At the bottom of each tile are messages reporting whether or not usage of the resources listed in the column are near or at service limits for the tenancy. For resources that are near or at service limits, you can request a service limit increase.

**Operations Section**

The tiles for alarms, activity, announcements, and service health allow you to quickly assess whether any of your Oracle Database resources need attention, how normal operations are proceeding, and if there are service-related announcements you need to know about to effectively manage your resources.

"The Alarms tile displays the Oracle Cloud Infrastructure Monitoring service alarms for your Database service resources. You can click the alarm icon in the Alarms tile to navigate to detailed information about the alarms. In the list view of your tenancy's alarms, you can limit the list by compartment, alarm status, and alarm severity. For more information on creating and using alarms to manage your Oracle Database resources, see the Monitoring documentation.

The Activity tile displays the number of in-progress work requests for your Database service resources. Click on the tile's activity icon to navigate to a complete list of in-progress work requests in your specified compartment.

The Announcements tile displays the number of unread Oracle Database announcements for your tenancy, if any. Click the tile's announcements icon to navigate to your unread announcements. See Console Announcements on page 260 for more information on Oracle Cloud Infrastructure announcements.

The Service Health tile displays the availability status of all Oracle Database instances in the selected region, and allows you to easily navigate to the Console's Oracle Cloud Infrastructure status page to check the availability status of all Oracle Cloud Infrastructure services, by region.
What's New and Help

The What's New list provides a view of the most recent updates to the Oracle Database service. The Help list provides quick access to information about each type of Oracle Database cloud offering.

To see a list of alarms for your tenancy's Oracle Database resources
1. Open the navigation menu. Under Database, click Overview.
2. Under Advanced, click Alarms.
3. Optional. Limit the scope of the list using the compartment selector under List Scope.
4. Optional. Limit the list to alarms with a particular status or severity using the available list filters.

To see a list of work requests for your tenancy's Oracle Database resources
1. Open the navigation menu. Under Database, click Overview.
2. Under Advanced, click Activity.
3. Optional. Limit the scope of the list using the compartment selector under List Scope.
4. Optional. Limit the list to work requests with a particular status or operation type using the available list filters.

To see a list of announcements for your tenancy's Oracle Database resources
1. Open the navigation menu. Under Database, click Overview.
2. Under Advanced, click Announcements.
3. Optional. Limit the list by announcement status, Oracle Database service type, announcement action type, and publication time.

To see details about your tenancy's Oracle Database resource categories that are at or near service limits
1. Open the navigation menu. Under Database, click Overview.
2. Under Advanced, click Limits.
3. Optional. Limit the scope of the information using the compartment selector under List Scope.
4. Optional. Limit the list by Oracle Database service type using the Service Type filter. This allows you to view limits information for either Autonomous Databases, co-managed databases, or Exadata infrastructure instances.
5. Optional. Limit the list to information about the Console's currently specified region, or to an availability domain within the current region, using the Scope filter.

Using Performance Hub to Analyze Database Performance

This topic describes how to use Performance Hub to analyze and tune the performance of a selected Oracle Cloud Infrastructure Autonomous Database. With this tool, you can view real-time and historical performance data. When you view historical data in the Performance Hub, you are viewing statistics collected as part of the hourly snapshots of your database.

Note:
Performance Hub supports only Autonomous Databases.

Note:
Using Identity and Access Management (IAM), you can create a policy that grants users access to Performance Hub while limiting actions they can take on an Autonomous Database. For more information, about policies and how to use them, see How Policies Work. The following example shows a policy that grants access only to performance data without allowing general use access on Autonomous Databases.

Allow group <groupname> to inspect autonomous-database-family in compartment <name>
Allow group <groupname> to use autonomous-database-family in compartment <name> where request.operation = 'RetrieveAutonomousDatabasePerformanceBulkData'

Performance Hub Features

The Performance Hub window consists of a graphical Time Range display that you use to select the time period of all data to be displayed. It includes the following tabs that display performance data:

- ASH Analytics
- SQL Monitoring
- Workload
- Blocking Sessions
- ADDM (available for databases using shared Exadata infrastructure).

These tabs, described in detail in this topic, provide information that you can use to analyze the performance of a selected database, including the following:

- How much of the database is waiting for a resource, such as CPU or disk I/O
- Whether database performance degraded over a given time period and what could be the likely cause
- Which specific modules may be causing a load on the system, and where most of database time is being spent on this module
- Which SQL statements are the key contributors to changes in database performance, and which executions are causing them
- Which user sessions are causing performance bottlenecks
- Which sessions are currently blocking and if there are outstanding requests for a lock

Time Range Selector

The time range selector is displayed at the top of the Performance Hub page. It consists of a graphically displayed time field as shown in the following illustration. The selected time range applies to all charts and graphs in the Performance Hub window.
You can hide the Activity Summary chart to save space and display only the main tab content. To do so, click the **Hide Activity Summary** checkbox that is located directly above the graph.

![Performance Hub Activity Summary](image)

**Figure 1: Performance Hub Activity Summary**

The time range field (#1 in the previous illustration) shows database activity in chart form for the specified **Time Range** period. The time range is the amount of time being monitored.

Use the **Quick Select** selector to set the time range. The menu includes five time choices, **Last Hour, Last 8 Hours, Last 24 Hours, Last Week,** and **Custom.** The default time range is Last Hour. You can also click the **Time Range** field to specify a custom time range. This opens the **Custom Time Range** dialog, allowing you to specify a custom range.

The **Activity Summary** graph displays the average number of active sessions broken down by **CPU, User I/O, and Wait.** Maximum threads are shown as a red line above the time field.

The sliding box (circled at right in the previous illustration) on the time range chart is known as the **time slider.** The time slider selects a section of the time range (#2 in the previous illustration) shown in the time range field. It shows the time being analyzed. In the illustration, the arrows inside the time slider point to the vertical 'handle' elements on the left and right boundaries of the slider box. The time slider works as follows:

- To change the start and end time of the analysis while keeping the same amount of time between them, left click anywhere inside the box. Then slide the box left or right along the time range without changing its size. The selected times are displayed below the time graph.
- To increase or decrease the length of time being analyzed, left click either one of the **handles** and drag it left or right to expand or contract the box.
- To refresh the data in Performance Hub according to the time range chosen, click **Refresh** (upper right corner of the window).

**Note:**

The time slider provides an extra display feature in the Workload tab. See the description in the Workload Tab section of this page.

Use the **Quick Select** menu to set the time duration. The menu includes the following five time choices: **Last Hour, Last 8 Hours, Last 24 Hours, Last Week,** and **Custom.** The default Time Range is Last Hour. The time slider selects the time period of the data displayed in Performance Hub. The time slider has a different default time period based on the selected Time Range.
Time Zone Selector

The Time Zone selector is located above the time range field, beside the Quick Select and Time Range selectors. By default, when you open Performance Hub, the tool displays data in UTC (Coordinated Universal Time) time. You can use the time zone selector to change the time zone to either your local web browser time, or the time zone setting of the database you are working with. When you change the time zone, the Performance Hub reports display data in your specified time zone.

ASH Analytics Tab

Displayed by default, the ASH (Active Session History) Analytics tab shows ASH analytics charts that you can use to explore ASH data. You can use this tab to drill down into database performance across multiple dimensions such as Consumer Group, Wait Class, SQL ID, and User Name. In the ASH Analytics tab, you can select an Average Active Sessions dimension and view the top activity for that dimension for the selected time period.

The Average Active Session chart has a control at the right end of the chart to select the displayed resolution of ASH data (low, medium, high, or maximum). For more information on ASH, see Active Session History (ASH) in Oracle Database Concepts.

ASH Sample Resolution

The ASH Sample Resolution menu gives users the ability to control the sampling of ASH data displayed in the Average Active Sessions chart. Data resolution means displaying more or fewer data points in the sample data in given time period. Lower resolution displays coarser data with better performance and less impact on the database. Higher resolution aggregates more data to display finer detail, but can have a corresponding cost in latency and impact on the database.

The Sample Resolution menu is displayed at the right side of the chart. The data resolution selections are:

- **Low** - the chart displays the fewest data points in the selected data sample.
- **Medium** - the chart displays more data points in the selected data sample.
- **High** - the chart displays more data points in the selected data sample.
- **Maximum** - the chart displays the most data points available in the selected data sample.

To use this feature, see To view the average active sessions data by a selected dimension on page 1602

Activity tables

By default, the two tables located below the Average Active Sessions graph display the top SQLs and user sessions for the time period covered by the Average Activity Sessions graph. Use the menus at the top left of each of the two tables to view activities by other dimensions.

SQL Monitoring Tab

The SQL Monitoring tab is not displayed by default. To view it, click SQL Monitoring on the Performance Hub page.

SQL statements are only monitored if they have been running for at least five seconds or if they are run in parallel. The table in this section displays monitored SQL statement executions by dimensions including Last Active Time, CPU Time, and Database Time. The table displays currently running SQL statements and SQL statements that completed, failed, or were terminated. The columns in the table provide information for monitored SQL statements including Status, Duration, and SQL ID.

The Status column includes the following icons:

- A spinning icon indicates that the SQL statement is executing.
- A green check mark icon indicates that the SQL statement completed its execution during the specified time period.
- A red cross icon indicates that the SQL statement did not complete. The icon displays when an error occurs because the session was terminated.
- A clock icon indicates that the SQL statement is queued.
To terminate a running or queued SQL statement, click **Kill Session**.

You can also click an SQL ID to go to the corresponding **Real-time SQL Monitoring** page. This page provides extra details to help you tune the selected SQL statement.

### Workload Tab

The Workload tab graphically displays four sets of statistics that you can use to monitor the database workload and identify spikes and bottlenecks. Each set of statistics is displayed in a separate region, as described in the following sections.

#### Monitored and analyzed time indications

The time slider has more functionality in the Workload tab than it does in the Active Session History and SQL Monitoring tabs. Note the following about the **Quick Select** time range options:

- **Last Hour**, **Last 8 Hours**, and **Last 24 Hours** - The charts in the Workload tab display data for the entire time period of specified time range. A shadowed area is displayed in each chart that corresponds to the position of the time slider in the time range.
- **Last Week** - The charts in the Workload tab display data for the selected time period of the time slider in the time range. There is no shadowed area displayed in this case.
- **Custom** - The shadowed area display depends on whether the time period is up to and including 24 hours, or greater than 24 hours.

#### Regions

The tab contains four regions: CPU Statistics, Wait Time Statistics, Workload Profile, and Sessions. Each region contains one or more charts that indicate the characteristics of the workload and the distribution of the resources. The data displayed on all the charts is for the same time period, as selected by the Time Range and time slider at the top of the window.

- **The CPU Statistics** region contains two charts:
  - **CPU Time** - This chart shows how much CPU time is being used by the foreground sessions every second. It identifies where the CPU time is mostly spent in the workload and pinpoints any unusual CPU spikes.
  - **CPU Utilization (%)** - This chart indicates the percentage of CPU time aggregated by consumer group as calculated by the resource manager.

- **The Wait Time Statistics** region contains a chart that displays the time used in different wait classes. To see the total average active sessions, select the **DB Time** check box. The activities are broken down by the 13 wait classes.

- **The Workload Profile** region contains a group of charts that indicate patterns of user calls, executions, transactions, and parses, as well as the number of running statements and queued statements. This region includes a menu that you can use to select the data to display. It contains the following options.
  - **User Calls** - This option displays the combined number of logons, parses, and execute calls per second.
  - **Executions** - This option displays the combined number of user and recursive calls that executed SQL statements per second.
  - **Transactions** - This option displays the combined number of user commits and user rollbacks per second.
  - **Parses** - This option displays the combined number of hard and soft parses per second.
  - **Running Statements** - This option displays the number of running SQL statements, aggregated by consumer group.
  - **Queued Statements** - This option displays the number of queued parallel SQL statements, aggregated by consumer group.

- **The Sessions** region contains charts that show the number of current logons and sessions. It contains a menu that includes the following options:
  - **Current Logons** - This option displays the number of current successful logons.
  - **Sessions** - This option displays the number of sessions.
Blocking Sessions Tab

The Performance Hub blocking sessions tab displays the current blocking and waiting sessions in a hierarchical display. You can view detailed information about each blocking session, and can view the sessions blocked by each blocking session. You can also use the tab to inspect or drill down into the SQL involved, to determine the cause of the blocking. You can perform several operations in the tab, including killing one or more of the listed sessions to resolve a waiting session problem. Instructions for the tab functions are located in this topic under Using the Oracle Cloud Infrastructure Console on page 1602.

The hierarchical display nests waiting sessions underneath the session that is blocking them in an easily viewable parent-child relationship. The hierarchy can contain any number of levels to correctly represent the structure of the sessions involved.

The sessions listed include sessions that are waiting for a resource and sessions that hold a resource that is being waited on that creates the blocking condition.

ADDM Tab

The Performance Hub Automatic Database Diagnostic Monitor (ADDM) tab includes controls to access the information stored by ADDM. ADDM analyzes the Automatic Workload Repository (AWR) data on a regular basis, then locates the root causes of performance problems, provides recommendations for correcting any problems, and identifies non-problem areas of the application. Because AWR is a repository of historical performance data, ADDM can be used to analyze performance issues after the event, often saving time and resources that would be needed to reproduce a problem.

ADDM provides the following benefits:

• Time-based quantification of application problem impacts and recommendation benefits
• Recommendations for treating the root causes of problems
• Identification of non-problem areas of the application

In addition to the benefits ADDM provides for production systems, it can be used on development and test systems to provide early warnings of application performance issues.

Instructions to use the ADDM tab are located below in Using the Oracle Cloud Infrastructure Console on page 1602.

Automatic Workload Repository Reports

The Automatic Workload Repository (AWR) collects, processes, and maintains performance statistics for problem detection and self-tuning purposes. This data is both in memory and stored in the database. From the Performance Hub, you can generate and download a report of the gathered data.

An AWR report shows data captured between two points in time (or snapshots). AWR reports are divided into multiple sections. The content of the report contains the workload profile of the system for the selected range of snapshots. The HTML report includes links that you can use to navigate quickly between sections.

The statistics collected and processed by AWR include:

• Object statistics that determine both access and usage statistics of database segments
• Time model statistics based on time usage for activities, displayed in the V$SYS_TIME_MODEL and V$SESS_TIME_MODEL views
• Some of the system and session statistics collected in the V$SYSSTAT and V$SESSTAT views
• SQL statements that are producing the highest load on the system, based on criteria such as elapsed time and CPU time
• ASH statistics, representing the history of recent sessions activity

To generate and download an AWR report, see To download an AWR report on page 1603.
Using the Oracle Cloud Infrastructure Console
To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database

1. Open the navigation menu. Under Database, click Autonomous Transaction Processing or Autonomous Data Warehouse.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click the display name of the database you want to analyze using Performance Hub reports.
4. Click Performance Hub.

To view the average active sessions data by a selected dimension

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database which you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information.
   • The database name is displayed at the top of the Performance Hub page.
   • The time period for which information is available on the Performance Hub is displayed in the Time Range field.
   • The selected time period is indicated on the time slider graph by the adjustable time slider box.
   • The ASH Analytics tab is displayed with the top activity for a selected dimension in the selected time period.
2. Use the Quick Select selector to set the exact time period for which data is displayed in the ASH Analytics tables and graphs. By default, the last hour is selected. The time range is the total amount of time available for analysis.
3. Use the box on the time slider to further narrow down the time period for which performance data is displayed on the ASH Analytics tab.
4. Select a dimension in the Average Active Sessions drop-down list to display ASH analytics by that dimension. When the Consumer Group dimension is selected, the data is categorized by default to the High, Medium, or Low service name that is associated with the Autonomous Database.
   Optionally, you can:
   • Click the Maximum Threads check box to view the number of Max CPU Threads. The red line on the chart shows this limit.
   • Click the Total Activity check box to view a black border that denotes total activity of all the components of the selected dimension on the chart. This option is selected by default when you use the filtering capabilities to only view the data for a particular component within a dimension. For information on filtering Average Active Sessions data, see Filter Average Active Sessions Data.
5. Use the Sample Resolution menu to select the sampling of ASH data displayed in the Average Active Sessions chart. To select a resolution, click Sample Resolution to display the following menu and click the desired resolution to display the data.
   • Low - the graph displays the fewest data points available in the selected data sample.
   • Medium - the graph displays more data points in the selected data sample.
   • High - the graph displays more data points in the selected data sample.
   • Maximum - the graph displays the most data points available in the selected data sample.
6. For the dimension selected in the Average Active Sessions drop-down list, you can further drill down into session details by selecting dimensions in the two sections at the bottom of the ASH Analytics tab. By default, the following dimensions are selected:
   • SQL ID by Consumer Group, which displays the SQL statements with the top average active sessions activity for consumer groups for the selected time period. You can right-click the bar charts to sort the SQL statements in ascending or descending order or click the SQL ID to go the SQL Details page.
   • User Session by Consumer Group, which displays the user sessions with the top average active sessions activity for consumer groups for the selected time period. You can right-click the bar charts to sort the user sessions in ascending or descending order or click the user session to go to the User Session page.
To filter average active sessions data

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database that you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information.
   - The database name is displayed at the top of the Performance Hub page.
   - The time period for which information is available on the Performance Hub is displayed in the Time Range field. The selected time period is indicated on the time slider graph by the adjustable time slider block.

   The ASH Analytics tab is displayed with the top activity for a selected dimension in the selected time period.

2. Use the Quick Select selector to set the exact time period for which data is displayed in the ASH Analytics tables and graphs. By default, the last hour is selected. The time range is the total amount of time available for analysis.

3. Use the adjustable time slider box to further narrow down the time period for which performance data is displayed on the ASH Analytics tab.

4. In the ASH Analytics tab, select a dimension in the Average Active Sessions by drop-down list. By default, Consumer Group is selected.

   The chart is displayed. Each color in the chart denotes a component of the selected dimension. For example, the Consumer Group dimension has High, Medium, and Low, which are predefined service names assigned to your Autonomous Database to provide different levels of concurrency and performance.

5. Click a component in the legend. The selected component is displayed in the Applied Filters field and the chart is updated to only display data pertaining to that component. The total activity, which includes all the components of the dimension, is defined by a black outline and is displayed by default when you filter data.

