAuthenticationDetailsProvider(OciConfigProfileName);

            // Create a client for the service to enable using its APIs
            var client = new IdentityClient(provider, new ClientConfiguration());

            try
            {
                await ListOciRegions(client);
                await ListOciRegionSubscriptions(client, compartmentId);
            }
            catch (Exception e)
            {
                logger.Info($"Received exception due to {e.Message}");
            }
        }
    }
}
```
private static async Task ListOciRegions(IdentityClient client)
{
    // Create a retry configuration to override defaults
    RetryConfiguration retryConfiguration = new RetryConfiguration
    {
        // Enable exponential backoff
        GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds,
        // Defines total duration in seconds for which the retry attempts.
        TotalElapsedTimeInSecs = 600,
        // Defines the total number of retry attempts.
        MaxAttempts = 4,
        // Retryable status code family - this will make the SDK retry for all 5xx status codes
        RetryableStatusCodeFamilies = new List<int>(new int[] { 5 }),
        // Retry on the following HTTP status and error codes
        RetryableErrors = new Collection<Tuple<int, string>>(new
            Tuple<int, string>[] {
                new Tuple<int, string>(409, "IncorrectState"),
                new Tuple<int, string>(429, "TooManyRequests")
            })
    };
    // List regions
    var listRegionsRequest = new ListRegionsRequest();
    ListRegionsResponse listRegionsResponse = await client.ListRegions(listRegionsRequest, retryConfiguration);
    logger.Info("List Regions");
    logger.Info("==========");
    {
        logger.Info($"{reg.Key} : {reg.Name}");
    }
}
private static async Task ListOciRegionSubscriptions(IdentityClient client, string compartmentId)
{
    // List RegionSubscriptions
    ListRegionSubscriptionsRequest listRegionSubscriptionsRequest = new ListRegionSubscriptionsRequest
    {
        TenancyId = compartmentId
    };
    RetryConfiguration retryConfiguration = new RetryConfiguration
    {
        // Enable exponential backoff with Full Jitter.
        GetNextDelayInSeconds = GetJitterDelayInSeconds
    };
    ListRegionSubscriptionsResponse listRegionSubscriptionsResponse = await client.ListRegionSubscriptions(listRegionSubscriptionsRequest, retryConfiguration);
    List<RegionSubscription> regionSubscriptions = listRegionSubscriptionsResponse.Items;
    logger.Info("List RegionSubscriptions");
    logger.Info("=================================");
    foreach (RegionSubscription regionSubscription in regionSubscriptions)
    {

logger.Info("{regionSubscription.RegionName} : 
{regionSubscription.RegionKey} ");
}

/// <summary>
/// Defining a custom retry strategy that mimics an exponential
/// backoff with full jitter to reduce
/// contention between competing calls
/// </summary>
private static double GetJitterDelayInSeconds(int retryAttempt)
{
    Random random = new Random();
    return random.NextDouble() * Math.Pow(2, retryAttempt);
}

Paginated Responses
For large result sets, most OCI calls supported paginated responses. Paginated responses require you to make multiple
calls to the list operation, passing in the value of the most recent response's next token. The pagination module allows
you to:
  • Load all possible results from a list call in one call
  • Lazily load results using token-based paginated responses
For an example on how to use these functions, please see GitHub.

Polling with Waiters
The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can
be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the
desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write
into an easy-to-use single method call.
Waiters are obtained through the service client (client.Waiters). Both a Get<Resource>Request and the
desired lifecycle state are passed in to the Waiters.For<Resource> method.
For example:
using Oci.CoreService;
public static Instance WaitForInstanceProvisioningToComplete(ComputeClient computeClient, String instanceId)
{
    GetInstanceRequest getInstanceRequest = new GetInstanceRequest
    { InstanceId = instanceId }; 
    GetInstanceResponse getInstanceResponse = computeClient.Waiters.ForInstance(getInstanceRequest,
    Instance.LifecycleStateEnum.Running).Execute();
    return getInstanceResponse.Instance;
}

Each waiters.for<Resource> method has two versions:
One version uses the default polling values. For example:
Waiters.ForInstance(getInstanceRequest, Instance.LifecycleStateEnum.Running)
The other version gives you full control over how long to wait and how much time between polling attempts. For
example:
using Oci.Common.Waiters;
Some API requests return work request identifiers to track the progress of the request. Waiters can be used to wait until the work request has reached the desired state.

For example:

```csharp
using Oci.Common.Waiters;
using Oci.ContainerengineService;
using Oci.ContainerengineService.Responses;
using Oci.ContainerengineService.Requests;

CreateClusterResponse clusterResponse = await containerEngineClient.CreateCluster(createClusterRequest);
GetWorkRequestResponse workRequestResponse =
    WaitForWorkRequestFinished(containerEngineClient, workRequestId);
private static GetWorkRequestResponse
    WaitForWorkRequestFinished(ContainerEngineClient containerEngineClient, string workRequestId)
    {
        var waiterConfiguration = new WaiterConfiguration
        {
            MaxAttempts = 5,
            GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds
        };
        GetWorkRequestRequest getWorkRequestRequest = new GetWorkRequestRequest
        {
            WorkRequestId = workRequestId
        };
        return
            containerEngineClient.Waiters.ForWorkRequest(getWorkRequestRequest,
                waiterConfiguration, WorkRequestStatus.Succeeded).Execute();
    }
```

Further examples on waiters can be found on Github.

Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or service code. You can also get the request ID when handling an exception by looking at the opcRequestId property of the error object.

For example:

```csharp
try {
    var response = await identityClient.ListAllUsersResponses(listUserReq);
} catch (OciException e) {
    logger.Info("requestId: {0}".Format(e.OpcRequestId));
    logger.Info("StatusCode: {0}".Format(e.StatusCode));
    logger.Info("ServiceCode: {0}".Format(e.ServiceCode));
}
```

Authenticating with Instance Principals
**Instance principals** is an IAM service feature that enables instances to be authorized actors (or principals) that can perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

*Note:*
For more information on instance principals, see Calling Services from an Instance.

While using the .NET SDK on an OCI Instance, you can use `InstancePrincipalsAuthenticationDetailsProvider` class as shown in the following example. You will not need to provide your authentication details when you use this class.

```csharp
using Oci.Common.Auth;
using Oci.IdentityService;

// Creates an Instance Principal provider that holds authentication details of the OCI Instance
var instanceProvider = new InstancePrincipalsAuthenticationDetailsProvider();

// Create a client for the service to enable using its APIs
var client = new IdentityClient(instanceProvider);
```

A full working example of using instance principals with the OCI .NET SDK can be found on GitHub.

**Examples**

**GitHub**

Examples of SDK usage can be found on GitHub, including:

- Example: Create an instance
- Example: Invoke Oracle Function
- Example: Move Compartment

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

**SDK Reference**

In addition to the examples found on GitHub, the SDK for .NET API reference contains code examples that you can copy and modify to run in your own environment.

**Running Examples**

1. Use git to clone the OCI SDK for .NET repository: `git clone https://github.com/oracle/oci-dotnet-sdk.git`
2. Create a configuration file in your home directory (`~/.oci/config`). See SDK and CLI Configuration File on page 6051 for more information.
3. Change directory into the .NET Examples folder. For example: `cd ./oci-dotnet-sdk/Examples/`
4. All of the examples require the environment variable `OCI_COMPARTMENT_ID` populated with the tenant ID or compartment ID.
5. From the command line, run `dotnet run`. The Audit example runs by default.
6. To run any other example, make sure it has a `Main()` function.

**SDK for Go**

The Oracle Cloud Infrastructure SDK for Go enables you to write code to manage Oracle Cloud Infrastructure resources.
This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** Download the SDK from GitHub.

**Documentation:** The reference documentation is available from Oracle here and at godoc.org.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
</table>

**Cloud Shell:** The SDK for Go is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Go from within Cloud Shell, see SDK for Go Cloud Shell Quick Start on page 6056.

**Oracle Linux Cloud Developer image:** The SDK for Go is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

**Requirements**

To use the SDK for Go, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies, you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Configure the SDK.
- Go versions 1.14, 1.15, or 1.16.

**Services Supported**

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Go, along with other Oracle development tools.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Go. GoLang 1.16.3 will also be installed.

For Oracle Linux 7:

```bash
sudo yum-config-manager --enable ol7_developer
sudo yum install go-oci-sdk
```

For Oracle Linux 8:

```bash
sudo yum-config-manager --enable ol8_developer
sudo yum install go-oci-sdk
```

The OCI Go SDK will be located in /usr/share/gocode/src/github.com/oracle/oci-go-sdk.

Golang 1.16.3 enables the go module by default, even when no go.mod is present. You need to turn the go module off to ensure that the OCI Go SDK can be referenced from the filesystem where yum installed the Go SDK. To do so, set the following environment variables:

```bash
export GOPATH=/usr/share/gocode
export GO111MODULE=off
```

SDK for Ruby

The Oracle Cloud Infrastructure SDK for Ruby enables you to write code to manage Oracle Cloud Infrastructure resources.

Note:

The Oracle Cloud Infrastructure SDK for Ruby currently supports Ruby versions 2.6 and 2.7.

Note:

This project is no longer being actively developed by Oracle. We will continue to address security vulnerabilities for the foreseeable future, and will respond to questions on github, but have no plans to introduce any new functionality, and may not be able to address any non-security related issues. We encourage developers to migrate to other OCI SDKs, and developers may fork the project and enhance it as they desire.

This SDK and sample are dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The SDK for Ruby is available on GitHub or RubyGems.

Documentation: SDK for Ruby documentation.

Tip:

The SDK for Ruby is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Ruby.

The following example shows how to use yum to install the OCI SDK for Ruby 2.6 on Oracle Linux 7:

```
sudo yum-config-manager --enable ol7_developer
ds(9) yum install -y oci-ruby-sdk
source /opt/rh/rh-ruby26/enable
export GEM_PATH="/usr/share/gems:`gem env gempath`"
```

The following example shows how to use yum to install the OCI SDK for Ruby 2.6 on Oracle Linux 8:

```
sudo yum-config-manager --enable ol8_developer
sudo yum install -y oci-ruby-sdk
source /opt/rh/rh-ruby26/enable
export GEM_PATH="/usr/share/gems:`gem env gempath`"
```

PL/SQL SDK
The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write PL/SQL code to manage Oracle Cloud Infrastructure resources.

The latest version of the SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

Requirements
To use the PL/SQL SDK, you must have the following:
• An Oracle Cloud Infrastructure account.
• A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 80. For a list of typical policies you may want to use, see Common Policies.
• A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key.

Services Supported
• Analytics Cloud
• Announcements
• API Gateway
• Classic Migration Service
• Audit
• Autoscaling (Compute)
• Big Data
• Blockchain Platform

Examples

This section contains examples of how to use the PL/SQL SDK.

Working with Object Storage Buckets
The following example shows examples of how to use the PL/SQL SDK to create and delete buckets using the OCI Object Storage service:

```sql
-- #################################################################
-- ## Create bucket    ##
-- #################################################################
set serveroutput on
declare
  response_body  dbms_cloud_oci_object_storage_bucket_t;
  response       dbms_cloud_oci_obs_object_storage_create_bucket_response_t;
  bucket_details dbms_cloud_oci_object_storage_create_bucket_details_t;
  json_obj       json_object_t;
  l_keys         json_key_list;
begin
  bucket_details := dbms_cloud_oci_object_storage_create_bucket_details_t();
  bucket_details.name := 'bucketname';
  bucket_details.compartment_id := 'compartment_OCID';

  response := dbms_cloud_oci_obs_object_storage.create_bucket(
    namespace_name => 'namespace-string',
    opc_client_request_id => 'random-request-id',
    create_bucket_details => bucket_details,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

  response_body := response.response_body;

  -- Response Headers
  dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
  json_obj := response.headers;
  l_keys := json_obj.get_keys;
  for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
      json_obj.get(l_keys(i)).to_string);
  end loop;

  -- Response status code
  dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
  dbms_output.put_line(CHR(10));

  -- Response body
  dbms_output.put_line(response_body.namespace);
  dbms_output.put_line(response_body.name);
  dbms_output.put_line(response_body.compartment_id);
  dbms_output.put_line(response_body.metadata.to_string());
  dbms_output.put_line(response_body.created_by);
  dbms_output.put_line(response_body.time_created);
  dbms_output.put_line(response_body.approximate_count);
  dbms_output.put_line(response_body.approximate_size);
  dbms_output.put_line(response_body.etag);
  dbms_output.put_line(response_body.public_access_type);
  dbms_output.put_line(response_body.storage_tier);
  dbms_output.put_line(response_body.freeform_tags.to_string());
  dbms_output.put_line(response_body.defined_tags.to_string());
  dbms_output.put_line(response_body.kms_key_id);
  dbms_output.put_line(response_body.object_lifecycle_policy_etag);
  dbms_output.put_line(response_body.id);
end;
/
set serveroutput on
declare
response       dbms_cloud_oci_obs_object_storage_delete_bucket_response_t;
json_obj       json_object_t;
l_keys         json_key_list;
beginn
response := dbms_cloud_oci_obs_object_storage.delete_bucket(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) || '------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
    json_obj.get(l_keys(i)).to_string);
end loop;

-- Response status code
dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
CHR(10) || response.status_code);
dbms_output.put_line(CHR(10));
end;
/

Working with Object Storage Objects

The following example shows how to use the PL/SQL SDK to store and retrieve objects using the OCI Object Storage service:

declare
my_blob_data   blob;
response       dbms_cloud_oci_obs_object_storage_put_object_response_t;
json_obj       json_object_t;
l_keys         json_key_list;
beginn
/* Some processing producing BLOB data and populating my_blob_data */
response := dbms_cloud_oci_obs_object_storage.put_object(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    object_name => 'objectname',
    put_object_body => my_blob_data,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) || '------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
    json_obj.get(l_keys(i)).to_string);
end loop;
Listing Compartments

The following example shows how to list compartments using the PL/SQL SDK:
```sql
-- ListCompartments
set serveroutput on
declare
response_body dbms_cloud_oci_id_identity_list_compartments_response_t;
response dbms_cloud_oci_id_identity_list_compartments_response_t;
json_obj json_object_t;
l_keys json_key_list;
begindbms_cloud_oci_id_identity.list_compartments( compartment_id => 'compartment_OCID', limit => 2, credential_name => 'OCI_KEY_CRED', region => 'region-identifier');
response_body := response.response_body;
-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) || '------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
dbms_output.put_line(l_keys(i)||':'||json_obj.get(l_keys(i)).to_string);
end loop;
-- Response status code
dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
CHR(10) || response.status_code);
dbms_output.put_line(CHR(10));
-- Response body
dbms_output.put_line('Contents: ' ||
UTL_RAW.cast_to_varchar2(response_body));
end;
/```
Working With Streams

The following example shows how to create and delete stream pools using the PL/SQL SDK:

```
--  #####################################################################
--  # Create stream pool  #
--  #####################################################################
set serveroutput on
declare
    response_body  dbms_cloud_oci_streaming_stream_pool_t;
    response       dbms_cloud_oci_st_stream_admin_create_stream_pool_response_t;
    stream_pool_details
                    dbms_cloud_oci_streaming_create_stream_pool_details_t;
    json_obj       json_object_t;
    l_keys         json_key_list;
begin
    stream_pool_details  :=
                   dbms_cloud_oci_streaming_create_stream_pool_details_t();
    stream_pool_details.name := 'streampoolname';
    stream_pool_details.compartment_id := 'compartment_OCID';
    response := dbms_cloud_oci_st_stream_admin.create_stream_pool(  
        create_stream_pool_details => stream_pool_details,
        opc_request_id       => 'random-request-id',
        credential_name     => 'OCI_KEY_CRED',
        region              => 'region-identifier');
    response_body := response.response_body;
    -- Response Headers
    dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
    json_obj := response.headers;
    l_keys := json_obj.get_keys;
    for i IN 1..l_keys.count loop
        dbms_output.put_line(l_keys(i)||':'||
            json_obj.get(l_keys(i)).to_string);
    end loop;
    -- Response status code
    dbms_output.put_line('Status Code: ' || CHR(10) ||CHR(10) || response.status_code);
    dbms_output.put_line(CHR(10));
    -- Response body
    dbms_output.put_line('id: ' || response_body.id);
    dbms_output.put_line('name: ' || response_body.name);
    dbms_output.put_line('compartment_id: ' || response_body.compartment_id);
    dbms_output.put_line('lifecycle_state: ' || response_body.lifecycle_state);
    for i in 1 .. response_body.private_endpoint_settings.nsg_ids.count loop
        dbms_output.put_line(response_body.private_endpoint_settings.nsg_ids(i));
    end loop;
end;
```
DevOps Tools and Plug-ins

Oracle Cloud Infrastructure provides a number of DevOps tools and plug-ins for working with Oracle Cloud Infrastructure services. These can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery.

**Terraform Provider** - Manage "infrastructure as code" with this component that connects Terraform to a given Oracle Cloud Infrastructure service.
- **Documentation**: Terraform Provider on page 6155
- **Download**: GitHub

**OCI Modules for PowerShell** - A set of cmdlet modules that can be used with PowerShell Core to manage Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.
- **Documentation**: OCI Modules for PowerShell on page 6214
- **Download**: GitHub or PowerShell Gallery

**Ansible Collection** - Automate provisioning and configuring of Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.
- **Documentation**: Ansible Collection on page 6230
- **Download**: GitHub

**Compute Jenkins Plug-in** - Bring up and down services or nodes as required to serve Jenkins Build Jobs and dynamically allocate Oracle Cloud Infrastructure resources for continuous integration tasks.
- **Documentation**: Compute Jenkins Plug-in on page 6249
- **Download**: GitHub

**OCI DevOps Plug-in for Jenkins** - Upload artifacts, and run deployments on Oracle Cloud Infrastructure from Jenkins. A Jenkins master instance with the DevOps plug-in can upload artifacts to the Artifacts Registry repository, and trigger the deployment pipeline for deploying those artifacts.
• **Documentation**: OCI DevOps Plug-in for Jenkins
• **Download**: GitHub

**Chef Knife Plug-in** - Manage Oracle Cloud Infrastructure resources with Chef Knife, a command line tool that provides an interface between a local chef-repo and the Chef server.
• **Documentation**: Chef Knife Plug-in on page 6249
• **Download**: GitHub

**Grafana Plug-in** - Visualize metrics from the Monitoring service in your Grafana instance.
• **Documentation**: Grafana Plug-in on page 6250
• **Download**: GitHub

**Terraform Kubernetes Installer** - Provision and configure the resources needed to run a highly available and configurable Kubernetes cluster.
• **Download**: GitHub

**Kubernetes Volume Provisioner** - Enable dynamic provisioning of storage resources when running Kubernetes on Oracle Cloud Infrastructure.
• **Download**: GitHub

**DevOps Integrations**

• **Jenkins X Integration**: Create a new Kubernetes cluster on Oracle Cloud Infrastructure Container Engine for Kubernetes.
• **Packer Integration**: Create reusable custom images.

**Other Services and Features for DevOps**

Oracle Cloud Infrastructure provides other services and features relevant to DevOps professionals.
• **Container Engine for Kubernetes (OKE)** Reliably build, deploy, and manage cloud-native containerized applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing tenancy.
• **Oracle Cloud Infrastructure Registry** Store, share, and manage development artifacts like Docker images. As Oracle Cloud Infrastructure Registry is managed by Oracle, your applications are deployed reliably and you don't have to deal with operational issues.

**Terraform Provider**

Terraform is an open source tool that allows you to programmatically manage, version, and persist infrastructure through the "infrastructure-as-code" model. Terraform configurations codify your infrastructure in declarative files that contain the steps required to provision your infrastructure and maintain its state. You can share these files among team members, treat them as code, edit, review, and version them.

Terraform uses providers to interface between the Terraform engine and the supported cloud platform. The Oracle Cloud Infrastructure (OCI) Terraform provider is a component that connects Terraform to the OCI services that you want to manage.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Storing Sensitive Data on page 6189 for more information.</td>
</tr>
</tbody>
</table>

You can use the OCI Terraform provider to manage OCI resources wherever you use a Terraform distribution, including Terraform Cloud and the OCI Resource Manager. Oracle Public Cloud has its own Terraform provider. Resource Manager is an Oracle Cloud Infrastructure service that uses Terraform to automate the process of provisioning your Oracle Cloud Infrastructure.
Tip:
You can migrate existing Terraform state files to Resource Manager using an Import State job.

See Getting Started to begin using the Terraform provider to manage your OCI resources.

Licensing: This provider and samples are licensed under the Mozilla Public License 2.0; third-party content is separately licensed as described in the code.

Availability
The Oracle Cloud Infrastructure Terraform provider is region agnostic. You can use the Terraform provider to work with supported services in all Oracle Cloud Infrastructure regions in which they are available. Government Cloud customers should use the FIPS-compatible OCI Terraform provider.

See Regions and Availability Domains on page 206 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Contributions
Got a fix for a bug, or a new feature you’d like to contribute? The Terraform provider is open source and accepting pull requests on GitHub.

Notifications
To be notified when a new version of the OCI Terraform provider is released, subscribe to the Atom feed.

Questions or Feedback
Refer to Troubleshooting Basics and a list of common issues to see if your question has an answer.

You can also use GitHub to file bugs and submit feature requests.

What's New
Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules all have the ability to introduce changes or add new functionality.

Terraform Updates
Major Terraform releases might include changes in behavior you should consider when upgrading.

Terraform v0.14
The Oracle Cloud Infrastructure (OCI) Terraform provider now supports Terraform v0.14.

Terraform v0.14 changes the output of the `terraform plan` command and introduces a dependency lock file you can use to track the version of the (OCI) Terraform provider used to interact with your OCI resources.

Refer to the official Terraform v0.14 upgrade guide for more information.

Concise Terraform plan output
To reduce the verbosity of `terraform plan` output, Terraform output now omits any attribute that has not changed, except for some attributes whose values often contain human-recognizable identifying information.

You can temporarily re-enable verbose output by setting the environment variable `TF_X_CONCISE_DIFF=0` when you run Terraform.

Sensitive values in Terraform plan output
Because Terraform v0.14 tracks expressions whose result is derived from a sensitive input variable or sensitive output value, you might find that more values are obscured in the `terraform plan` output than would have been in earlier versions.

If a different module uses a value in its output that was derived from a sensitive variable or value, you must set `sensitive = true` in the output of the second module.

Provider dependency lock file
In Terraform v0.13 and earlier, the `terraform init` command would always install the newest version of any provider in the configuration that would meet the configured version constraints. To keep the behavior of an already
tested configuration as stable as possible unless intentionally changed by the user, Terraform v0.14 introduces a new dependency lock file.

Terraform generates this file automatically after running `terraform init` in the same directory as the configuration's root module. The dependency lock file includes the specific version numbers selected for each provider, including the OCI Terraform provider. After running `terraform init` for the first time after upgrading to Terraform v0.14, you will find a new file `.terraform.lock.hcl` in your root module directory. Future initializations of Terraform automatically read and respect the entries in that file.

Because of this new feature, manually placing extra plugins into the local cache directory `.terraform/plugins` is no longer effective.

**Terraform v0.12**

If upgrading to Terraform v0.12, the Oracle Cloud Infrastructure (OCI) Terraform provider and some existing configurations might need to be updated as well.

See **Upgrading Configurations to Terraform v0.12** on page 6178 for detailed information.

**Tutorials**

For step-by-step instructions and examples of using Terraform and Oracle Cloud Infrastructure, see the following tutorials:

- Set Up the OCI Terraform Provider
- Create a Compartent
- Create a Compute Instance
- Create a Virtual Cloud Network
- Set Up a Simple Infrastructure
- Create a Kubernetes Cluster
- Set Up Resource Discovery
- Create Scripts and State Files with Resource Discovery
- HashiCorp Learn: Get Started with Oracle Cloud Infrastructure

**For More Information**

For more information, see the following resources:

- Blog: Getting Started Using Terraform with OCI

**Examples, Templates, and Solutions**

The Oracle Cloud Infrastructure (OCI) Terraform provider uses Terraform configuration files to manage your OCI infrastructure.

Referring to existing example configurations, sample solutions, and templates can help you understand HashiCorp Configuration Language format (HCL) and see how it is used to define OCI resources.

You can also modify examples or entire solution sets to meet your needs.

**Example Configurations**

We provide many example Terraform configuration files that show you how to create specific OCI resources. These examples are intended to be as simple as possible. In most cases, they contain only the specific resource and any dependencies required for it to run.

Examples are grouped by service, including Compute, Database, Networking, Load Balancing, and several others.

These do not represent production configurations or real world scenarios, but they can serve as a starting point and be modified and combined as necessary.

**Templates**

Oracle also provides templates for Resource Manager. Resource Manager uses Terraform to automate deployment and operations for OCI resources.
Templates can help those new to infrastructure-as-code and those who are updating production configurations. Use templates to try out Resource Manager and inspect the underlying oracle-terraform-modules to familiarize yourself with Terraform configuration files.

Architecture Center

The Oracle Architecture Center contains reference architectures, solution playbooks, and best practices. You can filter the content to see Terraform-specific information that you can use with the OCI Terraform provider or Resource Manager.

Guides

This section describes how to configure the Oracle Cloud Infrastructure (OCI) Terraform provider for specific use cases and write Terraform configuration files that manage specific OCI resources.

See the following topics for additional information:

- Authoring Configurations on page 6158
- Specifying Versions on page 6164
- Enabling FIPS Compatibility on page 6166
- Managing Volumes on page 6171
- Migrating an Exadata DB System to the New Resource Model on page 6174
- Targeting Multiple Regions on page 6176
- Upgrading Configurations to Terraform v0.12 on page 6178
- Using Object Storage for State Files on page 6181

Authoring Configurations

Using Terraform, you can describe your Oracle Cloud Infrastructure using the HashiCorp Configuration Language format (HCL) in Terraform configuration files (see Configuration Syntax). Terraform configuration files can use either of two formats: Terraform domain-specific language (HashiCorp Configuration Language format [HCL]), which is the recommended approach, or JSON format if the files need to be machine-readable. Configuration files that use the HCL format end with the .tf file extension; those using JSON format end with the .tf.json file extension. The Terraform format is human-readable, while the JSON format is machine readable.

Use Terraform configurations to define your Oracle Cloud Infrastructure (OCI) resources, variable definitions, data sources, and a great deal more. Terraform, then, converts your OCI configurations into a set of API calls against OCI API endpoints. The key to writing Terraform configuration is understanding how to abstract the wanted infrastructure conceptually into Terraform configuration syntax.

Important:

While the Oracle Cloud Infrastructure API uses camelCase extensively, Terraform does not support camelCase in configuration files. For this reason, in the configurations you see underscores rather than capitalization as separators. For example, where the API uses availabilityDomain, the Terraform configuration uses availability_domain.

Configuration File Requirements

Terraform configuration (.tf) files have specific requirements, depending on the components that are defined in the file. For example, you might have your Terraform provider defined in one file (provider.tf), your variables defined in another (variables.tf), your data sources defined in yet another.

Note:

For example configuration files, see Terraform Provider Examples on the Oracle Cloud Infrastructure GitHub.

Provider Definitions

The following example using Terraform syntax illustrates the requirements for an OCI Terraform provider definition, and also shows associated variable definitions. The provider definition relies on variables so that the configuration
file itself does not contain sensitive data. Including sensitive data creates a security risk when exchanging or sharing configuration files.

```hcl
variable "tenancy_ocid" {} 
variable "user_ocid" {} 
variable "fingerprint" {} 
variable "private_key_path" {} 
variable "region" {} 

provider "oci" { 
  tenancy_ocid = "${var.tenancy_ocid}" 
  user_ocid = "${var.user_ocid}" 
  fingerprint = "${var.fingerprint}" 
  private_key_path = "${var.private_key_path}" 
  region = "${var.region}" 
}
```

The `region` attribute specifies the geographical region in which your provider resources are created. To target multiple regions in a single configuration, you simply create a provider definition for each region and then differentiate by using a provider alias, as shown in the following example. Notice that only one provider, named "oci" is defined, and yet the `oci` provider definition is entered twice, once for the `us-phoenix-1` region (with the alias "phx"), and once for the region `us-ashburn-1` (with the alias "iad").

```hcl
variable "tenancy_ocid" {} 
variable "user_ocid" {} 
variable "fingerprint" {} 
variable "private_key_path" {} 
variable "compartment_ocid" {} 

provider "oci" { 
  region = "us-phoenix-1" 
  alias = "phx" 
  tenancy_ocid = "${var.tenancy_ocid}" 
  user_ocid = "${var.user_ocid}" 
  fingerprint = "${var.fingerprint}" 
  private_key_path = "${var.private_key_path}" 
}

provider "oci" { 
  region = "us-ashburn-1" 
  alias = "iad" 
  tenancy_ocid = "${var.tenancy_ocid}" 
  user_ocid = "${var.user_ocid}" 
  fingerprint = "${var.fingerprint}" 
  private_key_path = "${var.private_key_path}" 
}
```

For more information, see Provider Configuration.

Variable Definitions

Variables in Terraform represent parameters for Terraform modules. In variable definitions, each block configures a single input variable, and each definition can take any or all of three optional arguments:

- **type** (optional): Defines the variable type as one of three allowed values: `string`, `list`, and `map`. If this argument is not used, the variable type is inferred based on `default`. If no `default` is provided, the type is assumed to be `string`.
- **default** (optional): Sets the default value for the variable. If no default value is provided, the caller must provide a value or Terraform throws an error.
- **description** (optional): A human-readable description of the variable.
Following are examples of several variable definitions. Some definitions include optional parameters.

```hcl
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

variable "AD" {
    default     = "1"
    description = "Availability Domain"
}

variable "CPUCoreCount" {
    default = "2"
    type    = "string"
}
```

For more information, see Input Variable Configuration. See also Input Variables.

Output Configuration

Output variables provide a means to support Terraform end-user queries. This allows users to extract meaningful data from among the potentially massive amount of data associated with a complex infrastructure. For example, you might be interested only in a handful of key values at any given time and defining output variables allows you to extract exactly the information that you need.

Following is a simple example in which only a few output variables (instance IP addresses and boot volume IDs) are defined:

```hcl
# Output the private and public IPs of the instance
output "InstancePrivateIDs" {
    value = ["${oci_core_instance.TFInstance.*.private_ip}"]
}

output "InstancePublicIDs" {
    value = ["${oci_core_instance.TFInstance.*.public_ip}"]
}

# Output the boot volume IDs of the instance
output "BootVolumeIDs" {
    value = ["${oci_core_instance.TFInstance.*.boot_volume_id}"]
}
```

For more information, see Output Variables. See also Output Configuration.

Resources

Resources are components of your Oracle Cloud Infrastructure. These resources include everything from low-level components such as physical and virtual servers, to higher-level components such as email and database providers, your DNS record.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

---

**Caution:**

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Sensitive Data in State for more information.
Declaring Resources

Following is a simple example of a resource definition that illustrates their basic structure.

```hcl
resource "oci_core_virtual_network" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = "$\{var.compartment_ocid\}\"
  display_name = "vcn1"
}
```

The resource declaration on the first line of the example uses the keyword "resource" and takes two parameters, resource type and resource name ("oci_core_virtual_network" and "vcn1" in the example). Inside the code block, then, is the resource configuration.

For more information, see Resource Configuration.

Resource Dependencies

When a resource references another resource within its resource block, Terraform automatically infers the primary resource's dependency on the referenced resource. A resource might also depend on resources that are not explicitly referenced within its block. For example, you might need to create policies for a resource before creating the resource itself.

To define hidden dependencies that Terraform cannot automatically infer, you can use the depends_on meta-argument in the resource block.

The following example creates an oci_datascience_notebook_session resource and an oci_identity_policy resource for related policies. Adding the depends_on meta-argument to the oci_datascience_notebook_session resource ensures that the policies are created first:

```hcl
resource "oci_datascience_notebook_session" "ods-notebook-session" {
  count = var.enable_ods ? var.ods_number_of_notebooks : 0

  #Required
  compartment_id = var.compartment_ocid

  notebook_session_configuration_details {
    #Required
    shape = var.ods_compute_shape
    subnet_id = local.private_subnet_id

    #Optional
    block_storage_size_in_gbs = var.ods_storage_size
  }

  project_id = oci_datascience_project.ods-project[0].id

  display_name = "$\{var.ods_notebook_name\}-\{\{count.index\}\}"

  depends_on = ["oci_identity_policy.ods-policy"]
}
```

```hcl
resource "oci_identity_policy" "ods-policy" {
  provider = oci.home
  compartment_id = var.compartment_ocid
  description = "Data Science Policies"
  name = var.ods_policy_name
  statements = var.enable_vault ? concat(local.ods_policies , local.vault_policies) : local.ods_policies
}
```
Referencing Resources in Another Stack

You can reference resources that exist in other stacks. The Terraform `remote_state` data source allows you to read output variables from state files.

For example, when writing a Terraform configuration for a new web application, you can make the web application use the subnet previously created from your network stack, as long as the required subnet values were output in the network stack state file. In the Terraform configuration for your new web application, do the following:

- Pull the state file of the existing network stack into the context of your current Terraform configuration.
- Load the pulled state file to a data source for remote state files.
- Populate the subnet data source in your current configuration with values from the relevant output variables of the referenced state file.
- Optionally print the identifying information for the populated data source to confirm expected values.

**Note:**

In addition to permissions required for Resource Manager operations, you’ll need appropriate permissions for resource types you’re referencing, in the compartment that you’re referencing them. In this example, you need read permissions for network resources in the compartment where they’re located.

The following Terraform configuration excerpt references a subnet in another stack:

```terraform
# The following example assumes that the source stack (defined by `stack_id`) has output a value named `subnet_id` # Terraform v0.12 is assumed
variable "stack_id" {}

# Pull the state file of the existing Resource Manager stack (the network stack) into this context
data "oci_resourcemanager_stack_tf_state" "stack1_tf_state" {   stack_id = "$\{var.stack_id\}"   local_path = "stack1.tfstate" }

# Load the pulled state file into a remote state data source
data "terraform_remote_state" "external_stack_remote_state" {   backend = "local"   config = {     path = "$\{data.oci_resourcemanager_stack_tf_state.stack1_tf_state.local_path\}"   } }

# Populate a data source in this configuration using a value from the remote state data source
data "oci_core_subnet" "subnet1" {   subnet_id = "$\{data.terraform_remote_state.external_stack_remote_state.outputs.subnet_id\}" }

# Print the values of the populated data source
output "print-subnet1" {   value = "$\{data.oci_core_subnet.subnet1\}" }
```

Data Sources
Data sources represent read-only views of existing infrastructure intended for semantic use in Terraform configurations. Following is a simple example of a data source configuration to illustrate its basic structure:

```hcl
# Gets a list of Availability Domains
data "oci_identity_availability_domains" "ADs" {
    compartment_id = "${var.tenancy_ocid}"}

# Get DB node list
data "oci_database_db_nodes" "DBNodeList" {
    compartment_id = "${var.compartment_ocid}".
    db_system_id = "${oci_database_db_system.TFDBNode.id}"}

# Get DB node details
data "oci_database_db_node" "DBNodeDetails" {
    db_node_id = "${lookup(data.oci_database_db_nodes.DBNodeList.db_nodes[0],
"id")}"}

# Gets the OCID of the first (default) vNIC
data "oci_core_vnic" "DBNodeVnic" {
    vnic_id = "${data.oci_database_db_node.DBNodeDetails.vnic_id}"}

For more information, see Data Source Configuration.

Filtering Data Sources

Data sources that return lists of resources support filtering semantics. To use a filter, include this block in your data source definition:

```hcl
filter {
    name = ""
    values = ["""
}
```

The `name` value corresponds to the qualified property name to filter with and the `values` lists can contain one or more values filter with.

Nested properties and map elements can be addressed by qualifying the property name with parent property name. Example `r1` will give all the instances which have `source_type` image. Example `r2` will give all the instances which contain a defined tag with value "42" for key CostCenter in the namespace Operations.

```hcl
data "oci_core_instances" "r1" {
    ...
    filter {
        name = "source_details.source_type"
        values = ["image"]
    }
}

data "oci_core_instances" "r2" {
    ...
    filter {
        name = "defined_tags.Operations.CostCenter"
        values = ["42"]
    }
}
Multiple values work as an **OR** type filter. In the shape example below, the resulting data source would contain both VM shapes **Standard 1.1** and **Standard 1.2**:

```hcl
data "oci_core_shape" "t" {
  ... 
  filter {
    name = "name"
    values = ["VM.Standard1.1", "VM.Standard1.2"]
  }
}
```

Multiple filters blocks can be composed to form **AND** type comparisons. The example below will return a data source containing **running instances** in the **first AD** of a region:

```hcl
data "oci_core_instances" "s" {
  ... 
  filter {
    name = "availability_domain"
    values = ["\w*-AD-1"]
    regex = true
  }
  filter {
    name = "state"
    values = ["RUNNING"]
  }
}
```

As shown above, filters can also employ regular expressions. By setting `regex = true`, each item in the `values` list will be treated as a regular expression. Backslashes in strings for regular expression special characters need to be escaped with another slash, shown above as the first `\` before `\w` in "\w*-AD-1".

**Note:**
Drilling into lists of structured objects is not currently supported. If these properties are targeted no results will be returned from the datasource.

**Functions**

Terraform offers a number of built-in functions that you can use in your configuration files. These functions allow you to modify strings, perform calculations against numeric values, manage collections, and much more.

For more information, see [Functions](#).

**For More Information**

- [Creating Terraform Modules](#)
- [Terraform Configurations](#)
- [Terraform Configuration Syntax](#)

**Specifying Versions**

Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules you call in your configuration files all introduce changes or add new functionality from time to time. As these changes are made, new versions are released.

In order to ensure that your configurations are applied consistently to OCI resources, you can explicitly set the version of these components in Terraform configuration files.

**Terraform CLI Version**
If your Terraform configuration requires that you use a particular version of the Terraform CLI, you can specify that within the `terraform` block using the `required_version` setting. For example:

```terraform
terraform {
  required_version = ">= 0.12.16"
}
```

For more information, see [Specifying a Required Terraform Version](#).

**Note:**
- Resource Manager manages the Terraform version based on the stack version. Any CLI version specified is ignored by Resource Manager.

### Provider Version

You can control the version of the OCI Terraform provider that Terraform uses when interacting with OCI resources. This ability is especially helpful when your configuration relies on features introduced with a particular version of the provider or it has only been tested with a particular version of the provider.

You can use the `>=` or `=` operators to specify the version, depending on your use case.

For more information, see [Specifying Provider Requirements](#).

#### Using Terraform v0.12 or earlier

Terraform v0.12 or earlier allowed you to specify `version` within the `provider` block. For example:

```terraform
provider "oci" {
  version          = ">= 3.27.0"
  region           = "${var.region}"
  ...
}
```

#### Using Terraform v0.13

Terraform v0.13 deprecated `version` within `provider` blocks. Instead, versions should be specified within a `required_providers` block. For example:

```terraform
terraform {
  required_providers {
    oci = {
      source  = "hashicorp/oci"
      version = ">= 4.0.0"
    }
  }
  ...
}
```

### Module Version

In addition to specifying the version of the Terraform CLI and the OCI Terraform provider, you can also specify the version of Terraform modules.

If a module has been upgraded to use a newer version of Terraform core, but you still use an earlier version of Terraform, you can specify a compatible version of the module. If your configurations have only been tested with a specific version of the module, you can specify that version to ensure compatibility.

Modules accept the `version` argument. For example:

```terraform
module "oke" {
  source  = "oracle-terraform-modules/oke/oci"
  version = "1.0.0"
}
```
FIPS encryption

To ensure the highest security standards, traffic from Terraform to OCI endpoints should transit over a TLS connection established with an HTTP client using FIPS certified encryption.

The standard OCI Terraform provider is implemented in Go. Go’s native cryptography implementations, while fully capable of establishing secure TLS connections with OCI endpoints, have not been FIPS certified.

For Terraform traffic to transit to OCI endpoints over FIPS-compliant connections, you must use a special version of the Terraform provider that uses FIPS certified cryptography. This version of the OCI Terraform provider uses the FIPS 140-2 certified Oracle Cloud Infrastructure Cryptographic Library for Kubernetes instead of Go’s native cryptography implementation. Read more about the Oracle Cloud Infrastructure Cryptographic Library for Kubernetes here.

Installing the FIPS-Compliant Terraform Provider

The FIPS-compliant OCI Terraform provider is only available for Oracle Linux. You can install the provider using yum.

Tip:
Before installing the OCI Terraform provider, download and install Terraform from HashiCorp, or install Terraform using yum.

If any existing OCI Terraform provider packages are already installed on the Oracle Linux machine, remove them first:

```
yum remove terraform-provider-oci
```

Install the FIPS-compatible OCI Terraform provider by running the following yum command from an Oracle Linux machine:

```
yum install terraform-provider-oci-fips
```

Configuring the Terraform Provider

1. Add an environment variable to set the target region for Terraform:

```
echo "export TF_VAR_region='<your_region>'" >> ${HOME}/.bash_profile
```

2. Add an environment variable to disable interprocess traffic encryption between Terraform and the OCI Terraform provider:

```
echo "export TF_DISABLE_PLUGIN_TLS=1" >> ${HOME}/.bash_profile
```

3. Add an environment variable to prevent Terraform from accessing the HashiCorp Checkpoint service:

```
echo "export CHECKPOINT_DISABLE=1" >> ${HOME}/.bash_profile
```

4. Configure the authentication method for the Terraform provider. See Authentication for more information.

Operating Terraform in a Single Region
To ensure that traffic between Terraform and OCI services does not transit over public internet infrastructure, we recommend that you run Terraform and the OCI Terraform provider from a Compute instance that is hosted in the same region as the resources they create and manage.

Creating a Compute Instance

After Terraform and the OCI Terraform provider are installed on an Oracle Linux machine, you can use Terraform and the following sample Terraform configuration file to:

- Create a designated compute instance you can use to provision additional infrastructure within the same region.
- Install Terraform and the latest FIPS compliant OCI Terraform provider on the new instance.
- Restrict communication with the instance to OCI endpoints and HTTPS using a service gateway.
- Enable instance principal authentication.

See Authoring Configurations on page 6158 for more information.

To create the compute instance:

1. Copy the main.tf file to your Oracle Linux machine.
2. Gather the information required to populate the Terraform configuration file's variables.
3. Refer to Platform Images on page 1013 to locate the Oracle Linux image OCID value for your region. Modify the oel-image value in the Terraform configuration file.
4. Initialize Terraform in the directory that contains the Terraform configuration file:

   ```bash
   terraform init
   ```

5. Apply the Terraform configuration:

   ```bash
   terraform plan
terraform apply
   ```

**Important:**

The instance-ip output variable provides the IP address you will need to use to sign in to the new compute instance.

```haskell
main.tf

variable "tenancy_ocid" {
}

variable "user_ocid" {
}

variable "fingerprint" {
}

variable "private_key_path" {
}

variable "region" {
}

variable "compartment_ocid" {
}

variable "ssh_public_key" {
}

variable "ssh_private_key" {
}
```
locals {
  prefix    = "terraform"
  oel-image = "<Oracle_Linux_image_OCID>"
  vm-shape  = "VM.Standard2.1"
}

user-data = <<EOF
#!/bin/bash -x
echo "export TF_VAR_auth='InstancePrincipal'" >> ~/.bash_profile
echo "export TF_VAR_region='${var.region}'" >> ~/.bash_profile
yum install -y terraform terraform-provider-oci-fips
EOF
EOF
}

provider "oci" {
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
  region           = var.region
}

  }

  create_vnic_details {
    subnet_id = oci_core_subnet.subnet1.id
    assign_public_ip = true
  }
}

output "instance-ip" {
  value = [oci_core_instance.instance1.public_ip]
}

Signing in to the Instance

Use the following SSH command to access the instance:

$ ssh -i <private_key_path> <username>@<instance_ip_address>

<private_key_path> is the full path and name of the file that contains the private key associated with the instance you want to access.

$username> is the default username for the instance. For Oracle Linux images, the default username is opc.

$instance_ip_address> is the instance IP address that was the output of the Terraform commands.

Installing and Configuring Terraform on the Instance

1. Use yum to install Terraform and the FIPS compatible OCI Terraform provider on the instance:

    yum install -y terraform terraform-provider-oci-fips

2. Add an environment variable to enable instance principal authentication to the bash profile:

    echo "export TF_VAR_auth='InstancePrincipal'" >> $(HOME)/.bash_profile

3. Add an environment variable to set the target region for Terraform:

    echo "export TF_VAR_region='<your_region>" >> $(HOME)/.bash_profile
4. Add an environment variable to disable interprocess traffic encryption between Terraform and the OCI Terraform provider:

```bash
echo "export TF_DISABLE_PLUGIN_TLS=1" >> ${HOME}/.bash_profile
```

5. Add an environment variable to prevent Terraform from accessing the HashiCorp Checkpoint service:

```bash
echo "export CHECKPOINT_DISABLE=1" >> ${HOME}/.bash_profile
```

6. Exit the instance:

```bash
exit
```

Implementing Security Rules

Before using the new instance to run Terraform, you should update the security rules to prevent egress traffic to any third-party endpoints other than OCI services. You can do this by removing the following egress rule from the Terraform configuration file's `security-list1` resource and running `terraform apply` from the Oracle Linux machine:

```bash
// outbound tcp traffic on all ports
// remove this rule or comment it out to prevent egress traffic to third-party endpoints
#egress_security_rules {
  # destination = "0.0.0.0/0"
  # protocol    = "6"
  #}
```

**Tip:**

You can also use the OCI Console to update your security rules on the new instance.

Running Terraform from the Instance

After creating the instance, installing and configuring Terraform on the instance, and updating the security rules, you can use Terraform to provision additional OCI infrastructure within the same region. Copy any additional Terraform configuration files to your instance, sign in to the instance, and run your Terraform commands like any other Terraform provider:

```bash
ssh -i <private_key_path> opc@<instance_ip_address>
terraform init
terraform apply
```

Managing Volumes

This guide details the following scenarios:

1. Preserving boot volumes when performing compute instance scaling
2. Boot volume troubleshooting and repair
3. Replicating volumes to another availability domain

To read more about boot volumes, see Boot Volumes.

Preserving Boot Volumes

You may want to change compute instance shape while using the same boot volume. When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. This approach is useful for scenarios where instance shape cannot be changed while resizing instances.

To achieve this, you need to detach the boot volume from the running instance. This can be performed by either terminating the instance while preserving the boot volume or by stopping the instance and detaching the boot volume,
All Terraform resources of type `oci_core_instance` have the parameter `preserve_boot_volume` set as `true` by default. This parameter ensures that upon termination of the instance, the attached boot volume is not terminated.

```terraform
resource "oci_core_instance" "TFInstance" {
  ...  
  state = "STOPPED"                  // set this state to stop the instance
  preserve_boot_volume = true 
}

output "bootVolumeFromInstance" {
  value = [oci_core_instance.TFInstance.boot_volume_id]
}
```

Once the boot volume is detached, the OCID of the boot volume can be referred as the source of the new instance, as illustrated below:

```terraform
resource "oci_core_instance" "TFScaleInstance" {
  ...  
  source_details {  
    source_type = "bootVolume"
    // reference the original boot volume id here
    source_id   = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
  }  
}
```

### Detaching Boot Volumes for Troubleshooting and Repair

If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Once the boot volume has been detached, the OCID of the boot volume can be referred as the block volume parameter for another instance.

```terraform
resource "oci_core_volume_attachment" "TFBlockAttach" {
  ...  
  attachment_type = "iscsi"
  compartment_id  = "ocid1.compartment.oc1..exampleuniqueID"
  instance_id     = "ocid1.instance.oc1.phx.exampleuniqueID"
  volume_id       = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
}
```

Once you have resolved the issue, detach this volume from the second instance and attach it as a boot volume to the original instance.

```terraform
resource "oci_core_instance" "TFScaleInstance" {
  ...  
  source_details {  
    source_type = "bootVolume"
    // attach back as boot volume
    // reference the volume id here
    source_id   = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
  }  
}
Replicate a Volume to an Availability Domain within the Region

You can use Terraform to replicate existing compute instance boot and block volumes to another availability domain within the same region.

To replicate a volume:

1. Create a data source for the volume using `oci_core_boot_volume` or `oci_core_volume`.
2. Use the `oci_core_boot_volume_backup` or `oci_core_volume_backup` resource to create a backup of the source volume.
3. Define the target volume resource to be created from the backup.

The following example Terraform configuration replicates both a boot volume and a block volume:

```terraform
provider "oci" {
  region = "us-ashburn-1"
}

locals {
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"
  target_ad = "ilMx:US-ASHBURN-AD-2"
  source_boot_id = "ocid1.bootvolume.oc1.iad.exampleuniqueID"
  source_volume_id = "ocid1.volume.oc1.iad.exampleuniqueID"
}

# Boot Volume Clone
data "oci_core_boot_volume" "source" {
  boot_volume_id = local.source_boot_id
}

resource "oci_core_boot_volume_backup" "backup" {
  boot_volume_id = data.oci_core_boot_volume.source.id
  type = "FULL"
}

resource "oci_core_boot_volume" "target" {
  availability_domain = local.target_ad
  compartment_id = local.compartment_id
  source_details {
    id = oci_core_boot_volume_backup.backup.id
    type = "bootVolumeBackup"
  }
  display_name = "Test Cloned Boot Volume"
}

# Block Volume Clone
data "oci_core_volume" "source" {
  volume_id = local.source_volume_id
}

resource "oci_core_volume_backup" "backup" {
  volume_id = data.oci_core_volume.source.id
  type = "FULL"
}

resource "oci_core_volume" "target" {
  availability_domain = local.target_ad
  compartment_id = local.compartment_id
  source_details {
    id = oci_core_volume_backup.backup.id
    type = "volumeBackup"
  }
  display_name = "Test Cloned Block Volume"
}
You can use these steps to move an instance to the second availability domain or to create a disaster recovery deployment in the second availability domain.

If this method is used for a pure retargeting scenario where the source volumes (and the backups) will be removed after the duplication, then the Terraform configuration must be refactored after the source volumes are removed to avoid destroying the target instances on the next apply.

If using this scenario for disaster recovery cold standby, you can regularly use the Terraform `taint` command to mark the volume for destruction and recreation on the next application of the configuration.

Migrating an Exadata DB System to the New Resource Model

The X8M generation of Exadata hardware introduces a new resource model that replaces the Exadata DB system. The new resource model uses new APIs to provision and manage its resources. The existing DB system APIs for Exadata will be deprecated by Oracle Cloud Infrastructure for all users following written notification and a transition period allowing you to switch to the new API and Console interfaces.

If you have existing Exadata DB systems in Oracle Cloud Infrastructure, you can use Terraform to switch them to the new resource model and APIs.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switching an Exadata DB system to the new resource model and APIs cannot be reversed. If you have automation for your system that utilizes the DB system APIs, you may need to update your applications prior to switching.</td>
</tr>
</tbody>
</table>

Switching to the new resource model:

- Does not impact the DB system's existing Exadata databases or client connections
- Does not change the underlying hardware or shape family of your Exadata Cloud Service instance
- Will not affect bare metal and virtual DB systems

After converting your DB system, you will have two new resources in place of the DB system resource: a cloud Exadata infrastructure resource, and a cloud VM cluster resource.

What to expect after switching:

- Your new cloud Exadata infrastructure resource and cloud VM cluster are created in the same compartment as the DB system they replace
- Your new cloud Exadata infrastructure resource and cloud VM cluster use the same networking configuration as the DB system they replace
- After the switch, you cannot perform operations on the old Exadata DB system resource
- Switching is permanent, and the change cannot be undone
- X6, X7, X8 and Exadata base systems retain their fixed shapes after the switch, and cannot be expanded

To Migrate an Exadata DB System

These migration steps use the following example, which shows an existing Exadata Cloud Service instance using the old DB system resource model:

```terraform
resource "oci_database_db_system" "test_db_system" {
  availability_domain = data.oci_identity_availability_domain.ad.name
  compartment_id      = var.compartment_ocid
  cpu_core_count      = var.cpu_core_count
  database_edition    = var.db_edition
  time_zone           = var.time_zone

  db_home {
    database {
      admin_password = var.db_admin_password
    }
  }
}
```
To migrate the system to the new resource model, first create the `oci_database_migration` resource:

```sql
// This is 1 time action to migrate test_db_system into db ExaCS
// and the test_db_system will become `Migrated`
resource "oci_database_migration" "test_migration" {
  #Required
db_system_id = "${oci_database_db_system.test_db_system.id}"
}
```
Provisioning the `oci_database_migration` resource creates two new resources:
`oci_database_cloud_exadata_infrastructure` and `oci_database_cloud_vm_cluster`.

You can get OCIDs of these two resources from the `oci_database_migration` resource:

```json
output "cloud_exadata_infrastructure_id" {
  value = oci_database_migration.test_migration.cloud_exadata_infrastructure_id
}

output "cloud_vm_cluster_id" {
  value = oci_database_migration.test_migration.cloud_vm_cluster_id
}
```

Create a Terraform configuration for the two new resources:

```terraform
resource "oci_database_cloud_exadata_infrastructure" "test_cloud_exadata_infrastructure"{
}
resource "oci_database_cloud_vm_cluster" "test_cloud_vm_cluster" {}
```

Then run the Terraform import command:

```bash
terraform import
oci_database_cloud_exadata_infrastructure.test_cloud_exadata_infrastructure <cloud_exadata_infrastructure_id>
terraform import
oci_database_cloud_vm_cluster.test_cloud_vm_cluster <cloud_vm_cluster_id>
```

Terraform now manages the two new resources. After switching to the new Exadata resource model, remove the old `oci_database_db_system` config.

---

**Tip:**

After the migration, you can use `resource discovery` to create a full configuration and state file for importing these two new resources.

---

**Targeting Multiple Regions**

You can use a single Terraform configuration to create Oracle Cloud Infrastructure (OCI) resources in multiple regions.

**Create a Provider for Each Region**

A Terraform configuration may have only a single OCI Terraform provider block, but to apply configurations to multiple regions, you need to create multiple provider blocks.

A typical OCI Terraform provider block might look like the following:

```terraform
provider "oci" {
  region           = var.region
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}
```

---

**Tip:**

All parameters should be set using variables.
If you want to use more than one region within a single Terraform config, multiple providers are required. Each provider must be given an alias. For example:

```terraform
provider "oci" {
  alias            = "home"
  region           = var.region
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}

provider "oci" {
  alias            = "region2"
  region           = var.region2
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}
```

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region, which is your **home region**. The home region has special properties. For example, IAM resources can only be created in your home region. For that reason, you should designate that region with an appropriate alias, like `home`. Use simple aliases for other regions so that users can easily map configurations to the regions that they want (for example, `region2`).

**Note:**
Specific regions (us-phoenix-1, us-ashburn-1, and so on) are not hardcoded into either the `region` or `alias` fields.

Finding Your Home Region

When deploying to multiple OCI regions, you might want to look up your home region dynamically, so you don't have to explicitly pass the home region as a configuration variable.

One typical use case might require provisioning resources to a specific region using a Terraform configuration that also creates a compartment. Since the compartment must be created in your home region, you could use code like the following to automatically look up the home region:

```terraform
provider oci ()

provider oci {
  alias = "home" region = lookup(local.region_map,
    data.oci_identity_tenancy.tenancy.home_region_key) }

variable tenancy_id ()

data oci_identity_regions regions {}

data oci_identity_tenancy tenancy {
  tenancy_id = var.tenancy_id
}

locals {
  region_map = { for r in data.oci_identity_regions.regions.regions :
    r.key => r.name } }

output home_region {
  value = lookup(local.region_map,
    data.oci_identity_tenancy.tenancy.home_region_key) }
```
Provision a Resource

To provision a resource in a region, specify the aliased provider name in the resource.

For example:

```terraform
resource "oci_core_instance" "test_instance" {
    provider = oci.home
    ...
}
```

Modules and Multiple Regions

Typically, a module should use only a single region. If more regions are needed, you should use separate modules.

If the config contains multiple providers, the module should specify the provider to use by using the following format:

```terraform
module "compartments" {
    source       = "./compartments"
    providers = {
        oci = "oci.home"
    }
}
```

Upgrading Configurations to Terraform v0.12

With the release of Terraform v0.12, Oracle Cloud Infrastructure Terraform providers need to be upgraded and some existing configurations may need to be updated as well.

Upgrading the Terraform Provider

Oracle Cloud Infrastructure (OCI) Terraform provider versions 3.26.0 and below are not compatible with Terraform v0.12. OCI Terraform provider version 3.27.0 is the earliest version that supports Terraform v0.12.

**Note:**

All OCI Terraform provider versions remain compatible with Terraform v0.11 and v0.10.

The simplest way to begin using the latest v0.12-compatible provider from the HashiCorp provider registry is to place an explicit version requirement in your `provider configuration block`, as shown here:

```terraform
provider "oci" {
    version          = ">= 3.27.0"
    region           = "${var.region}"
    tenancy_ocid     = "${var.tenancy_ocid}"
    user_ocid        = "${var.user_ocid}"
    fingerprint      = "${var.fingerprint}"
    private_key_path = "${var.private_key_path}"  
}
```

For guidance using additional version configuration options, see **Provider Versions**.

Upgrading Terraform Configurations

Some users may find that no changes are needed to run existing Terraform configurations with v0.12.

For configurations that do need to be upgraded, see **Upgrading Terraform configuration**.
Upgrading configurations while preserving v0.11 compatibility

As recommended in Upgrading Terraform configuration, the simplest way to upgrade your configurations is to use the `terraform 0.12upgrade` command. Using the `terraform 0.12upgrade` command to upgrade your configurations, however, renders them incompatible with Terraform v0.11 and earlier.

**Caution:**
Prior to making configuration changes, it is strongly recommended that configuration and state files are backed up using version control or another preferred mechanism.

It may be possible to manually upgrade configurations to work with v0.12 while preserving compatibility with v0.11. Not all possible configurations can be made compatible with both v0.11 and v0.12. This method should only be used as a best-effort to preserve compatibility with v0.11.

The following cases detail where it is possible to convert existing v0.11 usage to be compatible with both v0.11 and v0.12.

**Attributes vs. Blocks**
In v0.11, it was possible to treat attributes and nested blocks interchangeably. Note how the attribute `metadata` and the nested block `source_details` are both assigned using only braces.

```
// v0.11 compatible representation
resource "oci_core_instance" "my_instance" {
  metadata {
    ssh_authorized_keys = "${var.ssh_public_key}" 
  }
  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
    kms_key_id  = "${oci_kms_key.test_key.id}"
  }
}
```

In v0.12, attributes need to be assigned using the `=` operator while blocks need to be assigned using only braces. Note how the attribute `metadata` is now assigned with `=`. This usage is still compatible with v0.11.

```
// v0.12 and v0.11 compatible representation
resource "oci_core_instance" "my_instance" {
  metadata = {
    ssh_authorized_keys = "${var.ssh_public_key}" 
  }
  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
    kms_key_id  = "${oci_kms_key.test_key.id}"
  }
}
```

**Nested blocks with multiple elements**
In v0.11, it was possible to wrap lists of nested blocks inside `[]` like this example.

```
// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" {
  public_prefixes = [
    { cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block}" }]
}
```
In v0.12, it is required to specify each nested block individually without wrapping it in `[ ]`. This usage is still compatible with v0.11.

```
// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" {
  public_prefixes {
    cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block2}" 
  }
  public_prefixes {
    cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block3}" 
  }
}
```

Quotes around attribute names

In v0.11, it was possible to put quotation marks " around attribute names. Note how the `min` and `max` attributes have quotation marks around them.

```
// v0.11 compatible representation
resource "oci_core_security_list" "bastion" {
  egress_security_rules {
    destination = "${var.vcn_cidr}"
    protocol   = "${local.tcp_protocol}" 
    tcp_options {
      "min" = 22
      "max" = 22
    }
  }
}
```

In v0.12, quotation marks " around attribute names are no longer allowed.

```
// v0.11 and v0.12 compatible representation
resource "oci_core_security_list" "bastion" {
  egress_security_rules {
    destination = "${var.vcn_cidr}"
    protocol   = "${local.tcp_protocol}" 
    tcp_options {
      min = 22
      max = 22
    }
  }
}````
Variable names starting with non-alphabetical characters

In v0.11, it was possible to specify variable names that begin with non-alphabetical characters.

```plaintext
// v0.11 compatible representation
variable "2TB" {
    default = "2048"
}
```

In v0.12, variable names must begin with alphabetical characters.

```plaintext
// v0.11 and v0.12 compatible representation
variable "Size2TB" {
    default = "2048"
}
```

Computing list index values

In v0.11, division operations often resulted in integer values that could be used as a valid index in a list.

```plaintext
// v0.11 compatible representation
instance_id = "${oci_core_instance.TFInstance.*.id[count.index / var.NumParavirtualizedVolumesPerInstance]}"
```

In v0.12, division operations can result in floating point values that may no longer be valid. To avoid this situation, use the `floor` interpolation to convert floating point values to an index.

```plaintext
// v0.11 and v0.12 compatible representation
instance_id = "${oci_core_instance.TFInstance.*.id[floor(count.index / var.NumParavirtualizedVolumesPerInstance)]}"
```

Using Object Storage for State Files

You can store Terraform state files in Oracle Cloud Infrastructure (OCI) Object Storage. Doing so requires that you configure a backend using one of the Terraform backend types.

Terraform supports various backend types to allow flexibility in how state files are loaded into Terraform. (For more information, see Terraform Backend Types.) For our purposes, we address two of these approaches:

- Using an HTTP remote state backend
- Using an S3-compatible remote state backend

**Note:**

Terraform backend types are defined in the `terraform` block. The `terraform` block does not accept variables or locals. All backend configuration values must be hardcoded.

Using an HTTP Backend

Using the HTTP backend type allows you to store state using a simple REST client. With the HTTP backend type, you can easily fetch, update, and purge state using the HTTP GET, POST, and DELETE methods.

To configure the HTTP backend to store your OCI Terraform state files, do the following:
Create a Pre-Authenticated Request

Creating a pre-authenticated request in Oracle Object Storage enables accessing a bucket or object in the OCI without needing to provide credentials. To do so, you must create a pre-authenticated request that has read/write permissions to the object store where you intend to save the Terraform state file. You can do so in any of three ways: by using the Console UI, by using the command line interface (CLI), or by using the REST APIs.

**Note:**

A state file must exist in the bucket before you create the pre-authenticated request. This file can be an existing state file, or an empty file for the initial state.

For guidance, see Using Pre-Authenticated Requests on page 4979.

Upload Existing State

If you have an existing state file, you can upload it using Curl to make an HTTP PUT request to the object store URL, as shown here:

```bash
curl -X PUT -H "Content-Type: text/plain" --data-binary @path/to/local/tfstate" http://<prefix>/<my-access-uri>
```

Configure HTTP as a Terraform Backend

The HTTP backend type stores state using a simple REST client and allows you to easily fetch, update, and purge state using the HTTP GET, POST, and DELETE methods.

The access URI for addressing OCI Terraform configurations must be of the form: `https://objectstorage.us-phoenix-1.oraclecloud.com/my-access-uri` (where region and access URI are specific to you).

For more example configuration and state files that reference code, and a summary of configuration variables, see Standard Backends: HTTP.

Following is an example Terraform configuration. The region in the URL can be something other than the Phoenix region.

```terraform
terraform {
  backend "http" {
    address = "https://objectstorage.us-phoenix-1.oraclecloud.com/<my-access-uri>"
    update_method = "PUT"
  }
}
```

Reinitialize Terraform

Finally, you must reinitialize Terraform and then run the apply command:

```bash
terraform init
terraform apply
```

After completing these steps, you are able to use Oracle Cloud Infrastructure as the backend for storing Terraform state files.

Using an S3-Compatible Backend

Configuring the S3-compatible backend requires that the account be enabled with S3 authentication keys, which are set on a per-user basis.
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Under **User Details**, click **Customer Secret Key**. For guidance, see **Working with Customer Secret Keys**.

2. Set the location for the credentials file. The default location is `~/.aws/credentials`. You can set an alternate location by using the S3 backend `shared_credentials_file` option.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Never set the <code>access_key</code> and the <code>secret_key</code> attributes in the same Terraform backend configuration, since this creates a security risk.</td>
</tr>
</tbody>
</table>

3. Configure the `[default]` entry in the credentials file with the appropriate Object Storage credentials. The file can contain any number of credential profiles. If you provide a different profile name, you must also update the backend `profile` option in your Terraform configuration file.