To view the SQL Monitoring report

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database which you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information.
   - The database name is displayed at the top of the Performance Hub page.
   - The time period for which information is available on the Performance Hub is displayed in the Time Range field. The selected time period is indicated on the time slider graph by the adjustable time slider box.

2. Click SQL Monitoring to display the SQL monitoring tab.

3. Optionally, you can get detailed information on a specific SQL statement by clicking an ID number in the SQL ID column. When you click an ID number, the Real-time SQL Monitoring page is displayed.

4. Click Download Report to download the report data for your selected SQL statement.

To download an AWR report

For databases version 18c and older:

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database which you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information.
   - The database name is displayed at the top of the Performance Hub page.
   - The time period for which information is available on the Performance Hub is displayed in the Time Range field. The selected time period is indicated on the time slider graph by the adjustable time slider box.

2. Click AWR to display the Generate AWR Report dialog.

3. You can choose to generate a report either from two snapshots closest to the current time and date or from a custom time range of your choice.

4. You can choose to generate a report either from two snapshots closest to the current time and date or from a custom time range of your choice.

5. If you choose to generate a report from a custom time range, then select Custom and select start and end times for your range. Click Download.

6. Oracle Database generates a report named AWRReport_date_range.html that downloads to the default download folder for your browser. View the report after the download completes.
For databases version 19c and newer:

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database which you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information.
   - The database name is displayed at the top of the Performance Hub page.
   - The time period for which information is available on the Performance Hub is displayed in the Time Range field. The selected time period is indicated on the time slider graph by the adjustable time slider box.

2. In the Quick Select menu, choose a time period for which an AWR report will be generated.

3. In the upper right corner, click Reports > Automatic Workload Repository.
   
   The Generate Automatic Workload Repository dialog box is displayed.

4. Use the Start Snapshot and End Snapshot menus to select the beginning and end of the snapshot time range to generate the report.

5. Click Download. The database generates the report named AWRReport_date_range.html. When the report is complete, the report name is displayed at the top of the screen, and the report is automatically downloaded to the default download folder for your browser.

6. Open the default download folder for your browser on your system and view the report from there.

To view the Workload metrics

1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database that you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information. The database name is displayed at the top of the Performance Hub page.

2. Use the Quick Select selector to set the exact time period for which data is displayed in the ASH Analytics tables and graphs. By default, the last hour is selected. The time range is the total amount of time available for analysis.

3. Use the time slider to further narrow down the time period for which performance data is displayed on the Workload tab. All charts show data for the entire specified time range if within 24 hours.

4. Click Workload to view the Workload tab. The four regions and their associated charts are displayed.
   
   - **CPU Statistics** The CPU Statistics region contains two charts, CPU Time and CPU Utilization (%).
     
     To display how much CPU Time is being consumed by the foreground sessions per second, select CPU Time in the menu in this region. This identifies where the CPU time is mostly spent in the workload and pinpoints any unusual CPU spikes. When CPU time is selected optionally click the Maximum Threads check box to show the maximum CPU time available. This shows the CPU time component of Average Active Sessions.
     
     To display the CPU Utilization (%) chart, select CPU Utilization (%) in the menu. This chart displays the percentage of CPU time aggregated by consumer group, as calculated by the resource manager.
   
   - **Wait Time Statistics** The Wait Time Statistics region contains one chart that displays the time used in different wait classes. To see the total average active sessions, select the DB Time check box. The activities are broken down by the 13 wait classes.
   
   - **Workload Profile** To change the metrics displayed in the Workload Profile, click the menu and select the metric that you want to view.
     
     - Select User Calls to display the combined number of logons, parses, and execute calls per second.
     
     - Select Executions to display the combined number of user and recursive calls that executed SQL statements per second.
     
     - Select Transactions to display the combined number of user commits and user rollbacks per second.
     
     - Select Parses to display the combined number of hard and soft parses per second
     
     - Select Running Statements to display the number of running SQL statements, aggregated by consumer group.
     
     - Select Queued Statements to display the number of queued parallel SQL statements, aggregated by consumer group.
• **Sessions** To change the metrics displayed in the Sessions region, click the menu and select the metric that you want to view:
  
  • Select **Current Logons** to display the number of current successful logons.
  • Select **Sessions** to display the number of sessions.

**To view blocking and waiting sessions**

1. Go to the **Performance Hub** page of the Oracle Cloud Infrastructure Console for the database that you want to manage. See **To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database** on page 1602 for more information.
   
   • The database name is displayed at the top of the Performance Hub page.
   • The time period for which information is available on the Performance Hub is displayed in the **Time Range** field. The selected time period is indicated on the time slider graph by the adjustable time slider box. See the Time Range information in **Performance Hub Features** on page 1597 to learn how to set the duration of the time to be monitored.

2. Click **Blocking Sessions** to display details about current blocking and waiting sessions. Analysis of historical sessions is not supported.

3. Click the link in each column of the table to view the details of the listed blocking and waiting sessions, as shown in the following table.

<table>
<thead>
<tr>
<th>Tab Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Name</td>
<td>This is the name of the user.</td>
</tr>
<tr>
<td>Status</td>
<td>The status indicates whether the session is active, inactive, or expired.</td>
</tr>
<tr>
<td>Lock</td>
<td>This is the lock type for the session. Click the lock type to display a table with more information about the session lock. It lists the Lock Type, Lock Mode, Lock Request, Object Type, Subobject Type, Time, ID1, ID2, Lock Object Address, and Lock Address of the selected session.</td>
</tr>
<tr>
<td>User Session</td>
<td>The user session lists the Instance, SID, and Serial number.</td>
</tr>
<tr>
<td>SQL ID</td>
<td>This is the ID of the SQL associated with the session.</td>
</tr>
<tr>
<td>Wait Event</td>
<td>This is the wait event for the session. Click the wait event to show additional wait event details.</td>
</tr>
<tr>
<td>Object Name</td>
<td>This is the name of the locked database object.</td>
</tr>
<tr>
<td>Blocking Time</td>
<td>This is the time that a blocking session has been blocking a session.</td>
</tr>
<tr>
<td>Wait Time</td>
<td>This is the time that a session has been waiting.</td>
</tr>
</tbody>
</table>

**Note:**

If you see an error message that says the server failed to get performance details for the selected session at the selected time, try the selection again. If the same error message is displayed, try a different time selection. If that fails, contact Oracle Support.

**Setting the Minimum Wait Time**

The minimum wait time works like a filter for the Blocking Sessions information. It sets the minimum time that a session must wait before it is displayed in the tab. For example, if the minimum wait time is set to three seconds, and a session has waited only two seconds, it is not displayed in the table. But if you change the minimum wait time to one second, the session that waited only two seconds is added to the display.
Killing a Session
1. Click the check box at the left of the session User Name to select a session. The Kill Session button is enabled.
2. Click Kill Session. The Kill Session confirmation dialog box is displayed.
3. Click Kill Session to end the session.

Displaying Lock Details
1. In the session Lock column, click the name of the lock type (Lock or Exclusive Lock) for the session. The Wait Event Details message box is displayed.
2. Note the information in the table and use as needed to determine any action to take.

Displaying Wait Event Information
1. In the session Wait Event column, click the name of the wait event for the selected session. The Session Lock Information table is displayed.
2. Note the information in the message box and use as needed to determine any action to take.

Displaying Session Details
1. In the session User Session column, click the session identifier for the session. The Performance Hub Session Details page is displayed.
2. Optionally move the time slider to display a specific time range of the session.
3. Use the Session Details page to explore additional details about the session.

Displaying SQL Details
1. In the session SQL ID column, click the SQL ID associated with the session. The Performance Hub SQL Details page is displayed.
2. Optionally move the time slider to display a specific time range of the session.
3. Select one or more of the following tabs, note the information in them, and take any action needed.
   • Summary. This tab displays the SQL Overview and Source details.
   • ASH Analytics. This tab displays the SQL average active sessions.
   • Execution Statistics. This tab displays the SQL plans and plan details.
   • SQL Monitoring. This tab displays information about monitored SQL executions.
   • SQL Text. This tab displays the SQL.

To view ADDM data
This procedure explains how to view Automatic Database Diagnostic Monitor (ADDM) information with Performance Hub.
1. Go to the Performance Hub page of the Oracle Cloud Infrastructure Console for the database that you want to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database on page 1602 for more information. The database name is displayed at the top of the Performance Hub page.
2. Click the ADDM tab to open it.
3. Use the menu located below Quick Select to select a time range. The data for that time range is displayed.
4. In the **Activity Summary** area, just below the data, click one of the **gray AWR snapshot icons** to display findings for the associated ADDM task. A white check mark in the gray icon indicates that there are problem findings available. When selected, the gray icon changes to blue.

**Note:**

You can alternatively select an ADDM task from the menu below the ADDM tab or by positioning the time slider above an icon.

**Note:**

When you manually change the ADDM task selection, either by clicking the gray icon for an associated AWR snapshot, or by selecting an option from the ADDM task menu, the time slider position and size are adjusted to cover the analysis period for the ADDM task.

5. Hover over the icon to display a message about the AWR snapshot and ADDM task, including the number of findings for the ADDM task. The findings are displayed in two tables:

- **Findings table.** When there are findings, the Findings table shows the Name of the finding, the Impact, Number of recommendations, and Average Active Sessions for that finding. If there are no findings available, the table displays a message that says no findings are available for the selected analysis period.

- **Warnings and Information table.** The Warnings and Information table is displayed below the Findings table. It lists messages related to the findings.
  - Warning messages identify issues such as missing data in the AWR that may affect the completeness or accuracy of the ADDM analysis.
  - Information messages provide information that is relevant to understanding the performance of the database but does not represent a performance problem. This may include identification of non-problem areas of the database and automatic database maintenance activity.

**Note:**

Both the Findings table and the Warnings and Information table are collapsible to save space when many findings are found. Click the **minus icon** to collapse a table. Click the **plus icon** to expand the table again.

6. If a finding has ADDM recommendations available, the name of the finding is displayed as a link. Click the **name of the finding** to display more information about the finding, including a table of recommendations for corrective actions. Each recommendation includes the problem area, the suggested action to take to solve it, and the estimated benefit that will result when the action is taken.

7. Click the **expand icon** at the end of a row in the recommendations table to view a rationale for the recommendation.

### Migrating Databases to the Cloud

You can migrate your on-premises Oracle Database to an Oracle Cloud Infrastructure Database service database using a number of different methods that use several different tools. The method that applies to a given migration scenario depends on several factors, including the version, character set, and platform endian format of the source and target databases.

**Tip:**

Oracle now offers the **Zero Downtime Migration** service, a quick and easy way to move on-premises Oracle Databases and Oracle Cloud Infrastructure Classic databases to Oracle Cloud Infrastructure. You can migrate databases to the following types of Oracle Cloud Infrastructure systems: Exadata, Exadata Cloud@Customer, bare metal, and virtual machine.

Zero Downtime Migration leverages Oracle Active Data Guard to create a standby instance of your database in an Oracle Cloud Infrastructure system. You switch over only when you are ready, and your source database remains
Choosing a Migration Method

Not all migration methods apply to all migration scenarios. Many of the migration methods apply only if specific characteristics of the source and destination databases match or are compatible. Moreover, additional factors can affect which method you choose for your migration from among the methods that are technically applicable to your migration scenario.

Some of the characteristics and factors to consider when choosing a migration method are:

• On-premises database version
• Database service database version
• On-premises host operating system and version
• On-premises database character set
• Quantity of data, including indexes
• Data types used in the on-premises database
• Storage for data staging
• Acceptable length of system outage
• Network bandwidth

To determine which migration methods are applicable to your migration scenario, gather the following information.

1. Database version of your on-premises database:
   • Oracle Database 12c Release 2 version 12.2.0.1
   • Oracle Database 12c Release 1 version 12.1.0.2 or higher
   • Oracle Database 12c Release 1 version lower than 12.1.0.2
   • Oracle Database 11g Release 2 version 11.2.0.3 or higher
   • Oracle Database 11g Release 2 version lower than 11.2.0.3

2. For on-premises Oracle Database 12c Release 2 and Oracle Database 12c Release 1 databases, the architecture of the database:
   • Multitenant container database (CDB)
   • Non-CDB

3. Endian format (byte ordering) of your on-premises database’s host platform

   Some platforms are little endian and others are big endian. Query V$TRANSPORTABLE_PLATFORM to identify the endian format, and to determine whether cross-platform tablespace transport is supported.

   The Oracle Cloud Infrastructure Database uses the Linux platform, which is little endian.

4. Database character set of your on-premises database and the Oracle Cloud Infrastructure Database database.

   Some migration methods require that the source and target databases use compatible database character sets.

5. Database version of the Oracle Cloud Infrastructure Database database you are migrating to:
   • Oracle Database 12c Release 2
   • Oracle Database 12c Release 1
   • Oracle Database 11g Release 2

   Oracle Database 12c Release 2 and Oracle Database 12c Release 1 databases created on the Database service use CDB architecture. Databases created using the Enterprise Edition software edition are single-tenant, and databases created using the High Performance or Extreme Performance software editions are multitenant.

After gathering this information, use the “source” and “destination” database versions as your guide to see which migration methods apply to your migration scenario:

• Migrating from Oracle Database 11g to Oracle Database 11g in the Cloud on page 1616
Migration Connectivity Options

You have several connectivity options when migrating your on-premises databases to the Oracle Cloud Infrastructure. The options are listed below in order of preference.

1. **FastConnect**: Provides a secure connection between your existing network and your virtual cloud network (VCN) over a private physical network instead of the internet. For more information, see FastConnect on page 3173.

2. **IPSec VPN**: Provides a secure connection between a dynamic routing gateway (DRG) and customer-premise equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components forming a site-to-site VPN between a VCN and your on-premises network. For more information, see VPN Connect on page 2932.

3. **Internet gateway**: Provides a path for network traffic between your VCN and the internet. For more information, see Internet Gateway on page 3243.

Migration Methods

Many methods exist to migrate Oracle databases to the Oracle Cloud Infrastructure Database service. Which of these methods apply to a given migration scenario depends on several factors, including the version, character set, and platform endian format of the source and target databases.

- **Data Pump Conventional Export/Import** on page 1621
- **Data Pump Full Transportable** on page 1622

Migrating an On-Premises Database to Oracle Cloud Infrastructure by Creating a Backup in the Cloud

**Note:**

This topic is not applicable to Exadata DB systems.

You can migrate an on-premises database to Oracle Cloud Infrastructure by creating a backup of your on-premises database in Oracle Cloud Infrastructure's Database service.

Oracle provides a Python script to create a backup of your database. The script invokes an API call to create the backup and then places the backup in Oracle Cloud Infrastructure. You can then use the Console or the API to create a new database or DB system from that backup. Backups created using the instructions in this topic appear under Standalone Backups in the console.
The Python script is bundled as a part of the Oracle Cloud Infrastructure CLI installation. Oracle provides the migration script and associated files at no cost. Normal Object Storage charges apply for the storage of your backup in Oracle Cloud Infrastructure.

**Compatibility**

The scripted migration process is compatible with the following bare metal and virtual machine DB system configurations:
<table>
<thead>
<tr>
<th>Configuration</th>
<th>Version or Type</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Version</td>
<td>19.x</td>
<td>• For versions 19c, 18c, 12.2.0.1, and 12.1.0.2:</td>
</tr>
<tr>
<td></td>
<td>18.x</td>
<td>• Only Container Databases (CDBs) are supported. The scripted migration process may work with non-CDB databases for these database</td>
</tr>
<tr>
<td></td>
<td>12.2.0.1</td>
<td>versions, but Oracle does not provide support for the migration of non-CDB databases using the script described in this topic.</td>
</tr>
<tr>

<td>RAC</td>
<td></td>
</tr>
</tbody>
</table>

**Prerequisites**

On the source database host:

• Outbound internet connectivity for installing Python packages, running yum install, and access to the Oracle Cloud Infrastructure API and Object Storage.

• RMAN configuration to autobackup controlfile and spfile:

```
RMAN> CONFIGURE CONTROLFILE AUTOBACKUP ON;
```

**Note:**

RMAN configuration changes must be completed prior to running the script. The script may modify RMAN parameters as required to complete the backup and migration tasks.
To Migrate an On-Premises Database Using a Standalone Backup

Perform the following tasks on the source database host:

1. Create a directory named `/home/oracle/migrate`.

   Tip:
   You can name the `migrate` portion of the directory path anything you want. If you use a different name, you must adjust all of the paths that appear in this task accordingly. The following examples assume the name `migrate` for simplicity and clarity.

2. As `root`, run the CLI installer in the directory you created in step 1. (For example, `/home/oracle/migrate`.)
   See Installing the CLI for instructions on running the installer script in either Windows or the Bash environment (for MacOS, Linux, and Unix).

   The installer installs Python 3.6.0 if either Python 2.7 or Python 3.6 does not exist on the machine. The installer also installs the Python script required to create and migrate a standalone backup from an on-premises database.

   On Oracle Linux 6, a newer version of Python (such as Python 3.6.0) is usually required. Use the following instructions to configure Oracle Linux 6 before running the backup script.

3. Copy the following files into the new directory:
   - Oracle Database Backup Module (`opc_install.jar`)
   - Your API *.pem key file.

4. Respond to the prompts as follows:

   (yum install)  
   Is this ok [y/N]: y  

   ==> Missing native dependencies. Continue and install the following dependencies: gcc, libffi-devel, python36u-devel, openssl-devel? (Y/n): Y  

   ==> In what directory would you like to place the install? (leave blank to use '/root/lib/oracle-cli'): /home/oracle/migrate/lib/oracle-cli  

   ==> In what directory would you like to place the 'oci' executable? (leave blank to use '/root/bin'): /home/oracle/migrate/bin  

   ==> In what directory would you like to place the OCI scripts? (leave blank to use '/root/bin/oci-cli-scripts'): /home/oracle/migrate/bin/oci-cli-scripts  

   ==> Currently supported optional packages are: ['db (will install cx_Oracle)'] What optional CLI packages would you like to be installed (comma separated names; press enter if you don't need any optional packages)?: db  

   ==> Modify profile to update your $PATH and enable shell/tab completion now? (Y/n): Y  

   ==> Enter a path to an rc file to update (leave blank to use '/root/.bashrc'): /home/oracle/.bashrc

5. Perform the following file operations:

6. Edit the `/home/oracle/migrate/config.txt` file

```
[DEFAULT]
tenancy=<your_tenancy_OCID>
user=<your_user_OCID>
fingerprint=<fingerprint>
key_file=/home/oracle/migrate/<your_api_key>.pem
region=<region>
```

If you do not know your API signing key's fingerprint, see How to Get the Key's Fingerprint on page 4183.

7. As oracle user (not root), run one of the following sets of commands, depending on the type of database you are migrating.

**For a non-TDE database:**

```
export AD=<destination_availability_domain>
export C=<destination_compartment_OCID>
export ORACLE_SID=<ORACLE_SID>
export ORACLE_HOME=<ORACLE_HOME>
export PATH=$PATH:$ORACLE_HOME/bin
export LC_ALL=en_US.UTF-8
export ORACLE_UNQNAME=<source_DB_unique_name>
rm -rf /home/oracle/migrate/onprem_upload
cd /home/oracle/migrate/bin/oci-cli-scripts/
./create_backup_from_onprem --config-file /home/oracle/migrate/config.txt
--display-name <example_display_name> --availability-domain $AD --edition ENTERPRISE_EDITION_EXTREME_PERFORMANCE --opc-installer-dir /home/oracle/migrate --tmp-dir /home/oracle/migrate/onprem_upload --compartment-id $C
--rman-password <password>
```

**For a TDE-enabled database:**

```
export AD=<destination_availability_domain>
export C=<destination_compartment_OCID>
export ORACLE_SID=<ORACLE_SID>
export ORACLE_HOME=<ORACLE_HOME>
export PATH=$PATH:$ORACLE_HOME/bin
rm -rf /home/oracle/migrate/onprem_upload
cd /home/oracle/migrate/bin/oci-cli-scripts/
./create_backup_from_onprem --config-file /home/oracle/migrate/config.txt
--display-name <example_display_name> --availability-domain $AD --edition ENTERPRISE_EDITION_EXTREME_PERFORMANCE --opc-installer-dir /home/oracle/migrate --tmp-dir /home/oracle/migrate/onprem_upload --compartment-id $C
```

See the following list of parameters used by the script for more details.

8. Create a new database or launch a new DB system using the backup you created in the preceding step. See Creating Databases on page 1414 for information on creating a new database from a backup. See Creating Bare Metal and Virtual Machine DB Systems on page 1370 for information on creating a new DB system from a backup.
Configuring Oracle Linux 6 to install Python

In Oracle Linux 6 use the following /etc/yum.repos.d/ol6.repo file to ensure that a compatible version of Python is installed by the script if a compatible version is not already installed. Include this file before attempting to run the script with the ./install.sh command.

```
[ol6_latest]
name=Oracle Linux $releasever Latest ($basearch)
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1
```

Parameters used by the script

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--config-file</code></td>
<td>The path to the oci-cli config file. The default path is as follows: ~/.oci/config</td>
<td>No</td>
</tr>
<tr>
<td><code>--profile</code></td>
<td>The profile in the config file to load. This profile will also be used to locate any default parameter values which have been specified in the OCI CLI-specific configuration file. The default value is DEFAULT.</td>
<td>No</td>
</tr>
<tr>
<td><code>--compartment-id</code></td>
<td>The compartment OCID of the Oracle Cloud Infrastructure compartment that will contain your standalone backup.</td>
<td>Yes</td>
</tr>
<tr>
<td><code>--display-name</code></td>
<td>The name of the backup, as you want it to be displayed in the OCI Console under Standalone Backups. Avoid entering confidential information.</td>
<td>Yes</td>
</tr>
<tr>
<td><code>--availability-domain</code></td>
<td>The availability domain where the backup is to be stored.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
| `--edition`        | The edition of the Oracle Cloud Infrastructure DB system that will contain the database created from the standalone backup. You can choose the same edition as the on-premises database, or any addition above the on-premises database. The choices, listed from lowest to highest, are the following:  
  - STANDARD_EDITION  
  - ENTERPRISE_EDITION  
  - ENTERPRISE_EDITION_HIGH_PERFORMANCE  
  - ENTERPRISE_EDITION_EXTREME_PERFORMANCE | Yes      |
The script will produce a standalone backup of your on-premises database in your Oracle Cloud Infrastructure tenancy. You can check the Console for your backup by viewing the *Standalone Backups* page in the Database service, under *Bare Metal, VM, and Exadata*.

**Tip:**
To access command line help for the backup script, run the following command in the `/home/oracle/migrate/bin/oci-cli-scripts/` directory:

```
create_backup_from_onprem --help
```

### Migrating from Oracle Database 11g to Oracle Database 11g in the Cloud

You can migrate Oracle Database 11g databases from on-premises to Oracle Database 11g databases in the Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database’s character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- **Data Pump Conventional Export/Import**
  
  This method can be used regardless of the endian format and database character set of the on-premises database.

  For the steps this method entails, see *Data Pump Conventional Export/Import* on page 1621.

- **Data Pump Transportable Tablespace**
  
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.

  For the steps this method entails, see *Data Pump Transportable Tablespace* on page 1625.

- **RMAN Transportable Tablespace with Data Pump**
  
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.

  For the steps this method entails, see *RMAN Transportable Tablespace with Data Pump* on page 1631.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--opc-installer-dir</code></td>
<td>The directory containing the <code>opc_installer.jar</code> file. This is the directory you created in step 1 of this procedure.</td>
<td>Yes</td>
</tr>
<tr>
<td><code>--additional-opc-args</code></td>
<td>Optional additional arguments for the <code>opc installer</code>.</td>
<td>No</td>
</tr>
<tr>
<td><code>--tmp-dir</code></td>
<td>Optional temporary directory for intermediate files.</td>
<td>No</td>
</tr>
<tr>
<td><code>--rman-password</code></td>
<td>The RMAN password to use for the standalone backup. The password must have 8 or more characters.</td>
<td>Required if TDE is not enabled</td>
</tr>
<tr>
<td><code>--rman-channels</code></td>
<td>RMAN channels. The default value is 5.</td>
<td>No</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Displays in-line help for the script in the OCI-CLI environment.</td>
<td>No</td>
</tr>
</tbody>
</table>
• **RMAN CONVERT Transportable Tablespace with Data Pump**

  This method can be used only if the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.

  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the `RMAN CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

  For the steps this method entails, see [RMAN CONVERT Transportable Tablespace with Data Pump](#) on page 1633.

**Migrating from Oracle Database 11g to Oracle Database 12c in the Cloud**

You can migrate Oracle Database 11g databases from on-premises to Oracle Database 12c databases in the Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database’s version, database character set and platform endian format.

If you have not already done so, determine the database version and database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

• **Data Pump Conventional Export/Import**

  This method can be used regardless of the endian format and database character set of the on-premises database.

  For the steps this method entails, see [Data Pump Conventional Export/Import](#) on page 1621.

• **Data Pump Transportable Tablespace**

  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see [Data Pump Transportable Tablespace](#) on page 1625.

• **RMAN Transportable Tablespace with Data Pump**

  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see [RMAN Transportable Tablespace with Data Pump](#) on page 1631.

• **RMAN CONVERT Transportable Tablespace with Data Pump**

  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.

  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the `RMAN CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

  For the steps this method entails, see [RMAN CONVERT Transportable Tablespace with Data Pump](#) on page 1633.

• **Data Pump Full Transportable**

  This method can be used only if the source database release version is 11.2.0.3 or later, and the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see [Data Pump Full Transportable](#) on page 1622.
Migrating from Oracle Database 12c CDB to Oracle Database 12c in the Cloud

You can migrate Oracle Database 12c CDB databases from on-premises to Oracle Database 12c databases in the Oracle Cloud Infrastructure Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database’s character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- **Data Pump Conventional Export/Import**
  This method can be used regardless of the endian format and database character set of the on-premises database.
  For the steps this method entails, see Data Pump Conventional Export/Import on page 1621.

- **Data Pump Transportable Tablespace**
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database database are compatible.
  For the steps this method entails, see Data Pump Transportable Tablespace on page 1625.

- **RMAN Transportable Tablespace with Data Pump**
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.
  For the steps this method entails, see RMAN Transportable Tablespace with Data Pump on page 1631.

- **RMAN CONVERT Transportable Tablespace with Data Pump**
  This method can be used only if the database character sets of your on-premises database and the Database database are compatible.
  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN CONVERT command to enable transport between platforms with different endianness. Query \$TRANSPORTABLE_PLATFORM to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.
  For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump on page 1633.

- **RMAN Cross-Platform Transportable Tablespace Backup Sets**
  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see RMAN Cross-Platform Transportable Tablespace Backup Sets on page 1629.

- **Data Pump Full Transportable**
  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see Data Pump Full Transportable on page 1622.

- **Unplugging/Plugging (CDB)**
  This method can be used only if the on-premises platform is little endian, and the on-premises database and Database database have compatible database character sets and national character sets.
  For the steps this method entails, see Unplugging/Plugging a PDB on page 1644.
• Remote Cloning (CDB)

This method can be used only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

For the steps this method entails, see Remote Cloning a PDB on page 1627.

• RMAN Cross-Platform Transportable PDB

This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

For the steps this method entails, see RMAN Cross-Platform Transportable PDB on page 1628.

• SQL Developer and SQL*Loader to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL*Loader to load the data into your cloud database.

For the steps this method entails, see SQL Developer and SQL*Loader to Migrate Selected Objects on page 1644.

• SQL Developer and INSERT Statements to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL INSERT statements to load the data into your cloud database.

For the steps this method entails, see SQL Developer and INSERT Statements to Migrate Selected Objects on page 1644.

Migrating from Oracle Database 12c Non-CDB to Oracle Database 12c in the Cloud

You can migrate Oracle Database 12c non-CDB databases from on-premises to Oracle Database 12c databases in Oracle Cloud Infrastructure Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database’s character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

• Data Pump Conventional Export/Import

This method can be used regardless of the endian format and database character set of the on-premises database.

For the steps this method entails, see Data Pump Conventional Export/Import on page 1621.

• Data Pump Transportable Tablespace

This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database database are compatible.

For the steps this method entails, see Data Pump Transportable Tablespace on page 1625.

• RMAN Transportable Tablespace with Data Pump

This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

For the steps this method entails, see RMAN Transportable Tablespace with Data Pump on page 1631.
• RMAN CONVERT Transportable Tablespace with Data Pump

This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.

This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN CONVERT command to enable transport between platforms with different endianness. Query V$TRANSPORTABLE_PLATFORM to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump on page 1633.

• RMAN Cross-Platform Transportable Tablespace Backup Sets

This method can be used only if the database character sets of your on-premises database and the Database database are compatible.

For the steps this method entails, see RMAN Cross-Platform Transportable Tablespace Backup Sets on page 1629.

• Data Pump Full Transportable

This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.

For the steps this method entails, see Data Pump Full Transportable on page 1622.

• Unplugging/Plugging (non-CDB)

This method can be used only if the on-premises platform is little endian, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c non-CDB database to Oracle Database 12c in the cloud. This method provides a way to consolidate several non-CDB databases into a single Oracle Database 12c CDB on the cloud.

For the steps this method entails, see Unplugging/Plugging Non-CDB on page 1645.

• Remote Cloning (non-CDB)

This method can be used only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the remote cloning method to copy an Oracle Database 12c non-CDB on-premises database to your Oracle Database 12c database in the cloud.

For the steps this method entails, see Remote Cloning Non-CDB on page 1628.

• SQL Developer and SQL*Loader to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL*Loader to load the data into your cloud database.

For the steps this method entails, see SQL Developer and SQL*Loader to Migrate Selected Objects on page 1644.

• SQL Developer and INSERT Statements to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL INSERT statements to load the data into your cloud database.

For the steps this method entails, see SQL Developer and INSERT Statements to Migrate Selected Objects on page 1644.
Database

**Data Pump Conventional Export/Import**

You can use this method regardless of the endian format and database character set of the on-premises database.

To migrate an on-premises source database, tablespace, schema, or table to the database on a Database service database deployment using Data Pump Export and Import, you perform these tasks:

1. On the on-premises database host, invoke Data Pump Export and export the on-premises database.
2. Use a secure copy utility to transfer the dump file to the Database service compute node.
3. On the Database service compute node, invoke Data Pump Import and import the data into the database.
4. After verifying that the data has been imported successfully, you can delete the dump file.

For information about Data Pump Import and Export, see these topics:

- "Data Pump Export Modes" in *Oracle Database Utilities* for Release 12.2, 12.1 or 11.2.
- "Data Pump Import Modes" in *Oracle Database Utilities* for Release 12.2, 12.1 or 11.2.

**Data Pump Conventional Export/Import: Example**

This example provides a step-by-step demonstration of the tasks required to migrate a schema from an on-premises Oracle database to a Database service database.

This example illustrates a schema mode export and import. The same general procedure applies for a full database, tablespace, or table export and import.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, invoke Data Pump Export to export the schemas.
   a. On the on-premises database host, create an operating system directory to use for the on-premises database export files.

   ```
   $ mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
   ```

   b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the **SYSTEM** user.

   ```
   $ sqlplus system
   Enter password: <enter the password for the SYSTEM user>
   ```

   c. Create a directory object in the on-premises database to reference the operating system directory.

   ```
   SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
   ```

   d. Exit from SQL*Plus.

   e. On the on-premises database host, invoke Data Pump Export as the **SYSTEM** user or another user with the `DATAPUMP_EXP_FULL_DATABASE` role and export the on-premises schemas. Provide the password for the user when prompted.

   ```
   $ expdp system SCHEMAS=fsowner DIRECTORY=dp_for_cloud
   ```
2. Use a secure copy utility to transfer the dump file to the Database service compute node.
   In this example the dump file is copied to the /u01 directory. Choose the appropriate location based on the size of the file that will be transferred.
   a. On the Database service compute node, create a directory for the dump file.
      
      ```bash
      $ mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
      ```
   b. Before using the `scp` command to copy the export dump file, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.
   c. On the on-premises database host, use the SCP utility to transfer the dump file to the Database service compute node.
      
      ```bash
      $ scp -i private_key_file \\
      /u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp \\
      oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem
      ```
3. On the Database service compute node, invoke Data Pump Import and import the data into the database.
   a. On the Database service compute node, invoke SQL*Plus and log in to the database as the `SYSTEM` user.
      
      ```bash
      $ sqlplus system
      Enter password: <enter the password for the SYSTEM user>
      ```
   b. Create a directory object in the Database service database.
      
      ```sql
      SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
      ```
   c. If they do not exist, create the tablespace(s) for the objects that will be imported.
   d. Exit from SQL*Plus.
   e. On the Database service compute node, invoke Data Pump Import and connect to the database. Import the data into the database.
      
      ```bash
      impdp system SCHEMAS=fsowner DIRECTORY=dp_from_onprem
      ```
4. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` file.

## Data Pump Full Transportable

You can use this method only if the source database release version is 11.2.0.3 or later, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.

You can use the Data Pump full transportable method to copy an entire database from your on-premises host to the database on a Database service database deployment.

To migrate an Oracle Database 11g on-premises database to the Oracle Database 12c database on a Database service database deployment using the Data Pump full transportable method, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump full transportable export by placing the user-defined tablespaces in `READ ONLY` mode.
2. On the on-premises database host, invoke Data Pump Export to perform the full transportable export.
3. Use a secure copy utility to transfer the Data Pump Export dump file and the datafiles for all of the user-defined tablespaces to the Database service compute node.
4. Set the on-premises tablespaces back to `READ WRITE`.
5. On the Database service compute node, prepare the database for the tablespace import.
6. On the Database service compute node, invoke Data Pump Import and connect to the database.
7. After verifying that the data has been imported successfully, you can delete the dump file.
Data Pump Full Transportable: Example

This example provides a step-by-step demonstration of the tasks required to migrate an Oracle Database 11g database to a Database service 12c database.

In this example, the source database is on a Linux host.

1. On the source database host, prepare the database for the Data Pump full transportable export.
   a. On the source database host, create a directory in the operating system to use for the source export.

      $ mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud

   b. On the source database host, invoke SQL*Plus and log in to the source database as the SYSTEM user.

      $ sqlplus system
      Enter password: <enter the password for the SYSTEM user>

   c. Create a directory object in the source database to reference the operating system directory.

      SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/ dpdump/for_cloud';

   d. Determine the name(s) of the tablespaces and data files that belong to the user-defined tablespaces by querying DBA_DATA_FILES. These files will also be listed in the export output.

      SQL> SELECT tablespace_name, file_name FROM dba_data_files;
      +-----------------+--------------------------------------------------+
      | TABLESPACE_NAME | FILE_NAME                                        |
      |-----------------+--------------------------------------------------|
      | USERS           | /u01/app/oracle/oradata/orcl/users01.dbf         |
      | UNDOTBS1        | /u01/app/oracle/oradata/orcl/undotbs01.dbf       |
      | SYSAUX          | /u01/app/oracle/oradata/orcl/sysaux01.dbf        |
      | SYSTEM          | /u01/app/oracle/oradata/orcl/system01.dbf        |
      | EXAMPLE         | /u01/app/oracle/oradata/orcl/example01.dbf       |
      | FSDATA          | /u01/app/oracle/oradata/orcl/fsdata01.dbf        |
      | FSINDEX         | /u01/app/oracle/oradata/orcl/fsindex01.dbf       |
      | SQL>            |                                                 |

   e. On the source database host, set all tablespaces that will be transported (the transportable set) to READ ONLY mode.

      SQL> ALTER TABLESPACE example READ ONLY;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsindex READ ONLY;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsdata READ ONLY;
      Tablespace altered.
      SQL> ALTER TABLESPACE users READ ONLY;
      Tablespace altered.
      SQL>

   f. Exit from SQL*Plus.

2. On the source database host, invoke Data Pump Export to perform the full transportable export. Specify FULL=y and TRANSPORTABLE=always. Because this is an Oracle Database 11g database and full transportable is an Oracle Database 12c feature, specify VERSION=12. Provide the password for the SYSTEM user when prompted.

      $ expdp system FULL=y TRANSPORTABLE=always VERSION=12 DUMPFILE=expdat.dmp
      DIRECTORY=dp_for_cloud
3. Use a secure copy utility to transfer the Data Pump Export dump file and the datafiles for all of the user-defined tablespaces to the Database service compute node.