Following is an example of Object Storage credentials:

```plaintext
[default]
aws_access_key_id=ocid1.credential.oc1..exampleuniqueID
aws_secret_access_key=mSTdaWhlbWj3ty4JZX1m0NUZV52x1ImWjayJL6OH9A=
```

Where `aws_access_key_id` and `aws_secret_access_key` are user-specific values provided from the Console. The key values provided in the example are not valid and provided as examples only.

4. Set the object storage endpoint value in the following format:

   ```plaintext
   https://<namespace>.compat.objectstorage.<region>.oraclecloud.com
   ```

5. Reinitialize Terraform and then run the `apply` command:

   ```plaintext
   terraform init
   terraform apply
   ```

Following is a full example of an Object Storage backend configuration:

```plaintext
terraform {
  backend "s3" {
    bucket   = "terraform-states"
    key      = "networking/terraform.tfstate"
    region   = "us-phoenix-1"
    endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"
    shared_credentials_file = "../terraform-states_bucket_credentials"
    skip_region_validation  = true
    skip_credential_validation = true
    skip_metadata_api_check = true
    force_path_style        = true
  }
}
```

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the same bucket is used across multiple Terraform configurations, the key must be unique to avoid overwriting the state file. This example uses a single bucket (<code>terraform-states</code>) to store all Terraform state files, but uses a unique prefix for the object name based on the resource (<code>networking</code>).</td>
</tr>
</tbody>
</table>

Once you have configured the backend, you must run `terraform init` to finish the setup. If you already have an existing `terraform.tfstate` file, then Terraform prompts you to confirm that the current state file is the one to upload to the remote state.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The S3 backend configuration can also be used for the <code>terraform_remote_state</code> data source to enable sharing state across...</td>
</tr>
</tbody>
</table>
Accessing Remote States

You can use the `terraform_remote_state` data source to access properties of objects in one Terraform configuration from another configuration.

For example, you might use one configuration to define compartments and another to define VCNs. If your resources were in the same Terraform configuration folder, you could refer to a compartment OCID from the VCN configuration by using something like this: `module.iam_compartment_SANDBOX.compartment_id`.

But assume that our definitions do not share a state file and we have a file structure similar to the following:

```
.# governance
#   ### compartments.tf
#   ### outputs.tf
#   ### remote-backend.tf
#   ### variables.tf
### networking
#   ### outputs.tf
#   ### remote-backend.tf
#   ### remote-state-data_governance.tf
#   ### variables.tf
#   ### vcns.tf
### terraform-states_bucket_credentials
```

Both `governance` and `networking` configurations store their respective state files on an OCI Object Storage bucket using the `remote-backend.tf` and `terraform-states_bucket_credentials` files.

In this example, the `compartments.tf` file creates a compartment at the root level using the `iam-compartment` module from the Terraform Registry as follows:

```
module "iam_compartment_SANDBOX" {
    source = "oracle-terraform-modules/iam/oci//modules/iam-compartment"
    version = "2.0.0"
    tenancy_ocid = var.tenancy_ocid
    compartment_id = var.tenancy_ocid # define the parent compartment.
    compartment_name = "SANDBOX"
    compartment_description = "Test and evaluate OCI features here"
    compartment_create = true # if false, a data source with a matching name is created instead
    enable_delete = true # if false, on `terraform destroy`, compartment is deleted from the terraform state but not from oci
}
```

Defining Outputs

The `terraform_remote_state` data source can access output values from another Terraform configuration using the latest state file with a remote backend. For your `networking` configuration to access the `governance` configuration and dynamically retrieve Terraform resources properties, you must define outputs for the `governance` Terraform configuration. Without a defined output, the values cannot be used from outside of its configuration.

Your `governance/outputs.tf` file would look like the following:

```
output "iam_compartment_SANDBOX" {
    description = "compartment ocid, parent ocid, name, description"
    value = {
        id = module.iam_compartment_SANDBOX.compartment_id
    }
}
```
Referencing a Remote State

In this example, we are using the `vcn` module from Terraform Registry to define a new VCN. The `networking` configuration refers to the `governance` configuration to define the VCN's compartment OCID:

```terraform
module "vcn_hub1iad" {
  source = "oracle-terraform-modules/vcn/oci"
  version = "2.2.0"

  # general oci parameters
  compartment_id = data.terraform_remote_state.governance.outputs.iam_compartment_SANDBOX["id"]
  tags = var.tags

  # vcn parameters
  create_drg = false
  internet_gateway_enabled = true
  lockdown_default_seclist = true
  nat_gateway_enabled = false
  service_gateway_enabled = false
  vcn_cidr = "10.0.0.0/16"
  vcn_dns_label = "hub1iad"
  vcn_name = "hub1"
}
```

But, for the `compartment_id = data.terraform_remote_state.governance.outputs.iam_compartment_SANDBOX["id"]` line to be correctly interpreted, you must define a `data.terraform_remote_state` object.

Defining the Remote State Data Source

After the following `terraform_remote_state` data source is added to the `networking` configuration, you can access the `governance` Terraform outputs from configurations within the `networking` folder:

```terraform
data "terraform_remote_state" "governance" {
  backend = "s3"
  config = {
    bucket = "terraform-states"
    key = "governance/terraform.tfstate"
    region = "us-phoenix-1"
    endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"
    shared_credentials_file = "../terraform-states_bucket_credentials"
    skip_region_validation = true
    skip_credentials_validation = true
    skip_metadata_api_check = true
    force_path_style = true
  }
}
```

If you define your remote state data source in a separate file, such as `remote-state-data_governance.tf`, you can copy and paste the file as needed. Each new configuration can then refer to your compartment in the same way.

For More Information
Best Practices

This section documents some best practices that you can apply when you use the Oracle Cloud Infrastructure (OCI) Terraform provider to manage OCI resources.

See the following topics for more information:

- Managing Default VCN Resources on page 6186
- Referencing Availability Domains on page 6187
- Referencing Images on page 6189
- Storing Sensitive Data on page 6189
- Tagging Resources on page 6189

Managing Default VCN Resources

When you create an `oci_core_vcn` resource, it will also create the following associated resources by default:

- `oci_core_security_list`
- `oci_core_dhcp_options`
- `oci_core_route_table`

These default resources will be implicitly created even if they are not specified in the Terraform configuration. Their OCIDs are returned by the following attributes under the `oci_core_vcn` resource:

- `default_security_list_id`
- `default_dhcp_options_id`
- `default_route_table_id`

Default resources must be configured in Terraform using a separate resource type. Here are the mappings between the resource and the new resource type to use for configuring default resources:

- `oci_core_security_list` => `oci_core_default_security_list`
- `oci_core_dhcp_options` => `oci_core_default_dhcp_options`
- `oci_core_route_table` => `oci_core_default_route_table`

Default resources types are configured in the same way as their non-default counterparts. The only difference is specifying the ID of the default resource using the `manage_default_resource_id` argument.

Consequently, the `vcn_id` is no longer necessary for default resources.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

The following example modifies a VCN's default DHCP options:

```terraform
resource "oci_core_vcn" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = var.compartment_ocid
  display_name = "vcn1"
}

resource "oci_core_default_dhcp_options" "default-dhcp-options" {
  manage_default_resource_id = oci_core_vcn.vcn1.default_dhcp_options_id

  // required
  options {
```
Developer Tools

```python
type = "DomainNameServer"
    server_type = "VcnLocalPlusInternet"
}

// optional
options {
    type = "SearchDomain"
    search_domain_names = [ "abc.com" ]
}
}
```

Limitations

Default resources can only be removed when the associated oci_core_vcn resource is removed. When attempting a targeted removal of a default resource, the resource will be removed from the Terraform state file but the resource may still exist in OCI with empty settings.

Examples of targeted removal include:

- Removing a default resource from a Terraform configuration that was previously applied
- Running a `terraform destroy -target=<default_resource>` command
- Changing the `manage_default_resource_id` for a default resource that was previously applied

Referencing Availability Domains

With respect to availability domains, we caution against a common pattern, as shown here:

```python
// Get all availability domains for the region
data "oci_identity_availability_domains" "ads" {
    compartment_id = "$\{var.tenancy_ocid\}\"
}

// Then either use it to get a single AD name based on the index:
resource "oci_core_instance" "nat" {
    availability_domain = "$\{lookup(data.oci_identity_availability_domains.ads.availability_domains[\$var.nat_instance_ad], "name")\}
    ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
    count = "$\{length(data.oci_identity_availability_domains.ads.availability_domains)\}\"
    availability_domain = "$\{lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")\}
    ...
}
```

The recommendation, then, is to explicitly list the availability domain names for the regions in your configuration. To do so, use a variable that you have defined as follows:

```python
variable "ad_list" {
    type = "list"
}
```

You can then use the variable as shown here:

```python
// Index:
resource "oci_core_instance" "nat" {
    availability_domain = "$\{var.ad_list[\$var.nat_instance_ad_index]\}\"
    ...
```
// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "$\{\text{length}(\text{var.ad_list})\}$
  availability_domain = "$\{\text{var.ad_list}[\text{count.index}]\}$
...}

You can then set the ad_list variable directly by using the availability domain names for your tenant and region, as shown here:

variable "ad_list" {
  type = "list"
  default = ["kIdk:PHX-AD-1","kIdk:PHX-AD-2","kIdk:PHX-AD-3"]
}

The advantage of using this method is that it gives you control over your availability domain usage and prevents unexpected changes over time. However, this approach is problematic when configurations are shared between tenancies and regions, since availability domain names are tenancy- and region-specific.

A convenient alternative is to instead set the ad_list value by using the oci_identity_availability_domains data source. You should do this in the configuration, then pass them into the modules. This effectively centralizes the list of ADs, making it easy to switch to an explicit list later, should that become necessary: Note that the modules themselves should not use the oci_identity_availability_domains data source.

data "oci_identity_availability_domains" "ad" {
  compartment_id = "$\{\text{var.tenancy_ocid}\}$"
}

data "template_file" "ad_names" {
  count = "$\{\text{length}(\text{data.oci_identity_availability_domains.ad.availability_domains})\}$
  template = "$\{\text{lookup}(\text{data.oci_identity_availability_domains.ad.availability_domains}[\text{count.index}], "name")\}$"
}

module "ssm_network" {
  ad_list = "$\{\text{data.template_file.ad_names.*.rendered}\}$
...}

Regions with a Single Availability Domain

Some Oracle Cloud Infrastructure regions have a single availability domain. When writing configurations that use plural data sources, like oci_identity_availability_domains, ensure that you account for a single domain if required by your region.

The following example uses the oci_identity_availability_domains data source when listing fault domains in a single-availability domain region. The availability_domains index must be 0. Any other index value is invalid in this region:

data "oci_identity_availability_domains" "AvailabilityDomains" {
  compartment_id = var.tenancy_ocid
}

data "oci_identity_fault_domains" "FaultDomains" {
  availability_domain =
    data.oci_identity_availability_domains.AvailabilityDomains.availability_domains[0]["name"]
  compartment_id = "$\{\text{var.compartment_ocid}\}$"
The full reference of the OCI Terraform provider’s supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Referencing Images

When launching compute instances, your Terraform configuration should use the same image every time you run a Terraform apply job.

To ensure this, specify the image OCID directly, rather than locating it using the `oci_core_image` data source. This is because the `oci_core_image` data source calls into the `ListImages` API, whose return values can change over time because over time images are added and older ones deleted. For a list of Oracle-provided images and their OCIDs, see Oracle-Provided Images. For more information, see Results of `oci_core_images` will change over time for Oracle-provided images.

We recommend the following pattern for specifying an image for a given region:

```python
variable "image_id" {
  type = "map"
  default = {
    // See https://docs.cloud.oracle.com/iaas/images/
    // Oracle-provided image "Oracle-Linux-7.4-2018.02.21-1"
    us-phoenix-1 = "ocid1.image.oc1.phx..<unique_ID>"
    us-ashburn-1 = "ocid1.image.oc1.iad..<unique_ID>"
    eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-1..<unique_ID>"
    uk-london-1 = "ocid1.image.oc1.uk-london-1..<unique_ID>"
  }
}
```

A compute instance can use this in the following way:

```python
resource "oci_core_instance" "TFInstance" {
  image = "{var.image_id[var.region]}"
  ...
}
```

Storing Sensitive Data

**Caution:**

Terraform configuration files and state files may contain sensitive data.

When configuring your Oracle Cloud Infrastructure (OCI) Terraform provider, you should use variables to define your provider instead of including sensitive information within the file.

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state itself as sensitive data. Please refer to Sensitive Data in State for more details.

Tagging Resources

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate them, report on them, or take bulk actions on them. Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

There are two types of tags:

**Defined tags** are set up in your tenancy by an administrator. Only users granted permission to work with the defined tags can apply them to resources. Defined tags provide a key/value map and are organized by combining the tag namespaces with tag keys using dot notation. For example, a tag namespace called `HumanResources` could have a key named `CostCenter`. You then associate the namespace and key `HumanResource.CostCenter` and then assign the tag.
**Free-form tags** can be applied by any user with permissions on the resource. Freeform tags are simple key/value maps.

- Refer to the `oci_identity_tag_namespace` reference for guidance on managing the lifecycle of tag namespaces.
- Refer to the `oci_identity_tag` reference for guidance on managing tags.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

For more detailed information about tags and their features, see Tagging Overview.

**Propagation of Tagging on Resources**

OCI services propagate all of a primary resource's freeform tags and defined tags to secondary resources when both resources support the type of tags. For example, if your Terraform configuration has a compute instance as a primary resource and a VNIC as a nested secondary resource, any tags on the compute instance are propagated to the VNIC.

This propagation could cause a drift in the Terraform state resulting in a diff after apply. To avoid potential drift, explicitly add all the primary resource's freeform tags and defined tags on the secondary resources as part of the configuration.

The same behavior can be seen while using the Tag Default or Required Tags feature. Avoid drift by applying the Tag Default or Required Tags on all resources (primary and secondary, if any) in the tenancy where Tag Default or Required Tags exist.

**Resource Discovery**

You can use the Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature to search for deployed resources in your compartment and export them to Terraform configuration and state files.

Resource discovery simplifies the move from manually managed infrastructure to Terraform-managed infrastructure. With a single command, you can generate a file that captures your existing compartment's baseline configuration and state.

**Important:**

Resource discovery is not a migration tool. When cloning or migrating resources, configurations generated by resource discovery are a starting point. They may require changes.

Common uses cases for your new Terraform configuration and state files include:

- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
- Duplication or rebuild of your existing infrastructure architecture in a new tenancy or region.
- Detection of state drift. Run reports to see if the state of your Terraform-managed resources has changed and differs from your base configuration.

**Note:**

Terraform resource discovery is available with OCI Terraform provider version 3.50 and above.

**Supported Services**

Refer to Terraform Provider Services Reference for the list of services the OCI Terraform provider's resource discovery feature supports. You can also see the list of supported services by running this command:

```
terraform-provider-oci -command=list_export_services
```

**Note:**

Terraform resource discovery may not be available for all services that the OCI Terraform provider supports.
Supported Resources

Each supported service has one or more discoverable resources. You can see the list of supported resources by running this command:

```
terraform-provider-oci -command=list_export_resources
```

Using Resource Discovery

The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature uses HashiCorp's `terraform-exec` to import the discovered OCI resources into Terraform configuration and state files.

Prerequisites

Terraform-exec requires the Terraform CLI to be present on your system. See Download and Install Terraform for installation details.

**Note:**

If you are using Terraform version v0.11, this tool cannot generate a state file. Only configurations are supported in v0.11. By default the configurations are generated in v0.12.

If you use v0.13.* of the Terraform CLI, make sure that the version is compatible with v0.12 syntax.

Additionally, you must have the OCI Terraform provider downloaded and installed. See Download and Install the Provider for download instructions.

**Adding the Tools to Your Path**

To run the OCI Terraform provider as an executable and use resource discovery, you can:

- Add `terraform-provider-oci` to your system path.
- Run the provider from the directory where it is located.
- Specify the full path to the provider when you run resource discovery commands.

Because resource discovery commands use `terraform-exec` to call Terraform on your behalf, your system must specify the location of the Terraform CLI using either of the following methods:
• Provide the full path including name for the Terraform CLI using the `terraform_bin_path` environment variable. See Environment Variables for more information on setting variables.

• Add the Terraform CLI to your system path.

Authentication

To discover resources in your compartment, the OCI Terraform provider needs authentication information about the user, tenancy, and region with which to discover the resources. It is recommended that you specify a user that has access to inspect and read the resources to discover.

You can use API Key Authentication and Environment Variables or Instance Principal Authorization to provide the required information.

Exporting Resources

After you have specified the location of the Terraform CLI and authentication settings, either of the following commands can be used to export a compartment's resources:

```
terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```

```
terraform-provider-oci -command=export -compartment_id=<compartment_OCID> -output_path=<output_path>
```

These commands discover all supported resources within the compartment and generate Terraform configuration files in the given output_path. The generated `.tf` files contain the Terraform configuration with the resources that the command has discovered.

**Note:**

The `compartment_id` parameter is required if using Instance Principal Authorization.

Common parameter combinations below export the resources described:

• `compartment_id=<empty_or_tenancy_OCID> services=<empty_or_not_specified>` - All tenancy and compartment scope resources.

• `compartment_id=<empty_or_tenancy_OCID> services=<comma_seperated_list>` - Tenancy and compartment scope resources for the services specified.

• `compartment_id=<non-root_OCID> services=<empty_or_not_specified>` - All compartment scope resources.

• `compartment_id=<non-root_OCID> services=<comma_seperated_list>` - Compartment scope resources for the services specified. Tenancy scope resources will not be discovered even if services with such resources are specified.

**Note:**

Export of compartment resources supports only the target compartment. Resources in child compartments are not discovered.

**Parameters**

You can use the following parameters to control the behavior of the resource discovery tool.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>The command to run. Supported commands include:</td>
</tr>
<tr>
<td></td>
<td>• <code>export</code> - discovers OCI resources within your compartment and generates Terraform configuration files for them</td>
</tr>
<tr>
<td></td>
<td>• <code>list_export_resources</code> - lists the Terraform OCI resource types that are discovered by the <code>export</code> command</td>
</tr>
<tr>
<td></td>
<td>• <code>list_export_services</code> - lists the allowed values for services arguments along with scope in JSON format</td>
</tr>
<tr>
<td>compartment_id</td>
<td>The OCID of the compartment to export. If <code>compartment_id</code> or <code>compartment_name</code> is not specified, the root compartment is used. Required if using Instance Principal Authorization.</td>
</tr>
<tr>
<td>compartment_name</td>
<td>The name of a compartment to export. If <code>compartment_id</code> or <code>compartment_name</code> is not specified, the root compartment is used.</td>
</tr>
<tr>
<td>generate_state</td>
<td>Provide this flag to import the discovered resources into a state file in addition to the Terraform configuration files.</td>
</tr>
<tr>
<td>ids</td>
<td>A comma-separated list of resource IDs to export. The ID could either be an OCID or a Terraform import ID. By default, all resources are exported.</td>
</tr>
<tr>
<td>list_export_services_path</td>
<td>The full path, including the filename, to use as the output for list of supported services, in JSON format.</td>
</tr>
<tr>
<td>output_path</td>
<td>The absolute path to output the generated configurations and state files of the exported compartment.</td>
</tr>
<tr>
<td>parallelism</td>
<td>The number of threads that will be used to discover resources in parallel. The default value is <code>1</code>.</td>
</tr>
<tr>
<td>services</td>
<td>A comma-separated list of service resources to export. If not specified, all resources within the given compartment (excluding IAM resources) are exported.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Supported Services</a> on page 6190 for accepted values and <a href="#">Exporting Identity Resources</a> on page 6201 for related information.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Details</td>
</tr>
<tr>
<td>-----------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| tf_version | The version of Terraform syntax to use when generating configuration files. The default is v0.12. The allowed values are:  
  • 0.11  
  • 0.12  
  If you specify 0.11 as the syntax version, you should use v0.11 of the Terraform CLI to discover resources.  
  If you use Terraform CLI v0.13 and above to discover resources, make sure the version is compatible with v0.12 syntax.  
  State files are generated in Terraform syntax matching the version of the Terraform CLI used to discover resources. The tf_version parameter does not apply to state files. |

**Verbose Logging**

To get verbose console output when the provider is running, precede your resource discovery command with the TF_LOG or OCI_TF_LOG flags. For example:

```
TF_LOG=DEBUG terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```

```
OCI_TF_LOG=DEBUG terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```

The TF_LOG level and OCI_TF_LOG flags can also be set as environment variables.  
To redirect verbose console output to a log file, set the OCI_TF_LOG_PATH environment variable and provide the path.

**Exit Status**

If there is any error related to the OCI APIs or service unavailability while discovering resources, the tool moves on to find next resource. All errors encountered are displayed after the discovery is complete.  
- Exit code 0 - Success.  
- Exit code 1 - Failure because of errors such as incorrect environment variables, arguments, or configuration.  
- Exit code 64 - Partial success. Resource discovery was not able to find all the resources because of service failures.

Exporting Identity Resources

Some resources, such as identity resources, exist only at the tenancy level and cannot be discovered within a specific compartment. To discover such resources, use the following command, which omits any compartment parameter:

```
terraform-provider-oci -command=export -output_path=<output_path> -services=identity
```

**Note:**

When exporting identity resources, the compartment_id value, if provided, is ignored.

Exporting Resources to Another Compartment
Once you have reviewed the generated Terraform configuration files and made any necessary changes, the
configuration can be used with Terraform. One such use case is the re-deploying of those resources in a new
compartment or tenancy, using Terraform.

To do so, specify the following environment variables:

```
export TF_VAR_tenancy_ocid=<target_tenancy_OCID>
export TF_VAR_compartment_ocid=<target_compartment_OCID>
```

Then run the following command:

```
terraform apply
```

Generating a Terraform State File

**Caution:**
The state file contains all resource attributes that are specified as part of
configuration files. If you manage any sensitive data with Terraform, like
database or user passwords or instance private keys, you should treat the state
file itself as sensitive data. See Storing Sensitive Data on page 6189 for
more information.

It is also possible to generate a Terraform state file to manage the discovered resources. To do so, run the following
command, which includes the `-generate_state` flag:

```
terraform-provider-oci -command=export -compartment_id=<compartment_OCID> -
output_path=<output_path> -generate_state
```

The results of this command are both the `.tf` files representing the Terraform configuration and a
`terraform.tfstate` file representing the state. See State for more information.

**Note:**
The Terraform state file generated by this command is only compatible with
Terraform v0.12.4 and above.

Output File Contents

The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery `export` command discovers
resources that are in an active or usable state. Resources that have been terminated or otherwise made inactive are
generally excluded from the generated configuration.

By default, the Terraform names of the discovered resources share the same name as the display name for that
resource, if one exists.

The attributes of the resources are populated with the values that are returned by the OCI services.

In some cases, a required or optional attribute may not be discoverable from the OCI services and may be omitted
from the generated Terraform configuration. This omission may be expected behavior from the service, which may
prevent discovery of certain sensitive attributes or secrets. In such cases, a placeholder value is set along with a
comment like this:

```
admin_password = "" #Required attribute not found in discovery, placeholder
value set to avoid plan failure
```

The missing required attributes are also added to lifecycle `ignore_changes`. This addition is done to avoid
Terraform plan failure when moving manually-managed infrastructure to Terraform-managed infrastructure. Any
changes made to such fields are not reflected in the Terraform plan. If you want to update these fields, remove them
from `ignore_changes`.
Resources that are dependent on availability domains will be generated under `availability_domain.tf` file. These include:

- `oci_core_boot_volume`
- `oci_file_storage_file_system`
- `oci_file_storage_mount_target`
- `oci_file_storage_snapshot`

**Services Reference**

This topic provides a reference of the Oracle Cloud Infrastructure (OCI) services that the Terraform provider supports.

**Full Reference Documentation**

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at [docs.oracle.com](http://docs.oracle.com) and HashiCorp.

Data sources and resources are grouped by service within the reference.

**Supported Services**

The following table lists the services supported by the OCI Terraform provider and the services supported by the `resource discovery` feature. This list also includes the values accepted by resource discovery's `services` parameter.

<table>
<thead>

**Deprecated Resources**

This topic covers the list of resources and data sources that have been marked deprecated by the Oracle Cloud Infrastructure (OCI) Terraform provider and their respective suggested replacements, if any.

Resources and data sources marked for deprecation will trigger warnings during Terraform `plan` and `apply` operations. For example:

The 'oci_autonomous_data_warehouse' resource has been deprecated. Please use 'oci_autonomous_database' instead.

Resources on path to deprecation may stop working in future, use the respective guide, if available, on how to migrate using the new replacements.

**Deprecated Resources and Data Sources**

Resources that have a migration path have deprecation guides available on how to rename and migrate them to their new replacements. Data sources do not have deprecation guide as you can directly replace them in their Terraform configuration and refresh the state.
Caution:

Before executing any deprecation guide, ensure that you have backed up your Terraform state file to avoid any data loss.

### Column Details

- **Provider Version**: Provider version in which said resource or data source was marked deprecated.
- **Type**: Type of the deprecated resource or data source.
- **Old Deprecated Resource Name**: Deprecated resource or data source name.
- **New Resource Name**: New resource or data source name that will provide the same functionality.
- **Migration?**: If migration is possible to the new resource through Terraform state import.
- **Guide**: Link to deprecation guide on how to rename and migrate to new resource, if applicable.

### Deprecated Fields

Deprecation notices for fields can be found in any of the previously released CHANGELOG. Deprecated fields are also shown as deprecated during Terraform plan and apply operations. For example:

The 'size_in_mbs' field has been deprecated. Please use 'size_in_gbs' instead.

<td>Use the tsig_key_id argument to reference an oci_dns_tsig_key resource instead of embedding TSIG keys directly within external_masters.</td>
</tr>
</tbody>
</table>

### Troubleshooting the Terraform Provider

This topic describes how to troubleshoot common Oracle Cloud Infrastructure (OCI) Terraform provider issues.

Start with Troubleshooting Basics and then refer to the following sections:
Troubleshooting Basics

When troubleshooting or getting support for the Oracle Cloud Infrastructure (OCI) Terraform provider, it is often useful to first check the status of the OCI services, the version of Terraform and the provider, and enable and collect verbose logging.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checking service status and verbose log output can help you determine whether an issue is related to the Terraform provider or the OCI service the provider is using.</td>
</tr>
</tbody>
</table>

Refer to the list of common issues after you start with the basics.

**Checking OCI Service Status and Outages**

To check on the latest status and whether there are any outages in OCI, see [OCI Status](#).

**Checking the Terraform and OCI Terraform Provider Versions**

To verify the version of Terraform and the OCI Terraform provider, initialize Terraform from a directory with your configurations and then run the `--version` command. For example:

```bash
terraform init

terraform --version
```

The versions are displayed:

```
Terraform v0.12.20
+ provider registry.terraform.io/hashicorp/oci v3.95.0
```

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Newer versions of the OCI Terraform provider include the version of the provider in error messages.</td>
</tr>
</tbody>
</table>

The OCI Terraform provider documentation reflects the latest version. You can view documentation for earlier provider versions by visiting the HashiCorp reference and selecting a specific version. You can also [download and install a specific version of the provider](#).

**Verbose Logging for OCI Terraform Provider**

To get verbose console output when the provider is running, precede your Terraform command with the `TF_LOG` and `OCI_GO_SDK_DEBUG` flags. For example:

```bash
TF_LOG=DEBUG OCI_GO_SDK_DEBUG=v terraform plan
```

The `TF_LOG` level and `OCI_GO_SDK_DEBUG` flags can also be set as environment variables.

Automatic Retries

While applying, refreshing, or destroying a plan, Terraform may encounter some intermittent OCI errors (such as 429 or 500 errors) that could succeed on retry. By default, the OCI Terraform provider automatically retries such
operations for up to 10 minutes. The following fields can be specified in the provider block to further configure the retry behavior:

- disable_auto_retries - Disable automatic retries for retriable errors.
- retry_duration_seconds - The minimum duration (in seconds) to retry a resource operation in response to HTTP 429 and HTTP 500 errors. The actual retry duration may be slightly longer due to jittering of retry operations. This value is ignored if the disable_auto_retries field is set to true.

Concurrency Control Using Retry Backoff and Jitter

To alleviate contention between parallel operations against OCI services; the OCI Terraform provider schedules retry attempts using quadratic backoff and full jitter. Quadratic backoff increases the maximum interval between subsequent retry attempts, while full jitter randomly selects a retry interval within the backoff range.

For example, the wait time between the first and second retry attempts is chosen randomly between 1 and 8 seconds. The wait time between the second and third retry attempts is chosen randomly between 1 and 18 seconds. Regardless of the number of retry attempts, the retry interval time is capped after the 12th attempt at 288 seconds.

Note that the retry_duration_seconds field only affects retry duration in response to HTTP 429 and 500 errors; as these errors are more likely to result in success after a long retry duration. Other HTTP errors (such as 400, 401, 403, 404, and 409) are unlikely to succeed on retry. The retry_duration_seconds field does not affect the retry behavior for such errors.

Common Issues

Note:

See Terraform state drift with tag defaults and tags for secondary resources for a known issue with tags related to Terraform.

Resources Are Destroyed When Applying Changes

Existing OCI resources might be destroyed and re-created when Terraform configurations attempt to update a resource property that is not updatable. Terraform warns you when changes will destroy a resource. Always run terraform plan before applying changes to see what resources will be affected. See Destructive Changes for more information.

Resource Cannot Be Destroyed or Updated

You can prevent an OCI resource from being destroyed by including the lifecycle and prevent_destroy = true meta-arguments in the resource block of your Terraform configuration file. The following configuration, for example, results in an Object Storage bucket that cannot be destroyed:

```terraform
resource "oci_objectstorage_bucket" "test_bucket" {
  #Required
  compartment_id = var.tenancy
  name = "test"
  namespace = "exampleNamespace"

  lifecycle {
    prevent_destroy = true
  }
}
```

This meta-argument prevents the use of terraform destroy. Because certain configuration updates require resources to be destroyed before they can be applied, this setting can make some updates impossible to apply as well. In this example, name is a property that cannot be updated without destroying and re-creating the resource. Therefore, you cannot update the name of the bucket without removing or changing the lifecycle meta-argument.

See The lifecycle Meta-Argument for more information.

Resource Argument Cannot Be Unset
Many Oracle Cloud Infrastructure resources managed by the OCI Terraform provider accept configuration arguments that are optional. Once set, whether during resource creation or a subsequent update, these arguments cannot be unset by passing an empty string or removing the argument from the configuration. Attempts to unset these arguments are ignored by Terraform.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

Referencing Triggers in Lifecycle Meta-arguments

Terraform v0.14 and later might require that you replace global variables in your configuration files with a combination of local variables and triggers. To reference a trigger in `lifecycle` and `ignore_changes` meta-arguments and avoid executing the configuration on subsequent Terraform apply operations, reference the trigger as follows:

```terraform
resource "null_resource" "exampleB" {
  depends_on = [null_resource.exampleA]
  triggers = {
    os_user = var.os_user
  }
  lifecycle {
    ignore_changes = [
      triggers["os_user"]
    ]
  }
}
```

Cannot Delete Compartment

By default, the Terraform provider does not delete a compartment when using the `destroy` command. You must set the `enable_delete` argument to `true` for the provider to attempt to delete the compartment. For example:

```terraform
resource "oci_identity_compartment" "test_compartment" {
  compartment_id = var.compartment_id
  description = var.compartment_description
  name = var.compartment_name
  enable_delete = true
}
```

**Note:**
To destroy a compartment, the compartment must also be empty. Use the `depends_on` argument to ensure that any hidden dependencies are defined. See Resources on page 6160 for more information.

"Operation Timeout" Error

If the Terraform CLI returns an error message like the following:

```
Error: Operation CLI Timeout
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: timeout while waiting for state to become 'SUCCEEDED, FAILED, CANCELED' (last state: 'IN_PROGRESS', timeout: 15m)
```

Then the specified OCI service is indicating that the resource has not yet reached the expected state after polling for some time.
You may need to increase the operation timeout for your resource to continue polling for longer. See Operation Timeouts for details on how to do this.

"Unexpected LifeCycle state" Error

If the Terraform CLI returns an error message like the following:

```
Error: Unexpected LifeCycle state
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: During deletion, Terraform expected the resource to reach state: TERMINATED, but the service reported unexpected state: RUNNING.
Resource OCID: exampleuniqueID
Suggestion: Please retry or contact support for help with service: <service>
```

Then the specified OCI service encountered an unknown error. Retry, or contact support regarding that service.

Terraform CLI Issues

This section contains information dealing with the installation and configuration of the Terraform CLI.

"No such file" Error After Upgrading the OCI Terraform Provider

If the Terraform CLI returns an error message like the following:

```
Error asking for user input: 1 error(s) occurred:
* provider.oci: dial unix /var/folders/6r/8fk5dmbj4_z3s10mc_y_fhjw0000gn/T/plugin811254328|netrpc: connect: no such file or directory
```

You are likely using a version of the OCI Terraform provider that is not compatible with the Terraform binary you have installed. For OCI Provider versions v3.x.x and above, a minimum Terraform version of v.0.10.1 is required.

"TCP...i/o timeout" Message When Connecting Via Proxy

If the Terraform CLI returns an error message like the following:

```
* provider.oci: ... dial tcp 134.70.16.0:443: i/o timeout
```

Then you may not have properly configured your proxy settings. The OCI Terraform provider supports http_proxy, https_proxy and no_proxy variables where the inclusion or exclusion lists can be defined as follows:

```
export http_proxy=http://www.your-proxy.com:80/
export https_proxy=http://www.your-proxy.com:80/
export no_proxy=localhost,127.0.0.1
```

"x509: certificate signed by unknown authority" Error Message

If the Terraform CLI returns an error message like the following:

```
Error: Get https://iaas.<region>.oraclecloud.com/20160918/services: x509: certificate signed by unknown authority
on ../modules/network/modules/main/main.tf line 3...
```

Ensure that Terraform is using trusted TLS certificates and the certificate chain is valid. See Terraform runs failing with "x509: certificate signed by unknown authority" error for more information. If using MacOS Catalina, refer to the MacOS section of the document for more specifics on resolving certificate issues.

"Outdated GPG key...unable to verify new provider releases" Error Message
If the Terraform CLI returns an error message like the following:

```
Warning: registry.terraform.io:
This version of Terraform has an outdated GPG key and is unable to verify
new provider releases.
Please upgrade Terraform to at least <version> to receive new provider
updates.
For details see: https://discuss.hashicorp.com/t/hcsec-2021-12-codecov-security-event-and-hashicorp-gpg-key-exposure/23512
```

This message means that the Terraform registry is omitting the Terraform provider versions signed by a new GPG key. The Terraform CLI will install the last version of the OCI Terraform provider that it can successfully verify, which might not be the latest version.

To remove this message and ensure you can use the latest version of the OCI Terraform provider, upgrade the Terraform CLI to the latest maintenance release available for the major Terraform version you are using. For example, if you are using Terraform v0.12.21, upgrade to the latest available version of v0.12.

### Terraform Provider Issues

This section contains information related to the installation and configuration of the OCI Terraform provider.

#### "NotAuthenticated" Error When Using Terraform

If the Terraform CLI returns an error message like the following:

```
Error: 401-NotAuthenticated
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
Error Message: The required information to complete authentication was not
provided or was incorrect.
OPC request ID: exampleuniqueID
Suggestion: Please retry or contact support for help with service: <service>
```

- Verify you have properly set `user_ocid`, `tenancy_ocid`, `fingerprint` and `private_key_path`.
- Verify your `private_key_path` is pointing to your private key and not the corresponding public key.
- Verify you have added the corresponding public key to the user account you have specified with `user_ocid`.
- Verify the public/private key pairs you are using are of the correct format. See Required Keys for details on the correct format and how to generate keys.
- Verify the user account is part of a group with the appropriate permissions to perform the actions in the plan you are executing.
- Verify your Tenancy has been subscribed to the Region you are targeting in your plan.

#### "Can not create client, bad configuration: did not find a proper configuration for tenancy" Message When Using Aliases

If the Terraform CLI returns a message like this, it might indicate an issue with your environment:

```
Error: can not create client, bad configuration: did not find a proper
configuration for tenancy
```

If your provider configuration includes an alias, your resources should explicitly specify the provider alias using `provider = "oci.aliased_name"`. If a resource does not use the alias to specify the provider, Terraform creates a default provider to use with such resources. The default provider loads configuration values from environment variables or the `~/.oci/config` file. These values may differ from those used by your aliased provider and cause the configuration error.

Either remove the alias in your provider configuration, or ensure that every resource specifies the provider by the proper alias. Read more about using alias in the official Terraform documentation, and see Configuring the Provider for more information about how Terraform uses environment variables and the OCI config file.

#### "Field cannot be set" Error Message
If the Terraform CLI returns an error message like the following:

```
* Error: "field_name": this field cannot be set
```

You are likely using an older version of the OCI Terraform provider and the field you are trying to set was released in a later version. Use the following command to check your Terraform provider version.