   In this example the dump file is copied to the /u01 directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

      $ mkdir /u01/app/oracle/admin/ORCL/dpdump/from_source

   b. Before using the scp utility to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your source host.

   c. On the source database host, use the scp utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.

      $ scp -i private_key_file \
          /u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp  \
          oracle@compute_node_IP_address:/u01/app/oracle/admin/ORCL/dpdump/from_source

      $ scp -i private_key_file \
          /u01/app/oracle/oradata/orcl/example01.dbf  \
          oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

      $ scp -i private_key_file \
          /u01/app/oracle/oradata/orcl/fsdata01.dbf  \
          oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

      $ scp -i private_key_file \
          /u01/app/oracle/oradata/orcl/fsindex01.dbf  \
          oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

      $ scp -i private_key_file \
          /u01/app/oracle/oradata/orcl/users01.dbf  \
          oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

4. Set the source tablespaces back to READ WRITE.

   a. Invoke SQL*Plus and log in as the SYSTEM user.

   b. Set the user-defined tablespaces back to READ WRITE mode.

      SQL> ALTER TABLESPACE example READ WRITE;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsdata READ WRITE;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsindex READ WRITE;
      Tablespace altered.
      SQL> ALTER TABLESPACE users READ WRITE;
      Tablespace altered.

   c. Exit from SQL*Plus.

5. On the Database service compute node, prepare the PDB for the tablespace import.

   a. On the Database service compute node, invoke SQL*Plus and log in to the PDB as the SYSTEM user.

   b. Create a directory object in the PDB.

      SQL> CREATE DIRECTORY dp_from_source AS '/u01/app/oracle/admin/ORCL/dpdump/from_source';
6. On the Database service compute node, invoke Data Pump Import and connect to the PDB.

   Import the data into the database using the `TRANSPORT_DATAFILES` option.

   ```shell
   $ impdp system@PDB2 FULL=y DIRECTORY=dp_from_source \
   TRANSPORT_DATAFILES="/u02/app/oracle/oradata/ORCL/PDB2/example01.dbf", "/u02/app/oracle/oradata/ORCL/PDB2/fsdata01.dbf", "/u02/app/oracle/oradata/ORCL/PDB2/fsindex01.dbf", "/u02/app/oracle/oradata/ORCL/PDB2/users01.dbf"
   ```

7. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` dump file.

### Data Pump Transportable Tablespace

You can use this method only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.

The Transportable Tablespace method is generally much faster than a conventional export/import of the same data because the data files containing all of the actual data are simply copied to the destination location. You use Data Pump to transfer only the metadata of the tablespace objects to the new database.

To migrate an on-premises source database to the database deployment on the Database service using the Data Pump Transportable Tablespace method, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
3. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.
4. Set the on-premises tablespaces back to `READ WRITE`.
5. On the Database service compute node, prepare the database for the tablespace import.
6. On the Database service compute node, invoke Data Pump Import and connect to the database.
7. Set the tablespaces on the Database service database to `READ WRITE` mode.
8. After verifying that the data has been imported successfully, you can delete the dump file.

### Data Pump Transportable Tablespace: Example

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises Oracle database to a Database service database.

This example performs a migration of the `FSDATA` and `FSINDEX` tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
   a. On the on-premises database host, create a directory in the operating system to use for the on-premises export.
      ```bash
      mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
      ```
   b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the `SYSTEM` user.
      ```bash
      sqlplus system
      Enter password: <enter the password for the SYSTEM user>
      ```
   c. Create a directory object in the on-premises database to reference the operating system directory.
      ```sql
      SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
      ```
   d. Determine the name(s) of the datafiles that belong to the `FSDATA` and `FSINDEX` tablespaces by querying `DBA_DATA_FILES`. These files will also be listed in the export output.
      ```sql
      SQL> SELECT file_name FROM dba_data_files
      ```
2  WHERE tablespace_name = 'FSDATA';

FILE_NAME
-----------------------------------------------
/u01/app/oracle/oradata/orcl/fsdata01.dbf

SQL> SELECT file_name FROM dba_data_files
  2  WHERE tablespace_name = 'FSINDEX';

FILE_NAME
-----------------------------------------------
/u01/app/oracle/oradata/orcl/fsindex01.dbf

e. On the on-premises database host, set all tablespaces that will be transported (the transportable set) to READ ONLY mode.

   SQL> ALTER TABLESPACE fsindex READ ONLY;
   Tablespace altered.
   SQL> ALTER TABLESPACE fsdata READ ONLY;
   Tablespace altered.

f. Exit from SQL*Plus.

2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.

   On the on-premises database host, invoke Data Pump Export and connect to the on-premises database. Export the on-premises tablespaces using the TRANSPORT_TABLESPACES option. Provide the password for the SYSTEM user when prompted.

   expdp system TRANSPORT_TABLESPACES=fsdata,fsindex TRANSPORT_FULL_CHECK=YES DIRECTORY=dp_for_cloud

3. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the /u01 directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

      mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem

   b. Before using the scp utility to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

   c. On the on-premises database host, use the scp utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.

      scp -i private_key_file \
      /u01/app/oracle/admin/orcl/dpdump/from_cloud/expdat.dmp \ 
      oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem

      $ scp -i private_key_file \
      /u01/app/oracle/oradata/orcl/fsdata01.dbf \ 
      oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL

      $ scp -i private_key_file \
      /u01/app/oracle/oradata/orcl/fsindex01.dbf \ 
      oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL

4. Set the on-premises tablespaces back to READ WRITE.

   a. Invoke SQL*Plus and log in as the SYSTEM user.

   b. Set the FSDATA and FSINDEX tablespaces back to READ WRITE mode.

      SQL> ALTER TABLESPACE fsdata READ WRITE;
      Tablespace altered.
SQL> ALTER TABLESPACE fsindex READ WRITE;
Tablespace altered.

c. Exit from SQL*Plus.

5. On the Database service compute node, prepare the database for the tablespace import.
   a. On the Database service compute node, invoke SQL*Plus and log in to the database as the SYSTEM user.
   b. Create a directory object in the Database service database.

      SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';

   c. If the owners of the objects that will be imported do not exist in the database, create them before performing
      the import. The transportable tablespace mode of import does not create the users.

      SQL> CREATE USER fsowner
          2  PROFILE default
          3  IDENTIFIED BY fspass
          4  TEMPORARY TABLESPACE temp
          5  ACCOUNT UNLOCK;

6. On the Database service compute node, invoke Data Pump Import and connect to the database.

   Import the data into the database using the `TRANSPORT_DATAFILES` option.

      impdp system DIRECTORY=dp_from_onprem \
      TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', \
      '/u02/app/oracle/oradata/ORCL/fsindex01.dbf'

7. Set the tablespaces on the Database service database to `READ WRITE` mode.
   a. Invoke SQL*Plus and log in as the SYSTEM user.
   b. Set the `FSDATA` and `FSINDEX` tablespaces to `READ WRITE` mode.

      SQL> ALTER TABLESPACE fsdata READ WRITE;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsindex READ WRITE;
      Tablespace altered.

c. Exit from SQL*Plus.

8. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` dump file.

Remote Cloning a PDB

You can use this method only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2
or higher, and the on-premises database and Database service database have compatible database character sets and
national character sets.

You can use the remote cloning method to copy a PDB from your on-premises Oracle Database 12c database to a
PDB in an Oracle Database 12c database on the Database service.

Migration Tasks

To migrate an Oracle Database 12c PDB to a PDB in a Database service database deployment using the remote
cloning method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB and then reopen it in `READ
   ONLY` mode.
2. On the Database service compute node, invoke SQL*Plus and create a database link that enables a connection to
   the on-premises database.
3. On the Database service compute node, execute the `CREATE PLUGGABLE DATABASE` command to clone the
   on-premises PDB.
4. On the Database compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.

5. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises PDB back to READ WRITE mode.

For more information, see "Cloning a Remote PDB or Non-CDB" in Oracle Database Administrator's Guide for Release 12.2 or 12.1.

**Remote Cloning Non-CDB**

You can use this method only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the remote cloning method to copy an Oracle Database 12c non-CDB on-premises database to a PDB in an Oracle Database 12c database on the Databaseservice.

**Migration Tasks**

To migrate an Oracle Database 12c non-CDB database to a Database service database deployment using the remote cloning method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and set the on-premises database to READ ONLY mode.
2. On the Database service compute node, invoke SQL*Plus and create a database link that enables a connection to the on-premises database.
3. On the Database service compute node, execute the `CREATE PLUGGABLE DATABASE` command to clone the on-premises non-CDB database.
4. On the Database service compute node, execute the `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` script.
5. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.
6. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises database back to READ WRITE mode.

For more information, see "Cloning a Remote PDB or Non-CDB" in Oracle Database Administrator's Guide for Release 12.2 or 12.1.

**RMAN Cross-Platform Transportable PDB**

This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

To migrate an Oracle Database 12c PDB to a PDB in an Oracle Database 12c database on a Database service deployment using the RMAN cross-platform transportable PDB method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB.
2. On the on-premises database host, execute the `ALTER PLUGGABLE DATABASE UNPLUG` command to generate an XML file containing the list of datafiles that will be plugged in on the cloud database.
3. On the on-premises database host, invoke RMAN and connect to the root. Execute the `BACKUP FOR TRANSPORT PLUGGABLE DATABASE` command.
4. Use a secure copy utility to transfer the XML file and the backup set to the Database service compute node.
5. On the Database service compute node, invoke RMAN and connect to the root. Execute the `RESTORE ALL FOREIGN DATAFILES` command.
6. the Database service compute node, invoke SQL*Plus and connect to the root. Execute the `CREATE PLUGGABLE DATABASE` command.
7. the Database service compute node, execute the `ALTER PLUGGABLE DATABASE OPEN` command.

For more information, see "Performing Cross-Platform Data Transport in CDBs and PDBs" in Oracle Database Backup and Recovery User's Guide for Release 12.2 or 12.1.
**RMAN Cross-Platform Transportable Tablespace Backup Sets**

You can use this method only if the database character sets of your on-premises database and the Database service database are compatible.

**Note:**

For detailed information on a similar method that enables you to perform a cross-platform transport of an entire database, see the Oracle Database 12c Backup and Recovery User's Guide for Release 12.2 or 12.1. When you transport an entire database to a different platform, the source platform and the destination platform must use the same endian format.

To migrate Oracle Database 12c on-premises tablespaces to an Oracle Database 12c database on a Database service deployment using the RMAN cross-platform transportable backup sets method, you perform these tasks:

1. On the on-premises database host, prepare the database by placing the user-defined tablespaces that you intend to transport in **READ ONLY** mode.
2. On the on-premises database host, invoke RMAN and use the `BACKUP` command with the **TO PLATFORM** or **FOR TRANSPORT** clause and the `DATAPUMP` clause to create a backup set for cross-platform transport. See in "BACKUP" in Oracle Database Backup and Recovery Reference for Release 12.2 or 12.1 for more information on the BACKUP command.
3. Use a secure copy utility to transfer the backup sets, including the Data Pump export dump file, to the Database service compute node.
4. Set the on-premises tablespaces back to **READ WRITE**.
5. On the Database service compute node, prepare the database by creating the required schemas.
6. On the Database service compute node, invoke RMAN and use the `RESTORE` command with the `foreignFileSpec` subclause to restore the cross-platform backup.
7. On the Database service compute node, set the tablespaces on the database to **READ WRITE** mode.

For more information, see "Overview of Cross-Platform Data Transport Using Backup Sets" in Oracle Database Backup and Recovery User's Guide for Release 12.2 or 12.1.

**RMAN Cross-Platform Transportable Tablespace Backup Sets: Example**

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an Oracle Database PDB to a Database service database.

This example performs a migration of the FSDATA and FSINDEX tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, prepare the database by creating a directory for the export dump file and placing the user-defined tablespaces that you intend to transport in **READ ONLY** mode..
   a. On the on-premises database host, create a directory in the operating system to use for the export dump.
      ```bash
      mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
      ```
   b. On the on-premises data host, invoke SQL*Plus and log in to the PDB as the **SYSTEM** user.
      ```sql
      sqlplus system@pdb_servicename
      Enter password: enter the password for the SYSTEM user
      ```
   c. Create a directory object in the on-premises database to reference the operating system directory.
      ```sql
      SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
      ```
   d. On the on-premises database host, set all tablespaces that will be transported (the transportable set) to **READ ONLY** mode.
      ```sql
      SQL> ALTER TABLESPACE fsindex READ ONLY;
      ```
Database

SQL> ALTER TABLESPACE fsdata READ ONLY;

e. Exit from SQL*Plus.

2. On the on-premises database host, invoke RMAN and use the BACKUP command with the TO PLATFORM or FOR TRANSPORT clause and the DATAPUMP clause to create a backup set for cross-platform transport.

a. On the on-premises database host, create an operating system directory for the datafiles.

```bash
mkdir /u01/app/oracle/admin/orcl/rman_transdest
```

b. Invoke RMAN and log in as a user that has been granted the SYSDBA or SYSBACKUP privilege.

```bash
rman target username@pdb_servicename
```

c. Execute the BACKUP command.

```sql
RMAN> BACKUP FOR TRANSPORT
2> FORMAT '/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.bck'
3> TABLESPACE fsdata,fsindex
4> DATAPUMP FORMAT '/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.dmp';
```

d. Log out of RMAN.

e. Optionally, navigate to the directory you specified in the BACKUP command to view the files that were created.

```bash
cd /u01/app/oracle/admin/orcl/rman_transdest
$ ls
fs_tbs.bck  fs_tbs.dmp
```

3. Use a secure copy utility to transfer the backup set, including the Data Pump export dump file, to the Database service compute node.

a. On the Database service compute node, create a directory for the backup set and dump file.

```bash
mkdir /tmp/from_onprem
```

b. Before using the scp command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

c. On the on-premises database host, use the SCP utility to transfer the backup set and the dump file to the Database service compute node.

```bash
scp -i private_key_file 
/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.bck 
oracle@$IP_address_DBaaS_VM:/tmp/from_onprem

$ scp -i private_key_file 
/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.dmp 
oracle@$IP_address_DBaaS_VM:/tmp/from_onprem
```

4. Set the on-premises tablespaces back to READ WRITE.

a. Invoke SQL*Plus and log in to the PDB as the SYSTEM user.

```sql
SQL> ALTER TABLESPACE fsdata READ WRITE;
SQL> ALTER TABLESPACE fsindex READ WRITE;
```

c. Exit from SQL*Plus.
5. On the Database service compute node, prepare the database by creating the required schemas.
   a. On the Database service compute node, invoke SQL*Plus and log in to the PDB as the SYSTEM user.
   b. If the owners of the objects that will be imported do not exist in the database, create them before performing the RESTORE.

   SQL> CREATE USER fsowner
   2  PROFILE default
   3  IDENTIFIED BY fspass
   4  TEMPORARY TABLESPACE temp
   5  ACCOUNT UNLOCK;

6. On the Database service compute node, invoke RMAN and use the RESTORE command with the foreignFileSpec subclause to restore the cross-platform backup.
   a. Create an operating system directory for the Data Pump Dump file.

   mkdir /tmp/from_onprem

   b. Invoke RMAN and log in to the PDB as a user that has been granted the SYSDBA or SYSBACKUP privilege.

   rman target username@pdb_servicename

   c. Execute the RESTORE command.

   RMAN> RESTORE FOREIGN TABLESPACE fsdata,fsindex TO NEW
   2> FROM BACKUPSET '/tmp/from_onprem/fs_tbs.bck'
   3> DUMP FILE DATAPUMP DESTINATION '/tmp/datapump'
   4> FROM BACKUPSET '/tmp/from_onprem/fs_tbs.dmp';

   d. Exit from RMAN.

7. On the Database service compute node, set the tablespaces to READ WRITE mode.
   a. Invoke SQL*Plus and log in to the PDB as the SYSTEM user.
   b. Set the FSDATA and FSINDEX tablespaces to READ WRITE.

   SQL> ALTER TABLESPACE fsdata READ WRITE;
   SQL> ALTER TABLESPACE fsindex READ WRITE;

   c. Exit from SQL*Plus.

8. After verifying that the data has been imported successfully, you can delete the backup set files that were transported from the on-premises host.

**RMAN Transportable Tablespace with Data Pump**

You can use this method only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

You can use this method to eliminate placing the tablespaces in READ ONLY mode, as required by the Data Pump Transportable Tablespace method.

To migrate an on-premises source database to a database deployment on the Database service using the RMAN Transportable Tablespace with Data Pump method, you perform these tasks:

1. On the on-premises database host, invoke RMAN and create the transportable tablespace set.
2. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.
3. On the Database service compute node, prepare the database for the tablespace import.
4. On the Database service compute node, invoke Data Pump Import and connect to the database. Import the data into the database using the TRANSPORT_DATAFILES option.
5. After verifying that the data has been imported successfully, you can delete the dump file.
**RMAN Transportable Tablespace with Data Pump: Example**

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises Oracle database to a Database service database.

This example performs a migration of the **FSDATA** and **FSINDEX** tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, invoke RMAN and create the transportable tablespace set.
   
   a. On the on-premises database host, create an operating system directory for the datafiles.
      
      ```bash
      mkdir /u01/app/oracle/admin/orcl/rman_transdest
      ```
   
   b. On the on-premises data host, create an operating system directory for the RMAN auxiliary instance files.
      
      ```bash
      mkdir /u01/app/oracle/admin/orcl/rman_auxdest
      ```
   
   c. Invoke RMAN and log in as the **SYSTEM** user. Enter the password for the **SYSTEM** user when prompted.
      
      ```bash
      rman target system
      ```
   
   d. Execute the **TRANSPORT TABLESPACE** command.
      
      ```bash
      RMAN> TRANSPORT TABLESPACE fsdata, fsindex
      2> TABLESPACE DESTINATION '/u01/app/oracle/admin/orcl/rman_transdest'
      3> AUXILIARY DESTINATION '/u01/app/oracle/admin/orcl/rman_auxdest';
      ```
   
   e. Log out of RMAN.
   
   f. Optionally, navigate to the directory you specified for the TABLESPACE DESTINATION and view the files that were created by the TRANSPORT TABLESPACE operation.
      
      ```bash
      cd /u01/app/oracle/admin/orcl/rman_transdest
      $ ls
      dmpfile.dmp fsdata01.dbf fsindex01.dbf impscrpt.sql
      ```

2. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.
   
   a. On the Database service compute node, create a directory for the dump file.
      
      ```bash
      mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
      ```
   
   b. Before using the `scp` command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.
   
   c. On the on-premises database host, use the SCP utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.
      
      ```bash
      scp -i private_key_file  
      /u01/app/oracle/admin/orcl/rman_transdest/dmpfile.dmp  
      oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem
      $ scp -i private_key_file  
      /u01/app/oracle/admin/orcl/rman_transdest/fsdata01.dbf  
      oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL
      $ scp -i private_key_file  
      /u01/app/oracle/admin/orcl/rman_transdest/fsindex01.dbf  
      oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL
      ```
3. On the Database service compute node, prepare the database for the tablespace import.
   a. On the Database service compute node, invoke SQL*Plus and log in to the database as the SYSTEM user.
   b. Create a directory object in the Database service database.

   ```sql
   SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
   ```
   c. If the owners of the objects that will be imported do not exist in the database, create them before performing
      the import. The transportable tablespace mode of import does not create the users.

   ```sql
   SQL> CREATE USER fsowner
       2   PROFILE default
       3   IDENTIFIED BY fsa
       4   TEMPORARY TABLESPACE temp
       5   ACCOUNT UNLOCK;
   ```

4. On the Database service compute node, invoke Data Pump Import and connect to the database.

   Import the data into the database using the `TRANSPORT_DATAFILES` option.

   ```sql
   impdp system DIRECTORY=dp_from_onprem DUMPFILE='dmpfile.dmp' \
   TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', \
   '/u02/app/oracle/oradata/ORCL/fsindex01.dbf'
   ```

5. After verifying that the data has been imported successfully, you can delete the `dmpfile.dmp` dump file.

**RMAN CONVERT Transportable Tablespace with Data Pump**

You can use this method only if the database character sets of your on-premises database and the Database service

database are compatible.

This method is similar to the Data Pump Transportable Tablespace method, with the addition of the

RMAN `CONVERT` command to enable transport between platforms with different endianness. Query `V

$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform
tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian
format.

To migrate tablespaces from your on-premises Oracle database to a database deployment on the Database service
using RMAN, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
3. On the on-premises database host, invoke RMAN and use the `CONVERT TABLESPACE` command to convert the
   tablespace datafile to the Database service platform format. Refer to the Oracle Database Backup and Recovery
   Reference for more information on the `CONVERT` command.
4. Use a secure copy utility to transfer the Data Pump Export dump file and the converted tablespace datafiles to the
   Database service compute node.
5. Set the on-premises tablespaces back to `READ WRITE`.
6. On the Database service compute node, prepare the database for the tablespace import.
7. On the Database service compute node, invoke Data Pump Import and connect to the database.
8. On the Database service compute node, set the tablespaces in the database to `READ WRITE` mode.
9. After verifying that the data has been imported successfully, you can delete the dump file.

**RMAN CONVERT Transportable Tablespace with Data Pump: Example**

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises
Oracle database to a Database service database.

In this example, the on-premises database is on a Linux host.
1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
   a. On the on-premises database host, create a directory in the operating system to use for the on-premises export.
      
      ```bash
      mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
      ```
   b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the `SYSTEM` user.
      
      ```sql
      sqlplus system
      Enter password: <enter the password for the SYSTEM user>
      ```
   c. Create a directory object in the on-premises database to reference the operating system directory.
      
      ```sql
      SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
      ```
   d. On the on-premises database host, set all tablespaces that will be transported (the transportable set) to READ ONLY mode.
      
      ```sql
      SQL> ALTER TABLESPACE fsindex READ ONLY;
      Tablespace altered.
      SQL> ALTER TABLESPACE fsdata READ ONLY;
      Tablespace altered.
      ```
   e. Exit from SQL*Plus.

2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
   On the on-premises database host, invoke Data Pump Export and connect to the on-premises database. Export the on-premises tablespaces using the `TRANSPORT_TABLESPACES` option. Provide the password for the `SYSTEM` user when prompted.
      
      ```sql
      expdp system TRANSPORT_TABLESPACES=fsdata,fsindex TRANSPORT_FULL_CHECK=YES DIRECTORY=dp_for_cloud
      ```

3. On the on-premises database host, invoke RMAN and use the `CONVERT TABLESPACE` command to convert the tablespace datafile to the Database service platform format.
   a. Invoke RMAN.
      
      ```sql
      rman target /
      ```
   b. Execute the RMAN `CONVERT TABLESPACE` command to convert the datafiles and store the converted files in a temporary location on the on-premises database host.
      
      ```sql
      RMAN> CONVERT TABLESPACE fsdata, fsindex
      2> TO PLATFORM 'Linux x86 64-bit'
      3> FORMAT '/tmp/%U ';
      ...
      input datafile file number=00006 name=/u01/app/oracle/oradata/orcl/fsdata01.dbf
      converted datafile=/tmp/data_D-ORCL_I-1410251631_TS-FSDATA_FNO-6_0aqc9un3
      ...
      input datafile file number=00007 name=/u01/app/oracle/oradata/orcl/fsindex01.dbf
      converted datafile=/tmp/data_D-ORCL_I-1410251631_TS-FSINDEX_FNO-7_0bqc9un6
      ...
      ```
   c. Take note of the names of the converted files. You will copy these files to the Database service compute node in the next step.
   d. Exit RMAN.
4. Use a secure copy utility to transfer the Data Pump Export dump file and the converted tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the /u01 directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

   

   ```
   mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
   ```

   b. Before using the `scp` command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

   c. On the on-premises database host, use the `scp` utility to transfer the dump file and all data files of the transportable set to the Database service compute node.

   ```
   scp -i private_key_file 
   /u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp 
   oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem
   
   $ scp -i private_key_file 
   /tmp/data_D-ORCL_I-1410251631_TS-FSDATA_FNO-6_0aqc9un3 
   oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL/fsdata01.dbf
   
   $ scp -i private_key_file 
   /tmp/data_D-ORCL_I-1410251631_TS-FSINDEX_FNO-7_0bqc9un6 
   oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL/fsindex01.dbf
   ```

5. Set the on-premises tablespaces back to READ WRITE.

   a. Invoke SQL*Plus and log in as the SYSTEM user.

   b. Set the FSDATA and FSINDEX tablespaces back to READ WRITE mode.

   ```
   SQL> ALTER TABLESPACE fsdata READ WRITE;
   Tablespace altered.
   SQL> ALTER TABLESPACE fsindex READ WRITE;
   Tablespace altered.
   ```

   c. Exit from SQL*Plus.

6. On the Database service compute node, prepare the database for the tablespace import.

   a. On the Database service compute node, invoke SQL*Plus and log in to the database as the SYSTEM user.

   b. Create a directory object in the Database service database.

   ```
   SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/ 
   dpdump/from_onprem';
   ```

   c. If the owners of the objects that will be imported do not exist in the database, create them before performing the import. The transportable tablespace mode of import does not create the users.

   ```
   SQL> CREATE USER fsowner
   2  PROFILE default
   3  IDENTIFIED BY fspass
   4  TEMPORARY TABLESPACE temp
   5  ACCOUNT UNLOCK;
   ```

7. On the Database service compute node, invoke Data Pump Import and connect to the database.

   Import the data into the Database service database using the `TRANSPORT_DATAFILES` option.

   ```
   impdp system DIRECTORY=dp_from_onprem 
   TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', 
   '/u02/app/oracle/oradata/ORCL/fsindex01.dbf'
   ```
8. On the Database service compute node, set the tablespaces in the database to READ WRITE mode.
   a. Invoke SQL*Plus and log in as the SYSTEM user.
   b. Set the FSDATA and FSINDEX tablespaces to READ WRITE mode.

```sql
SQL> ALTER TABLESPACE fsdata READ WRITE;
Tablespace altered.
SQL> ALTER TABLESPACE fsindex READ WRITE;
Tablespace altered.
```
   c. Exit from SQL*Plus.

9. After verifying that the data has been imported successfully, you can delete the expdat.dmp dump file.

RMAN DUPLICATE from an Active Database

This topic explains how to migrate an entire, active container database (CDB) or non-CDB database to Oracle Cloud Infrastructure by using RMAN Active Duplication. The database to be migrated can reside on-premises or in Oracle Cloud Infrastructure Classic. This topic does not cover duplicating a pluggable database, or migrating a pluggable database or non-CDB to a CDB in the cloud.

The following terms are used throughout this topic:

- **Source database**: The active database to be migrated.
- **Target database**: The new database (duplicated from the source database) on a DB system in the Oracle Cloud Infrastructure.

**Note:**

Version 11.2.0.4 databases running on bare metal DB systems will be migrated to a DB system using ACFS storage.

**Prerequisites**

For the source database to be migrated, you'll need:

- The source database name, database unique name, listener port, service name, database home patch level, and the password for SYS.
- A copy of the sqlpatch directory from the source database home. This is required for rollback in case the target DB system does not include these patches.
- If the source database is configured with Transparent Data Encryption (TDE), you'll need a backup of the wallet and the wallet password to allow duplication of a database with encrypted data.

When migrating a source database to an existing target database, Oracle recommends that you patch the source environment to the same database bundle patch level as the target database home. If the source environment has an interim patch (previously known as a "one-off" patch) that includes a sqlpatch component, and that sqlpatch is missing from the target environment (or a different cumulative patch is applied), the interim patch should be rolled back in the source environment before the migration, if possible.

**Tip:**

To check for interim patches installed on the source or target database, use the `$ORACLE_HOME/OPatch/opatch lspatches` command. To roll back SQL changes in the target database, copy the `$ORACLE_HOME/sqlpatch/&lt;patch#&gt;/postdeinstall.sql` script from the source environment to the cloud environment and execute the `postdeinstall.sql` script.

For the target database, you'll need:

- A target DB system that supports the same database edition as the source database edition. When you launch a DB system, an initial database is created on it. If necessary, you can delete that database and create a new one by using the dbcli command line interface. For more information on creating a DB system, see Creating Bare Metal
• The target database name, database unique name, auxiliary service name, and database home patch level.
• A free TCP port in the target database to setup the auxiliary instance.

If you need to roll back interim patches in the target environment so that the patch level matches that of the source environment, copy the source DB $ORACLE_HOME/sqlpatch/<patch_number> directory to the target database home.

**Migrating Source Databases That Include Patch Set Updates (PSUs)**

In Oracle Cloud Infrastructure DB systems, the database home includes an installation of Database Proactive Bundle Patches. If the source DB uses Patch Set Updates (PSUs), follow the instructions in MOS Note:1962125.1 (Oracle Database - Overview of Database Patch Delivery Methods) for migrating the DB into Oracle Cloud Infrastructure.

**Verifying the Environment**

Perform the following steps before you begin the migration:

1. Make sure the source DB system is reachable from the target DB system. You should be able to SSH between the two hosts.
2. On the target host, use the TNSPING utility to make sure the source host listener port works. For example:

   ```
   tnsping <source_host>:1521
   ```

3. On the target host, use Easy Connect to verify the connection to the source database:

   ```
   <host>:<port>/<service_name>
   ```

   For example:

   ```
   sqlplus system@129.145.0.164:1521/proddb
   ```

   Make sure the connection string does not exceed 64 characters.

4. Copy the required sqlpatch files (for rollback) from the source database home to the target database.
5. Make sure at least one archivelog has been created on the source database, otherwise, the RMAN duplication will fail with an error.
6. If the source database uses wallets, back up the password-based wallet and copy it to the standard location in the DB system:

   ```
   /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>/
   ```

7. Make sure the compatibility parameters in the source database are set to at least:

   - 18.0.0.0.0 for an 18.1.0.0 database
   - 12.1.0.2.0 for a 12.1.0.2 or a 12.2.0.1 database
   - 11.2.0.4.0 for an 11.2.0.4 database

**Setting Up Storage on the DB System**

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use sudo su – with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).

   ```
   login as: opc
   ```
Use the Dbstorage Commands on page 1521 to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the tdest database.

```
[root@dbsys ~]# dbcli create-dbstorage --dbname tdest --dataSize 10 -- dbstorage ACFS
```

**Note:**
When migrating a version 11.2 database, ACFS storage must be specified.

4. Use the Dbstorage Commands on page 1521 command to list the storage ID. You'll need the ID for the next step.

```
[root@dbsys ~]# dbcli list-dbstorages
```

```
ID                                       Type   DBUnique Name
---------------------------------------- ------ --------------------
---------
9dcdfb8e-e589-4d5f-861a-e5ba981616ed     Acfs   tdest
Configured
```

5. Use the Dbstorage Commands on page 1521 command with the storage ID from the previous step to list the DATA, RECO and REDO locations.

```
[root@dbsys ~]# dbcli describe-dbstorage --id 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
```

```
DBStorage details
------------------
ID: 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
DB Name: tdest
DBUnique Name: tdest
DB Resource ID:
  Storage Type: Acfs
  DATA Location: /u02/app/oracle/oradata/tdest
  RECO Location: /u03/app/oracle/fast_recovery_area/
  REDO Location: /u03/app/oracle/redo/
  State: ResourceState(status=Configured)
Created: August 24, 2016 5:25:38 PM UTC
UpdatedTime: August 24, 2016 5:25:53 PM UTC
```

Note the locations. You'll use them later to set the `db_create_file_dest`, `db_create_online_log_dest`, and `db_recovery_file_dest` parameters for the database.

**Choosing an ORACLE_HOME**

Decide which ORACLE_HOME to use for the database restore and then switch to that home with the correct ORACLE_BASE, ORACLE_HOME, and PATH settings.

To get a list of existing ORACLE_HOMEs, use the Dbhome Commands on page 1518 command. To create a new ORACLE_HOME, use the Dbhome Commands on page 1518 command.

**Copying the Source Database Wallets**

Skip this section if the source database is not configured with TDE.

1. On the DB system, become the oracle user:

```
sudo su - oracle
```

2. Create the following directory if it does not already exist:

```
mkdir /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
```
3. Copy the ewallet.p12 file from the source database to the directory you created in the previous step.

4. On the target host, make sure that $ORACLE_HOME/network/admin/sqlnet.ora contains the following line:

   ```
   ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/
   opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
   ```

   Add the line if it doesn't exist in the file. (The line might not be there if this is a new home and no database has been created yet on this host.)

5. Create the autologin wallet from the password-based wallet to allow auto-open of the wallet during restore and recovery operations.

   For version 12c, use the `ADMINISTER KEY MANAGEMENT` command:

   ```bash
   $ cat create_autologin_12.sh
   
   #!/bin/sh
   if [ $# -lt 2 ]; then
     echo "Usage: $0 <db_unique_name> <remote_wallet_location>"
     exit 1;
   fi
   mkdir /opt/oracle/dcs/commonstore/wallets/tde/$1
   cp $2/ewallet.p12* /opt/oracle/dcs/commonstore/wallets/tde/$1
   rm -f autokey.ora
   echo "db_name=$1" > autokey.ora
   autokeystoreLog="autologinKeystore_`date +%Y%m%d_%H%M%S_%N`.log"
   echo "Enter Keystore Password:" read -s keystorePassword
   echo "Creating AutoLoginKeystore -> "
   sqlplus "/as sysdba" <<EOF
   spool $autokeystoreLog
   set echo on
   startup nomount pfile=autokey.ora
   ADMINISTER KEY MANAGEMENT CREATE AUTO_LOGIN KEYSTORE
   FROM KEYSTORE '/opt/oracle/dcs/commonstore/wallets/tde/$1' -- Keystore
   location
   IDENTIFIED BY "$keystorePassword";
   shutdown immediate;
   EOF
   ```

   For version 11g, use the `orapki` command:

   `orapki wallet create -wallet wallet_location -auto_login [-pwd <password>]`

### Setting Up the Static Listener

Set up the static listener for the auxiliary instance for RMAN duplication.

1. On the DB system, create `$ORACLE_HOME/network/admin/listener.ora` and add the following content to it.

   ```
   LISTENER_aux_<db_unique_name> =
   (DESCRIPTION=
     (ADDRESS_LIST=
       (ADDRESS=(PROTOCOL=TCP)(HOST=<hostname> or <ip_address>)(PORT=<available_TCP_port>))
     )
   )
   SID_LIST_LISTENER_aux_<db_unique_name> =
   (SID_LIST=
     (SID_DESC=
   ```
(GLOBAL_DBNAME=<auxServiceName_with_domain>)
(ORACLE_HOME=<Oracle_home_for_target_database>)
(SID_NAME=<database_name>)
(ENVS="TNS_ADMIN=<path_to_tnsnames.ora>")
(ENVS="ORACLE_UNQNAME=<db_unique_name(in lower case)>")
)

2. Make sure the port specified in (PORT=<available_TCP_port>) is open in the DB system's iptables and in the DB system's cloud network Security List.

Using the RMAN Duplicate Command to Migrate the Database

1. Set the following environment variables for RMAN and SQL Plus sessions for the database:

   ORACLE_HOME=<path_of_Oracle_home_where_the_database_is_to_be_restored>
   ORACLE_SID=<database_name>
   ORACLE_UNQNAME=<db_unique_name(in lower case)>
   NLS_DATE_FORMAT="mm/dd/yyyy hh24:mi:ss"

2. Start the listener:

   lsnrctl start listener_aux_<db_unique_name>

3. Create an init.ora file with the minimal required parameters as described in Creating an Initialization Parameter File and Starting the Auxiliary Instance and use it for the auxiliary instance.

4. Start the auxiliary instance in nomount mode:

   startup nomount

5. Run the following commands to duplicate the database. Note that the example below uses variables to indicate the values to be specified:

   rman target sys/$sourceSysPassword@$sourceNode:$sourceListenerPort/
   $sourceDb auxiliary sys/$auxSysPassword@$targetNode:$targetListenerPort/
   $auxService<<EOF
   spool log to "`date +%Y%m%d_%H%M%S_%N`_duplicate_"=
   $targetDbUniqueName}_from_"$sourceDb).log"
   set echo on
   duplicate target database to $targetDb from active database
   password file
   spfile
   PARAMETER_VALUE_CONVERT $sourceDb $targetDb $sourceDbUniqueNameCaps
   $targetDbUniqueNameCaps
   set cluster_database='false'
   set db_name='$targetDb'
   set db_unique_name='$targetDbUniqueName'
   set db_create_file_dest='$dataLoc'
   set db_create_online_log_dest_1='$redoLoc'
   set db_recovery_file_dest='$recoLoc'
   set audit_file_dest = '$auditFileDest'
   reset control files
   nofilenamesearch
; EOF

Preparing to Register the Database

Before you register the database:
1. Make sure the database COMPATIBLE parameter value is acceptable.
   For a 11.2 database, the minimum compatibility value is 11.2.0.4.
   For a 12c database, the minimum compatibility value is 12.1.0.2.
   If the value is less than the minimum, the database cannot be registered until you upgrade the database compatibility.