```
terraform --version
```

The OCI Terraform provider documentation reflects the latest version.

"Could not get info about the first DbHome in the dbSystem" Error Message When Importing db_home

If the `oci_database_db_system` being imported is missing a primary `db_home`, an empty placeholder for `db_home` is set in the Terraform state file. To keep configurations consistent with the imported state, add an empty placeholder for `db_home` to your configuration. For example:

```
# Add this placeholder into your oci_database_db_system configuration to indicate that the primary db home is empty.
db_home {
  database {
    admin_password = ""
  }
}
```

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

"Failed to query available provider packages" Error Message When Running Resource Discovery

If the Terraform CLI returns an error message like the following when using resource discovery:

```
Failed to query available provider packages
Could not retrieve the list of available versions for provider hashicorp/oci: the previously-selected version is no longer available
```

Then you can ensure that Terraform uses an existing local provider binary by specifying its location using the `provider_bin_path` environment variable. For example:

```
export provider_bin_path=/Users/user/go/bin/
```

Terraform attempts to download the latest version of the OCI Terraform provider when you use resource discovery.

Service API Errors

Because the Terraform provider interacts with OCI services on your behalf, many error messages surfaced by the Terraform provider come directly from OCI services. The API Errors on page 6279 reference lists common errors returned by all services.

Service error messages returned by the OCI Terraform provider include the following information:

- **Error** - the HTTP status and API error codes
- **Provider version** - the version of the OCI Terraform provider used to make the request
- **Service** - the OCI service responding with the error
- **Error message** - details regarding the error returned by the service
- **OPC request ID** - the request ID
- **Suggestion** - suggested next steps
For example:

```
Error: <http_code>-<api_error_code>
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: <error_message>
OPC request ID: exampleuniqueID
Suggestion: <next_steps>
```

This section details a few of the more commonly returned service errors.

"400-InvalidParameter" Error

If the Terraform CLI returns an error message like the following:

```
Error: 400-InvalidParameter
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: <error_message>
OPC request ID: exampleuniqueID
Suggestion: Please update the parameter(s) in the Terraform config as per error message: <error_message>
```

Update the parameter specified in the error message in the Terraform configuration for the resource.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

"400-LimitExceeded" Error

While using Terraform, you might encounter errors indicating that you have reached or exceeded the service limits for a resource. For example:

```
Error: 400-LimitExceeded
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: Fulfilling this request exceeds the Oracle-defined limit for this tenancy for this resource type.
OPC request ID: exampleuniqueID
Suggestion: Request a service limit increase for this resource <service>
```

To understand more about your OCI service limits and how to request a limit increase, see Service Limits.

"404-NotAuthorized" Error

If the Terraform CLI returns an error message like the following:

```
Error: 404-NotAuthorizedOrNotFound
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: Authorization failed or requested resource not found.
OPC request ID: exampleuniqueID
Suggestion: Either the resource has been deleted or service <service> need policy to access this resource. Policy reference: <link>
```

Verify the user account is part of a group with the appropriate permissions to perform the actions in the plan you are executing. Refer to the Policy Reference for your service for more information.
"500-InternalError" Error

If the Terraform CLI returns an error message like the following:

```
Error: 500-InternalError
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: Internal error occurred
OPC request ID: exampleuniqueID
Suggestion: The service for this resource encountered an error. Please contact support for help with service <service>
```

The service responded to the request from the Terraform provider with an internal error. If you contact support for this issue, reference the information in the message.

OCI Modules for PowerShell

The Oracle Cloud Infrastructure Modules for PowerShell is a set of cmdlet modules that can be used with PowerShell Core to manage Oracle Cloud Infrastructure resources. You can invoke these cmdlets from the PowerShell command-line and with the associated PowerShell scripting language.

Requirements

To use the OCI Modules for PowerShell, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies you may want to use, see Common Policies.
- A configuration file and key pair used for signing API requests, with the public key uploaded to Oracle Cloud using Oracle Cloud Infrastructure Console. Only the user calling the API should possess the private key.
- A supported version of PowerShell installed on Windows, Linux, or macOS operating systems.

**Note:**
For installation instructions, see Installing PowerShell.

Supported PowerShell Versions

To use the OCI Modules for PowerShell, you must have the following:

- PowerShell Core version 6.0 or 7.1.

**Note:**
For more information, see Installing PowerShell.

Services Supported

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Classic Migration Service
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data

Getting Started
This topic describes how to install and configure the OCI Modules for PowerShell.

Prerequisites
Be sure to satisfy all the requirements listed here.

Installing Modules
1. Start a PowerShell session:
   a. On Windows, launch PowerShell from the Start Menu.
   b. On Linux or MacOS, run pwsh from a shell prompt:

   ```
   $ pwsh
   PowerShell 7.1.0
   Copyright (c) Microsoft Corporation. All rights reserved.
   https://aka.ms/powershell
   Type 'help' to get help.
   ```
2. To install all OCI modules, install the base module:

   Install-Module OCI.PSMODULES

**Note:**

Uninstalling the OCI.PSMODULES module will not uninstall other OCI modules. To uninstall a specific OCI module installed by this module, the OCI.PSMODULES module will have to be uninstalled first.

3. You can install just the modules for an individual service. Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual Powershell module named OCI.PSMODULES.<ServiceName>.

4. Continue to either Installing from PowerShell Gallery or Installing from GitHub on page 6217.

Installing from PowerShell Gallery

1. By default, PowerShell Gallery ("PS Gallery") is configured as a PSRepository. This can be verified by running the Get-PSRepository command:

   PS /> Get-PSRepository

<table>
<thead>
<tr>
<th>Name</th>
<th>InstallationPolicy</th>
<th>SourceLocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSGallery</td>
<td>Untrusted</td>
<td><a href="https://www.powershellgallery.com/api/v2">https://www.powershellgallery.com/api/v2</a></td>
</tr>
</tbody>
</table>

2. You can set PS Gallery as a trusted repository to avoid prompts every time you attempt to install a module from PS Gallery:

   PS /> Set-PSRepository -Name PSGallery -InstallationPolicy Trusted

3. PowerShell modules that correspond to a supported OCI service are called **service modules**. To install a service module run the Install-Module command. This example installs the service module for the OCI Identity service:

   PS /> Install-Module -Name OCI.PSMODULES.Identity

**Note:**

Each service module depends on the OCI.PSMODULES.Common (Common Module), which offers functionality common to all service modules. Installing a service module will also install the corresponding version of OCI.PSMODULES.Common for that service module.

4. Installed modules can be found in the path specified by the $Env:PSModulePath environment variable, or by running the Get-Module command with the ListAvailable parameter.

   PS /> Get-Module -ListAvailable

Installing from GitHub

To install the OCI PowerShell modules from GitHub:

1. Download the latest OCI Modules artifacts and extract them into a local directory.

   **Note:**

   Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual Powershell module named OCI.PSMODULES.<ServiceName>.
2. Register the extracted directory as the local PowerShell repository:

```powershell
PS /> Register-PSRepository -Name "LocalRepo" -SourceLocation <extractedlocation>
```

3. Find the modules available in the local repository:

```powershell
PS /> Find-Module -Repository "LocalRepo"
```

4. Install a specific module:

```powershell
PS /> Install-Module -Name OCI.PSModules.Objectstorage -Verbose -Repository LocalRepo
```

**Note:**
Each service module depends on the OCI.PSModules.Common (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of OCI.PSModules.Common for that service module.

5. Installed modules can be found in the path specified by the `$Env:PSModulePath` environment variable, or by running the `Get-Module` command with the `ListAvailable` parameter.

```powershell
PS /> Get-Module -ListAvailable
```

### Installing with Yum

If you are using Oracle Linux version 7.x, the OCI PowerShell Modules packages can be installed with yum.

1. To install the OCI PowerShell modules using yum:

```bash
$ sudo yum install oci-powershell-modules
```

2. Start a PowerShell Session and register the downloaded directory `/usr/lib/dotnet/NuPkgs` as a local PowerShell repository using the following command:

```powershell
$ pwsh
PS /> Register-PSRepository -Name "LocalRepo" -SourceLocation /usr/lib/dotnet/NuPkgs
```

3. Find the modules available in the local repository using the following command:

```powershell
PS /> Find-Module -Repository "LocalRepo"
```

4. Install a specific module:

```powershell
PS /> Install-Module -Name OCI.PSModules.Objectstorage -Verbose -Repository LocalRepo
```

**Note:**
Each service module depends on the OCI.PSModules.Common (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of OCI.PSModules.Common for that service module.

5. Installed modules can be found in the path specified by the `$Env:PSModulePath` environment variable, or by running the `Get-Module` command with the `ListAvailable` parameter.

```powershell
PS /> Get-Module -ListAvailable
```
Follow **these installation steps** if you haven't installed the required modules.

Before invoking cmdlets in OCI Modules, you need to **set up the configuration file**, and then optionally **import the required modules** into a PowerShell session.

**Configuration File**

A configuration file provides essential **configuration information**, like user credentials and tenancy OCID. This configuration information is used by the OCI Modules for PowerShell to authenticate and interact with Oracle Cloud services. You can create this file using a **setup cmdlet**, or manually using a text editor.

**Set-OCIClientConfig**

The `Set-OCIClientConfig` cmdlet included in the Common module will walk you through setting up a configuration file. This cmdlet prompts you for information required by the configuration file, including the key pair used to sign API requests.

For more information about how to find the required information, see:

- **Where to Get the Tenancy's OCID and User's OCID**
- **Regions and Availability Domains**

**Manual Setup**

If you want to set up the API signing key pair manually and write your own configuration file, see **SDK and Tool Configuration** and **Required Keys**.

**Note:**

Use the `New-OCIClientKeys` cmdlet to generate a API signing key pair to include in the configuration file.

**Importing Modules**

PowerShell will automatically import the module (and its dependencies) into your session the first time you run any command from the installed module. To **explicitly** import a module, run the `Import-Module` command.

For example, to import the version 1.0.0 of the Identity service module:

```
PS /> Import-Module OCI.PSModules.Identity -RequiredVersion 1.0.0 -Verbose
```

To find all imported modules in your current PowerShell Session, run the `Get-Module` command:

```
PS /> Get-Module
```

<table>
<thead>
<tr>
<th>ModuleType</th>
<th>Name</th>
<th>ExportedCommands</th>
</tr>
</thead>
</table>
| Binary     | OCI.PSModules.Common                   | {Clear-OCICmdletHistory, Get-OCIClientSession}, Get-OCICmdletHistory, ...
| Binary     | OCI.PSModules.Identity                 | {Add-OCIIdentityUserToGroup,...

**Note:**

Each service module depends on the `OCI.PSModules.Common` (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of `OCI.PSModules.Common` for that service module.

**Updating Modules**

New versions of the OCI PowerShell modules release weekly. To update the installed OCI PowerShell modules to the latest version, run the `Update-Module` command.
Before updating any OCI module, you should first uninstall the module. To avoid dependency conflicts when importing modules into PowerShell session, update all installed OCI Modules to the same version.

```
PS /> Update-Module -Name "OCI.PSModules.*" -Verbose
```

**Uninstalling Modules**

To remove any installed module, you can either use the Uninstall-Module cmdlet or delete the module folder located in the path in the $Env:PSModulePath environment variable.

For example:

```
PS /> Uninstall-Module -Name OCI.PSModules.Identity
```

**Next Steps**

Now that you’ve taken care of installation and setup, you can proceed directly to Working with Cmdlets, or continue to Advanced Concepts on page 6224.

**Working with Cmdlets**

The OCI Modules for PowerShell cmdlets are built on the Oracle Cloud Infrastructure SDK for .NET. These cmdlets make calls to Oracle Cloud Infrastructure REST APIs with the passed cmdlet parameter values.

**Note:**

Cmdlet parameters are named corresponding to the respective REST API parameters as listed in the API reference.

The OCI REST APIs use HTTPS requests and responses. For more information, see About the API.

**Cmdlet Discovery**

OCI Cmdlets are named using a verb -noun pair pattern, where verb is the operation performed on the resource denoted by the noun, which usually includes the service name followed by the name of the resource in that service.

For example, the following command returns all cmdlets available to work with a compute instance resource in the Compute service, which is part of the OCI Core PowerShell module:

```
PS /> Get-Command -Module OCI.PSModules.Core -Noun "*ComputeInstance*"
```

<table>
<thead>
<tr>

</table>
Sample Cmdlet

This example shows how to invoke a simple OCI cmdlet that calls the `GetNamespace` operation of the OCI Object Storage service. This operation returns the name of the Object Storage namespace for the user making the request.

**Note:**
Install and import the ObjectStorage service before trying out this example. For more information, see Installation.

```
PS /> Get-OCIObjectStorageNamespace
us-phx-test-namespace
```

Cmdlet Help

To get help information for a cmdlet, use the `Get-Help` cmdlet, passing in the name of the cmdlet as a parameter.

**Note:**
For more detailed help information, use the `-Full` parameter.

This example shows help output for the `Get-OCIObjectStorageNamespace` cmdlet:

```
PS /> Get-Help Get-OCIObjectStorageNamespace
NAME
Get-OCIObjectStorageNamespace
SYNOPSIS
   Invokes ObjectStorage service - GetNamespace operation.
SYNTAX
DESCRIPTION
   Each Oracle Cloud Infrastructure tenant is assigned one unique and uneditable Object Storage namespace. The namespace is a system-generated string assigned during account creation. For some older tenancies, the namespace string may be the tenancy name in all lower-case letters. You cannot edit a namespace. GetNamespace returns the name of the Object Storage namespace for the user making the request. If an optional compartmentId query parameter
```
is provided, GetNamespace returns the namespace name of the corresponding tenancy, provided the user has access to it.

REMARKS
To see the examples, type: "Get-Help Get-OCIObjectStorageNamespace -Examples"
For more information, type: "Get-Help Get-OCIObjectStorageNamespace -Detailed"
For technical information, type: "Get-Help Get-OCIObjectStorageNamespace -Full"
For online help, type: "Get-Help Get-OCIObjectStorageNamespace -Online"

Common Parameters
This section describes the optional global cmdlet parameters common to all cmdlets present in any OCI PowerShell service module.

**ConfigFile**
The path to the configuration file that supplies credentials for the Oracle Cloud.

**Endpoint**
Indicates the service endpoint to use for OCI API calls, including any required API version path. For example, https://audit.us-ashburn-1.oraclecloud.com

**FullResponse**
By default, OCI Cmdlets output the response body of the REST API operation. Including the FullResponse switch parameter indicates that the cmdlet should output the complete response returned by the API operation wrapped in its associated .NET type (an object containing API response headers in addition to an optional response body).

**NoRetry**
A switch parameter to disable default retry logic for calls to services.
By default, OCI Modules for PowerShell retry failed API calls that return status codes 400, 401, 404, 409, 429 and 500. Retry attempts use an exponential backoff algorithm with a maximum of 5 attempts over a maximum time span of 10 minutes. Include this switch parameter in the cmdlet invocation to disable the default retry logic.

**Profile**
Specifies which profile to load from the configuration file. This parameter expects a case-sensitive profile name existing in the configuration file.

**Region**
Specifies the Region-ID of the region to make calls against. For example: us-phoenix-1 or ap-singapore-1.

**TimeOutInMillis**
Specifies the maximum wait time in milliseconds for the API request to complete. The default value is 100,000 milliseconds (100 seconds).
**AuthType**

Defines the type of authentication to use for making API requests. By default the API Key in your config file is used. Valid values are ApiKey or InstancePrincipal.

Cmdlet Input and Output

This section describes how the OCI Cmdlets process input and output.

**Cmdlet Input**

OCI Cmdlets currently accept inputs from command line parameters or through pipeline by property names. To see an example on passing inputs through pipeline by property name refer this sample.

**Cmdlet Output**

By default, OCI Cmdlets return only the API response body encapsulated in an associated .NET type. For use cases that require the users to inspect the complete API response including the response headers, use the `FullResponse` switch parameter in the cmdlet invocation.

In the following example, the `GetConfiguration` operation in the OCI Audit service returns a Configuration resource in the response body.

**Note:**

To run the following example, import `OCI.PSMODULES.Audit`.

```powershell
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId | gm
```

```
TypeName: Oci.AuditService.Models.Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>-----------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>RetentionPeriodDays</td>
<td>Property</td>
<td>System.Nullable[int] RetentionPeriodDays</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{get;set;}</td>
</tr>
</tbody>
</table>
```

In the example output above, the default invocation only returns the .NET object that encapsulates the API response body.

To get an output object that includes the complete API response include the `-FullResponse` parameter in the cmdlet invocation. For example:

```powershell
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId - FullResponse | gm
```

```
TypeName: Oci.AuditService.Responses.GetConfigurationResponse

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>-----------</td>
<td>------------</td>
</tr>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{get;set;}</td>
</tr>
</tbody>
</table>
```
Asynchronous Calls

For Oracle Cloud APIs that return an asynchronous work request response, with opc-work-request-id in the response header and no response body, OCI PowerShell Cmdlets return a Oci.PSModules.Common.Cmdlets.WorkRequest object containing the OpcWorkRequestId property.

For example:

<p>| TypeName: Oci.PSModules.Common.Cmdlets.WorkRequest |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>OpcWorkRequestId</td>
<td>Property</td>
<td>string OpcWorkRequestId {get;set;}</td>
</tr>
</tbody>
</table>

Error Handling

If an error occurs when running an OCI Cmdlet, the cmdlet throws a terminating error with an error record containing the exception and an error message about the underlying cause.

Advanced Concepts

This section covers PowerShell SDK concepts.

Managing Session Preferences

The OCI Modules for PowerShell support the use of environment variables in a PowerShell session to specify values some optional common parameters. These environment variables can be configured directly in the PowerShell session or by using the Set-OCIClientSession cmdlet. Values assigned to these environment variables are used for making API calls only in the PowerShell session in which they are set.

Set Environment Variables Directly from PowerShell

The following environment variables can be used to specify values for some parameters used by the OCI Modules for PowerShell:

<table>
<thead>
<tr>
<th>Cmdlet Parameter</th>
<th>Environment Variable Name</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>OCI_PS_REGION</td>
<td>If a value is not specified, region value from the user preferred profile is used.</td>
</tr>
<tr>
<td>Profile</td>
<td>OCI_PS_PROFILE</td>
<td>If a value is not specified, the DEFAULT profile is used.</td>
</tr>
<tr>
<td>ConfigFile</td>
<td>OCI_PS_CONFIG</td>
<td>If a value is not specified, config file at ~/.oci/config will be used.</td>
</tr>
<tr>
<td>NoRetry</td>
<td>OCI_PS_NORETRY</td>
<td>If a value is not specified, default retry strategy is used to attempt retries.</td>
</tr>
<tr>
<td>TimeOutInMillis</td>
<td>OCI_PS_TIMEOUT</td>
<td>If a value is not specified, the default value of 100,000 milliseconds (100 seconds) is used.</td>
</tr>
<tr>
<td>AuthType</td>
<td>OCI_PS_AUTH</td>
<td>If a value is not specified, the API key defined in the config file is used.</td>
</tr>
</tbody>
</table>

For example, to set the region:

PS /> $Env:OCI_PS_REGION="us-phoenix-1"
Set Environment Variables using Cmdlets

You can use the Set-OCIClientSession and Get-OCIClientSession cmdlets to set and retrieve the session preference environment variables.

Set-OCIClientSession

This cmdlet sets the Region, Profile and Config file preferences for the PowerShell session through the environment variables shown above.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import OCI.PSMODULES.COMMON before running the following example.</td>
</tr>
</tbody>
</table>

```
PS /> Set-OCIClientSession -RegionId "us-ashburn-1" -Profile "Test" -Config "~/.oci/testconfig"
```

RegionId     Profile Config
--------     ------- ------
us-ashburn-1 Test    ~/.oci/testconfig

To remove a session preference environment variable, run the Clear-OCIClientSession cmdlet with the appropriate parameters.

Get-OCIClientSession

The Get-OCIClientSession cmdlet in the common module is used to retrieve the session preference values set for the common parameters from the current PowerShell session.

```
PS /> Get-OCIClientSession
```

RegionId     Profile Config
--------     ------- ------
us-ashburn-1 Test

Parameter Precedence

When evaluating parameters, the OCI Modules for PowerShell follows this order of precedence:

1. The value specified in the cmdlet parameter.
2. The value specified in the session preferences.
3. The value specified in the user-selected profile of the OCI configuration file located at ~/.oci/config.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The OCI Modules for PowerShell use the DEFAULT profile as a fall back profile. Any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile.</td>
</tr>
</tbody>
</table>

History Store

By default, OCI Cmdlets output the response body of the underlying REST API operation. The history store provides users with a PowerShell variable that can be used to look into OCI Cmdlet invocations and their complete API responses from OCI services.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each PowerShell session gets its own history store.</td>
</tr>
</tbody>
</table>

You can use the history store to:

- Use the previous Cmdlet's response object values in the next Cmdlet
Developer Tools

- Inspect the complete API response, including the response headers - for example, the use of e-tags for optimistic concurrency, or the OpcNextPage header for pagination
- Examine cmdlet invocation sequences for diagnostic purposes

For more information, see the History Store example on GitHub.

History Store Properties

This section explains the properties contained in the history store object stored in $OCICmdletHistory.

<table>
<thead>
<tr>
<th>TypeName:</th>
<th>Oci.PSModules.Common.Cmdlets.CmdletHistory.OCICmdletHistoryStore</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>MemberType Definition</td>
</tr>
<tr>
<td>Entries</td>
<td>Property</td>
</tr>
<tr>
<td>LastResponse</td>
<td>Property</td>
</tr>
<tr>
<td>Size</td>
<td>Property</td>
</tr>
</tbody>
</table>

**Size**

Indicates the maximum number of commands that can be saved in the history store. The default value is 20. Valid values are from 1 and 100000 (inclusive). To modify the size of history store, use Set-OCICmdletHistory.

**Note:**
We recommend keeping the history size to a minimum to limit memory usage.

**Entries**

The Oci.PSModules.Common.Cmdlets.CmdletHistory.OCICmdletHistory object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartTime</td>
<td>System.DateTime</td>
<td>Start time of cmdlet execution.</td>
</tr>
<tr>
<td>EndTime</td>
<td>System.DateTime</td>
<td>End time of cmdlet execution.</td>
</tr>
<tr>
<td>Command</td>
<td>System.Management.Automation.InvocationInfo</td>
<td>Describes how and where this command was invoked.</td>
</tr>
</tbody>
</table>

**LastResponse**

History Store Cmdlets

Oci.PSModules.Common module provides the following cmdlets for working with the History Store. See the GitHub example.
Get-OCICommandHistory
Gets the cmdlet history stored in the current PowerShell session.

Set-OCICommandHistory
Sets properties of the history store.

Clear-OCICommandHistory
Deletes the cmdlet history stored in the current PowerShell session.

Pagination
OCI Cmdlets that invokes list API operations have the ability to paginate results, allowing you to retrieve the available results in batches (automatically following pagination tokens) until no more records are available.

Note:
Examples in this topic call the ListImages operation in the Compute service. Be sure to import OCI.PSMODULES.Core before trying out the examples in this section.

Get First Page Results
The default behavior of a cmdlet that supports pagination is to get only the first page of results when invoked without the -Page parameter specified.

For example, to get the first page of compute images available invoke the Get-OCIComputeImagesList with your compartment ID:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId | Measure-Object
Count : 100
```

The above example implicitly sets the -Page parameter to NULL.

Note:
The maximum number of results per page is defined by the service and can be found in the service API reference.

Limit Results
The -Limit parameter specifies the maximum number of results returned per page.

This example sets the maximum number of results returned per page to 5:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 5 | Measure-Object
Count : 5
```

Get Next Page Results
The -Page parameter is used to get the next page of results by passing the pagination token from the 'opc-next-page' response header contained in the previous cmdlet response.

Note:
You can use the history store to get the previous cmdlet response.
This example shows how to retrieve the results remaining from a previous paginated call by passing the $OCICmdletHistory.LastResponse.OpcNextPage property from the history store as the argument to the -Page parameter:

```powershell
Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Page $OCICmdletHistory.LastResponse.OpcNextPage | Measure-Object
```

**Get All Results**

OCI Cmdlets that support pagination can auto paginate and fetch results from all available pages. Let the cmdlet do the pagination by passing -All switch parameter when running the cmdlet.

```powershell
Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -All | Measure-Object
```

**Waiters and Asynchronous Calls**

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your command to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action. You can poll a resource to determine its state.

OCI Modules for PowerShell offer waiter parameters that allow your cmdlet to wait until a resource reaches a desired state. A cmdlet with waiter parameters can be invoked in a blocking manner to wait until either one of the desired states is reached or a timeout is exceeded. Waiters abstract the polling logic that you would otherwise have to add before taking further actions on a resource or a workrequest.

For example, when you call LaunchInstance in the Compute service, the response header contains a work-request-id. The OCI Modules for PowerShell uses this ID when you specify the -WaitForStatus parameter, which causes your script to wait until the work request succeeds before proceeding.

For example:

```powershell
#Create a new compute instance and wait for the instance work request to succeed or fail,
appearing every 60 seconds and attempting 20 times max
$ComputeInstance = New-OCIComputeInstance -LaunchInstanceDetails $LaunchDetails
-WaitForStatus Succeeded,Failed -MaxWaitAttempts 20 -WaitIntervalSeconds 60
```

**Waiter parameters**

This section describes the parameters used for asynchronous calls.

**WaitForStatus**

Specify this parameter to perform the action and then wait until the resource reaches the desired lifecycle state. Multiple states can be specified, returning when the resource reaches one of the desired states.

**WaitIntervalSeconds**

Check every WaitIntervalSeconds to see whether the resource has reached one of the desired states. Default value for this parameter is 30 seconds.

**MaxWaitAttempts**

Maximum number of attempts to be made until the resource reaches one of the desired states. Default value for this parameter is 3 attempts.
Note:
Currently, OCI Cmdlets do not accept maximum wait time for cmdlets that support waiters. You can work around this limitation by controlling the values of MaxWaitAttempts and/or WaitIntervalSeconds.

On successful completion, the cmdlet returns the original response object received. In case of an error like the resource failing to reach the desired state within the given limits, an exception containing the error message would be thrown.

Stream Inputs and Outputs

Some OCI Cmdlets interact with APIs that accept or return stream type objects (for example, the InvokeFunctions operation in the Functions service). These OCI cmdlets accept parameters that can take a file path and implicitly convert files to streams and back.

Note:
You can either pass a stream parameter or the equivalent file parameter, but not both.

The file input parameter is named after the corresponding stream input parameter and file output parameter is named as OutputFile.

Note:
For an example, see the help text for the Invoke-OCIFunctionsInvokeFunction cmdlet in OCI.PSMODULES.Functions.

This sample on GitHub shows how to work with streams.

Logging

To facilitate troubleshooting, OCI Modules for PowerShell supports logging debug- and verbose-level messages on the console in addition to error messages. This feature has been integrated with the standard PowerShell Debug and Verbose parameters.

Pass the -Debug or -Verbose parameters in the cmdlet invocation to see log messages on the console.

For example:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Verbose
#More Verbose
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Debug
```

Authenticating with Instance Principals

Instance principals is an IAM service feature that enables instances to be authorized actors (or principals) that can perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

Note:
For more information on instance principals, see Calling Services from an Instance.

To enable instance principal authentication from OCI Cmdlets, call authorize the instance and set the AuthType parameter. For example:

```
PS /> Get-OCIIdentityRegionsList -AuthType InstancePrincipal
```
Examples

Examples of OCI PowerShell Cmdlet usage can be found on GitHub, including:

- Creating an instance using waiters
- Accessing OCI cmdlet history store
- Using OCI cmdlet common parameters
- Downloading an object from Object Storage
- Setting preferred region and profile per session
- List all available Compute Images
- Searching resources using polymorphic objects

If you'd like to see another example not already covered, file a GitHub issue.