2. Use the following command to verify that the database has registered with the local listener and service name.
   
   ```bash
   lsnrctl services
   ```

3. Use the following command to verify that the password file was restored or created for a new database.
   
   ```bash
   ls -ltr $ORACLE_HOME/dbs/orapw<$ORACLE_SID>
   ```
   If the file does not exist, create it using the orapwd command.
   
   ```bash
   orapwd file=<$ORACLE_HOME/dbs/orapw<$ORACLE_SID>> password=<sys_password>
   ```

4. Use the following command to verify that the restored database is open in read write mode.
   
   ```sql
   select open_mode from v$database;
   ```
   Read write mode is required to register the database later. Any PDBs must also be in read write mode.

5. From oracle home on the migrated database host, use the following command verify the connection to SYS.
   
   ```bash
   conn sys/<password>@<service_name> as sysdba
   ```
   This connection is required to register the database later. Fix any connection issues before continuing.

6. Copy the folder $ORACLE_HOME/sqlpatch from source database to the target database. This will enable the 
dbcli register-database command to rollback any conflicting patches.

   **Note:**
   If you are migrating a version 11.2 database, additional steps are required
   after you register the database. For more information, see Rolling Back
   Patches on a Version 11.2 Database on page 1642.

7. Use the following SQL*Plus command to make sure the database is using the spfile.
   
   ```sql
   SHOW PARAMETERS SPFILE
   ```

---

### Registering the Database on the DB System

The Database Commands on page 1505 command registers the migrated database to the dcs-agent so it can be managed by the dcs-agent stack.

**Note:**
The `dbcli register-database` command is not available on 2-node RAC DB Systems.

As the root user, use the `dbcli register-database` command to register the database on the DB system, for example:

```bash
[root@dbsys ~]# dbcli register-database --dbclass OLTP --dbshape odb1 --servicename crmdb.example.com --syspassword
Password for SYS:
{
  "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
  "status" : "Created",
  "message" : null,
}
Migrating a Version 12.1 or Later Database That Includes SQL Patch Components

For a 1-node DB system at version 12.1 or higher, the `dbcli register-database` command automates the datapatch execution. Before executing the `dbcli register-database` command, open all PDBs in read-write mode. If you have already run the `dbcli register-database` command and did not open all PDBs, or did not copy the SORACLE_HOME/sqlpatch directory from the source database home, manually rerun the datapatch utility to configure the SQL portion of existing interim patches. This can be done by executing the command 

```bash
$ORACLE_HOME/OPatch/opatch datapatch
```

Tip:  
If the source database includes patch 23170620 and the target database is running with the October 2017 patch or a later one, the `$ORACLE_HOME/sqlpatch` directory does not need to be copied to the target database, because the contents of the patch are already installed in the target database.

Rolling Back Patches on a Version 11.2 Database

For version 11.2 databases, the sqlpatch application is not automated, so any interim patches (previously known as a "one-off" patches) applied to the source database that are not part of the installed PSU must be rolled back manually in the target database. After registering the database, execute the `catbundle.sql` script and then the `postinstall.sql` script with the corresponding PSU patch (or the overlay patch on top of the PSU patch), as described below.

Tip:  
Some interim patches may include files written to the SORACLE_HOME/rdbms/admin directory as well as the SORACLE_HOME/sqlpatch directory. Oracle recommends that you roll back these patches in the source database using the instructions in the patch read-me prior to migrating the database to OCI environment. Contact Oracle Support if you need assistance with rolling back these patches.

1. On the DB System, use the `dbcli list-dbhomes` command to find the PSU patch number for the version 11.2 database home. In the following sample command output, the PSU patch number is the second number in the DB Version column:

```bash
[root@dbsys ~]# dbcli list-dbhomes
ID                                   Name               DB Version
Home Location                             Status
------------------------------------ -----------------  
-------------------------------------  ----------
59d9bc6f-3880-4d4f-b5a6-c140f16f8c64 OraDB11204_home1 11.2.0.4.160719
(23054319, 23054359)   /u01/app/oracle/product/11.2.0.4/dbhome_1
Configured
```

(The first patch number, 23054319 in the example above, is for the OCW component in the database home.)

2. Find the overlay patch, if any, by using the `lsinventory` command. In the following example, patch number 24460960 is the overlay patch on top of the 23054359 PSU patch.

```bash
$ $ORACLE_HOME/OPatch/opatch lsinventory ...
```
Installed Top-level Products (1):

Oracle Database 11g
11.2.0.4.0

There are 1 products installed in this Oracle Home.

Interim patches (5):

Patch 24460960: applied on Fri Sep 02 15:28:17 UTC 2016
Unique Patch ID: 20539912
Created on 31 Aug 2016, 02:46:31 hrs PST8PDT
Bugs fixed:
23513711, 23065323, 21281607, 24006821, 23315889, 22551446, 21174504
This patch overlays patches:
23054359
This patch needs patches:
23054359
as prerequisites

3. Start SQL*Plus and execute the catbundle.sql script, for example:

```sql
SQL> startup
SQL> connect / as sysdba
SQL> @$ORACLE_HOME/rdbms/admin/catbundle.sql psu apply
exit
```

4. Apply the sqlpatch, using the overlay patch number from the previous step, for example:

```sql
SQL> connect / as sysdba
SQL> @$ORACLE_HOME/sqlpatch/24460960/postinstall.sql
exit
```

Creating a Backup Configuration (Optional)

If you would like to manage the database backup with the dbcli command line interface, you can associate a new or existing backup configuration with the migrated database when you register it or after you register it. A backup configuration defines the backup destination and recovery window for the database. As the root user, use the following commands to create, list, and display backup configurations:

- [Backupconfig Commands](#) on page 1491
- [Backupconfig Commands](#) on page 1491
- [Backupconfig Commands](#) on page 1491

Post Migration Checklist

After the database is migrated and registered on the DB system, use the following checklist to verify the results of the migration and perform any post-migration customizations.

1. Make sure the database files were restored in OMF format.
2. Make sure the database is listed in the [Database Commands](#) on page 1505 command output.
3. Check for the following external references in the database and update them if necessary:
   - External tables: If the source database uses external tables, back up that data and migrate it to the target host.
   - Directories: Customize the default directories as needed for the migrated database.
   - Database links: Make sure all the required TNS entries are updated in the tnsnames.ora file in ORACLE_HOME.
   - Email and URLs: Make sure any email addresses and URLs used in the database are still accessible from the DB system.
   - Scheduled jobs: Review the jobs scheduled in source database and schedule similar jobs as needed in the migrated database.
4. If you associated a backup configuration when you registered the database, run a test back up using the Backup Commands on page 1487 command.
5. Verify that patches have been applied to all PDBs if the migrated database contains CDB and PDBs.
6. Validate the database performance by using Database Replay and SQL Performance Analyzer for SQL. For more information, see the Database Testing Guide.

**SQL Developer and INSERT Statements to Migrate Selected Objects**

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database service.

In this method, you use SQL INSERT statements to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in a Database service deployment using SQL Developer and INSERT statements, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to migrate.
2. In SQL Developer, click the Export Cart icon and select “Insert” in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and execute the generated script to create the database objects.
4. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and run the generated script to create the objects and load the data.

**SQL Developer and SQL*Loader to Migrate Selected Objects**

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database.

In this method, you use SQL*Loader to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in the Database service deployment using SQL Developer and SQL*Loader, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to load into your cloud database.
2. In SQL Developer, click the Export Cart icon and select “loader” in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database on the Database service and execute the generated script to create the database objects.
4. Use a secure copy utility to transfer the SQL*Loader control files and the SQL*Loader data files to the Database service compute node.
5. On the Database service compute node, invoke SQL*Loader to load the data using the SQL*Loader control files and data files for each object.

**Unplugging/Plugging a PDB**

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database service database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c PDB to a PDB in an Oracle Database 12c database on a Database service database deployment.

To migrate an Oracle Database 12c PDB to a PDB in the Oracle Database 12c database on an Oracle Cloud Infrastructure Database service database deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB.
2. On the on-premises database host, execute the ALTER PLUGGABLE DATABASE UNPLUG command to generate an XML file containing the list of datafiles that will be plugged in to the database on the Database service.
3. Use a secure copy utility to transfer the XML file and the datafiles to the Databaseservice compute node.
4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.

5. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.

For more information, see "Creating a PDB by Plugging an Unplugged PDB into a CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

### Unplugging/Plugging Non-CDB

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c non-CDB database to a PDB in an Oracle Database 12c database on a Database service database deployment. This method provides a way to consolidate several non-CDB databases into a single Oracle Database 12c multitenant database on the Database service.

To migrate an Oracle Database 12c non-CDB database to the Oracle Database 12c database on a Database service deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and set the on-premises database to `READ ONLY` mode.
2. On the on-premises database host, execute the `DBMS_PDB.DESCRIBE` procedure to generate an XML file containing the list of datafiles that will be plugged in on the cloud database.
3. Use a secure copy utility to transfer the XML file and the datafiles to the Database service compute node.
4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.
5. On the Database service compute node, execute the `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` script to delete unnecessary metadata from the `SYSTEM` tablespace of the new PDB.
6. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.
7. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises database back to `READ WRITE` mode.

For more information, see "Creating a PDB Using a Non-CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

### Troubleshooting

These topics cover some common issues you might run into and how to address them.

#### Bare Metal and Virtual Machine DB Systems

- Backup Failures on Bare Metal and Virtual Machine DB Systems on page 1646
- Patching Failures on Bare Metal and Virtual Machine DB Systems on page 1659
- Shape Change Failures for Virtual Machine DB Systems on page 1663

#### Exadata DB Systems

- Backup Failures on Exadata DB Systems on page 1665

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For bare metal and VM DB systems, you can create serial console connections to troubleshoot your system in single-user mode. See To create a serial console connection to your database system on page 1387 for information on creating a serial console connection in the Oracle Cloud Infrastructure Console.</td>
</tr>
</tbody>
</table>
Backup Failures on Bare Metal and Virtual Machine DB Systems

Database backups can fail for various reasons. Typically, a backup fails because either the database host cannot access the object store, or there are problems on the host or with the database configuration.

This topic includes information to help you determine the cause of a failure and fix the problem. The section that includes troubleshooting information is organized into several subsections, based on the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Finding the Problem on page 1646 to get started.

Finding the Problem

In the Console, a failed database backup either displays a status of Failed or hangs in the Backup in Progress or Creating state. If the error message does not contain enough information to point you to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the backup failure

1. Log on to the host as the root user and navigate to /opt/oracle/dcs/bin/.
2. Determine the sequence of operations performed on the database.
   
   dbcli list-jobs | grep -i <dbname>

   Note the last job ID listed with a status other than Success.
3. With the job ID you noted from the previous step, use the following command to check the details of that job:
   
   dbcli describe-job -i <job_ID> -j

   Typically, running this command is enough to reveal the root cause of the failure.
4. If you require more information, review the /opt/oracle/dcs/log/dcs-agent.log file.
   
   You can find the job ID in this file by using the timestamp returned by the job report in step 2.
5. If the problem details suggest an RMAN issue, review the RMAN logs in the /opt/oracle/dcs/log/<hostname>/rman/bkup/<db_unique_name>/rman_backup/<yyyy-mm-dd> directory.

   Note:
   
   If the database failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform. Occasionally you might need to restart the dcsagent program if it has the status of stop/waiting to resolve a backup failure.

To restart the database service agent

1. From a command prompt, check the status of the agent:
   
   initctl status initdcsagent

2. If the agent is in the stop/waiting state, try to restart the agent:
   
   initctl start initdcsagent

3. Check the status of the agent again to confirm that it has the start/running status:
   
   initctl status initdcsagent
Oracle Clusterware Issues

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. Occasionally you might need to restart the Clusterware program to resolve a backup failure.

To restart the Oracle Clusterware

1. From command prompt, check the status of Oracle Clusterware:

   `crsctl check crs`
   
   `crsctl stat res -t`

2. If Oracle Clusterware is not online, try to restart the program:

   `crsctl start crs`

3. Check the status of Oracle Clusterware to confirm that it is online:

   `crsctl check crs`

Object Store Connectivity Issues

Backing up your database to Oracle Cloud Infrastructure Object Storage requires that the host can connect to the applicable Swift endpoint. You can test this connectivity by using a Swift user.

To ensure your database host can connect to the object store

1. Create a Swift user in your tenancy. See Working with Auth Tokens on page 2456.

2. With the user you created in the previous step, use the following command to verify the host can access the object store.

   `curl -v -X HEAD -u <user_ID>:<auth_token>' https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>`

   See Object Storage FAQ for the correct region to use. See Understanding Object Storage Namespaces on page 3395 for information about your Object Storage namespace.

3. If you cannot connect to the object store, refer to Prerequisites on page 1436 for how to configure object store connectivity.

Host Issues

One or more of the following conditions on the database host can cause backups to fail:

Interactive Commands in the Oracle Profile

If an interactive command such as `oraenv`, or any command that might return an error or warning message, was added to the `.bash_profile` file for the grid or oracle user, Database service operations like automatic backups can be interrupted and fail to complete. Check the `.bash_profile` file for these commands, and remove them.

The File System Is Full

Backup operations require space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the space available for backups. If the file system has insufficient space, you can remove old log or trace files to free up space.

Incorrect Version of the Oracle Database Cloud Backup Module

Your system might not have the required version of the backup module (opc_installer.jar). See Unable to use Managed Backups in your DB System for details about this known issue. To fix the problem, you can follow the procedure in that section or simply update your DB system and database with the latest bundle patch.
Changes to the Site Profile File (glogin.sql)

Customizing the site profile file ($ORACLE_HOME/sqlplus/admin/glogin.sql) can cause managed backups to fail in Oracle Cloud Infrastructure. In particular, interactive commands can lead to backup failures. Oracle recommends that you not modify this file for databases hosted in Oracle Cloud Infrastructure.

Database Issues

An improper database state or configuration can lead to failed backups.

Database Not Running During Backup

The database must be active and running (ideally on all nodes) while the backup is in progress.

To check that the database is active and running

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database's instance status. The instance status must be Open for the backup to succeed. If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the Open status, use the following commands to access the SQL*Plus command prompt and set the status to Open:

```
sqlplus / as sysdba
alter database open;
```

Archiving Mode Set to NOARCHIVELOG

When you provision a new database, the archiving mode is set to ARCHIVELOG by default. This is the required archiving mode for backup operations. Check the archiving mode setting for the database and change it to ARCHIVELOG, if applicable.

To check and set the archiving mode

Open an SQL*Plus command prompt and enter the following command:

```
select log_mode from v$database;
```

If you need to set the archiving mode to ARCHIVELOG, start the database in Mount status (and not Open status), and use the following command at the SQL*Plus command prompt:

```
alter database archivelog;
```

Confirm that the db_recovery_file_dest parameter points to +RECO, and that the log_archive_dest_n parameter is set to USE_DB_RECOVERY_FILE_DEST.

For RAC databases, one instance must have the Mount status when enabling archivelog mode. To enable archivelog mode for a RAC database, perform the following steps:

1. Shut down all database instances:

```
srvctl stop database -d
```
2. Start one of the database instances in mount state:

```
srvc1 start instance -d <db_unique_name> -i <instance_name> -o mount
```

3. Access the SQL*Plus command prompt:

```
sqlplus / as sysdba
```

4. Enable archive log mode:

```
alter database archivelog;
```

```
exit;
```

5. Stop the database:

```
srvc1 stop instance -d <db_unique_name> -i <instance_name>
```

6. Restart all database instances:

```
srvc1 start database -d <db_unique_name>
```

7. At the SQL*Plus command prompt, confirm the archiving mode is set to ARCHIVELOG:

```
select log_mode from v$database;
```

**Stuck Database Archiver Process and Backup Failures**

Backups can fail when the database instance has a stuck archiver process. For example, this can happen when the flash recovery area (FRA) is full. You can check for this condition using the `srvc1 status database - db <db_unique_name> -v` command. If the command returns the following output, you must resolve the stuck archiver process issue before backups can succeed:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Stuck Archiver
```

Refer to ORA-00257: Archiver Error (Doc ID 2014425.1) for information on resolving a stuck archiver process.