Running Examples

1. Clone the OCI PowerShell Modules project from GitHub.

   ```
   PS /> git clone https://github.com/oracle/oci-powershell-modules.git
   ```

2. Navigate to the examples folder inside the cloned repository.

   ```
   PS /> cd ./oci-powershell-modules/Examples
   ```

3. Install the required modules. Find additional details about setting up and running examples from the README page.

4. Run the example scripts after setting the required environment variables.

   ```
   PS /oci-powershell-modules/Examples> ./Waiter_Core.ps1
   ```

Ansible Collection

This topic provides information about the Oracle Cloud Infrastructure (OCI) Ansible collection.

Collections are Ansible's recommended method of packaging and releasing modules, roles, playbooks, and documentation. See Getting Started on page 6231 to begin using our Ansible collection.

OCI supports the use of Ansible modules to automate cloud infrastructure provisioning and configuration, orchestration of complex operational processes, and deployment and update of your software assets.

Ansible tracks your resources using inventory lists. The inventory can be a simple static .ini file or dynamically created, where a plugin assembles an up-to-date infrastructure inventory. For more information, see Working with Ansible Inventory on page 6234.

Ansible playbooks automate configuration, deployment, and orchestration tasks. Ansible playbooks use a declarative language (YAML) that allows you to describe infrastructure configuration, deployment policy, and the orchestration of complex process steps. OCI provides a set of Example Playbooks for your review.

The OCI Ansible collection supports Ansible Tower and AWX. For more information on how to set up the collection with Ansible Tower, refer to the Using Oracle Cloud Infrastructure with Ansible Tower and AWX blog post. To install the free version of Ansible Tower (AWX) on an OCI compute instance, you can use our solution on GitHub.

- Services supported: Refer to the list of currently supported services for details.
- Licensing: Copyright © 2020, Oracle and/or its affiliates. This software is made available to you under the terms of the GPL 3.0 license or the Apache 2.0 license. See LICENSE.txt for details.
- Documentation: Additional OCI Ansible collection documentation is available on docs.oracle.com, readthedocs.io, and GitHub.
- Download: To download our Ansible collection, follow the steps in Getting Started on page 6231.
Tip:
The OCI Ansible collection is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Notifications
To be notified when new versions of our Ansible collection are released, subscribe to the Oracle Cloud Infrastructure Ansible collection Atom feed.

Questions or Feedback
Ways to get in touch:
• GitHub: To file bugs and feature requests only.
• Stack Overflow: Use the oci-ansible and oracle-cloud-infrastructure tags in your post.
• Developer Tools section of the Oracle Cloud forums.

Getting Started
This topic discusses how to get started using the Oracle Cloud Infrastructure (OCI) Ansible collection. The OCI Ansible collection replaces our legacy Ansible modules.

Note:
If you currently use our legacy Ansible modules and would like to start using collections, refer to our migration guide.

To start using Ansible with OCI, ensure that you meet the prerequisites, then install the Ansible collection using yum or manually.

Tip:
You can use Resource Manager to preinstall the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes Ansible, the OCI Ansible collection and its dependencies, and preconfigures the required authorization.
Both Ansible and our Ansible collection also come preinstalled and preauthenticated on Cloud Shell.

Prerequisites for Using Ansible with Oracle Cloud Infrastructure
• You must have an Oracle Cloud Infrastructure account.
• You must have a user in that account in a security group with a policy that grants necessary permissions for working with resources in the account compartments. For guidance, see How Policies Work.
• You must have the necessary credentials and OCID information.

Installing the Ansible Collection with Yum
If you're running Oracle Linux 7 or Oracle Linux 8, you can use yum to install the Oracle Cloud Infrastructure Ansible collection RPM.
The Ansible collection RPM installs the OCI Ansible collection and its required dependencies: the OCI SDK for Python and Ansible.

Note:
This installation uses Python version 3.6 and Ansible version 2.9 or later.

Use one of the following commands to enable the Oracle Linux developer repository and install the Ansible collection RPM, depending on your Oracle Linux version.
Oracle Linux 7:

```
yum install -y oci-ansible-collection --enablerepo ol7_developer --
enablerepo ol7_developer_EPEL
```

Oracle Linux 8:

```
yum install -y oci-ansible-collection --enablerepo ol8_developer --
enablerepo ol8_developer_EPEL
```

After installing the RPM, you must configure the SDK and CLI configuration file as explained in Configuring Authentication on page 6233.

**Test the Installation**

To test the installation of the RPM and configuration of the SDK, you can run a sample Ansible playbook.

If you're using Oracle Linux 7, use the following command to test your installation:

```
ansible-3 localhost -m oracle.oci.oci_object_storage_namespace_facts
```

If you're using Oracle Linux 8, use the following command to test your installation:

```
ansible localhost -m oracle.oci.oci_object_storage_namespace_facts
```

**Manual Installation**

**Installing the Oracle Cloud Infrastructure SDK for Python**

1. Download and install the SDK for Python by following instructions in the topic, SDK for Python. For additional guidance, see Downloading and Installing the SDK.
2. After installing the SDK for Python, you must configure it using instructions in the topic Configuring the SDK.

**Installing and Configuring Ansible**

- To install Ansible, follow the instructions provided in the Ansible Installation Guide.
- For guidance configuring Ansible, see Configuring Ansible.

**Note:**

The OCI Ansible collection requires Ansible version 2.9 or later. If you are using an earlier version of Ansible, refer to the documentation for our legacy modules.

**Installing the Oracle Cloud Infrastructure Ansible Collection**

Install the OCI Ansible collection from Ansible Galaxy by using the following command:

```
$ ansible-galaxy collection install oracle.oci
```

If you've already installed the collection, you can update its modules to the latest version by adding the `--force` flag to the command. For example:

```
$ ansible-galaxy collection install --force oracle.oci
```

**Sample Playbooks**

Sample playbooks are available in the Oracle Cloud Infrastructure Ansible collection GitHub project. The samples library is updated regularly with the addition of new samples. See Example Ansible Playbooks on page 6243 for more information.

**Writing a Sample Playbook**
After your installation is complete, or if you're using the Cloud Shell, you can write a sample playbook that uses Ansible modules. Following is an example playbook (named list_buckets.yml) that uses the `oci_object_storage_bucket_facts` module to fetch facts pertaining to the buckets in your compartment.

---
- name: List summary of existing buckets in OCI object storage
  collections:
    - oracle.oci
  connection: local
  hosts: localhost
  tasks:
    - name: List bucket facts
      oci_object_storage_bucket_facts:
        namespace_name: '<yournamespace>'
        compartment_id: '<yourcompartmentocid>'
        register: result
    - name: Dump result
      debug:
        msg: '{{result}}'

Executing the Playbook

Execute the Ansible playbook using Python by invoking this command:

$ ansible-playbook list_buckets.yml

How to Obtain Module Documentation

Detailed information about using our Ansible modules is available on docs.oracle.com and readthedocs.io.

To obtain access to detailed information about using Ansible modules in the CLI, use the `ansible-doc` command on the module's name. For example, to get the documentation for the `oci_object_storage_bucket_facts` module, execute the following command:

$ ansible-doc oracle.oci.oci_object_storage_bucket_facts

Configuring Authentication

When creating and configuring Oracle Cloud Infrastructure resources, Ansible modules use authentication information that is outlined in the SDK and CLI Configuration File on page 6051.

**Caution:**

**User Credentials** that are referenced in Oracle Cloud Infrastructure SDK configuration files grant access to Oracle Cloud Infrastructure resources. Therefore, it is important to secure the credentials to prevent unauthorized access to these resources. To secure the credentials on the controller node where your Ansible playbooks run, follow guidelines outlined in the document **Securing IAM** on page 5289 (see section entitled "IAM Credentials").

Ansible modules permit you to override authentication information specified in the SDK configuration file by using module options and environment variables. Documentation for authentication overrides is provided internally, as described in How to Obtain Module Documentation. However, using environment variables and Ansible module options to override authentication information must be avoided in production scenarios.

We recommend using Oracle Cloud Infrastructure SDK configuration files to specify authentication information. To support multiple users, use the "profiles" feature in the SDK configuration file. When distributing roles that use Ansible modules, ensure that no IAM credentials are included with the roles.

For More Information

- Using collections
**Working with Ansible Inventory**

Ansible tracks configuration resources by preserving lists, called inventory lists, as simple files (also sometimes called a *hostfile*). These inventory lists can be static or dynamic. Dynamic lists can automatically update when inventory resources are added, deleted, or moved.

Because many Oracle Cloud Infrastructure (OCI) resources are added and deleted over time, static inventory lists can easily become obsolete. Tools such as Terraform or the OCI SDKs also may affect your resources.

Oracle Cloud Infrastructure provides a dynamic inventory plugin for maintaining accurate Ansible inventory.

For more information about Ansible inventory files, see Working with Inventory and Working with Dynamic Inventory.

**Enabling the Inventory Plugin**

If you have an existing `ansible.cfg` file and that configuration already enables plugins using `enable_plugins`, you must enable the OCI inventory plugin by adding it as well. For example:

```
[inventory]
enable_plugins = oracle.oci.oci
```

If you do not already have an `ansible.cfg` file that contains `enable_plugins`, you do not need to add the OCI inventory plugin to the configuration.

**Configuring the Inventory Plugin**

The only requirement for using the OCI inventory plugin after it is enabled is to provide an inventory source you have permissions to parse. Inventory sources are defined in a YAML configuration file. See User Permissions on page 6242 for more information.

To start using the inventory plugin with a YAML configuration source, create a file with with one of the following accepted filenames:

- `<filename>.oci.yml`
- `<filename>.oci.yaml`

Add `plugin: oracle.oci.oci` to the YAML configuration file.

The minimum inventory source file needed to run the OCI inventory plugin looks like this, for example:

```
# demo.oci.yml
plugin: oracle.oci.oci

# Optional fields to specify oci connection config:
config_file: ~/.oci/config
config_profile: DEFAULT
```

This example uses the `config_file` and `config_profile` parameters so the plugin can use authentication information that is outlined in the SDK and CLI Configuration File on page 6051. Some parameters can also be provided as environment variables.

For a complete list of parameters and environment variables that the plugin supports, see OCI Inventory Plugin. The inventory scenarios include many of the available parameters.

**Important:**

By default, the OCI inventory plugin discovers and lists only compute instances that have a public IP address. See Hostname Format Preferences on page 6236 for more information.

**Order of Precedence**

The inventory plugin uses the following order of precedence when an option is provided in more than one location:
1. YAML file settings.
2. Environment variables.
3. Configuration settings in the selected profile in your OCI configuration file.

Fetching Database Hosts

By default, the OCI inventory plugin discovers and lists only compute instances. Database nodes are servers running database software. Database nodes are fetched by setting the option `fetch_db_hosts` to `true`. For example:

```yaml
# demo.oci.yml
# DB Hosts
plugin: oracle.oci.oci
fetch_db_hosts: true
```

Using the Inventory Plugin

Ansible inventory plugins allow you to define the data sources used to compile an inventory of hosts that Ansible uses to target tasks. These data sources are accessed by using either the `-i /path/to/file` or the `-i 'host1, host2'` command line parameters, or from other configuration sources.

You can run the inventory with this command, for example:

```
ansible-inventory -i <filename>.oci.yml --graph
```

This produces output similar to the following:

```
@all:
  --@oci:
    |--compute_instance1
    |--compute_instance2
  @ungrouped:
```

**Important:**

By default, the inventory is generated for all the compartments in the tenancy. You must have `COMPARTMENT_INSPECT` permission on the root compartment for this script to be able to access all compartments. However, when `compartment_ocid` is specified, the inventory is generated for only the specific compartment, so you only need `COMPARTMENT_INSPECT` permission on the specified compartment. For more information, see How Policies Work.

To fetch all instance details, you must also have permission to list and read instances and VNICs, and read VCNs and subnets. See User Permissions on page 6242 for more information.

You can add inventory plugins to your plugin path and set the default inventory path to simplify your commands. Add the default inventory path to the `[defaults]` section of your `ansible.cfg` file, or use the `ANSIBLE_INVENTORY` environment variable to point your inventory sources. You can then run the following command to yield the same output as when you pass your YAML configuration sources directly:

```
ansible-inventory --graph
```

Inventory plugins normally only execute at the start of a run, before playbooks, plays, and roles are loaded. You can ‘re-execute’ a plugin by using the `meta: refresh_inventory` task, which clears out the existing inventory and rebuilds it.

Inventory Output

The inventory list that is generated by the inventory plugin is grouped using the following attributes:
• The region in which the compute instance resides
• The name of the compartment the compute instance belongs to
• The Availability Domain the compute instance is in
• The vcn_id of the VCN the compute instance is in
• The subnet_id of the subnet the compute instance is in
• The security_list_ids of the subnet the compute instance is in
• The image_id of the image used to launch the compute instance
• Shape of the compute instance
• The compute instance's free-form tags, with the group name set to tag_<tag_name>=<tag_value>
• The compute instance's defined tags, with the group name set to <tag_namespace>#<tag_name>=<tag_value>
• OCI compute instance metadata (key-value pairs), with the group name set to <metadata-key>=<metadata-value>
• OCI compute instance extended metadata (key-value pairs), with the group name set to <metadata-key>=<metadata-value>

Hostname Format Preferences

The inventory generated by the OCI inventory plugin contains only instances that have a public IP address by default. This is useful in cases where the Ansible controller node is outside of the VCN, since Ansible can only reach instances that have public IP addresses.

You can configure the inventory_hostname to private_ip or any custom hostname by passing Jinja2 expressions as a list to the hostname_format_preferences option. The hostname_format_preferences option takes a list of Jinja2 expressions in order of precedence to compose inventory_hostname. The inventory plugin ignores expressions if the result is an empty string or "None" value. The instance is ignored if none of the hostname_format_preferences expressions result in a non-empty value.

The following example sets the inventory_hostname to either "display_name+'.oci.com'" or "private_ip" or "public_ip":

```yaml
hostname_format_preferences:
  - "display_name+'.oci.com'"
  - "private_ip"
  - "public_ip"
```

Expressions are evaluated on host_vars of every instance. Evaluation respects the order of precedence in your configuration to compose inventory_hostname. In the preceding example, "display_name+.oci.com'" is evaluated before "private_ip" and "public_ip".

Filtering Hosts

The OCI inventory plugin comes with various filtering options to filter the hosts returned by the plugin.

Exclude Hosts from Inventory

You can pass a list of Jinja2 conditional expressions to the exclude_host_filters parameter. Each expression in the list is evaluated for each host. When the expression is true, the host is excluded from the inventory. The exclude_host_filters parameter takes priority over the include_host_filters and filters options.

The following example excludes hosts that are not in the region 'iad' from the inventory:

```yaml
exclude_host_filters:
  - "region not in ['iad']"
```
Exclude Hosts Using Freeform Tags

To exclude a host from the inventory using freeform tags, you can use the following syntax:

```yaml
exclude_host_filters:
  # filter the hosts with freeform tag with key <tag_key> which has value <tag_value>
  - "'<tag_value>' == freeform_tags.<tag_key>"
  # filter the hosts which has <tag_key> freeform tag
  - "'<tag_key>' in freeform_tags"
```

For example:

```yaml
exclude_host_filters:
  - "'operating_system' in freeform_tags"
  - "'linux' == freeform_tags.operating_system"
```

Exclude Hosts Using Defined Tags

To exclude a host from the inventory using defined tags, you can use the following syntax:

```yaml
exclude_host_filters:
  # filter the hosts with defined tag in <namespace> with <tag_key> and <tag_value>
  - "'<tag_value>' == defined_tags.<namespace>..<tag_key>"
  # filter the hosts which has <tag_key> in the <namespace> in defined tags
  - "'<tag_key>' in defined_tags.<namespace>"
```

For example:

```yaml
exclude_host_filters:
  - "'ansible' == defined_tags.ansible_collections_tag_namespace.managed_by"
  - "'managed_by' in defined_tags.ansible_collections_tag_namespace"
```

Include Hosts in Inventory

You can pass a list of Jinja2 conditional expressions to the `include_host_filters` parameter. Each expression in the list is evaluated for each host. When the expression is true, the host is included in the inventory.

The following example includes only the hosts that have a `display_name` ending with `.oci.com` in the inventory:

```yaml
include_host_filters:
  - "'display_name is match('.*.oci.com')"
```

Note:
The `include_host_filters` and `filters` options cannot be used together.

Include Hosts Using Freeform Tags

To include a host from the inventory using freeform tags, you can use the following syntax:

```yaml
include_host_filters:
  # filter the hosts with freeform tag with key <tag_key> which has value <tag_value>
  - "'<tag_value>' == freeform_tags.<tag_key>"
  # filter the hosts which has <tag_key> freeform tag
  - "'<tag_key>' in freeform_tags"
```
For example:

```yaml
include_host_filters:
  - "'operating_system' in freeform_tags"
  - "'linux' == freeform_tags.operating_system"
```

**Include Hosts Using Defined Tags**

To include a host from the inventory using defined tags, you can use the following syntax:

```yaml
include_host_filters:
  # filter the hosts with defined tag in <namespace> with <tag_key> and <tag_value>
  - "'<tag_value>' == defined_tags.<namespace>.<tag_key>
  # filter the hosts with <tag_key> in the <namespace> in defined tags
  - "'<tag_key>' in defined_tags.<namespace>"
```

For example:

```yaml
include_host_filters:
  - "'ansible' == defined_tags.ansible_collections_tag_namespace.managed_by"
  - "'managed_by' in defined_tags.ansible_collections_tag_namespace"
```

**Enabling Caching**

Caching can be enabled to speed lookups. You can set caching options for an individual YAML configuration source or for multiple inventory sources using environment variables or Ansible configuration files. If you enable caching for an inventory plugin without providing inventory-specific caching options, the inventory plugin uses fact-caching options.

Here is an example of enabling caching for an individual YAML configuration file:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci_inventory
cache_prefix: oci
```

**Using Dynamic Groups**

You can create dynamic groups using host variables with the constructed **keyed_groups** option. The option groups can also be used to create groups and create and modify host variables. Syntax for keyed groups and groups that use tags follows:

```yaml
keyed_groups
- key: freeform_tags.<tag_key>
  prefix: <my_prefix>
- key: defined_tags.<namespace>.<tag_key>
  prefix: <my_prefix>

groups:
  <group_name>: "'<tag_value>' == freeform_tags.<tag_key>"
  <group_name>: "'<tag_value>' == defined_tags.<namespace>.<tag_key>"
  <group_name>: "'<tag_key>' in defined_tags.<namespace>"
```
For example:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
regions:
  - us-phoenix-1
  - us-ashburn-1
keyed_groups:
  # add hosts to tag_Name_value groups for each oci host's tags.Name variable
  - key: tags.Name
    prefix: tag_Name_
    groups:
      # add hosts to the group development if any of the dictionary's keys or values is the word 'devel'
      development: "'devel' in (tags|list)"
      # add hosts with freeform_tags that has 'operating_system' key and 'linux' value to 'linux' group
      linux: "'linux' == freeform_tags.operating_system"
      # add hosts with freeform tags that has 'operating_system' key to os group
      os: "'operating_system' in freeform_tags"
      # add hosts with defined tags in the namespace 'ansible_collections_tag_namespace' with tag 'managed_by' and value 'ansible'
      ansible_managed: "'ansible' == defined_tags.ansible_collections_tag_namespace.managed_by"
      # add hosts with defined tags in the namespace 'ansible_collections_tag_namespace' with tag 'managed_by'
      cm_managed_hosts: "'managed_by' in defined_tags.ansible_collections_tag_namespace"
```

This example produces output similar to the following:

```plaintext
@all:
   |--@development:
   |   |--compute_instance1
   |   |--compute_instance2
   |--@linux:
   |   |--compute_instance1
   |--@os:
   |   |--compute_instance1
   |   |--compute_instance2
   |--@ansible.managed:
   |   |--compute_instance1
   |--@cm_managed_hosts:
   |   |--compute_instance1
   |   |--compute_instance2
   |--@ungrouped
```

If a host does not have the variables specified in the configuration, the host is not added to groups other than those that the inventory plugin creates and the ansible_host host variable is not modified.

Inventory Scenarios

The following sections include configuration examples that cover common inventory scenarios.

Fetch All Compute Hosts

To fetch all hosts, your configuration can be as simple as the following example:

```yaml
plugin: oracle.oci.oci
```

Fetch Only DB Hosts
To fetch all nodes hosting database software while excluding Compute hosts, your configuration would look like the following example:

```python
plugin: oracle.oci.oci
# fetch database hosts
fetch_db_hosts: true
# don't fetch Compute hosts
fetch_compute_hosts: False
```

**Fetch Hosts from Specific Regions**

To fetch hosts only in specified regions, your configuration would look similar to the following example:

```python
plugin: oracle.oci.oci
# Fetch only the hosts in the regions us-ashburn-1, us-phoenix-1
regions:
  - us-ashburn-1
  - us-phoenix-1
```

**Set Inventory Hostname**

To set the format of the inventory hostname used in the inventory, your configuration would include a section similar to the following example:

```python
plugin: oracle.oci.oci
# Sets the inventory_hostname to either "display_name+.oci.com",
# "public_ip", "private_ip", or "id"
# "display_name+.oci.com" has more preference than "public_ip",
# "private_ip", "id".
hostname_format_preferences:
  - "display_name+.oci.com"
  - "public_ip"
  - "private_ip"
  - "id"
```

See [Hostname Format Preferences](#) on page 6236 for more information.

**Exclude Hosts from Inventory**

To use a Jinja2 conditional expression to exclude hosts from the inventory, your configuration would include a section similar to the following example:

```python
plugin: oracle.oci.oci
# Excludes hosts that are not in the region 'iad' from the inventory
exclude_host_filters:
  - "region not in ['iad']"
```

See [Filtering Hosts](#) on page 6236 for more information.

**Include Hosts in Inventory**

To use a Jinja2 conditional expression to include hosts in inventory, your configuration would include a section similar to the following example:

```python
plugin: oracle.oci.oci
# Includes only the hosts that have a display_name ending with '.oci.com' in
# the inventory
include_host_filters:
```
- "display_name is match('.*.oci.com')"

See Filtering Hosts on page 6236 for more information.

**Note:**
The include_host_filters and filters options cannot be used together.

Fetch Hosts from Specific Compartments

The following example shows how to fetch all hosts from the specified compartments:

```yaml
# Fetch all hosts
plugin: oracle.oci.oci

# Select compartment by OCID or name
compartments:
  - compartment_ocid: <ocid1.compartment.oc1..exampleuniqueID>
    fetch_hosts_from_subcompartments: false
  - compartment_name: "<compartment_name>"
    parent_compartment_ocid: <ocid1.tenancy.oc1..exampleuniqueID>
```

Other Options

The following example configuration combines the preceding scenarios with more configuration options:

```yaml
# Fetch all hosts
plugin: oracle.oci.oci

# Optional fields:
config_file: ~/.oci/config
config_profile: DEFAULT

# Example select regions
regions:
  - us-ashburn-1
  - us-phoenix-1

# Enable threads to speedup lookup
enable_parallel_processing: yes

# Select compartment by ocid or name
compartments:
  - compartment_ocid: <ocid1.compartment.oc1..exampleuniqueID>
    fetch_hosts_from_subcompartments: false
  - compartment_name: "<compartment_name>"
    parent_compartment_ocid: <ocid1.tenancy.oc1..exampleuniqueID>

# Sets the inventory_hostname. Each item is a Jinja2 expression and it gets evaluated on host_vars.
hostname_format_preferences:
  - "display_name+'.oci.com'"
  - "private_ip"
  - "public_ip"

# Excludes a host from the inventory when any of the Jinja2 expression evaluates to true.
xclude_host_filters:
  - "region not in ['iad']"
  - "'<tag_key>' in freeform_tags"
  - "'<tag_value>' == freeform_tags.<tag_key>'"
# Includes a host in the inventory when any of the Jinja2 expression evaluates to true.
include_host_filters:
- "display_name is match('.*.oci.com')"
- "<tag_key>' in freeform_tags"
- "<tag_value>' == freeform_tags.<tag_key>"
- "<tag_value>' == defined_tags.<namespace>.<tag_key>"
- "<tag_key>' in defined_tags.<namespace>"

# Example group results by key
keyed_groups
- key: freeform_tags.<tag key>
  prefix: <my_prefix>
- key: defined_tags.<namespace>.<tag key>
  prefix: <my_prefix>

groups:
  <group_name>: "<tag_value>' == freeform_tags.<tag_key>"
  <group_name>: "<tag_value>' == defined_tags.<namespace>.<tag_key>"
  <group_name>: "<tag_key>' in defined_tags.<namespace>"

# Example to create and modify a host variable
compose:
  ansible_host: display_name+'.oracle.com'

# Example flag to turn on debug mode
debug: true

default:
  connect_timeout: 7200
  retries: 5

# Enable Cache
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci-cache
cache_prefix: oci_

# DB Hosts
fetch_db_hosts: True

# Compute Hosts (bool type)
fetch_compute_hosts: True

# Process only the primary vnic of a compute instance
primary_vnic_only: True

Troubleshooting the Inventory Plugin

If the inventory list generated by the OCI inventory plugin does not include every compute instance in your tenancy, review the following information.

User Permissions

Ensure that the user has the following policy permissions. The user OCID is specified using either the OCI_USER environment variable, or the profile section in your SDK and CLI configuration file.

To see a list of permissions for API operations, see Details for the Core Services.

The inventory plugin makes API calls for the following operations:

- ListCompartments
- GetCompartment
- ListVNICAttachments
Developer Tools

- GetVNIC
- GetSubnet
- GetVLAN
- GetVCN
- ListInstances
- GetInstance
- ListDBNodes
- ListDBSystems
- ListRegionSubscriptions

For More Information

Detailed information about using the OCI inventory plugin is available on docs.oracle.com and readthedocs.io.

You can also use the following command to see the plugin documentation:

```bash
ansible-doc -t inventory oracle.oci.oci
```

Refer to the the official Ansible documentation for more information about inventory plugins.

**Example Ansible Playbooks**

This topic provides a catalog of sample Ansible playbooks for Oracle Cloud Infrastructure (OCI) that illustrate how to carry out common infrastructure provisioning and configuration tasks using our Ansible collection.

These samples and solutions are organized in sections associated with OCI services. You can find a brief description of each playbook along with links to each sample on the Oracle GitHub repository. Be sure to review the Readme.md file that is included in each playbook's root directory for additional instructions.

See Getting Started on page 6231 to begin using our Ansible collection.

Samples

**Block Volume**

**Attaching a block volume to a Compute instance**

This sample playbook shows how to attach a block volume to a compute instance using the iSCSI volume attachment type, and then connect it to the compute instance using `iscsiadm`. The sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from the key pair for connecting to the instance, and then launch the instance.
- Create a new Block Volume for the instance, attach the volume to the instance, and specify iSCSI as the volume attachment type.
- Connect to and then mount the volume from the Compute instance by executing `iscsiadm` commands over SSH using an Ansible module.

Go to the sample on Oracle GitHub.

**Compute**

**Launching an Always Free compute instance**

This sample shows how to launch and access an Always Free compute instance from the internet using SSH using OCI Ansible collections.

This sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from that key-pair to connect to the instance during instance launch.
- Connect to the newly launched instance using SSH.
**Launching a compute instance using App Catalog**

This sample shows how a public compute instance can be launched using app_catalog and accessed from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from that key-pair to connect to the instance during instance launch.
- Fetch app_catalog and its versions and create a subscription for it.
- Launch the instance using app_catalog and connect to it using SSH.

**Creating an instance pool**

This sample shows how to manage your compute instances using resources such as instance configurations and instance pools that are provided using OCI Ansible collections. Instance pools help you create and provision multiple compute instances within the same region based on a single instance configuration.

This sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from that key-pair to connect to the instance during instance launch.
- Create an instance configuration that defines settings for creating a compute instance as part of the instance pool. The configuration provides details such as base image, shape, and metadata.
- Use the instance pool to launch compute instances based on the instance configuration.
- Connect to one of the compute instances using SSH.

**Creating instance Console connections and capturing Console history**

This sample shows how a serial and VNC console connection can be created for a compute instance, and how the serial console data can be captured and fetched from a compute instance using OCI Ansible collections. For more information about Console connections, see Troubleshooting Instances Using Instance Console Connections.

This sample shows how to do the following:

- Generate a temporary SSH key pair for the serial Console connection.
- Create an instance Console connection for a compute instance.
- Capture serial Console data for a compute instance, and then save the data to a local machine so you can troubleshoot and debug issues.

**Launching a compute instance**

This sample shows how to launch and access a public compute instance from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from the key-pair for connecting to the instance, and then launch the instance.
- Connect to the newly launched instance using SSH.

Go to the sample on Oracle GitHub.
Enabling internet access from a compute instance using the OCI NAT Gateway

This sample shows how you can use OCI Ansible collections to enable internet access from compute instances in a private subnet using a NAT Gateway in a public subnet. For more information about NAT gateways, see NAT Gateway on page 4708 and Access Resources on the Public Internet Through an Oracle Cloud Infrastructure NAT Gateway.

This sample shows how to do the following:

- Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, and the necessary security lists and route rules.
- Provision a bastion instance in the public subnet and a private instance in the private subnet.

Once set up, the private instance will have outbound Internet access through the NAT gateway, and will be accessible using SSH from the bastion instance.

Go to the sample on Oracle GitHub.

Enabling internet access from a compute instance using an OCI NAT Instance

This sample shows how you can use OCI Ansible collections to enable internet access from compute instances in a private subnet using a NAT instance in a public subnet as discussed here and in the whitepaper here.

Note:

An NAT gateway is available as a reliable and highly available solution in the OCI Networking service. Please refer to the sample for more details.

This sample shows how to do the following:

- Set up the topology described in the whitepaper by creating the VCN, the internet gateway, the public and private subnets, and the necessary security lists and route rules. A NAT instance is provisioned in the public subnet and a private instance is provisioned in the private subnet.
- After the setup, the private instance has outbound internet access through the NAT instance in the public subnet.

Go to the sample on Oracle GitHub.

Accessing Object Storage from a private instance using a service gateway

This sample playbook shows how you can use OCI Ansible collections to enable private access to an Object Storage from a compute instance using a service gateway. For more information about service gateways, see Access to Oracle Services: Service Gateway on page 4717. To read a blog post discussing how to connect compute instances using the service gateway, see Connect Private Instances with Oracle Services Through an Oracle Cloud Infrastructure Service Gateway.

This sample shows how to do the following:

- Set up a user, group, and the policies required for managing buckets.
- Create and upload the required API keys to the user.
- Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, as well as the required security lists and route tables. A bastion instance is provisioned in the public subnet, and a private instance is provisioned in the private subnet.
- Provision a compute instance in the private subnet,
- Install the OCI command line interface (CLI) and configure the CLI using the cloud init script.
- Disable the NAT gateway to restrict public access to the private instance.
- Create a bucket from the private instance using the OCI CLI, then verify that the bucket is created.

Following this setup, the private instance has private access to Object Storage.

Go to the sample on Oracle GitHub.
Creating a cluster using Container Engine for Kubernetes

This sample creates a cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes (OKE) using OCI Ansible collections.

This sample shows how to do the following:

- Create and configure a VCN and related resources required for setting up an OKE cluster.
- Create a cluster.
- Create a node pool.
- Download the kubeconfig file for the cluster.

Go to the sample on Oracle GitHub.

Database

Creating an Always Free Autonomous Database

This sample shows how you can use the OCI Ansible collection to create an Always Free Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. See Overview of Autonomous Databases on page 1848 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
- Stop and start an Autonomous Database.
- Delete an Autonomous Database.

Go to the sample on Oracle GitHub.

Setting up an Autonomous Database

This sample shows how you can use the OCI Ansible collection to create an Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. Refer to the Overview of Autonomous Databases on page 1848 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
- Stop and start an Autonomous Database.
- Delete an Autonomous Database.

Go to the sample on Oracle GitHub.

Creating a Bare Metal and Virtual Machine DB system

This sample shows how you can use the OCI Ansible collection to create Bare Metal and Virtual DB systems. For more information about OCI co-managed DB Systems, see Bare Metal and Virtual Machine DB Systems on page 2065.

This sample shows how to do the following:

- Set up a Virtual Machine DB System.
- Get facts of a specific DB System and list available DB Homes.
- List all the databases available in specified DB Home and get facts of specific database.
- Collect DB Node's VNIC information of a specified DB system.
- Extract Public and Private IPs of the DB Node from VNIC.
Developer Tools

• Create a backup from initial database.
• Restore a database from latest backup.
• Create a new database from backup.
• Update database fields.

Go to the sample on Oracle GitHub.

File Storage

**Creating and mounting a file system**

This sample shows how you can use the OCI Ansible collection to create and access a File Storage file system through compute instances.

This sample shows how to do the following:

• Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
• Generate the certificates required by instances.
• Create File Storage components such as mount target, file system, export, and snapshot.
• Mount the file system through a compute instance and access the contents through another compute instance.

Go to the sample on Oracle GitHub.

**Exporting multiple file systems and mount targets**

This sample shows how you can use the OCI Ansible collection to export one file system using two different export paths on two different mount targets. It also demonstrates how a single mount target can export paths from two different file systems.

This sample shows how to do the following:

• Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
• Generate the certificates required by instances.
• Create File Storage components such as mount target, file system, export, and snapshot.
• Export one file system to two different mount targets.
• Export paths from a single mount target to two different file systems.
• Mount the file system through a compute instance.

Go to the sample on Oracle GitHub.

Identity

**Adding a user and group**

This sample shows how you can use the OCI Ansible collection to perform basic Oracle Cloud Infrastructure Identity and Access Management (IAM) tasks. The sample assumes the default user configured in the OCI configuration is in the Administrator group or has the required access for managing users, groups, policies.

This sample shows how to do the following:

• Create a new group.
• Create a policy.
• Create a user then add it to the group and policy.
• Create user password.
• Generate SSH keys and assign them to the user.

Go to the sample on Oracle GitHub.

Load Balancing
Creating a load balancer
This sample shows how you can use the OCI Ansible collection to create a public load balancer.
This sample shows how to do the following:
• Generate all network-related dependencies, like a VCN and subnets.
• Generate the certificates required by the load balancer.
• Create a public load balancer.
Go to the sample on Oracle GitHub.

Networking

Provisioning a VCN with private subnets
This sample shows how you can use the OCI Ansible collection to provision a virtual cloud network (VCN) with two private subnets in different availability domains and a Site-to-Site VPN. The Site-to-Site VPN uses a dynamic routing gateway (DRG), customer-premises equipment (CPE), and an IPSec connection. The provisioned resources are illustrated in this networking scenario.
This sample shows how to provision the following resources:
• A VCN
• Two private subnets
• A dynamic routing gateway
• Customer-premises equipment
• An IPSec connection between DRG & CPE
Finally, it retrieves IPSec connection configuration information and status.
Go to the sample on Oracle GitHub.

Object Storage

Getting a namespace
This sample playbook shows how to use the OCI Ansible collection to get the tenancy namespace in Object Storage.
Go to the sample on Oracle GitHub.

Listing objects and buckets
This sample playbook shows how to use the OCI Ansible collection to list all Object Storage objects from all buckets in a namespace.
Go to the sample on Oracle GitHub.

Deleting objects
This sample playbook shows how to use the OCI Ansible collection to delete objects created within a specified range of days from all buckets in a namespace. You can modify the sample so that it deletes objects older than a specified number of days, which helps you prune old or unwanted objects stored in the Object Storage service.
Go to the sample on Oracle GitHub.

Solutions

MuShop
MuShop is a showcase of several Oracle Cloud Infrastructure (OCI) services in a unified reference application. The sample application implements an e-commerce platform built as a set of microservices. The accompanying content can be used to get started with cloud native application development on OCI.
MuShop can be deployed in different ways to explore OCI based on your subscription. OCI offers Always Free tier with resources that can be used indefinitely.

This project is an example of how you can build OCI infrastructure using the OCI Ansible collection.

Go to the solution on Oracle GitHub.

**Compute Jenkins Plug-in**

This topic provides information about installing, configuring, and using the Compute Jenkins plug-in for Oracle Cloud Infrastructure services.

- **Licensing:** The Oracle Cloud Infrastructure Compute Jenkins plug-in is dual-licensed under the Universal Permissive License (UPL) and the Apache License 2.0; third-party content is separately licensed as described in the code.

DevOps Plug-in for Jenkins
This topic provides information about installing, configuring, and using the Oracle Cloud Infrastructure (OCI) DevOps plug-in for Jenkins.

You can use the DevOps plug-in to upload artifacts, and run deployments on OCI from Jenkins. A Jenkins controller instance with the DevOps plug-in can upload artifacts to the Artifacts Registry repository and trigger the deployment pipeline for deploying those artifacts.

- **Licensing:** The DevOps plug-in is Universal Permissive License (UPL) licensed; third-party content is separately licensed as described in the code.
- **Download:** GitHub
- **Documentation:** OCI DevOps Plug-in for Jenkins

Grafana Plug-in
This topic provides instructions for installing, configuring, and using the Oracle Cloud Infrastructure Data Source for Grafana, otherwise referenced as the Grafana Plug-in.

**Grafana Plug-in Overview**
Grafana is an open-source visualization and alerting tool that you can use for analytics and monitoring of time-series data (metrics). While metrics from Oracle Cloud Infrastructure Monitoring are visible in metrics charts through the Console, you can use Oracle Cloud Infrastructure Data Source for Grafana ("the Grafana Plug-in") to view metrics from resources across providers on a single Grafana dashboard.

**Prerequisites for Using the Grafana Plug-in**
- An Oracle Cloud Infrastructure account.
- A user in that account, in a security group with an IAM policy that grants necessary permissions for working with resources in the account compartments. The policy must give you access to the metric namespaces emitting metrics (such as Compute) as well as the related resources (such as a set of compute instances). If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.
  Administrators: For common policies that give groups access to metrics, see Let users access monitoring metrics in a compartment and Restrict user access to a specific metric namespace. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group through its matching rules, and then create a policy that allows that dynamic group access to metrics. To allow access across compartments, create the policy in the tenancy. Because of the concept of policy inheritance, instances in the indicated dynamic group can then access metrics in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy. See Let instances make API calls to access monitoring metrics in the tenancy.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 1241.
• Required keys and Oracle Cloud Infrastructure IDs (OCIDs). For guidance, see "Required Keys and OCIDs" in the Oracle Cloud Infrastructure User Guide.

**Download and Install the Grafana Plug-in**

**Note:**

Grafana must be installed before you can install the Grafana Plug-in. Version 3.0 or later required.

Authentication for metric access depends on where Grafana is running. If you are running Grafana on a local machine outside Oracle Cloud Infrastructure, you must call the Monitoring API using the Command Line Interface (CLI). If you are running Grafana on an Oracle Cloud Infrastructure compute instance that you created, then you can add the instance to a dynamic group by configuring a matching rule. In all scenarios, you have the option of calling the API using the CLI.

For instructions on installing the Grafana Plug-in (Oracle Cloud Infrastructure Data Source for Grafana), see https://github.com/oracle/oci-grafana-plugin.

**Configure the Grafana Plug-in**

This section describes how to add the Grafana Plug-in and set up a dashboard.

To configure the Grafana Plug-in

**Note:**

When installed locally, the Grafana plug-in accesses metrics using calls to the Monitoring API.

1. Set up the CLI for accessing Oracle Cloud Infrastructure APIs.
   
   You'll need to access the Monitoring API for authentication.

2. Navigate to the Grafana homepage at the following URL.

   [http://localhost:3000](http://localhost:3000)

3. Add the Grafana Plug-In (Oracle Cloud Infrastructure Data Source for Grafana).

   In addition to the steps below, see the Grafana instructions for adding data sources at [https://grafana.com/docs/grafana/latest/getting-started/getting-started/](https://grafana.com/docs/grafana/latest/getting-started/getting-started/).

   a. In Grafana, on the Home Dashboard, click the gear icon on the left.
   b. Click **Add data source**.
   c. In the Filter text box, type: oracle-oci-datasource
   d. In the filtered list, select **oracle-oci-datasource**.
   e. In the Settings page, fill in your Tenancy OCID, Default Region, and Environment. For Environment choose **local**.

4. Set up a dashboard of the type "Graph."

5. (Optional) To confirm access to metrics from Oracle Cloud Infrastructure, update your dashboard query ("Metrics") with a specific region, compartment, namespace, metric. You can also add one or more dimensions.

   Congratulations. You can now view your Oracle Cloud Infrastructure metrics in Grafana!

**Environment options**

- **local** is for Grafana deployments outside Oracle Cloud Infrastructure.
- **OCI Instance** is for Grafana deployments on Oracle Cloud Infrastructure resources.

The data source is now added, enabling you to set up a dashboard showing metrics from Oracle Cloud Infrastructure.
**Troubleshoot the Plug-In**

If the dashboard query ("Metrics") fails to populate with options, or if you have other issues accessing metrics, then the IAM policy used to access metrics may be malformed, or it may not include all required matching rules for your dynamic group (for running Grafana on an Oracle Cloud Infrastructure compute instance that you created).

To resolve this issue, do the following.

- Review your IAM policy to ensure that it matches prerequisites.
- If you updated your IAM policy, then restart the Grafana server and refresh the Grafana homepage.

**Other Tools**

**Tools and Plug-ins for SDKs and CLI**

Oracle Cloud Infrastructure provides additional developer tools for automating processes and facilitating development.

**Toolkit for Eclipse** - The toolkit is an open source plug-in for the Eclipse Integrated Development Environment (IDE) that enables Java developers to code and deploy applications more quickly and efficiently.

- **Documentation**: [Toolkit for Eclipse](#) on page 6270
- **Download**: To build and install the Toolkit, clone the GitHub repository then follow instructions in Getting Started with Toolkit for Eclipse.

**Oracle Developer Tools for Visual Studio** - The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can use the tools to view and manage your Oracle Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

- **Documentation**: [Oracle Developer Tools for Visual Studio](#) on page 6272
- **Download**: Refer to the documentation.

**HDFS Connector for Object Storage** - Read and write data with your Apache Hadoop application to and from the Oracle Cloud Infrastructure Object Storage service. Building the connector relies on Maven artifacts that are provided by the SDK for Java.

- **Documentation**: [HDFS Connector for Object Storage](#) on page 6252
- **Download**: GitHub

**Toolkit for Data Science** - The Oracle Accelerated Data Science (ADS) SDK is a Python library that is included as part of the Oracle Cloud Infrastructure Data Science service. ADS offers a friendly user interface that covers all the steps involved in the life-cycle of machine learning models, from connecting to different sources to using AutoML for model training to model evaluation and explanation. ADS also provides a simple interface to access the Oracle Cloud Infrastructure Data Science service model catalog and other Oracle Cloud Infrastructure services, including Object Storage.

- **Documentation**: [Oracle Accelerated Data Science (ADS) Python Library](#)
- **Download**: Oracle ADS Python library is pre-installed in the Oracle Cloud Infrastructure Data Science notebook session resource environment. It is not publicly available.

**HDFS Connector for Object Storage**

The Hadoop Distributed File System (HDFS) connector lets your Apache Hadoop application read and write data to and from the Oracle Cloud Infrastructure Object Storage service.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

- **Services supported**: Object Storage
- **Download**: GitHub or Maven
- **API Documentation**: [HDFS Connector API Reference](#)
**Requirements**

To use the HDFS connector, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions for any bucket you want to use. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 80. For a basic Object Storage policy, see Let Object Storage admins manage buckets and objects.
- Java 8
- A TTL value of 60. For more information, see Configuring JVM TTL for DNS Name Lookups on page 6253.

**Credentials and Passwords**

If you use an encrypted PEM file for credentials, the passphrase will be read from configuration using the getPassword Hadoop Configuration method. The getPassword option checks for a password in a registered security provider. If the security provider doesn't contain the requested key, it will fallback to reading the plaintext passphrase directly from the configuration file.

**Configuring JVM TTL for DNS Name Lookups**

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called time-to-live (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the networkaddress.cache.ttl property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, -1, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the $JAVA_HOME/jre/lib/security/java.security file:

  ```
  networkaddress.cache.ttl=60
  ```

- To set TTL only for your application, set the following in your application's initialization code:

  ```java
  java.security.Security.setProperty("networkaddress.cache.ttl", "60");
  ```

**Installation**

Copy the bundled jars from lib and third-party/lib the to each node of the Hadoop cluster so that they are included in Hadoop's CLASSPATH.

**SDK for Java and Maven Artifacts**

Building an HDFS connector relies on Maven artifacts that are provided by the Oracle Cloud Infrastructure SDK for Java. To obtain the artifacts, you must download the SDK for Java and build it locally. You can then build the HDFS connector.

**Important:**

The SDK for Java file version that you download from the Oracle Releases page must match the HDFS connector version, which you can find in the hdfs-connector/pom.xml file in the dependency tag block that has the groupId attribute.
HDFS Connector and Maven Artifacts

The HDFS connector is available on Maven Central and JCenter.

To use the HDFS connector in your project, import the following project dependency. For example:

```
<dependency>
  <groupId>com.oracle.oci.sdk</groupId>
  <artifactId>oci-hdfs-connector</artifactId>
  <!-- Replace the version below with your required version -->
  <version>2.9.2.0</version>
</dependency>
```

Properties

You can set the following HDFS connector properties in the core-site.xml file. The BmcProperties page lists additional properties that you can configure for a connection to Object Storage.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs.oci.client.hostname</code></td>
<td>The URL of the host endpoint. For example, <a href="https://www.example.com">https://www.example.com</a>.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td><code>fs.oci.client.auth.tenantId</code></td>
<td>The OCID of your tenancy. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td><code>fs.oci.client.auth.userId</code></td>
<td>The OCID of the user calling the API. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td><code>fs.oci.client.auth.fingerprint</code></td>
<td>The fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
</tbody>
</table>
### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs.oci.client.auth.pemfilepath</code></td>
<td>The full path and file name of the private key used for authentication. The file should be on the local file system.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
<tr>
<td><code>fs.oci.client.auth.passphrase</code></td>
<td>The passphrase used for the key, if it is encrypted.</td>
<td>String</td>
<td>Only if your key is encrypted.</td>
</tr>
<tr>
<td><code>fs.oci.client.regionCodeOrId</code></td>
<td>The region code or region identifier used to establish Object Storage endpoint name.</td>
<td>String</td>
<td>No</td>
</tr>
</tbody>
</table>

#### Note:

You can specify that a property value applies to a specific bucket by appending `.<bucket_name>,<namespace_name>` to the property name.

### Setting the Region Endpoint

There are several methods you can use to set the region endpoint for the HDFS Connector:

- Specifying the hostname property in `core-site.xml`
- Specifying the region code or region identifier property in `core-site.xml`
- Allowing the ObjectStorage client to pick up the endpoint via the instance metadata service

### Configuring Properties with core-site.xml

This example shows how properties can be configured in a `core-site.xml` file (the OCIDs are shortened for brevity):

```xml
<configuration>
  ...
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-ashburn-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.hostname.myBucket.myNamespace</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
  ...
</configuration>
```

Use Phoenix for myBucket@myNamespace -->
Using Instance Principals for Authentication

Oracle provides instance principals so that you no longer need to configure user credentials or provide PEM files on services running on instances. Each of these instances has its own identity and authenticates by using certificates added to the instance by instance principals.

To use instance principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator`.

Because using instance principals provides your instance with a custom authenticator, it is no longer necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
- `fs.oci.client.auth.passphrase`

The following example code illustrates using instance principals for authentication with the HDFS connector:

```xml
<configuration>
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.custom.authenticator</name>
    <value>com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator</value>
  </property>
</configuration>
```

For more information about instance principals, see [Announcing Instance Principals for Identity and Access Management](#).

Using Resource Principals for Authentication

Similar to instance principals, Oracle provides resource principals to authenticate the resources which are not instances (such as a jupyter notebook). Each resource has its own identity, and authenticates using the certificates that are added to it.

To use resource principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.ResourcePrincipalsCustomAuthenticator`.
Because using instance principals provides your instance with a custom authenticator, it is no longer necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
- `fs.oci.client.auth.passphrase`

The following example code illustrates using resource principals for authentication with the HDFS connector:

```xml
<?xml version="1.0"?>
<configuration>
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.custom.authenticator</name>
    <value>com.oracle.bmc.hdfs.auth.ResourcePrincipalsCustomAuthenticator</value>
  </property>
</configuration>
```

For more information about instance principals, see [Using Resource Principals in the Data Science Service](#).

### Using the Jersey Default HttpUrlConnectorProvider

Starting with version 3.3.0.7.0.0, the HDFS supports using the Apache client by default to make OCI service calls. This is because the HDFS Connector relies on the SDK for Java to send requests to the server. The SDK for Java supports using the Jersey `HttpUrlConnectorProvider` by default instead of the Jersey `ApacheConnectorProvider` to allow the Apache `HttpClient` to make OCI service calls.

To switch back to the old Jersey default client, set the property `fs.oci.client.jersey.default.connector.enabled` in the `core-site.xml` file to `true`. By default, this value is set to `false`.

### Performance optimization with the Apache Connector for HDFS

The Apache Connector supports two connection closing strategies:

- `ApacheConnectionClosingStrategy.GracefulClosingStrategy`
- `ApacheConnectionClosingStrategy.ImmediateClosingStrategy`

When using `ApacheConnectionClosingStrategy.GracefulClosingStrategy`, streams returned from a response are read until the end of the stream when closing the stream. This can introduce additional time when closing the stream with a partial read, depending on how large the remaining stream is. To avoid this delay, consider using `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` for large files with partial reads. With `ApacheConnectionClosingStrategy.ImmediateClosingStrategy`, streams are not read until the end when closing the stream, which can improve performance. Note that `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` takes longer when using partial read for smaller stream size (streams smaller than 1MB).

### Setting the connection closing strategy

Set the connection closing strategy by setting `fs.oci.client.apache.connection.closing.strategy` property in the `core-site.xml` file:

- To use `ApacheConnectionClosingStrategy.ImmediateClosingStrategy`, set the `fs.oci.client.apache.connection.closing.strategy` to `immediate`.
Note:
These closing strategies only work with the Apache Connector for HDFS and are ignored when using the Jersey default connector.

Switching back to the Jersey default connector

The Jersey default connector reads streams to the end and then reuses the stream, which can lead to better performance than the Apache Connector for HDFS in some scenarios. If these Apache Connector closing strategies do not give you optimal results for your use cases, you can switch back to Jersey Default `HttpUrlConnectorProvider`. You can switch back to the old Jersey default client by setting the `fs.oci.client.jersey.default.connector.enabled` property in the `core-site.xml` file to `true`. By default, this value is set to `false`.

For more information, see: https://github.com/oracle/oci-java-sdk/blob/master/ApacheConnector-README.md.

Connection Pooling in HDFS

You can set the maximum number of connections in the HDFS Connector connection pool.

To do this, change the property `fs.oci.client.apache.max.connection.pool.size` in the `core-site.xml` file to a positive integer that specifies how many connections to pool.

Note:
This property is only supported when using the ApacheConnector for HDFS; otherwise it is ignored.

Configuring a HTTP Proxy

You can set the following optional properties in the `core-site.xml` file to configure a HTTP proxy:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs.oci.client.proxy.uri</code></td>
<td>The URI of the proxy endpoint.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.proxy.username</code></td>
<td>The username to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.proxy.password</code></td>
<td>The password to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.allowed</code></td>
<td>Enables the upload manager to support multipart uploads</td>
<td>Boolean</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.minobjectsize.mb</code></td>
<td>Specifies the minimum object size in mebibytes in order to use the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.partsize.mb</code></td>
<td>Specifies the part size in mebibytes for the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
</tbody>
</table>
Note:
Configuring a proxy enables use of the ApacheConnectorProvider when making connections to Object Storage. It buffers requests into memory and can impact memory utilization when uploading large objects. It is recommended to enable multipart uploads and adjust the multipart properties to manage memory consumption.

Large Object Uploads

Large objects are uploaded to Object Storage using multipart uploads. The file is split into smaller parts that are uploaded in parallel, which reduces upload times. This also enables the HDFS connector to retry uploads of failed parts instead of failing the entire upload. However, uploads may transiently fail, and the connector will attempt to abort partially uploaded files. Because these files accumulate (and you will be charged for storage), list the uploads periodically and then after a certain number of days abort them manually using the SDK for Java.

Information about using the Object Storage API for managing multipart uploads can be found in Using Multipart Uploads on page 4974.

Note:
If you prefer not to use multipart uploads, you can disable them by setting the fs.oci.client.multipart.allowed property to false.

Best Practices

The following sections contain best practices to optimize usage and performance.

Directory Names

There are no actual directories in Object Storage. Directory grouping is a function of naming convention, where objects use / delimiters in their names. For example, an object named a/example.json implies there is a directory named a. However, if that object is deleted, the a directory is also deleted implicitly. To preserve filesystem semantics where the directory can exist without the presence of any files, the HDFS connector creates an actual object whose name ends in / with a path that represents the directory, (that is, create an object named a/). Now, deleting a/example.json doesn't affect the existence of the a directory, because the a/ object maintains its presence. However, it's entirely possible that somebody could delete that a/ object without deleting the files/directories beneath it. The HDFS connector will only delete the folder object if there are no objects beneath that path. The folder object itself is zero bytes.

Inconsistent Filesystem

Deleting a directory means deleting all objects that start with the prefix representing that directory. HDFS allows you to query for the file status of a file or a directory. The file status of a directory is implemented by verifying that the folder object for that directory exists. However, it's possible that the folder object has been deleted, but some of the objects with that prefix still exist. For example, in a situation with these objects:

- a/b/example.json
- a/b/file.json
- a/b/

HDFS would know that directory /a/b/ exists and is a directory, and scanning it would result in example.json and file.json. However, if object a/b/ was deleted, the filesystem would appear to be in an inconsistent state. You could query it for all files in directory /a/b/ and find the two entries, but querying for the status of the actual /a/b/ directory would result in an exception because the directory doesn't exist. The HDFS connector does not attempt to repair the state of the filesystem.

File Creation

Object Storage supports objects that can be many gigabytes in size. Creating files will normally be done by writing to a temp file and then uploading the contents of the file when the stream is closed. The temp space must be large
enough to handle multiple uploads. The temp directory used is controlled by the hadoop.tmp.dir configuration property.

Read/Seek Support

When in-memory buffers are enabled (fs.oci.io.read.inmemory), seek is fully supported because the entire file is buffered into a byte array. When in-memory buffer is not enabled (likely because object sizes are large), seek is implemented by closing the stream and making a new range request starting at the specified offset.

Directory Listing

Listing a directory is essentially a List bucket operation with a prefix and delimiter specified. To create an HDFS FileStatus instance for each key, the connector performs an additional HEAD request to get ObjectMetadata for each individual key. This will be required until Object Storage supports richer list operation data.

URI Format for Filesystems and Files

HDFS filesystems and files are referenced through URIs. The scheme specifies the type of filesystem, and the remaining part of the URI is largely free for the filesystem implementation to interpret as it wants.

Because Object Storage is an object store, its ability to name objects as if they were files in a filesystem is used to mimic an actual filesystem.

Root

The root of Object Storage filesystem is denoted by a path where the authority component includes the bucket name and the namespace name, as shown:

Note:
In the examples, "MyBucket" and "MyNamespace" are placeholders and should be replaced with appropriate values.

oci://MyBucket@MyNamespace/

This is always the root of the filesystem. The reason for using authority for both bucket and namespace is that HDFS only allows the authority portion to determine where the filesystem is; the path portion denotes just the path to the resource (so "oci/MyNamespace/MyBucket" won't work, for example). Note that the @ character is not a valid character for buckets or namespaces, and should allow the authority to be parsed correctly.

Sub-directories

Sub-directories do not actually exist, but can be mimicked by creating objects with / characters. For example, two files named a/b/c/example.json and a/b/d/path.json would appear as if they were in a common directory a/b. This would be achieved by using the Object Storage prefix- and delimiter-based querying. In the given example, referencing a sub-directory as a URI would be:

oci://MyBucket@MyNamespace/a/b/

Objects/Files

An object named a/b/c/example.json is referenced as:

oci://MyBucket@MyNamespace/a/b/c/example.json
Logging

Logging in the connector is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following example shows how to enable basic logging to standard output.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath
3. Add the following VM arg to enable debug level logging (by default, info level is used):
   ```bash
   Dorg.slf4j.simpleLogger.defaultLogLevel=debug
   ```

You can configure more advanced logging options by using the log4j binding.

Sample Hadoop Job

```java
package com.oracle.oci.hadoop.example;

import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;
import org.apache.commons.io.IOUtils;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.FSDataInputStream;
import org.apache.hadoop.fs.FSDataOutputStream;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.io.IntWritable;
import org.apache.hadoop.io.Text;
import org.apache.hadoop.mapreduce.Job;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import com.oracle.oci.hdfs.BmcFilesystem;

@RequiredArgsConstructor
public class SampleOracleBmcHadoopJob
{
    private static final String SAMPLE_JOB_PATH = "/samplehadoopjob";
    private static final String INPUT_FILE = SAMPLE_JOB_PATH + "/input.dat";
    private static final String OUTPUT_DIR = SAMPLE_JOB_PATH + "/output";

    // non-static since this is the runner class it needs to initialize
    after we set the properties
    private final Logger log = LoggerFactory.getLogger(SampleOracleBmcHadoopJob.class);

    /**
     * Runner for sample hadoop job. This expects 3 args: path to
     * configuration file, Object Store namespace, Object
     * Store bucket. To run this, you must:
     * *(@code
     * Create a standard hadoop configuration file
```
* Create the bucket ahead of time. *
*
* This runner will create a test input file in a file '/
samplehadoopjob/input.dat', and job results will be written
* to '/samplehadoopjob/output'.
*
* @param args
* 1) path to configuration file, 2) namespace, 3) bucket
* @throws Exception
*/

    @Override
    public void reduce(final Text key, final Iterable values, final Context context) throws IOException, InterruptedException {
        int sum = 0;
        for (final IntWritable val : values) {
            sum += val.get();
        }
        this.result.set(sum);
        context.write(key, this.result);
    }
}

Troubleshooting

This section contains troubleshooting information for the HDFS connector.

Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the HDFS connector. For information about common service errors returned by OCI, see API Errors.
Java Encryption Key Size Errors

The HDFS connector can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256. Use one of the following workarounds to fix this issue:

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Contributions

Got a fix for a bug, or a new feature you'd like to contribute? The SDK is open source and accepting pull requests on GitHub.

Notifications

If you wish to be notified when a new version of the HDFS connector is released, subscribe to the Atom feed.

Using the HDFS Connector with Spark

Introduction

This article provides a walkthrough that illustrates using the Hadoop Distributed File System (HDFS) connector with the Spark application framework. For the walkthrough, we use the Oracle Linux 7.4 operating system, and we run Spark as a standalone on a single computer.

Prerequisites

Following are prerequisites for completing the walkthrough:

- You must have permission to create a compute instance. For guidance, see Creating an Instance on page 1094.
- You must be able to connect to the service instance that you've launched. For guidance, see Connecting to an Instance on page 1139.
- You must have the appropriate OCID, fingerprint, and private key for the Identity and Access Management (IAM) user that you will use to interact with an Object Storage. For guidance, see Setup and Prerequisites on page 6045.
- You must have an Object Storage bucket that you can connect to.
- The IAM user must be able to read and write to that bucket using the Console.

Using Spark

Install Spark and Dependencies

Note:

For the purpose of this example, install Spark into the current user's home directory. Note that for production scenarios, you would not do this.

Note:

Versions 2.7.7.0 and later no longer install all of the required third party dependencies. Required third party dependencies are bundled under the
1. Create an instance of your Compute service. For guidance, see Creating an Instance on page 1094.
2. Ensure that your service instance has a public IP address so that you can connect using a Secure Shell (SSH) connection. For guidance, see Connecting to an Instance on page 1139.
3. Connect to your service instance using an SSH connection.
4. Install Spark and its dependencies, Java and Scala, by using the code examples that follow.

```bash
# We'll use wget to download some of the artifacts that need to be installed
sudo yum install wget
# First install Java
sudo yum install java-1.8.0-openjdk.x86_64
export JAVA_HOME=/usr/lib/jvm/jre-1.8.0-openjdk
# Should be something like: OpenJDK Runtime Environment (build 1.8.0_161-
b14)
java -version
# Then install Scala
sudo yum install scala-2.12.4.rpm
# Should be something like: Scala code runner version 2.12.4 -- Copyright
2002-2017, LAMP/EPFL and Lightbend, Inc.
scale -version
# Then download Spark
wget https://archive.apache.org/dist/spark/spark-2.2.1/spark-2.2.1-bin-
hadoop2.7.tgz
tar xvf spark-2.2.1-bin-hadoop2.7.tgz
export SPARK_HOME=$HOME/spark-2.2.1-bin-hadoop2.7
export PATH=$PATH:$SPARK_HOME/bin
# Start a Spark master
cd $SPARK_HOME
./sbin/start-master.sh
```

**Download the HDFS Connector and Create Configuration Files**

**Note:**
For the purposes of this example, place the JAR and key files in the current user's home directory. For production scenarios you would instead put these files in a common place that enforces the appropriate permissions (that is, readable by the user under which Spark and Hive are running).

Download the HDFS Connector to the service instance and add the relevant configuration files by using the following code example. For additional information, see HDFS Connector for Object Storage on page 6252.

```bash
wget https://github.com/oracle/oci-hdfs-connector/releases/download/
v2.9.2.1/oci-hdfs.zip
unzip oci-hdfs.zip -d oci-hdfs

cd $HOME
mkdir .oci
# Create or copy your API key into the $HOME/.oci directory

cd $SPARK_HOME/conf
# Create a core-site.xml (e.g. by transferring one you have, using vi etc.).
Consult
```

Oracle Cloud Infrastructure User Guide 6266
In the spark-defaults.conf file, add the following at the bottom:

```
spark.sql.hive.metastore.sharedPrefixes= shaded.oracle,com.oracle.bmc
```

### Prepare Data

For testing data, we will use the MovieLens data set.

2. Unzip the download file.
3. Upload the `movies.csv` file to your Object Storage bucket.

### Test Using the Spark Shell

With the data ready, we can now launch the Spark shell and test it using a sample command:

```
cd $SPARK_HOME
./bin/spark-shell
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
java.io.IOException: No FileSystem for scheme: oci
```

You receive an error at this point because the oci:// file system schema is not available. We need to reference the JAR file before starting the Spark shell. Here's an example for doing so:

```
./bin/spark-shell --jars $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar --driver-class-path $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
```

```
res0: org.apache.spark.rdd.RDD[(String, String)] = oci://
PipedUploadTest@sampletenancy/ MapPartitionsRDD[1] at wholeTextFiles at <console>:25
scala> sc.textFile("oci://PipedUploadTest@sampletenancy/movies.csv").take(20).foreach(println)
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
10,GoldenEye (1995),Action|Adventure|Thriller
11,"American President, The (1995)" ,Comedy|Drama|Romance
12,Dracula: Dead and Loving It (1995),Comedy|Horror
13,Balto (1995),Adventure|Animation|Children
14,Nixon (1995),Drama
15,Cutthroat Island (1995),Action|Adventure|Romance
16,Casino (1995),Crime|Drama
17,Sense and Sensibility (1995),Drama|Romance
18,Four Rooms (1995),Comedy
```
The command is successful so we are able to connect to Object Storage. Note that if you do not wish to pass the --jars argument each time the command executes, you can instead copy the oci-hdfs-full JAR file into the $SPARK_HOME/jars directory.

**Start the Spark Thrift Server**

Start the Spark Thrift Server on port 10015 and use the Beeline command line tool to establish a JDBC connection and then run a basic query, as shown here:

```bash
cd $SPARK_HOME
./sbin/start-thriftserver.sh --hiveconf hive.server2.thrift.port=10015
```

Once the Spark server is running, we can launch Beeline, as shown here:

```bash
cd $SPARK_HOME
./bin/beeline
```

Beeline version 1.2.1.spark2 by Apache Hive

```
beeline>
```

Next, connect to the server, as shown here:

```
beeline> !connect jdbc:hive2://localhost:10015 testuser testpass
```

For the purposes of this example, we have not configured any security, so any user name and password will be accepted. For production scenarios you would not do this.

```
Connected to: Spark SQL (version 2.2.1)
Driver: Hive JDBC (version 1.2.1.spark2)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

If we now check to see what tables exist, we see the following:

```
0: jdbc:hive2://localhost:10015> show tables;
+-----------------+-----------------+------------------+
| database | tableName | isTemporary |
+-----------------+-----------------+------------------+
No rows selected (0.724 seconds)
```

None exist presently; however, we can create a table and link it to the movies.csv file that we downloaded and placed in the Object Storage bucket, as shown here:

```
0: jdbc:hive2://localhost:10015> create table test_table (movieId integer, title string, genres string) using csv options (path "oci://myBucket@myTenant/movies.csv", header "true", delimiter ",");
0: jdbc:hive2://localhost:10015> describe formatted test_table;
```

Note:

For the purposes of this example, we have not configured any security, so any user name and password will be accepted. For production scenarios you would not do this.
<table>
<thead>
<tr>
<th>col_name</th>
<th>data_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>movieId</td>
<td>int</td>
</tr>
<tr>
<td>title</td>
<td>string</td>
</tr>
<tr>
<td>genres</td>
<td>string</td>
</tr>
</tbody>
</table>

# Detailed Table Information

| Database | default |
| Table    | test_table |
| Owner    | opc        |
| Created  | Thu Mar 01 20:45:18 GMT 2018 |
| Last Access | Thu Jan 01 00:00:00 GMT 1970 |
| Type     | EXTERNAL    |
| Provider | csv         |

| Location          | oci://PipedUploadTest@sampletenancy/movies.csv |
| Serde Library     | org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe |
| InputFormat       | org.apache.hadoop.mapred.SequenceFileInputFormat |
| OutputFormat      | org.apache.hadoop.hive.ql.io.HiveSequenceFileOutputFormat |
| Storage Properties| [delimiter=,, header=true, serialization.format=1] |

Note that the table stores its data externally in Object Storage and the data can be accessed using the HDFS Connector (the `oci://` file system scheme). Now that we have a table, we can query it:

```
0: jdbc:hive2://localhost:10015> select * from test_table limit 10;
+----------+-------------------------------------+-------------------------------------+
<table>
<thead>
<tr>
<th>movieId</th>
<th>title</th>
<th>genres</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Toy Story (1995)</td>
<td>Adventure</td>
</tr>
<tr>
<td>2</td>
<td>Jumanji (1995)</td>
<td>Adventure</td>
</tr>
<tr>
<td>3</td>
<td>Grumpier Old Men (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>4</td>
<td>Waiting to Exhale (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>5</td>
<td>Father of the Bride Part II (1995)</td>
<td>Comedy</td>
</tr>
</tbody>
</table>
```
### Developer Tools

### Toolkit for Eclipse

The Oracle Cloud Infrastructure Toolkit for Eclipse is an open source plug-in for the Eclipse Integrated Development Environment (IDE). The toolkit provides a set of features that help developers connect to Oracle Cloud Infrastructure from within Eclipse. For example, you can use the toolkit to deploy an application to a VM in the cloud by using the Oracle Container Engine for Kubernetes, or upload multiple files to Object Storage with one click. The Compute feature enables you to start a compute instance or restart it if needed. You can also switch between multiple accounts and regions from the Eclipse IDE.

**Download:** To install the Toolkit, download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub, then follow the instructions in [Getting Started with Toolkit for Eclipse](#) on page 6271.

**Requirements**

To use the Oracle Cloud Infrastructure Toolkit for Eclipse, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](#) on page 80. For a list of typical policies you may want to use, see [Common Policies](#).
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see [Required Keys and OCIDs](#) on page 6045.
- [SDK for Java](#) on page 6094
- Eclipse IDE for Java Developers 4.3 or later

**Services Supported**

- Compute
- Object Storage
- Autonomous Database
- Container Engine for Kubernetes

**Contact Us**

**Contributions**

Got a fix for a bug or a new feature you’d like to contribute? The plug-in is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the toolkit is released, subscribe to the [Atom feed](#).
Questions or Feedback

- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Getting Started with Toolkit for Eclipse

Downloading the Toolkit

You can download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub.

Installing the Toolkit

After downloading the toolkit, launch the Eclipse IDE.

1. From the top navigation bar, select Help > Install New Software...
2. In Install dialog, click Add...
3. In the Add Repository dialog, click Archive...
4. In the right pane of the Repository Archive window, select the zip file containing the toolkit. Click Open.
5. In the Add Repository dialog click Add.
6. In the Available Software dialog, select Oracle Cloud Infrastructure Toolkit for Eclipse, then click Next.
7. In the Install Details dialog, click Finish.

Configuring the Toolkit

Oracle Cloud Infrastructure Preferences

Before you can use the toolkit, you must configure the Oracle Cloud Infrastructure Preferences in the Eclipse IDE. This process will provide the necessary identifiers and credentials so the toolkit can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs on page 6045.

1. From the top navigation bar, select Preferences > Oracle Cloud Infrastructure Preferences.
2. For Profile Name, provide a short descriptive name.
3. From the Region dropdown, select your region.
4. Enter your User OCID and Tenancy OCID. For information on how to locate this information, see Where to Get the Tenancy's OCID and User's OCID on page 6050.
5. For Key File, click Browse and select the appropriate file. For more information, see How to Generate an API Signing Key on page 6046.
6. Enter the Fingerprint for the Key File. For more information, see How to Get the Key's Fingerprint on page 6050.
7. Enter the Passphrase, if you created one for the key pair. If not, leave this field blank.
8. Click Save Profile.
9. Click Apply and Close.

Proxy Settings

If you are on a network that uses a proxy to connect to the internet, you must configure Eclipse proxy settings. For more information, see Network Connections in the Eclipse IDE Documentation.

Uninstalling the Toolkit

Launch the Eclipse IDE.

1. From the top navigation bar, select Help > About Eclipse IDE
2. Click Installation Details.
3. In the Installation Details window, select the Installed Software tab.
4. Select Oracle Cloud Infrastructure Toolkit for Eclipse and click Uninstall...
5. In the Uninstall dialog, confirm the items to be uninstalled then click Finish.
6. Click **Restart**.

**Using Toolkit for Eclipse**

After configuring the Oracle Cloud Infrastructure Preferences on page 6271, you can connect to your tenancy via Eclipse and use the Oracle Cloud Infrastructure Explorer to view and update your resources. You can also switch between different accounts saved in the profile.

To change the region, click the region icon in the Explorer navigation bar and select from the dropdown.

To change the compartment, click the compartment icon and select from the dropdown.

**Using the Toolkit for Eclipse with Compute Instances**

In the Oracle Cloud Infrastructure Explorer, double-click **Compute** to view available resources.

Double-click **Instances** to display a list of instances. You can right-click each one in the list to start, stop, or reboot it.

You can also double-click **Block Volumes** to view a list of block volumes.

**Using the Toolkit for Eclipse with Object Storage**

In the Oracle Cloud Infrastructure Explorer, double-click Object Storage to view available resources.

**Working with Buckets**

To create a bucket, right-click **Object Storage** and select **Create New Bucket**.

To view content and details, double-click or right-click the bucket and select **Open Bucket**.

To delete a bucket, view the bucket's details and click **Delete Bucket**.

**Working with Objects**

To upload an object, select the destination bucket and view its details. Right-click the Object list and select **Upload Object**. You can also drag one or more files to the Object list to upload.

To download one or more objects, right-click and select **Download Object**.

To delete one or more objects, right-click and select **Delete Object**.

**Deploy Applications using Oracle Container Engine for Kubernetes**

**Prerequisites**

1. Install Docker Desktop v2.2.0.0 or higher.
2. Verify that Docker desktop is running, and that the Docker CLI client and Kubernetes CLI client (kubectl) are available in the command line.
3. Install the Oracle Cloud Infrastructure command line client (OCI CLI).
4. Verify that OCI CLI works by typing “oci” on command prompt. This should return a list of all the services supported by OCI CLI.

**Deploy an Application to Container Engine for Kubernetes**

1. In the Oracle Cloud Infrastructure Explorer, double-click **Container Engine for Kubernetes**.
2. Double-click **Container Cluster (OKE)** to display a list of available clusters. A cluster should be created prior to this step in the console.
3. Right click on the cluster name and select **Deploy Docker Image to OKE**.
4. Follow the deployment wizard steps to to deploy the application.

**Oracle Developer Tools for Visual Studio**

The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can use the tools to view and manage your Oracle
Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

Requirements

To use the Oracle Developer Tools for Visual Studio, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 80. For a list of typical policies you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 6045.
- The Oracle Cloud Infrastructure Command Line Interface (CLI) on page 6059 installed and configured.
- Microsoft Visual Studio 2019 or later
- Docker Desktop v2.2.0.0 or higher

Questions or Feedback

For questions or to provide feedback, please use one of the following resources:

- The Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Getting Started with Oracle Developer Tools for Visual Studio

Installing the Extension

The Oracle Developer Tools for Visual Studio is available in the Visual Studio Marketplace.

1. From the Visual Studio menu, select Extensions->Manage Extensions
2. From the list on the left side of the dialog, select Online and then Visual Studio Marketplace
4. Click on the Download button next to the extension.
5. A browser window opens with instructions to download the installer.

Configuring the Toolkit

Oracle Developer Tools for Visual Studio Preferences

Before you can use the developer tools, you must configure the Oracle Cloud Infrastructure Preferences. This process will provide the necessary identifiers and credentials so the developer tools can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs on page 6045.

1. The deployment wizard requires an Oracle Cloud Infrastructure user credentials configuration file. For more information, see SDK and CLI Configuration File on page 6051.
2. Run the "docker desktop" app, and ensure it has the Linux Containers option selected.
3. If behind a proxy, set the proxy values http_proxy and https_proxy in the environment variables for Windows and in the Docker Desktop settings (see the Resources->Proxies menu).

Uninstalling the Toolkit

1. From the Visual Studio menu, select Extensions, then Manage Extensions.
2. From the list on the left side of the dialog, select Installed.
3. Select "Oracle Developer Tools for Visual Studio 2019" from the middle menu and click on the Uninstall button that appears next to it.
Prerequisites

This topic assumes a working knowledge of OCI Container Engine for Kubernetes. The tutorials below will help understand some of the technologies and backend framework used by the wizard for deployment.

- Pushing an Image to Oracle Cloud Infrastructure Registry
- Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes
- Deploying an Application to OKE

Overview

Using the Oracle Developer Tools for Visual Studio assumes you've already created a docker image for your application. This workflow generally looks like this:

- Build your web application.
- Build a docker image for your application locally. For more information, see the Docker documentation.
- Push the docker image of the web application to the Oracle Cloud Infrastructure Registry. For more information on pushing a docker image to OCIR, see Push an Image to Oracle Cloud Infrastructure Registry.
- Create a cluster in Oracle Cloud using Oracle Container Engine Service for Kubernetes. See Create a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes and download the resulting kubeconfig file.
- Create a named secret containing OCI credentials to be used for Kubernetes deployment. For more information, see Pull an Image from Oracle Cloud Infrastructure Registry when Deploying a Load-Balanced Application to a Cluster.

Deploy an Application Using the Oracle Deployment Wizard

1. From the Visual Studio Extensions menu, select Oracle Cloud App Deployment -> Deploy to Oracle Cloud. The Oracle Deployment Wizard displays.
2. Click Next.
3. Select an Authentication Profile (make sure that this profile matches the OCI CLI profile) and click Next.
4. Select a deployment option:
   - **Redeploy using an existing deployment configuration**: This deployment choice should be used for re-deployment of a web application when there are no deployment configuration changes. If the developer needs to make changes only to his/her web application and then re-deploy, they can do so using this option. This option allows developers to do quick deployment in a few clicks with no new information asked for.
   - **Redeploy with a different deployment configuration**: This deployment choice should be used for re-deployment of a web application when there are deployment configuration changes. Scenarios where this is an
appropriate choice include deploying on a different cluster, using a different Docker image, or a change in the Kubernetes configuration.

**Note:**
If selecting a different cluster during re-deployment, delete the Kubernetes resources for your previous deployment using the "kubectl delete" command.

c. **Create a new deployment:** Use this option when deploying your web application for the first time using this wizard. The name for this deployment should be unique, must be no longer than 63 characters, must start and end with a lowercase letter or number, and may contain lowercase letters, numbers, and hyphens.

5. On the **Select A Cluster** panel, select an existing Kubernetes cluster from any of the compartments in your tenancy (the wizard does not support creating a cluster, so you should create a cluster using the console first). Click **Next**.

6. On the **Specify Deployment Details** panel, you can modify existing deployment details.

**Note:**
The deployment file created by the wizard can be modified in any editor and used for re-deployments using the wizard.

a. Select a Docker image from the drop-down list.
b. Select a Kubernetes Secret Name from the drop-down list.

7. Click **Next**.

8. Verify your deployment details, and then click **Deploy**. The window will actively update with the deployment status as it progresses. You can dismiss this dialog and check the deployment status later by selecting **Oracle Cloud App Deployment -> Check Deployment Status** from the Visual Studio menu.

**Deleting A Deployment**

The wizard doesn't support deleting a deployment using the Visual Studio IDE. To delete a deployment:

1. Delete the deployment from the OKE cluster using the following command: `kubectl delete -f <path-to-deployment-file> --kubeconfig <path-to-kubeconfig-file>` If the deployment file is not present, you can use the following command: `kubectl delete deploy/<deployment_name> svc/<service_name>

2. Delete the folder in `~/.oci/visualstudiowebapps/<your-application-deployment-name>` from the client machine.

**API Reference and Appendices**

This section covers general SDK concepts and references.

- **REST APIs** on page 6275
- **Client-Side Encryption** on page 6305 - Discusses how client-side encryption works for the Oracle Cloud Infrastructure SDK for Python and the SDK for Java.

**REST APIs**
The Oracle Cloud Infrastructure APIs are typical REST APIs that use HTTPS requests and responses. This topic describes basic information about using the APIs.

**API Reference and Endpoints**
For links to the Oracle Cloud Infrastructure API reference and a list of the regional API endpoints, see **API Reference and Endpoints**.
API Version

The base path of the endpoint includes the desired API version (for example, 20160918). Here's an example for a POST request to create a new VCN in the Ashburn region:

POST https://iaas.us-ashburn-1.oraclecloud.com/20160918/vcns

API Breaking Changes Policy

Oracle Cloud Infrastructure will provide 12 months advance notice prior to the date of removing or changing an existing API of a Cloud Service that you have deployed which would require you to update your code.

For more information, please see Section 6.3 in the Oracle PaaS and IaaS Public Cloud Services Pillar Documentation.

Request Signing Required

All Oracle Cloud Infrastructure API requests must be signed for authentication purposes. For information about the required credentials and how to sign the requests, see Request Signatures on page 6295.

HTTPS and TLS 1.2 Required

All Oracle Cloud Infrastructure API requests must support HTTPS and SSL protocol TLS 1.2.

Maximum Allowed Client Clock Skew

HTTP status code 401 (NotAuthenticated) is returned if the client's clock is skewed more than 5 minutes from the server's. To determine the server's clock time, use this curl command with the API endpoint:

```
curl -s --head <endpoint> | grep Date
```

For example:

```
curl -s --head https://iaas.us-phoenix-1.oraclecloud.com | grep Date
```

Request and Response Format

The Oracle Cloud Infrastructure APIs use standard HTTP requests and responses. Each may contain Oracle-specific headers for pagination, entity tags (ETags), and so on as described elsewhere in this topic and in the API documentation.

Each response includes a unique Oracle-assigned request ID (for example, bb3f3275-f356-462a-93c4-bf40fb82bb02) in the opc-request-id response header. If you need to contact Oracle about a particular request, please provide this request ID.

Many of the API operations require JSON in the request body or return JSON in the response body. The specific contents of the JSON are described in the API documentation for the individual operation. Notice that the JSON is not wrapped or labeled according to the operation's name or the object's name or type.

**Note:**

Make sure to set the `Content-Type` header to `application/json` in your POST and PUT requests that contain JSON in the body.

Example CreateVcn Request

```
POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/vcns
host: iaas.us-phoenix-1.oraclecloud.com
opc-retry-token: 239787fs987
Content-Type: application/json
HTTP headers required for authentication
Other HTTP request headers per the HTTP spec
```
Example CreateVcn Response

```json
200 OK
opc-request-id: 6c4d01a6-f764-4325-a3f8-720c8b5cae7b

{
  "id": "ocid1.vcn.oc1.phx.aaaaaaaa4ex5pqjtkjhdb4h4gcnko7vx5uto5puj5noa5awznspwjt3pqyq",  
  "compartmentId": "ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspi6xoxsfbeh3vy72fi4swgrkvuvq",  
  "displayName": "Apex Virtual Cloud Network",  
  "cidrBlock": "172.16.0.0/16"  
}
```

Error Format

If a request results in an error, the response contains a standard HTTP response code with 4xx for client errors and 5xx for server errors. The body also includes JSON with an error code and a description of the error. For example:

```json
{
  "code": "InvalidParameter",
  "message": "Description may not be empty; description size must be between 1 and 400"
}
```

For a list of common errors across all services, see API Errors.

Request Throttling

Oracle Cloud Infrastructure applies throttling to many API requests to prevent accidental or abusive use of resources. If you make too many requests too quickly, you might see some succeed and others fail. Oracle recommends that you implement an exponential back-off, starting from a few seconds to a maximum of 60 seconds. When a request fails due to throttling, the system returns response code 429 and the following error code and description:

```json
{
  "code": "TooManyRequests",
  "message": "User-rate limit exceeded."
}
```

Polling for Resource Status

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your code to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action.
You can poll a resource to determine its state. For example, when you call `GetInstance`, the response body contains an instance resource that includes the `lifecycleState` attribute. You might want your code to wait until the instance's `lifecycleState` is `RUNNING` before proceeding.

Different resources take different amounts of time to transition between states. Therefore, the optimal frequency and duration parameters for a polling strategy can vary among resources. The Oracle Cloud Infrastructure SDK waiters use the following default strategy:

- Use an exponential back-off, starting from a few seconds to a maximum of 30 seconds between poll attempts.
- Poll up to 20 minutes, and then stop.

Or more information on waiters, see:

- SDK for Java waiters documentation
- SDK for Ruby waiters documentation

**Where to Find Your Tenancy's OCID**

If you use the API, you'll need your tenancy's OCID in order to sign the requests (see Request Signatures on page 6295). You'll also need it for some of the IAM API operations. An OCID is an Oracle Cloud ID (see Resource Identifiers).

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu () and click Tenancy: `<your_tenancy_name>`.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

The tenancy OCID looks something like this (notice the word "tenancy" in it):

`ocid1.tenancy.oc1..<unique_ID>`.

**List Pagination**

Most List operations paginate results. For example, results are paginated for the `ListInstances` operation in the Core Services API. When you call a paginated List operation, the response indicates more pages of results by including the `opc-next-page` header.

**Note:**

A page can be empty even when more results remain. Anytime the `opc-next-page` header appears, there are more list items to get. For more information about resource list control, see Overview of Search on page 5220.

List pagination for Object Storage `ListObjects` works differently because the pagination controls are also used for object name filtering. `ListObjects` returns `nextStartWith` instead of `opc-next-page` in the response body. To
paginate through more objects, use the returned `nextStartWith` value with the `start` parameter. To filter which objects `ListObjects` returns, use the `start` and `end` parameters.

To get the next page of results

Make a new GET request against the same URL, modified by setting the page query parameter to the value from the `opc-next-page` header. Repeat this process until you get a response without an `opc-next-page` header. The absence of this header indicates that you have reached the last page of the list.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For an alternative to writing pagination code, see the functions in the pagination module provided with the SDK for Python.</td>
</tr>
</tbody>
</table>

To get the previous page of results

(Available with some APIs.) Make a new GET request against the same URL, modified by setting the page query parameter to the value from the `opc-prev-page` header. Repeat this process until you get a response without an `opc-prev-page` header. The absence of this header indicates that you have reached the first page of the list.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For an alternative to writing pagination code, see the functions in the pagination module provided with the SDK for Python.</td>
</tr>
</tbody>
</table>

To change the maximum number of results per page

In the GET request, set the `limit` to the number of items you want returned in the response.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The service will return no more than the number specified as <code>limit</code>, but might not return that exact number.</td>
</tr>
</tbody>
</table>

**Retry Token**

For some operations you can provide a unique retry token (`opc-retry-token`) so the request can be retried in case of a timeout or server error without the risk of executing that same action again. The token expires after 24 hours, but can be invalidated before then due to conflicting operations (for example, if a resource has been deleted and purged from the system, then a retry of the original creation request may be rejected).

**ETags for Optimistic Concurrency Control**

The API supports etags for the purposes of optimistic concurrency control. The GET and POST calls return an `etag` response header with a value you should store. When you later want to update or delete the resource, set the `if-match` header to the ETag you received for the resource. The resource will then be updated or deleted only if the ETag you provide matches the current value of that resource's ETag.

**Null vs. Empty Strings for Optional Parameters**

If you send an empty string (""") as the value of an optional parameter, the API validates the value as normal (for example, checks against minimum and maximum allowed length, and so on). Often the minimum allowed length is 1, so an error would be returned. If you don't set the value (it's null), the API performs no validation, and some other action may occur. For example: if you don't set a value for the `displayName` when creating a new VCN object, the service will auto-generate a value.

**API Errors**

**Common Errors Returned by All Services**

The following table lists the common errors returned by all the services for Oracle Cloud Infrastructure.
<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
<th>Retry</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>CannotParseRequest</td>
<td>The request is incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>InvalidParameter</td>
<td>A parameter is invalid or incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>LimitExceeded</td>
<td>Fulfilling this request exceeds the Oracle-defined limit for this tenancy for this resource type.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>MissingParameter</td>
<td>A required parameter is missing.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>QuotaExceeded</td>
<td>Fulfilling this request exceeds the administrator-defined quota for this compartment for this resource.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>RelatedResourceNotAuthorizedOrNotFound</td>
<td>A resource specified in the body of the request was not found, or you do not have authorization to access that resource.</td>
<td>No.</td>
</tr>
<tr>
<td>401</td>
<td>NotAuthenticated</td>
<td>The required authentication information was not provided or was incorrect. There are other reasons why this error code is generated. For more information, see HTML Status Code 401.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>NotAllowed</td>
<td>This operation must be directed at the home region.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>NotAuthorized</td>
<td>You do not have authorization to update one or more of the fields included in this request.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>SignUpRequired</td>
<td>This operation requires opt-in before it may be called.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>InvalidParameter</td>
<td>A dynamic path component is invalid or is syntactically valid but is not allowed.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>NotAuthorizedOrResourceNotSpecified</td>
<td>A resource specified via the URI (path or query parameters) of the request was not found, or you do not have authorization to access that resource. For more information, see HTML Status Code 404.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>NotFound</td>
<td>There is no operation supported at the URI path and HTTP method you specified in the request.</td>
<td>No.</td>
</tr>
<tr>
<td>405</td>
<td>MethodNotAllowed</td>
<td>The target resource does not support the HTTP method.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>Conflict</td>
<td>The requested state for the resource conflicts with its current state. This state is not transient.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>IncorrectState</td>
<td>The requested state for the resource conflicts with its current state but given some amount of time it will be in the correct state.</td>
<td>Yes, with backoff. Refer to the error description for any required actions before you retry.</td>
</tr>
</tbody>
</table>
### HTTP Status Codes

<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
<th>Retry</th>
</tr>
</thead>
<tbody>
<tr>
<td>409</td>
<td>InvalidatedRetryToken</td>
<td>The provided retry token was used in an earlier request that resulted in a system update, but a subsequent operation invalidated the token. This can happen, for example, in cases where an entity created with the same token has since been deleted. If the system state change that is associated with this request should be performed again, retry it using a different token.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>NotAuthorizedOrResourceAlreadyExists</td>
<td>You do not have authorization to perform this request, or the resource you are attempting to create already exists. This error code is returned only from create operations, where it is returned instead of the more general NotAuthorizedOrNotFound error code.</td>
<td>No.</td>
</tr>
<tr>
<td>412</td>
<td>NoEtagMatch</td>
<td>The ETag specified in the request does not match the ETag for the resource.</td>
<td>No.</td>
</tr>
<tr>
<td>413</td>
<td>PayloadTooLarge</td>
<td>The request entity is larger than limits defined by server.</td>
<td>No.</td>
</tr>
<tr>
<td>422</td>
<td>UnprocessableEntity</td>
<td>Payload is syntactically correct but semantically invalid.</td>
<td>No.</td>
</tr>
<tr>
<td>429</td>
<td>TooManyRequests</td>
<td>You have issued too many requests to the Oracle Cloud Infrastructure APIs in too short of an amount of time.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>431</td>
<td>RequestHeaderValueTooLarge</td>
<td>The request HTTP headers are too long. The request may be resubmitted after reducing the size of the request headers.</td>
<td>No.</td>
</tr>
<tr>
<td>500</td>
<td>InternalServerError</td>
<td>An internal server error occurred.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>501</td>
<td>MethodNotImplemented</td>
<td>The HTTP request target does not recognize the HTTP method.</td>
<td>No.</td>
</tr>
<tr>
<td>503</td>
<td>ServiceUnavailable</td>
<td>The service is currently unavailable.</td>
<td>Yes, with backoff.</td>
</tr>
</tbody>
</table>

### Error Details and Troubleshooting

**HTTP status code: 401**

- **Missing or incorrect authentication information.** Verify that all the required information (tenant OCID, user OCID, fingerprint, and private key) is provided and accurate. Verify that the public key corresponding to the fingerprint has been uploaded for the user. For more information, see Required Keys and OCIDs on page 6045.
- **Clock skew.** This status code is returned if the client's clock is skewed more than five (5) minutes from the server's clock. For more information, see Maximum Allowed Client Clock Skew on page 6276.
- **API request signature error.** This status code is returned if a required header is missing from a signing string. For more information, see Request Signatures on page 6295.

**Error Codes: NotAuthorizedOrNotFound, RelatedResourceNotAuthorizedOrNotFound , NotAuthorizedOrResourceAlreadyExists**

- **Authorization error.** Verify that the user is in a group that has the permissions to work with resources in a compartment.
- **Compartment or resource not found.** Verify that the compartment or resource exist and is referenced correctly. For example, this status code is returned for either of the following errors:
  - CompartmentNotFound if a compartment doesn't exist
  - VolumeNotFound if a volume doesn't exist
Asynchronous Work Requests

This topic describes asynchronous work requests for long-running operations against Oracle Cloud Infrastructure services. It also provides guidance on obtaining request status, and for inspecting the request response to enable filtering for affected resources.

Overview

API calls to Oracle Cloud Infrastructure services can launch long-running operations that do not complete the client's request before a response is returned. In these cases, the service spawns an asynchronous work request that allows for visibility into the progress of long-running, asynchronous operations. The response to the REST API call contains a work request ID in the `opc-work-request-id` header, which allows you to monitor its progress and status. The work request itself remains in a queue until the operation has completed.

You can monitor the status of the work request at any time by calling `GetWorkRequest` and passing in the work request ID.

Note:

Some services, such as Compute and Database, support work requests using Work Requests API, which contains the `GetWorkRequest` operation.

Some Oracle Cloud Infrastructure services offer work requests supported by the service API rather than the Work Requests API discussed in this topic. These service APIs each include operations that work in a similar manner to the `GetWorkRequest` operation used by the Work Requests API.

Services with their own work request APIs

- Classic Migration Service: View the State of a Work Request
- Application Performance Monitoring: Work Request API
- Bastion: WorkRequest API
- Blockchain Platform: Integration: Work Requests
- Cloud Advisor: Work Request API
- Content Management: Work Request API
- Data Catalog: Work Requests
- Data Integration: Work Requests
- Data Labeling: Work Requests
- Data Science: Creating Notebook Sessions and Deleting Projects
- Database Management: Work Request API
- Database Migration: WorkRequest API
- Database Tools: Work Request Reference
- DevOps: Work Request Reference
- GoldenGate: WorkRequest Reference
- IAM: To delete a compartment and Deleting Tag Key Definitions and Namespaces on page 5584
- Java Management: WorkRequest API
- Load Balancing: Work Request Management on page 3877
- Logging Analytics: WorkRequest API
- Management Agent: WorkRequest API
- Object Storage: Copy Object Work Requests on page 4994
- Service Connector Hub: Viewing the State of a Work Request on page 5398
- Vulnerability Scanning: WorkRequest API

Two features of the request response are of particular interest: the status of the work request, and a list of the resources that are affected by the work request. The status is important because asynchronous work requests must know when an operation has completed, is still running, or whether it has failed altogether.
To retrieve information about work request failures or errors, each service provides APIs for fetching information about errors, and logs. For links to API reference documentation for each of the service, see the section For More Information on page 6294.

Also important in cases where a work request operation affects several resources is having a list of the resources that a work request affects, along with each one's entityType and actionType attributes.

Work Request Status

Asynchronous work requests allow you to monitor their progress by providing a status attribute on the WorkRequest object. Each of the supported services provides its own API for obtaining status, as listed in the following sections.

**Note:**

There is a ContainerEngineWaiters class that allows you to create a callback using the forWorkRequest method. Use this API to forward a notification when an operation's status changes, for example, from IN_PROGRESS to COMPLETED.

The following table lists status attributes that are supported by the WorkRequest object on the respective services.

<table>

</table>
Filtering the Request Response

You sometimes need to know which resources are affected by a given asynchronous work request. In cases where the request response includes just one or two affected resources, the body of the request response is probably sufficient. However, in cases where a request response affects a great many resources, you must filter the response to identify the resources that you're interested in.

Filtering of resources listed in a work request response relies on two attributes of the WorkRequestResource type: entityType and actionType.

- **entityType**: Represents the resource type which the work request affects. This is an optional attribute, but each resource can have only one entityType.
- **actionType**: Represents how the specified resource is affected by the operation associated with the work request.
  
  Each service specifies a fixed list of allowable actionType values (shown in the sections following).

To obtain resource information on a work request, call `GetWorkRequest` and pass in the work request ID. The call returns a response in JSON format. Following is an example from calling `GetWorkRequest` on the Object Storage service.

```json
{
  operationType: "COPY_OBJECT",
  status: "IN_PROGRESS",
  id: "f54527d6-029b-4221-9046-a811b7686202",
  resources: [
    {
      entityType: "object",
      actionType: "READ",
      entityUri: "/n/mynamespace/b/backups/o/myobject"
    },
    {
      entityType: "object",
      actionType: "WRITTEN",
      entityUri: "/n/mynamespace/b/backups/o/copyofmyobject"
    }
  ],
  timeAccepted: 2017-10-13T17:23:46.000Z,
  timeStarted: 2017-10-13T17:23:52.198Z,
  percentComplete: 10.0
}
```

**Note:**

Different services provide slightly different responses. See the reference documentation for each service's work request API for details. Links to each are provided in the For More Information on page 6294 section.

The following table lists the entity types and action types that are supported by Oracle Cloud Infrastructure services.

**Request/Response Sample**

Following is a sequence of REST API calls to create a cluster, which is a common long-running operation. The caller retrieves the work request ID from the response to the initial POST call and then periodically polls the WorkRequest to determine the status of the operation. The request/response sequence that follows depicts this workflow:

1. The user issues a CreateCluster API call.
2. The service responds with status code 202, indicating that the request has been accepted and returns a work request ID in the Opc-Work-Request-Id header.
3. Next, the user issues a GET call on the work request ID to obtain the status of the work request.
4. The service responds with status code 200, indicating in the response body that the CLUSTER_CREATE operation has the status ACCEPTED.
5. With continued polling, we see another GET call for the work request.
6. The service responds with status code 200. The response body reports that the operation SUCCEEDED.

**Step 1. Initial API call to initiate a CLUSTER_CREATE operation.**

```plaintext
POST https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/clusters
Accept: application/json
authorization: <Redacted>
content-length: 480
Content-Type: application/json
date: Mon, 02 Jul 2018 18:20:03 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: D7A390ED909C47038C438BA3629FB612
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)
x-content-sha256: S8U8OKYHyLNViAzm6kxjvF4cFncJHJuRFx0yaA="
"name":"JavaSDK.CRUD",
"compartmentId":"ocid1.compartment.oc1..<unique_ID>",
"vcnId":"ocid1.vcn.oc1.eu-frankfurt-1.<unique_ID>",
"kubernetesVersion":"v1.10.3",
"options":{"serviceLbSubnetIds":["ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>"],
"ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>]})
```

**Step 2. The response to the initial API call, which contains the work request ID in the Opc-Work-Request-Id header.**

```plaintext
202
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 0
Date: Mon, 02 Jul 2018 18:20:04 GMT
Opc-Request-Id: D7A390ED909C47038C438BA3629FB612/33EEDCAA2E8450BB34AA75CD0FD86F4/8261D1CC89814E9BB934440A1F43DA09
Opc-Work-Request-Id: ocid1.clustersworkrequest.oc1.eu-frankfurt-1.<exampleuniqueID>
Uri: /20180222/clusters
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:53077
```

**Step 3. Because this is a long-running operation, the user periodically polls the work request using a GET call to determine its status.**

```plaintext
GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:20:04 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: E8F20DAC443346B3B0EA599F367EE294
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)
```
**Step 4.** The GET call returns the following response, which indicates in the response body that the CLUSTER_CREATE operation has a status of ACCEPTED.

```json
200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 717
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:20:05 GMT
Etag: 56a41efaf33d81a54933495ee910c24d7bce7a83adf18810f95e07bddd055805
Opc-Request-Id:
   E8F20DAC443346B30EA599F367EE294/8B19C9FC3B4442CEA14685D1973D0856/0BA60B0711764DE4A4373071632708C7
Retry-After: 30
Uri: /20180222/workRequests/_id_
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:43533
{
   "id": "ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID",
   "operationType": "CLUSTER_CREATE",
   "status": "ACCEPTED",
   "compartmentId": "ocid1.compartment.oc1..exampleuniqueID",
   "resources": [
      {
         "actionType": "IN_PROGRESS",
         "entityType": "cluster",
         "identifier": "ocid1.cluster.oc1.eu-frankfurt-1.exampleuniqueID",
         "entityUri": "/clusters/ocid1.cluster.oc1.eu-frankfurt-1.exampleuniqueID"
      }
   ],
   "timeAccepted": "2018-07-02T18:20:05Z",
   "timeStarted": null,
   "timeFinished": null
}
```

**Step 5.** The operation continues, and the user continues to poll the work request using the GET method.

```none
GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:24:13 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: 64595B97E39A471A886DA29966BB681D
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)
```

**Step 6.** The last GET call produced the following response, which indicates that the operation has completed. Note the entityType is "cluster" and the actionType is "CREATED".

```json
200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 750
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:24:14 GMT
```

**Request Signatures**

This topic describes how to sign Oracle Cloud Infrastructure API requests.

Signing samples are included for the following:

• **Java** on page 6299
• **Python** on page 6300
• **TypeScript** on page 6301
• **JavaScript** on page 6301
• **Ruby** on page 6302
• **Go** on page 6303
• **Bash** on page 6304
• **C#** on page 6305

**Signature Version 1**

The signature described here is *version 1* of the Oracle Cloud Infrastructure API signature. In the future, if Oracle modifies the method for signing requests, the version number will be incremented and your company will be notified.

**Required Credentials and OCIDs**

You need an API signing key in the correct format. See **Required Keys and OCIDs** on page 6045.

Caution: Client Clock Skew

If the client's clock is skewed more than 5 minutes, a 401 (NotAuthenticated) HTTP status code is returned. This will affect your API requests. For more information, see **Maximum Allowed Client Clock Skew**.

You also need the OCIDs for your tenancy and user. See **Where to Get the Tenancy's OCID and User's OCID** on page 6050.

**Summary of Signing Steps**

In general, these are the steps required to sign a request:

1. Form the HTTPS request (SSL protocol TLS 1.2 is required).
2. Create the signing string, which is based on parts of the request.
3. Create the signature from the signing string, using your private key and the RSA-SHA256 algorithm.
4. Add the resulting signature and other required information to the **Authorization** header in the request.

See the remaining sections in this topic for details about these steps.

**Specification You Need to Be Familiar With**

To learn how to perform steps 2-4 in the process above, refer to **draft-cavage-http-signatures-08**. It's a draft specification that forms the basis for how Oracle handles request signatures. It describes generally how to form the signing string, how to create the signature, and how to add the signature and required information to the request. The remaining sections in this topic assume you're familiar with it. Important details of the Oracle Cloud Infrastructure implementation of the reference are listed in the next section.

**Special Implementation Details**

The following sections describe important items to note about the Oracle Cloud Infrastructure implementation of the spec.
Authorization Header

The Oracle Cloud Infrastructure signature uses the "Signature" Authentication scheme (with an Authorization header), and not the Signature HTTP header.

Required Headers

This section describes the headers that must be included in the signing string.

Note:

Error if Required Header is Missing

If a required header is missing, your client will receive a 401 "Unauthorized" response.

For GET and DELETE requests (when there's no content in the request body), the signing string must include at least these headers:

- (request-target) (as described in draft-cavage-http-signatures-08)
- host
- date or x-date (if both are included, Oracle uses x-date)

For PUT and POST requests (when there's content in the request body), the signing string must include at least these headers:

- (request-target)
- host
- date or x-date (if both are included, Oracle uses x-date)
- x-content-sha256 (except for Object Storage PUT requests; see the next section)
- content-type
- content-length

Caution:

For PUT and POST requests, your client must compute the x-content-sha256 and include it in the request and signing string, even if the body is an empty string. Also, the content-length is always required in the request and signing string, even if the body is empty. Some HTTP clients will not send the content-length if the body is empty, so you must explicitly ensure your client sends it. If date and x-date are both included, Oracle uses x-date. The x-date is used to protect against the reuse of the signed portion of the request (replay attacks).

The one exception is for Object Storage PUT requests on objects (see the next section).

Special Instructions for Object Storage PUT

For Object Storage PutObject and UploadPart PUT requests, the signing string must include at least these headers:

- (request-target)
- host
- date or x-date (if both are included, Oracle uses x-date)

If the request also includes any of the other headers that are normally required for PUT requests (see the list above), then those headers must also be included in the signing string.

Case and Order of Headers

The headers must be all lowercase in the signing string.
The order of the headers in the signing string does not matter. Just make sure to specify the order in the headers parameter in the Authorization header, as described in the draft-cavage-http-signatures-05.

**Caution:**

The (request-target) includes the path and query string from the request. Oracle expects that you will create the signing string with the query parameters in the same order as they appear in the request. If the request query parameters change order after signing occurs, authentication will fail.

**URL Encoding of Path and Query String**

When forming the signing string, you must URL encode all parameters in the path and query string (but not the headers) according to RFC 3986.

**Key Identifier**

You must set keyId=":<TENANCY OCID>/<USER OCID>/<KEY FINGERPRINT>" in the Authorization header that you add to the request. To get those values, see Where to Get the Tenancy's OCID and User's OCID on page 6050. An example keyId looks like this (wrapped to better fit the page):

```
oci1.tenancy.oc1..<unique_ID>/oci1.user.oc1..<unique_ID>/key_fingerprint
```

**Signing Algorithm**

The signing algorithm must be RSA-SHA256, and you must set algorithm=":rsa-sha256" in the Authorization header (notice the quotation marks).

**Signature Version**

You should include version="1" in the Authorization header (notice the quotation marks). If you do not, it's assumed that you're using whatever the current version is (which is version 1 at this time).

**Example Header**

Here's an example of the general syntax of the Authorization header (for a request with content in the body):

```
Authorization: Signature
version="1",keyId="<tenancy_ocid>/<user_ocid>/<key_fingerprint>",algorithm="rsa-sha256",headers="(request-target) date x-content-sha256 content-type content-length",signature="Base64(RSA-SHA256(<signing_string>))"
```

**Test Values**

Here's an example key pair, two example requests, and the resulting Authorization header for each.

**Caution:**

The example signatures use the RSA 2048-bit keys below. Use these keys only for testing your signing code, not for sending production requests.

```
-----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDCFENGw33yGiHy92pDjZQh10C36rPJJj+CvfSC8+q28hxAl1QFNUdI3wcUCTucqQd2qsBe/2hFyc2DJGJ0hIL78+6Z4UNR7EOcpfdUE9HF3m/h5+FUR45uBEtDKHSPHd8bHKD6kV8FPGfJToct+2xjJw
oYi+1hqplfIEkaxsyQIDAQAB
-----END PUBLIC KEY-----

-----BEGIN RSA PRIVATE KEY-----

Oracle Cloud Infrastructure User Guide 6297
The public key is stored under keyId:

ocid1.tenancy.oc1.<unique_ID>/ocid1.user.oc1.<unique_ID>/key_fingerprint

For the following GET request (line breaks inserted between query parameters for easier reading; also notice the URL encoding as mentioned earlier):

GET https://iaas.us-phoenix-1.oraclecloud.com/20160918/instances
availabilityDomain=Pxwf%3A%20PHX-AD-1
&compartmentId=ocid1.compartment.oc1...<unique_ID>
&displayName=TeamXInstances
&volumeId=ocid1.volume.oc1.phx.abyhqljrgvttnlx73nmrwfaux7kvzfs3s66izvxf2h
Date: Thu, 05 Jan 2014 21:31:40 GMT

The signing string would be (line breaks inserted into the (request-target) header for easier reading):

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): get /20160918/instances
host: iaas.us-phoenix-1.oraclecloud.com

The Authorization header would be:

Signature version="1",headers="date (request-target) host",keyId="ocid1.tenancy.oc1.<unique_ID>/ocid1.user.oc1.<unique_ID>/key_fingerprint",algorithm="rsa-sha256",signature="<your_signature>

For the following POST request:

POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/volumeAttachments

Date: Thu, 05 Jan 2014 21:31:40 GMT

{  "compartmentId": "ocid1.compartment.oc1...<unique_ID>",
   "instanceId": "ocid1.instance.oc1.phx.abyhqljrgvtttnlx73nmrwfaux7kvzfs3s66izvxf2h4lgywndsnoiwr5q",
   "volumeId": "ocid1.volume.oc1.phx.abyhqljrgvtttnlx73nmrwfaux7kvzfs3s66izvxf2h4lgywndsnoiwr5q"
}

The signing string would be:

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): post /20160918/volumeAttachments
host: iaas.us-phoenix-1.oraclecloud.com
The Authorization header would be:

Signature version="1",headers="date (request-target) host content-length content-type x-content-sha256",
keyId="ocid1.tenancy.oc1..<unique_id>/ocid1.user.oc1.<unique_id>/<your_fingerprint>",
algorithm="rsa-sha256",signature="<your_signature>"

Sample Code

This section shows the basic code for signing API requests.

**Java**

import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.core.Response;
import com.google.common.net.UrlEscapers;
import com.oracle.bmc.http.signing.RequestSigningFilter;

public class RawRestCallExample {
    public static void main(String[] args) throws Exception {
        // TODO: fill this out
        String instanceId = null;

        String configurationFilePath = "~/.oci/config";
        String profile = "DEFAULT";

        // Pre-Requirement: Allow setting of restricted headers. This is required to
        // allow the SigningFilter
        // to set the host header that gets computed during signing of the request.
        System.setProperty("sun.net.http.allowRestrictedHeaders", "true");

        // 1) Create a request signing filter instance
        RequestSigningFilter requestSigningFilter = RequestSigningFilter
            .fromConfigFile(configurationFilePath, profile);

        // 2) Create a Jersey client and register the request signing filter
```
Client client =
  ClientBuilder.newBuilder().build().register(requestSigningFilter);

// 3) Target an endpoint. You must ensure that path arguments and query
// params are escaped correctly yourself
WebTarget target =
  client.target("https://iaas.us-phoenix-1.oraclecloud.com")
  .path("20160918")
  .path("instances")
  .path(UrlEscapers.urlPathSegmentEscaper().escape(instanceId));

// 4) Set the expected type and invoke the call
Invocation.Builder ib = target.request();
ib.accept(MediaType.APPLICATION_JSON);
Response response = ib.get();

// 5) Print the response headers and the body (JSON) as a string
MultivaluedMap<String, Object> responseHeaders = response.getHeaders();
System.out.println(responseHeaders);
InputStream responseBody = (InputStream) response.getEntity();
try (final BufferedReader reader =
     new BufferedReader(new InputStreamReader(responseBody,
                                               StandardCharsets.UTF_8))) {
  StringBuilder jsonBody = new StringBuilder();
  String line;
  while ((line = reader.readLine()) != null) {
    jsonBody.append(line);
  }
  System.out.println(jsonBody.toString());
}

Python

Important:
This Python sample code requires TLS 1.2, which is not included with the
default Python on Mac OS X.

        }
    }
}

Client-Side Encryption

The Oracle Cloud Infrastructure SDK for Python and SDK for Java support Client Side Encryption, which encrypts your data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

By default, the SDK generates a unique data key for each data object that it encrypts. Data is encrypted using a secure, authenticated, symmetric AES/GCM key algorithm with a 256-bit key length.
To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the `CreateKey` or `ImportKey` operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

**Java Prerequisites**

The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171, and 6u16. For those versions and later the policy files are included but not enabled by default.

Current versions of the JDK do not require these policy files. They are provided here for use with older versions of the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.

**Examples**

The following code example show how to encrypt a string:

**Java**

```java
// String encryption example
final byte[] plainText = "Hello World".getBytes();
String masterKeyId = "OCID....";
Map<String, String> context = Collections.singletonMap("Example", "value");

OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider, Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);

// Encrypt the data and embed the master key ID in the header
final OciCryptoResult encryptResult =
    ociCrypto.encryptData(kmsMasterKeyProvider, plainText, context);
final byte[] cipherText = encryptResult.getResult();

// Decrypt the data
final OciCryptoResult decryptResult =
    ociCrypto.decryptData(kmsMasterKeyProvider, cipherText);
```

**Python**

```python
import oci

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
data_to_encrypt_bytes = b"This is a secret message"

config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id)

kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key])
```
crypto_result = crypto.encrypt(kms_master_key_provider, 
data_to_encrypt_bytes)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
print("unencrypted text: {}".format(crypto_result.get_data()))

The following examples show how to encrypt a file stream:

**Java**

```java
// Create Encryption file stream
FileInputStream in = new FileInputStream(srcFile);
OciCrypto ociCrypto = new OciCrypto();
KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider,
Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId);
KmsMasterKeyProvider kmsMasterKeyProvider = new
KmsMasterKeyProvider(kmsMasterKey);
OciCryptoInputStream encryptingStream =
ociCrypto.createEncryptingStream(kmsMasterKeyProvider, in);

// Write the encrypted data to file
FileOutputStream out = new FileOutputStream(srcFile + ".encrypted");
IOUtils.copy(encryptingStream, out);
encryptingStream.close();
out.close();

// For decryption, no need to pass key info
KmsMasterKeyProvider kmsMasterKeyProvider = new
KmsMasterKeyProvider(authenticationProvider);
// Create the Decryption file stream.
in = new FileInputStream(srcFile + ".encrypted");
OciCryptoInputStream decryptingStream =
ociCrypto.createDecryptingStream(kmsMasterKeyProvider, in);

// Return the plaintext data
out = new FileOutputStream(srcFile + ".decrypted");
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
out.close();
```

**Python**

```python
import oci
import shutil

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
file_to_encrypt = "/file/to/encrypt/message.txt"
output_encrypted_file = "/tmp/message.txt.encrypted"
output_decrypted_file = "/tmp/message.txt.decrypted"

# setup OCI KMS keys
config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(config=config, master_key_id=master_key_id, vault_id=vault_id)  
```
kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

# encrypt stream example
with open(output_encrypted_file, 'wb') as output_stream,
    open(file_to_encrypt, 'rb') as stream_to_encrypt:
    with crypto.create_encryption_stream(
        kms_master_key_provider,
        stream_to_encrypt
    ) as encryption_stream:
        shutil.copyfileobj(encryption_stream, output_stream)

# decrypt stream example
with open(output_decrypted_file, 'wb') as output_stream,
    open(output_encrypted_file, 'rb') as stream_toDecrypt:
    with crypto.create_decryption_stream(
        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)
Glossary

A

AD-specific subnet

A subnet that is specific to a particular availability domain (AD). Historically, all subnets were AD-specific. Now, subnets can be either AD-specific or regional.

alarm

The trigger rule and query to evaluate, plus related configuration, such as the notification details to use when the trigger is breached. Alarms passively monitor your cloud resources by using metrics in the Monitoring service.

API key

A credential for securing requests to the Oracle Cloud Infrastructure REST API.

application (Classic Migration Service)

A combination of the artifacts and configuration deployed on one or more service instances running in the source environment.

attach (Block Volume)

To link a volume and instance together. Attaching lets an instance connect to and mount the volume as a hard drive.

attribute

The combination of a name and data type used to describe a data item, for example, a column in a table or a field in a file.

auth token

A token generated by Oracle Cloud Infrastructure that you use to authenticate with third-party APIs, such as a Swift client.

availability domain

One or more isolated, fault-tolerant Oracle data centers that host cloud resources such as instances, volumes, and subnets. A region contains one or more availability domains.

B

backend set

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy.

bare metal instance

A compute instance that uses hosted, dedicated physical hardware, unlike virtual machines. Bare metal instances ensure a high level of security and performance.

block storage volume

A virtual disk that provides persistent storage space for instances in the cloud.

bucket

A logical container for storing objects.
C

category
A grouping of logically related business terms in a glossary. You nest categories as needed to group terms.

Challenge-Handshake Authentication Protocol (CHAP)
A security protocol used by iSCSI for authentication between a volume and an instance.

Block Volume
A service that allows you to add block storage volumes to an instance to expand the available storage on that resource.

cloud network
A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

cluster network
A pool of high performance computing (HPC) instances that are connected with a high-bandwidth, ultra low-latency network.

compartment
A collection of related resources that can be accessed only by groups that have been given permission by an administrator in your organization.

Compute service
A service that lets you provision and manage compute hosts, known as instances.

connect
To make an attached volume usable by an instance's guest OS.

CPE (customer-premises equipment)
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when you set up Site-to-Site VPN (an IPSec connection) between Oracle and your on-premises network.

CPE Configuration Helper
A feature of the Oracle Console that generates information that a network engineer can use to configure the customer-premises equipment (CPE) at their end of a Site-to-Site VPN IPSec connection.

cross-connect
The physical cable that connects your existing network to Oracle in a FastConnect location. A cross-connect is used with FastConnect if you're using a third-party provider or are colocated with Oracle in a FastConnect location.

cross-connect group
A link aggregation group (LAG) that contains at least one cross-connect. A cross-connect group is used with FastConnect if you're using a third-party provider or are colocated with Oracle in a FastConnect location.

customer-premises equipment (CPE)
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when you set up Site-to-Site VPN (an IPSec connection) between Oracle and your on-premises network.
D

data asset (Data Catalog and Data Integration)

Represents a data source, such as a database, an object store, a file or document store, a message queue, or an application.

tag (Data Catalog)

Free-form labels or keywords that you create to logically identify data objects. Tags help in metadata classification and discovery. You create tags for data assets, data entities, and attributes. Using tags, you can search for all data objects with a specific tag name.

data entity (Data Catalog and Data Integration)

A collection of data, such as a database table or view, or a single logical file. A data entity normally has many attributes that describe its data.

data point (Monitoring)

A timestamp-value pair for a specified metric—for example, 2018-05-10T22:19:00Z, 10.4.

DB system

A dedicated bare metal instance running Oracle Linux, optimized for running one or more Oracle databases. A DB system is a Database service resource.

DHCP options

Configuration information that is automatically provided to the instances when they start up.

dimension (Monitoring)

A qualifier provided in a metric definition—for example, a resource identifier (resourceId) provided in the definitions of oci_computeagent metrics.

display name

A friendly name or description that helps you easily identify the resource.

DRG (dynamic routing gateway)

An optional virtual router that you can add to a virtual cloud network (VCN) to provide a path for private network traffic between the VCN and an on-premises network.

DRG attachment object

The result of attaching a dynamic routing gateway (DRG) to a virtual cloud network (VCN). To detach the DRG from the VCN, you delete the attachment object.

drift (Resource Manager)

The difference between the actual state of your infrastructure and the stack’s last executed configuration.

dynamic group

A special type of Identity and Access Management (IAM) group that contains instances that match rules that you define. As a result, membership in the groups changes dynamically as matching instances are terminated or launched. These instances act as “principal” actors and can make API calls to Oracle Cloud Infrastructure services according to IAM policies that you write for the dynamic group.

dynamic routing gateway (DRG)

An optional virtual router that you can add to a virtual cloud network (VCN) to provide a path for private network traffic between the VCN and an on-premises network.
**E**

**ephemeral public IP address**

A temporary public IP address (and related properties) that exists for the life of the instance that it's assigned to. It can be assigned only to the primary private IP address on a VNIC.

**export (File Storage)**

Controls how file systems are accessed by NFS clients when they connect to a mount target.

**export options (File Storage)**

A set of parameters that specify the level of access granted to NFS clients when they connect to a mount target.

---

**F**

**FastConnect**

A dedicated, private connection between your data center or existing network and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options and a more reliable and consistent networking experience compared to internet-based connections.

**FastConnect location**

A specific data center from which you can connect to Oracle Cloud Infrastructure by using FastConnect.

**fault domain**

A logical grouping of hardware and infrastructure within an availability domain. Fault domains isolate resources during hardware failure or unexpected software changes.

**file system**

An organized system of directories and folders in which data is stored.

**frequency (Monitoring)**

The time period between each posted raw data point for a given metric. (Raw data points are posted by the metric namespace to the Monitoring service.)

---

**G**

**glossary**

A collection of business concepts in your company. A glossary contains categories and business terms.

**group**

A collection of users who all need a particular type of access to a set of resources or compartment.

**guest operating system**

An operating system installed on a cloud instance.

**guest OS**

An operating system installed on a cloud instance.

---

**H**

**harvest**

A process that extracts technical metadata from your connected data sources into your Data Catalog repository.
health check

A test that confirms the availability of backend servers.

IaaS

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

IAM (Identity and Access Management)

The Oracle Cloud Infrastructure service that controls the authentication and authorization of users who need to use your cloud resources.

Identity and Access Management (IAM)

The Oracle Cloud Infrastructure service that controls the authentication and authorization of users who need to use your cloud resources.

identity provider (Idp)

A service that provides identifying credentials and authentication for federated users.

IdP (identity provider)

A service that provides identifying credentials and authentication for federated users.

image

A template of a virtual hard drive that determines the operating system and other software for an instance.

Infrastructure-as-a-Service

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

instance (Compute)

A bare metal or virtual machine compute host. The image used to create an instance determines its operating system and other software. The shape specified during the creation process determines the number of CPUs and memory allocated to the instance.

instance wallet (Autonomous Database)

A file that contains credentials and keys for only a single database instance.

internet gateway

An optional virtual router that you can add to a virtual cloud network (VCN). It provides a path for network traffic between the VCN and the internet.

interval (Monitoring)

The time window used to convert a given set of raw data points—for example, 5 minutes.

IPSec connection

The secure connection between a dynamic routing gateway (DRG) and customer-premises equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components that form a site-to-site VPN between a virtual cloud network (VCN) and your on-premises network.

IPv6

An object that contains an IPv6 address and related properties. IPv6 addressing is supported for all commercial and government regions. Only instances in IPv6-enabled virtual cloud networks (VCNs) and IPv6-enabled subnets can have IPv6 addresses.
Glossary

IQN (iSCSI qualified name)
A unique ID assigned to an iSCSI device. You use an IQN when you connect a volume to an instance.

iSCSI
A TCP/IP-based standard used for communication between a volume and attached instance.

iSCSI qualified name (IQN)
A unique ID assigned to an iSCSI device. You use an IQN when you connect a volume to an instance.

K
key pair
A security mechanism that consists of a public key and a private key. A key pair is required, for example, for Secure Shell (SSH) access to an instance.

L
listener
An entity that checks for incoming traffic on a load balancer's public floating IP address.

local peering gateway (LPG)
A component on a virtual cloud network (VCN) that routes traffic to a locally peered VCN. "Local" peering means that the two VCNs are in the same region.

local VCN peering
The process of connecting two virtual cloud networks (VCNs) in the same region so that their resources can communicate without routing the traffic over the internet or through your on-premises network.

LPG (local peering gateway)
A component on a virtual cloud network (VCN) that routes traffic to a locally peered VCN. "Local" peering means that the two VCNs are in the same region.

M
message (Notifications and Monitoring)
An alert published to all subscriptions in the specified topic. Each message is delivered at least once per subscription.

metric (Monitoring)
A measurement related to the health, capacity, or performance of a given resource. For example, CPU Utilization (CpuUtilization) measures the activity level from CPU, expressed as a percentage of total time.

metric definition (Monitoring)
A set of references, qualifiers, and other information provided by a metric namespace for a given metric.

metric namespace (Monitoring)
Indicates the resource, service, or application that emits a metric. The namespace is provided in the metric definition. For example, the CpuUtilization metric definition emitted by the Oracle Cloud Agent software on Compute instances lists the oci_computeagent metric namespace as the source of the metric.

metric stream (Monitoring)
An individual set of aggregated data for a metric, typically specific to a resource.
**migration (Classic Migration Service)**

The end-to-end workflow of moving an application from a source environment to Oracle Cloud Infrastructure.

**Monitoring Query Language (MQL) (Monitoring)**

The syntax used for metric and alarm queries. In the Console, the MQL syntax of queries is displayed in Advanced Mode.

**mount point (File Storage)**

A directory from which a client may access a remote file system.

**mount target (File Storage)**

A network file system (NFS) endpoint that allows a file system to be accessed by clients.

**MQL (Monitoring Query Language) (Monitoring)**

The syntax used for metric and alarm queries. In the Console, the MQL syntax of queries is displayed in Advanced Mode.

**N**

**NAT gateway**

An optional virtual router that you can add to your virtual cloud network (VCN) to perform Network Address Translation (NAT). A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

**network security group (NSG)**

One method for implementing security rules in a virtual cloud network (VCN). A network security group consists of a set of resources (VNICS or resources with VNICS) and security rules that apply to those resources.

**network source**

A group of IP addresses that can be used in policies to restrict access.

**notification destination (Monitoring)**

Protocol and other details for sending messages when the alarm transitions to another state, such as from OK to FIRING.

**NSG (network security group)**

One method for implementing security rules in a virtual cloud network (VCN). A network security group consists of a set of resources (VNICS or resources with VNICS) and security rules that apply to those resources.

**O**

**object**

Data stored in Object Storage. Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a **bucket**.

**OCID (Oracle Cloud Identifier)**

An Oracle-assigned unique ID for a cloud resource. This ID is included as part of the resource's information in both the Console and API.

**one-time password (OTP)**

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.
**Oracle Cloud Identifier (OCID)**

An Oracle-assigned unique ID for a cloud resource. This ID is included as part of the resource's information in both the Console and API.

**OTP (one-time password)**

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.

**policy (IAM)**

An Identity and Access Management (IAM) document that specifies who has what type of access to your resources. A policy can refer to several types of documents: an individual statement written in the policy language, a collection of statements in a single named "policy" document, and the overall body of policies that your organization uses to control access to resources.

**policy statement (IAM)**

An individual statement written in the policy language. Policies can contain one or more statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

**primary IP**

The private IP address that is automatically created and assigned to a VNIC when an instance is created.

**primary VNIC**

The VNIC that is automatically created and attached to an instance when it is created.

**private IP**

An object that contains a private IPv4 address and related properties, such as a hostname for DNS. Each instance automatically has a primary private IP address, and you can add secondary ones.

**private peering**

One of the ways to use FastConnect. Private peering lets you extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud). Communication across the connection is with IPv4 private addresses (typically those specified in RFC 1918).

**private subnet**

A subnet in which instances are not allowed to have public IP addresses.

**private virtual circuit**

A FastConnect virtual circuit that supports private peering.

**public IP**

An object that contains a public IP address and related properties. You control whether each private IP address on an instance has an assigned public IP address. The two types of public IP addresses are reserved and ephemeral.

**public peering**

One of the ways to use FastConnect. Public peering lets your on-premises network access public services in Oracle Cloud Infrastructure—for example, Object Storage, the Console and APIs, or public load balancers in your VCN—without using the internet. Communication across the connection is with IPv4 public IP addresses.

**public subnet**

A subnet in which instances are allowed to have public IP addresses. When you launch an instance in a public subnet, you specify whether the instance should have a public IP address.
public virtual circuit

A FastConnect virtual circuit that supports public peering.

Q
query (Monitoring)

The expression to evaluate for returning aggregated data. A valid query includes a metric, statistic, and interval. In the Console, you can view a query in Basic Mode or Advanced Mode. The latter displays the Monitoring Query Language (MQL) syntax.

R
realm

A logical collection of regions. Realms are isolated from each other and don’t share any data. Your tenancy exists in a single realm and can access the regions in that realm.

region

A collection of availability domains located in a single geographic location.

regional subnet

A subnet that spans all the availability domains in the region. Oracle recommends using regional subnets because they are more flexible and make it easier to implement failover across availability domains.

regional wallet (Autonomous Database)

A file that contains the credentials and keys for all Autonomous Databases in a specified region.

remote peering connection (RPC)

A component on a dynamic routing gateway that routes traffic to a remotely peered virtual cloud network (VCN). "Remote" peering means that the two VCNs are in different regions.

remote VCN peering

The process of connecting two virtual cloud networks (VCNs) in different regions so that their resources can communicate without routing their traffic over the internet or through your on-premises network.

reserved public IP address

A public IP address (and related properties) that you create in your tenancy and assign to your instances in a given region as needed. A reserved public IP address persists in your tenancy until you delete it. It can be assigned to any private IP on a given VNIC, not just the primary private IP.

resolution (Monitoring)

The period between time windows, or the regularity at which time windows shift—for example, 1 minute.

resource

The cloud objects that you create and use when interacting with Oracle Cloud Infrastructure.

route table

A virtual route table for your virtual cloud network (VCN) that maps the traffic from subnets through gateways to external destinations.

RPC (remote peering connection)

A component on a dynamic routing gateway that routes traffic to a remotely peered virtual cloud network (VCN). "Remote" peering means that the two VCNs are in different regions.
**S**

**secondary IP address**
An additional private IP address that you add to a VNIC on an instance. Each VNIC automatically comes with a primary private IP address that can't be removed.

**secondary VNIC**
An additional virtual network interface card (VNIC) that you add to an instance. Each instance automatically comes with a primary VNIC that can't be removed.

**security list**
A method for implementing security in a virtual cloud network (VCN). A security list consists of security rules that apply to all resources in any subnet that uses the security list.

**security rule**
Virtual firewall rules for your virtual cloud network (VCN). Each security rule specifies a type of ingress or egress traffic allowed in or out of a resource or VNIC.

**service gateway**
An optional virtual router that you can add to your virtual cloud network (VCN). The gateway enables on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

**shape**
A template that determines the number of CPUs, amount of memory, and other resources that are allocated to a compute instance.

**source (Classic Migration Service)**
The environment from which the application is being migrated.

**statement**
The part of a policy that gives a group a certain type of access to certain resources in a particular compartment.

**statistic (Monitoring)**
The aggregation function applied to the given set of raw data points—for example, SUM.

**subnet**
A subdivision of your virtual cloud network (VCN). Subnets separate your network into multiple smaller and distinct networks.

**subscription (Notifications)**
An endpoint for a topic, typically a URL or email address. Published messages are sent to each subscription for a topic.

**suppression (Monitoring)**
A configuration to avoid publishing messages during the specified time range. Suppression is useful for suspending alarm notifications during system maintenance.

**Swift password**
Deprecated. Use an auth token to authenticate with your Swift client in Object Storage.
**T**

tenancy

A secure and isolated partition within Oracle Cloud Infrastructure (OCI) where you can create, organize, and administer your cloud resources. When you sign up for OCI, a tenancy is created for your company. Tenancy also refers to the root compartment that contains all of your organization's compartments and other OCI resources.

tenant

The name assigned to a particular company's or organization's overall environment. Users provide their tenant when signing in to the Console.

term (Data Catalog)

The definition of a business concept as agreed on by different stakeholders in your company. You use terms to organize your data entities and attributes.

topic (Notifications)

A communication channel for sending messages to the subscriptions in a topic.

transit routing

A network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with a FastConnect private virtual circuit or VPN Connect. Then you configure the VCN routing so that traffic transits through the VCN to its destination beyond the VCN.

trigger rule (Monitoring)

The condition that must be met for an alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

**U**

user

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources.

**V**

VCN (virtual cloud network)

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual circuit

An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure. Virtual circuits are used with Oracle Cloud Infrastructure FastConnect.

virtual cloud network (VCN)

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual machine (VM)

A software-based emulation of a full computer that runs within a physical host computer.

virtual network interface card (VNIC)

Enables an instance to connect to a virtual cloud network (VCN) and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and
you can add secondary ones. Other types of cloud resources, such as load balancers and DB systems, also automatically get a VNIC when they are created.

**VM (virtual machine)**

A software-based emulation of a full computer that runs within a physical host computer.

**VNIC (virtual network interface card)**

Enables an instance to connect to a virtual cloud network (VCN) and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources, such as load balancers and DB systems, also automatically get a VNIC when they are created.

**volume**

A detachable block storage device that lets you dynamically expand the storage capacity of an instance.

**W**

**work request**

An object that reports on the current state of an asynchronous service request.
Release Notes

You can find the Oracle Cloud Infrastructure Release Notes online.