After resolving the stuck process, the command should return the following output:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Open
```

If the instance status does not change after you resolve the underlying issue with the device or resource being full or unavailable, try one of the following workarounds:

- Restart the database using the `srvc1` command to update the status of the database in the clusterware
- Upgrade the database to the latest patchset levels

**Temporary Tablespace Errors**

If fixed table statistics are not up to date on the database, backups can fail with errors referencing temporary tablespace present in the `dcs-agent.log` file. For example:

```
select status from v$rman_status where COMMAND_ID=<backup_id>
```

```
ERROR at line 1:
ORA-01652: unable to extend temp segment by 128 in tablespace TEMP
```
Gather your fixed table statics as follows to resolve this issue:

```
conn / as sysdba
exec dbms_stats.gather_fixed_objects_stats();
```

### RMAN Configuration and Backup Failures

Editing certain RMAN configuration parameters can lead to backup failures in Oracle Cloud Infrastructure. To check your RMAN configuration, use the `show all` command at the RMAN command line prompt.

See the following list of parameters for details about RMAN the configuration settings that should not be altered for databases in Oracle Cloud Infrastructure.

**RMAN configuration settings that should not be altered**

```
CONFIGURE RETENTION POLICY TO RECOVERY WINDOW OF 30 DAYS;
CONFIGURE CONTROLFILE AUTOBACKUP ON;
CONFIGURE DEVICE TYPE 'SBT_TAPE' PARALLELISM 5 BACKUP TYPE TO COMPRESSED BACKUPSET;
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' MAXPIECESIZE 2 G FORMAT '%d_%I_%U_%T_%t' PARMS 'SBT_LIBRARY=/opt/oracle/dcs/commonstore/pkgrepos/oss/odbcso/robipso.so ENV=(OPC_PFILE=/opt/oracle/dcs/commonstore/objectstore/odc_pofile/1578318329/odc_tiger_lad3c8.ora)';
CONFIGURE ARCHIVELOG DELETION POLICY TO BACKED UP 1 TIMES TO 'SBT_TAPE';
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE ENCRYPTION FOR DATABASE ON;
```

### RMAN Retention Policy and Backup Failures

The RMAN retention policy configuration can be the source of backup failures. Using the REDUNDANCY retention policy configuration instead of the RECOVERY WINDOW policy can lead to backup failures. Be sure to use the RECOVERY WINDOW OF 30 DAYS configuration.

**To configure the RMAN retention policy setting**

1. Find the database ID using the following command:

   ```
   dbcli list-databases
   ```

2. Find the `BackupConfigId` value for the database using the following command:

   ```
   dbcli describe-database -i <database_id>
   ```

3. Update the retention policy configuration to RECOVERY WINDOW OF 30 DAYS:

   ```
   dbcli update-backupconfig -i <backup_config_id> --recoverywindow 30
   ```
Loss of Object Store Wallet File and Backup Failures

RMAN backups fail when an object store wallet file is lost. The wallet file is necessary to enable connectivity to the object store.

To confirm that the object store wallet file exists and has the correct permissions

1. Find the database ID using the following command:

   `dbcli list-databases`

2. Find the BackupConfigId value for the database using the following command:

   `dbcli describe-database -i <database_id>`

3. Find the BackupLocation value for the database using the following command:

   `dbcli describe-backupconfig <backup_config_id>`

4. Find the file path of the backup config parameter file (`opc_<backup_location_value>_BC.ora`) using the following command:

   `locate opc_<backup_location_value>_BC.ora`

   For example:

   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# locate opc_b9naijWMAXzi9example_BC.ora
   /opt/oracle/dcs/commonstore/objectstore/opc_pfile/13aef284-9d6b-4eb6-8751-2988a9example/
   opc_b9naijWMAXzi9example_BC.ora
   ```

5. Find the file path to the wallet file in the backup config parameter file by inspecting the value stored in the `OPC_WALLET` parameter. To do this, navigate to the directory containing the backup config parameter file and use the following `cat` command:

   `cat <backup_config_parameter_file>`

   For example:

   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# cat opc_b9naijWMAXzi9example_BC.ora
   OPC_HOST=https://swift.objectstorage.us-ashburn-1.oraclecloud.com/v1/dbbackupiad
   OPC_WALLET='LOCATION=file:/opt/oracle/dcs/commonstore/objectstore/wallets/13aef284-9d6b-4eb6-8751-2988aexample CREDENTIAL_ALIAS=alias_opc'
   OPC_CONTAINER=b9naijWMAXzi9example
   ```

6. Confirm that the `cwallet.sso` file exists in the directory specified in the `OPC_WALLET` parameter, and confirm that the file has the correct permissions. The file permissions should have the octal value of "600" (`-rw-------`). Use the following command:

   `ls -ltr /opt/oracle/dcs/commonstore/objectstore/wallets/<backup_config_id>`

   For example:
TDE Wallet and Backup Failures

Incorrect TDE Wallet Location Specification

For backup operations to work, the `ORACLE_HOME/network/admin/sqlnet.ora` file must contain the `ENCRYPTION_WALLET_LOCATION` parameter formatted exactly as follows:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)
  (METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

**Important:**

In this wallet location entry, `$ORACLE_UNQNAME` is an environment variable and should not be replaced with an actual value.

To check the TDE wallet location specification

Use the `cat` command to check the TDE wallet location specification. For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora

ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)
  (METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

Incorrect State of the TDE Wallet

Database backups fail if the TDE wallet is not in the proper state. The following scenarios can cause this problem:

*The ORACLE_UNQNAME environment variable was not set when the database was started using SQL*Plus*

If the database was started using SQL*Plus, and the `ORACLE_UNQNAME` environment variable was not set, the wallet is not opened correctly.

To fix the problem, start the database using the `srvctl` utility:

```
srvctl start database -d <db_unique_name>
```

*A pluggable database was added with an incorrectly configured master encryption key*

In a multitenant environment for Oracle Database versions that support PDB-level keystore, each PDB has its own master encryption key. This encryption key is stored in a single keystore used by all containers. After you create or plug in a new PDB, you must create and activate a master encryption key for it. If you do not do so, the `STATUS` column in the `v$encryption_wallet` view shows the value `OPEN_NO_MASTER_KEY`.

To check the master encryption key status and create a master key, do the following:

1. Review the `STATUS` column in the `v$encryption_wallet` view, as shown in the following example:

```
SQL> alter session set container=pdb2;
```
Session altered.

```sql
SQL> select WRL_TYPE, WRL_PARAMETER, STATUS, WALLET_TYPE from v$encryption_wallet;
```

<table>
<thead>
<tr>
<th>WRL_TYPE</th>
<th>WRL_PARAMETER</th>
<th>STATUS</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>/opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/</td>
<td>OPEN_NO_MASTER_KEY</td>
<td>AUTOLOGIN</td>
</tr>
</tbody>
</table>

2. Confirm that the PDB is in READ WRITE open mode and is not restricted, as shown in the following example:

```sql
SQL> show pdbs
```

<table>
<thead>
<tr>
<th>CON_ID</th>
<th>CON_NAME</th>
<th>OPEN MODE</th>
<th>RESTRICTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>PDB$SEED</td>
<td>READ ONLY</td>
<td>NO</td>
</tr>
<tr>
<td>3</td>
<td>PDB1</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
<tr>
<td>4</td>
<td>PDB2</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
</tbody>
</table>

The PDB cannot be open in restricted mode (the RESTRICTED column must show NO). If the PDB is currently in restricted mode, review the information in the PDB_PLUG_IN_VIOLATIONS view and resolve the issue before continuing. For more information on the PDB_PLUG_IN_VIOLATIONS view and the restricted status, review the documentation on pluggable database for your Oracle database version.

3. Run the following DBCLI commands to change the status to OPEN:

```
$ sudo su -
# dbcli list-database
# dbcli update-tdekey -i <database_ID> -n <PDB_name> -p
```

The `update-tdekey` command shown will prompt you for the admin password.

4. Confirm that the status of the wallet has changed from OPEN_NO_MASTER_KEY to OPEN by querying the v$encryption_wallet view as shown in step 1.

**Incorrect Configuration Related to the TDE Wallet**

Several configuration parameters related to the TDE wallet can cause backups to fail.

*To check configuration related to the TDE wallet*

- Check that the environment's database unique name parameter (ORACLE_UNQNAME) is set correctly using the following command:

```
srvctl getenv database -d <db_unique_name>
```

For example:

```
[oracle@orcl tde]$ srvctl getenv database -d orclbkp_iadxyz
```
orclbkp_iadxyz:
ORACLE_UNQNAME=orclbkp_iadxyz
TZ=UTC

• Check your sqlnet.ora settings to confirm that the file has an ENCRYPTION_WALLET_LOCATION parameter with the correct DIRECTORY value. Use the following command:
cat $ORACLE_HOME/network/admin/sqlnet.ora

For example:

[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)
(METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME)))

• Confirm that the wallet status is open and the wallet type is auto login by checking the v $encryption_wallet view. For example:

    SQL> select status, wrl_parameter,wallet_type from v $encryption_wallet;

    STATUS                WRL_PARAMETER
    ------------------------
    ------------------------
    OPEN
    tde/example_iadxyz/ AUTOLOGIN

For pluggable databases (PDBs), be sure that you switch to the appropriate container before querying v $encryption_wallet view. For example:

    [oracle@paulo ~]$ sqlplus / as sysdba
    SQL> alter session set container=pdb1;
    Session altered.
    SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v $encryption_wallet;

    WRL_TYPE      WRL_PARAMETER
    STATUS        WALLET_TYPE
    ------------- ------------------------
    ------------- ------------------------
    FILE
    OPEN AUTOLOGIN
    /opt/oracle/dcs/commonstore/wallets/tde/tiger_iad3c8/
    AUTOLOGIN
**Missing TDE Wallet File**

The TDE wallet file (ewallet.p12) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME/ewallet.p12
-rwx------ 1 oracle oinstall 5680 Apr 18 13:09 /opt/oracle/dcs/
commonstore/wallets/tde/orclbkp_iadxzy/ewallet.p12
```

The TDE wallet file should have file permissions with the octal value ”700” (rwx------), and the owner of this file should be a part of the oinstall operating system group.

**Missing Auto Login Wallet File**

The auto login wallet file (cwallet.sso) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME/cwallet.sso
-rwx------ 1 oracle oinstall 5725 Apr 18 13:09 /opt/oracle/dcs/
commonstore/wallets/tde/orclbkp_iadxyz/cwallet.sso
```

The auto login wallet file should have file permissions with the octal value ”700” (rwx------), and the owner of this file should be a part of the oinstall operating system group.

**Other Causes of Backup Failures**

**Unmounted Commonstore Mount Point**

The mount point /opt/oracle/dcs/commonstore must be mounted, or backups will fail.

*To check the commonstore mount point*

Confirm that the mount point /opt/oracle/dcs/commonstore is mounted, as shown in the following example:

```
[root@orcl ~]# srvctl config filesystem -volume commonstore -diskgroup
data
Volume device: /dev/asm/commonstore-5
Diskgroup name: data
Volume name: commonstore
Canonical volume device: /dev/asm/commonstore-5
Accelerator volume devices:
Mountpoint path: /opt/oracle/dcs/commonstore
Mount point owner: oracle
Mount users:
Type: ACFS
```
To confirm that ora.data.commonstore.acfs is online

The state for ora.data.commonstore.acfs must be online, or backups will fail. Confirm as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v
NAME=ora.data.commonstore.acfs
TYPE=ora.acfs.type
LAST_SERVER=orcl
STATE=OFFLINE
TARGET=OFFLINE
... 
STATE_DETAILS=admin unmounted /opt/oracle/dcs/commonstore
...
[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore
```

If the STATE_DETAILS value is unmounted, mount the file system as shown in the following example:

```
[root@orcl ~]# srvctl start filesystem -volume commonstore -diskgroup data
```

Confirm that the change was successful as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v
NAME=ora.data.commonstore.acfs
TYPE=ora.acfs.type
LAST_SERVER=orcl
STATE=ONLINE on orcl
TARGET=ONLINE
CARDINALITY_ID=ONLINE
...
STATE_DETAILS=mounted on /opt/oracle/dcs/commonstore
```

List the contents of the commonstore directory to confirm that it is mounted, as shown in the following example:

```
[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore
```

```
   total 220
   drwx------  2 root    root 65536 Apr 18 10:50 lost+found
   drwx------  3 oracle oinstall 20480 Apr 18 11:02 wallets
```
The Database Is Not Properly Registered

Database backups fail if the database is not registered with the dcs-agent. This scenario can occur if you manually migrate the database to Oracle Cloud Infrastructure and do not run the `dbcli register-database` command.

To check whether the database is properly registered, review the information returned by running the `srvctl config database` command and the `dbcli list-databases` command. If either command does not return a record of the database, contact Oracle Support Services.

For instructions on how to register the database, refer to the following topics:

- Registering the Database on the DB System on page 1459
- Database Commands on page 1505

Getting Help

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

**To collect database information for use in problem reports**

Use the following commands to collect details about your database. Record the output of each command for reference:

```
dbcli list-databases
```

```
dbcli describe-database -i <database_id>
```

```
dbcli describe-component
```

**To collect diagnostic information regarding failed jobs**

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Run the following two commands to generate information about the failed job:

   ```
dbcli list-jobs | grep -i <dbname>
dbcli describe-job -i <job_ID> -j
   ```

   The `<job_ID>` in the second command should be the ID of the latest failed job reported from the first command.
3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.

   ```
diagcollector.py
   ```

   This command creates a file named `diagLogs-<timestamp>.zip` in the `/tmp` directory.

**To collect DCS agent log files**

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:

   ```
sudo /opt/oracle/dcs/bin/diagcollector.py
   ```
3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:

```
[opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py
Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip
Logs are being collected to:
/tmp/dcsdiag/diagLogs-1234567890.zip
```

To collect TDE configuration details

1. Run the `srvctl getenv database -d <db_unique_name>` command and record the output for reference.

2. Record the output of the view `v$encryption_wallet`. For example:

```
SQL> select status, wrl_parameter, wallet_type from v$encryption_wallet;

<table>
<thead>
<tr>
<th>STATUS</th>
<th>WRL_PARAMETER</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>/opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/ AUTOLOGIN</td>
<td></td>
</tr>
</tbody>
</table>
```

3. Record the output of the `ls -ltr <wrl_parameter>` command. For example:

```
[oracle@patchtst ~]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/
```

To collect the RMAN backup report file

Generate RMAN Backup Report File using the following command:

```
dbcli create-rmanbackupreport -i <db_id> -w detailed -rn <report_name>
```

For example:

```
[root@patchtst ~]# dbcli create-rmanbackupreport -i 57fvwxyz-9dc4-45d3-876b-5f850example -w detailed -rn bkpreport1
```

Locate the report file using the `dbcli describe-rmanbackupreport -in <report_name>` command. The location of the report is given in output. For example:

```
[root@patchtst ~]# dbcli describe-rmanbackupreport -in bkpreport1
```
Patching Failures on Bare Metal and Virtual Machine DB Systems

Patching operations can fail for various reasons. Typically, an operation fails because a database node is down, there is insufficient space on the file system, or the database host cannot access the object store.

This topic includes information to help you determine the cause of the failure and fix the problem. The information is organized into several sections, based on the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Determining the Problem on page 1659 to get started.

Determining the Problem

In the Console, you can identify a failed patching operation by viewing the patch history of a DB system or an individual database. A patch that was not successfully applied displays a status of Failed and includes a brief description of the error that caused the failure. If the error message does not contain enough information to point you to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the patching operation failure

1. Log on to the host as the root user and navigate to the /opt/oracle/dcs/bin/ directory.
2. Determine the sequence of operations performed on the database.
   
   dbcli list-jobs

   Note the last job ID listed with a status other than Success.
3. With the job ID you noted from the previous step, use the following command to check the details of that job:

   dbcli describe-job -i <job_ID> -j

   Typically, running this command is enough to reveal the root cause of the failure.
4. If you require more information, review the /opt/oracle/dcs/log/dcs-agent.log file.
   You can find the job ID in this file by using the timestamp returned by the job report in step 2.
5. If the patching failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform.

Resolving Patching Failures Caused By a Stopped Agent

Occasionally you might need to restart the dcsagent program if it has the status of stop/waiting to resolve a patching failure.
To restart the database service agent

1. From a command prompt, check the status of the agent:

   ```
   initctl status initdcsagent
   ```

2. If the agent is in the **stop/waiting** state, try to restart the agent:

   ```
   initctl start initdcsagent
   ```

3. Check the status of the agent again to confirm that it has the **start/running** status:

   ```
   initctl status initdcsagent
   ```

Resolving Patching Failures Caused By an Agent That Needs to Be Updated

Patching can also fail if your agent needs to be updated. The system gives the following error message for this failure:

```
Current DcsAgent version is less than or equal to minimum required version.
```

To resolve this issue, perform the steps in To have Oracle Support update the Oracle Cloud Infrastructure Database service agent on page 1660.

To have Oracle Support update the Oracle Cloud Infrastructure Database service agent

1. Confirm that the agent (dcsagent) and DCS Admin program (dcsadmin) are running using the following commands:

   ```
   initctl status initdcsagent
   ```

   ```
   initctl status initdcsadmin
   ```

   If these programs are not running, use the following commands to restart them:

   ```
   initctl start initdcsagent
   ```

   ```
   initctl start initdcsadmin
   ```

2. Follow the instructions in Obtaining Further Assistance on page 1662 to collect your DCS agent log files.

3. Contact Oracle Support for assistance with updating the agent.

Object Store Connectivity Issues

Oracle Cloud Infrastructure DB system and database patches are stored in Oracle Cloud Infrastructure Object Storage. Therefore, successful patching operations require connectivity between the DB system host and the Object Storage location from which the patches are downloaded.

To ensure your database host can connect to Oracle Cloud Infrastructure Object Storage

1. Use the following command to verify the host can access Oracle Cloud Infrastructure Object Storage:

   ```
   dbcli describe-latestpatch
   ```

   Example output indicating success:

   ```
   [root@<host> ~]# dbcli describe-latestpatch
   componentType availableVersion
   -------------------------------
   gi 12.2.0.1.180417
   gi 12.1.0.2.180417
   ```
Example output indicating failure:
```
[root@<host> ~]# dbcli describe-latestpatch
DCS-10032:Resource patch metadata is not found.Failed to download patchmetadata from objectstore
```

2. If you cannot connect to the object store, refer to Prerequisites on page 1436 for how to configure object store connectivity.

**Host and Oracle Clusterware Issues**

One or more of the following conditions on the database host can cause patching operations to fail:

**Database Node Not Running During the Patching Operation**

All nodes of the database must be active and running while a patching operation is in progress, whether you are patching the DB system or the database home. Use the Console to check that the status of each node is AVAILABLE, and start the node, if needed.

**The File System Is Full**

Patching operations require a minimum of 15 GB of free space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the available space. If the file system has insufficient space, you can remove old log or trace files to free up space.

**The Oracle Clusterware Is Not Running**

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. The cluster software program must be up and running on the DB system for patching operations to complete. Occasionally you might need to restart the Oracle Clusterware to resolve a patching failure.

*To restart the Oracle Clusterware*

1. From command prompt, check the status of Oracle Clusterware:

   ```
   crsctl check crs
   ```

   Example output:
   ```
   [grid@<host> ~]$/crsctl check crs
   CRS-4638: Oracle High Availability Services is online
   CRS-4537: Cluster Ready Services is online
   CRS-4529: Cluster Synchronization Services is online
   CRS-4533: Event Manager is online
   ```

   For more detailed status information, you can run `crsctl stat res -t`.

2. If Oracle Clusterware is not online, try to restart the program:

   ```
   crsctl start crs
   ```
3. Check the status of Oracle Clusterware to confirm that it is online:

   crsctl check crs

**The Oracle Grid Infrastructure (GI) Is Not Updated**

This problem occurs when you try to patch a database before you patch the DB system of that database. The error description indicates that the Oracle Grid Infrastructure must be updated first. To resolve this issue, patch the DB system to latest available version. After you patch the DB system, you can retry the database patching operation.

To get the current and latest-available GI versions for the DB system, use the following command:

   dbcli describe-component

**Database Issues**

An improper database state can lead to patching failures.

**Database Not Running During the Patching Operation**

The database must be active and running for all of the patching tasks to complete. Otherwise, you must run the datapatch task manually.

*To check that the database is active and running*

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

   srvctl status database -d <db_unique_name> -verbose

The system returns a message including the database instance status. The instance status must be **Open** for the patching operation to succeed.

If the database is not running, use the following command to start it:

   srvctl start database -d <db_unique_name> -o open

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

   sqlplus / as sysdba
   alter database open;

*To run the datapatch task*

Before you run the datapatch command, ensure that all pluggable databases (PDBs) are open. To open a PDB, you can use SQL*Plus to execute ALTER PLUGGABLE DATABASE `<pdb_name>` OPEN READ WRITE; against the PDB.

   $ORACLE_HOME/OPatch/datapatch

The datapatch command should be run on each database home.

**Obtaining Further Assistance**

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.
To collect diagnostic information regarding failed jobs

1. Log on to the host as the root user and navigate to the /opt/oracle/dcs/bin/ directory.
2. Run the following two commands to generate information about the failed job:

   `dbcli list-jobs`

   `dbcli describe-job -i <job_ID> -j`

   The `<job_ID>` in the second command should be the ID of the latest failed job reported from the first command.
3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.

   `diagcollector.py`

   This command creates a file named `diagLogs-<timestamp>.zip` in the /tmp directory.

To collect DCS agent log files

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:

   `sudo /opt/oracle/dcs/bin/diagcollector.py`

3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:

   `[opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py`
   
   Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip
   Logs are being collected to:
   /tmp/dcsdiag/diagLogs-1234567890.zip

To collect Oracle Grid Infrastructure and Database log files

If an Oracle Grid Infrastructure or Oracle Database patch failed, you can find log files for these failures in the following locations:

**Oracle Grid Infrastructure**

$GI_HOME/cfgtoollogs/

**Oracle Database**

$ORACLE_HOME/cfgtoollogs/

Shape Change Failures for Virtual Machine DB Systems

If your virtual machine DB system shape change does not successfully complete, you can use the procedures in this topic to troubleshoot and fix the issue. For multi-node DB systems, shape change operations proceed in a rolling fashion. Depending on where in the shape change operation the failure occurs, you may be able to re-try the operation using the console.
Using the Console to Troubleshoot

If your shape change operation fails, a message banner appears on the DB System Details page to provide details about the failure. If the failure happens on the first node of a multi-node system, and the operation is rolled back successfully, the Change Shape button remains available and the system remains online, in the Available state. Contact Oracle Support to get additional details about the failure. You can also follow the steps in Using dbcli to Troubleshoot on page 1664 to learn more about the failure and what issues need to be resolved. After determining that no issues remain, you can try the operation again.

If the failure leaves the system in a state where the operation cannot be rolled back, the system state is Needs Attention. In this case, contact Oracle Support as soon as you are aware of the issue so Oracle can help you resolve the issue and complete the shape change operation.

Using dbcli to Troubleshoot

Determine What Stage of the Shape Change Operation Failed

1. Login to the DB system as the root user.
2. Navigate to /opt/oracle/dcs/bin:
   
   ```
   cd /opt/oracle/dcs/bin
   ```
3. Update the CLI tool:
   
   ```
   ./cliadm update-dbcli
   ```
4. List the failed jobs:
   
   ```
   dbcli list-jobs | grep -i failed
   ```

5. Note if the failed job (or jobs) occurred during the pre_action, action, or post_action stage. Also note the job_id value of the failed job, which you will need to resolve the issue.

Troubleshooting Failures That Occur in the Pre_action Stage

1. Use the job_id value to get more information about the failure:
   
   ```
   dbcli describe-job -i <job_id>
   ```
2. Search for the error in the dcs-agent.log and dcs-agent-debug.log files (which are located in the /opt/oracle/dcs/log/ directory):
   
   For example:
   
   ```
   cd /opt/oracle/dcs/log
   grep -ir "DCS-10063:Failed to get node names from olsnodes." *
   ```
3. Using the information about the error recorded in the log file, correct the system configuration if possible.
4. Re-try the shape change operation. If the operation is still not successful, follow the instructions in Getting Additional Help on page 1664.

Getting Additional Help

If your failure occurs in the post_action stage, or if you are unable to resolve failures that occur in the pre_action stage, do the following:

1. Gather the information listed in the document Diagnostic Data Collection For Oracle Database Cloud Service Instance (OCI) (Doc ID 2397481.1)
2. Open a Support Request with My Oracle Support
Backup Failures on Exadata DB Systems

If your Exadata managed backup does not successfully complete, you can use the procedures in this topic to troubleshoot and fix the issue. The most common causes of backup failure are the following:

- The host cannot access Object Storage
- The database configuration on the host is not correct

The information that follows is organized by the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Determining the Problem on page 1665 to get started.

Determining the Problem

In the Console, a failed database backup either displays a status of Failed or hangs in the Backup in Progress or Creating state. If the error message does not contain enough information to point you to a solution, you can gather more information by using the dbaascli tool and by viewing the log files. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the backup failure

Database backups can fail during the RMAN configuration stage or during a running RMAN backup job. RMAN configuration tasks include validating object store connectivity, backup module installation, and RMAN configuration changes. The log files you examine depend on which stage the failure occurs.

1. Log on to the host as the root user.
2. Check the applicable log file:
   - If the failure occurred during RMAN configuration, navigate to the /var/opt/oracle/log/<database_name>/bkup/ directory and check the bkup.log file.
   - If the failure occurred during the backup job, navigate to the /var/opt/oracle/log/<database_name>/obkup/ directory and check the obkup.log file.

   **Note:**
   - Each execution of bkup and obkup commands generates a separate log file but bkup.log and obkup.log are symbolic links that point to the most recently generated log file.
   - Ensure that you check the log files on all of the Exadata DB system compute nodes because all nodes send backup pieces to Object Storage.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform. Occasionally you might need to restart the dcsagent program if it has the status of stop/waiting to resolve a backup failure. View the /opt/oracle/dcs/log/dcs-agent.log file to identify issues with the agent.

To restart the database service agent

1. From a command prompt, check the status of the agent:
   
   ```
   systemctl status dcsagent.service
   ```

2. If the agent is in the stop/waiting state, try to restart the agent:
   
   ```
   systemctl start dcsagent.service
   ```

3. Check the status of the agent again to confirm that it has the start/running status:
   
   ```
   systemctl status dcsagent.service
   ```
Object Store Connectivity Issues

Back up your database to Oracle Cloud Infrastructure Object Storage requires that the host can connect to the applicable Swift endpoint. Though Oracle controls the actual Swift user credentials for the storage bucket for managed backups, verifying general connectivity to Object Storage in your region is a good indicator that object store connectivity is not the issue. You can test this connectivity by using another Swift user.

To ensure your database host can connect to the object store

1. Create a Swift user in your tenancy. See Working with Auth Tokens on page 2456.
2. With the user you created in the previous step, use the following command to verify the host can access the object store.

```bash
curl -v -X HEAD -u <user_ID>:'<auth_token>' https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>
```

See Object Storage FAQ for the correct region to use. See Understanding Object Storage Namespaces on page 3395 for information about your Object Storage namespace.

3. If you cannot connect to the object store, refer to the Prerequisites on page 1320 section of the Managing Exadata Database Backups on page 1320 topic for information on configuring object store connectivity.

Host Issues

One or more of the following conditions on the database host can cause backups to fail:

Interactive Commands in the Oracle Profile

If an interactive command such as `oraenv`, or any command that might return an error or warning message, was added to the `.bash_profile` file for the grid or oracle user, Database service operations like automatic backups can be interrupted and fail to complete. Check the `.bash_profile` file for these commands, and remove them.

The File System Is Full

Backup operations require space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the space available for backups. If the file system has insufficient space, you can remove old log or trace files to free up space.

Incorrect Version of the Oracle Database Cloud Backup Module

Your system might not have the required version of the backup module (opc_installer.jar). See Unable to use Managed Backups in your DB System for details about this known issue. To fix the problem, you can follow the procedure in that section or simply update your DB system and database with the latest bundle patch.

Changes to the Site Profile File (glogin.sql)

Customizing the site profile file (`$ORACLE_HOME/sqlplus/admin/glogin.sql`) can cause managed backups to fail in Oracle Cloud Infrastructure. In particular, interactive commands can lead to backup failures. Oracle recommends that you not modify this file for databases hosted in Oracle Cloud Infrastructure.

Database Issues

An improper database state or configuration can lead to failed backups.

Database Not Running During Backup

The database must be active and running (ideally on all nodes) while the backup is in progress.
**To check that the database is active and running**

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database's instance status. The instance status must be **Open** for the backup to succeed. If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
alter database open;
```

**Archiving Mode Set to NOARCHIVELOG**

When you provision a new database, the archiving mode is set to ARCHIVELOG by default. This is the required archiving mode for backup operations. Check the archiving mode setting for the database and change it to ARCHIVELOG, if applicable.

**To check and set the archiving mode**

Open an SQL*Plus command prompt and enter the following command:

```
select log_mode from v$database;
```

If you need to set the archiving mode to ARCHIVELOG, start the database in **Mount** status (and not **Open** status), and use the following command at the SQL*Plus command prompt:

```
alter database archivelog;
```

Confirm that the `db_recovery_file_dest` parameter points to `+RECO`, and that the `log_archive_dest_1` parameter is set to USE_DB_RECOVERY_FILE_DEST.

For RAC databases, one instance must have the **Mount** status when enabling archivelog mode. To enable archivelog mode for a RAC database, perform the following steps:

1. Shut down all database instances:
   ```
srvctl stop database -d
```
2. Start one of the database instances in mount state:
   ```
srvctl start instance -d <db_unique_name> -i <instance_name> -o mount
```
3. Access the SQL*Plus command prompt:
   ```
sqlplus / as sysdba
```
4. Enable archive log mode:
   ```
alter database archivelog;
exit;
```
5. Stop the database:

```
srvctl stop instance -d <db_unique_name> -i <instance_name>
```

6. Restart all database instances:

```
srvctl start database -d <db_unique_name>
```

7. At the SQL*Plus command prompt, confirm the archiving mode is set to ARCHIVELOG:

```
select log_mode from v$database;
```

### Stuck Database Archiver Process and Backup Failures

Backups can fail when the database instance has a stuck archiver process. For example, this can happen when the flash recovery area (FRA) is full. You can check for this condition using the `srvctl status database -db <db_unique_name> -v` command. If the command returns the following output, you must resolve the stuck archiver process issue before backups can succeed:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Stuck Archiver
```

Refer to ORA-00257:Archiver Error (Doc ID 2014425.1) for information on resolving a stuck archiver process.

After resolving the stuck process, the command should return the following output:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Open
```

If the instance status does not change after you resolve the underlying issue with the device or resource being full or unavailable, try restarting the database using the `srvctl` command to update the status of the database in the clusterware.

### RMAN Configuration and Backup Failures

Editing certain RMAN configuration parameters can lead to backup failures in Oracle Cloud Infrastructure. To check your RMAN configuration, use the `show all` command at the RMAN command line prompt.

See the following list of parameters for details about RMAN the configuration settings that should not be altered for databases in Oracle Cloud Infrastructure.

**RMAN configuration settings that should not be altered**

```
CONFIGURE RETENTION POLICY TO RECOVERY WINDOW OF 30 DAYS;
CONFIGURE CONTROLFILE AUTOBACKUP ON;
CONFIGURE DEVICE TYPE 'SBT_TAPE' PARALLELISM 5 BACKUP TYPE TO COMPRESSED BACKUPSET;
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' PARMS 'SBT_LIBRARY=/var/opt/oracle/dbaas_acfs/<db_name>/opc/libopc.so, ENV=(OPC_PFILE=/var/opt/oracle/dbaas_acfs/<db_name>/opc/opc<db_name>.ora)';
CONFIGURE ARCHIVELOG DELETION POLICY TO BACKED UP 1 TIMES TO 'SBT_TAPE';
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
```
CONFIGURE ENCRYPTION FOR DATABASE ON;

**Loss of Object Store Wallet File and Backup Failures**

RMAN backups fail when an object store wallet file is lost. The wallet file is necessary to enable connectivity to the object store.

*To confirm that the object store wallet file exists and has the correct permissions*

1. Get the name of the database with the backup failure:

   ```sql
   SQL> show parameter db_name
   ```

2. Determine the file path of the backup config parameter file that contains the RMAN wallet information:

   ```bash
   locate opc_<database_name>.ora
   ```

   The default location is `/var/opt/oracle/dbaas_acfs/<database_name>/opc/opc<database_name>.ora`.

   For example:

   ```bash
   [root@khdyygw-mpjxb1Example /] # find / -name "opctestdb30.ora" -print
   /var/opt/oracle/dbaas_acfs/testdb30/opc/opctestdb30.ora
   ```

3. Find the file path to the wallet file in the backup config parameter file by inspecting the value stored in the `OPC_WALLET` parameter. To do this, navigate to the directory containing the backup config parameter file and use the following `cat` command:

   ```bash
   cat opc<database_name>.ora
   ```

   For example:

   ```bash
   [root@khdyygw-mpjxb1Example ]# cd /var/opt/oracle/dbaas_acfs/testdb30/opc/
   [root@khdyygw-mpjxb1Example ]# ls -altr *.ora
   opc3testdb30.ora
   [root@khdyygw-mpjxb1Example ]# cat opctestdb30.ora
   OPC_HOST=https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/dbbackupphx
   OPC_WALLET='LOCATION=file:/var/opt/oracle/dbaas_acfs/testdb30/opc/opc_wallet CREDENTIAL_ALIAS=alias_opc'
   OPC_CONTAINER=bUG3TFsSi8QzjWfuTxqqExample
   _OPC_DEFERRED_DELETE=false
   ```

4. Confirm that the `cwallet.sso` file exists in the directory specified in the `OPC_WALLET` parameter, and confirm that the file has the correct permissions. The file permissions should have the octal value of "600" (`-rw-------`). Use the following command:

   ```bash
   ls -ltr /var/opt/oracle/dbaas_acfs/<database_name>/opc/opc_wallet
   ```

   For example:

   ```bash
   [root@khdyygw-mpjxb1Example]# ls -altr /var/opt/oracle/dbaas_acfs/testdb30/opc/opc_wallet
   -rw------- 1 oracle oinstall 0 Oct 29 01:59 cwallet.sso.lck
   -rw------- 1 oracle oinstall 111231 Oct 29 01:59 cwallet.sso
   ```
TDE Wallet and Backup Failures

Incorrect TDE Wallet Location Specification

For backup operations to work, the $ORACLE_HOME/network/admin/sqlnet.ora file must contain the ENCRYPTION_WALLET_LOCATION parameter formatted exactly as follows:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet))
```

To check the TDE wallet location specification

Use the `cat` command to check the TDE wallet location specification. For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet))
```

Incorrect State of the TDE Wallet

Database backups fail if the TDE wallet is not in the proper state. The following scenarios can cause this problem:

**The ORACLE_UNQNAME environment variable was not set when the database was started using SQL*Plus**

If the database was started using SQL*Plus, and the ORACLE_UNQNAME environment variable was not set, the wallet is not opened correctly.

To fix the problem, start the database using the `srvctl` utility:

```
srvctl start database -d <db_unique_name>
```

**A pluggable database was added with an incorrectly configured master encryption key**

In a multitenant environment for Oracle Database versions that support PDB-level keystore, each PDB has its own master encryption key. For Oracle 18c databases, this encryption key is stored in a single keystore used by all containers. (Oracle Database 19c does not support a keystore at the PDB level.) After you create or plug in a new PDB, you must create and activate a master encryption key for it. If you do not do so, the STATUS column in the `v$encryption_wallet` view shows the value OPEN_NO_MASTER_KEY.

To check the master encryption key status and create a master key, do the following:

1. Review the the STATUS column in the `v$encryption_wallet` view, as shown in the following example:

```
SQL> alter session set container=pdb2;
Session altered.

SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;

WRL_TYPE   WRL_PARAMETER                                       STATUS   WALLET_TYPE
---------- ----------------------------------------------- -------- --------------------
FILE       /var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/      OPEN_NO_MASTER_KEY AUTOLOGIN
```
2. Confirm that the PDB is in READ WRITE open mode and is not restricted, as shown in the following example:

```
SQL> show pdbs
```

<table>
<thead>
<tr>
<th>CON_ID</th>
<th>CON_NAME</th>
<th>OPEN MODE</th>
<th>RESTRICTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>PDB$SEED</td>
<td>READ ONLY</td>
<td>NO</td>
</tr>
<tr>
<td>3</td>
<td>PDB1</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
<tr>
<td>4</td>
<td>PDB2</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
</tbody>
</table>

The PDB cannot be open in restricted mode (the RESTRICTED column must show NO). If the PDB is currently in restricted mode, review the information in the PDB_PLUG_IN_VIOLATIONS view and resolve the issue before continuing. For more information on the PDB_PLUG_IN_VIOLATIONS view and the restricted status, review the documentation on pluggable database for your Oracle database version.

3. Create and activate a master encryption key for the PDB:

- Set the container to the PDB:
  ```
  SQL> ALTER SESSION SET CONTAINER = pdb;
  ```
- Create and activate a master encryption key in the PDB by executing the following command:
  ```
  SQL> ADMINISTER KEY MANAGEMENT SET KEY USING TAG '<tag>' FORCE KEYSTORE IDENTIFIED BY <keystore-password> WITH BACKUP USING '<backup_identifier>';
  ```

Note the following:
- The USING TAG clause is optional and can be used to associate a tag with the new master encryption key.
- The WITH BACKUP clause is optional and can be used to create a backup of the keystore before the new master encryption key is created.

You can also use the dbaascli commands `dbaascli tde status` and `dbaascli tde rotate masterkey` to investigate and manage your keys.

4. Confirm that the status of the wallet has changed from OPEN_NO_MASTER_KEY to OPEN by querying the `v$encryption_wallet` view as shown in step 1.

**Incorrect Configuration Related to the TDE Wallet**

Configuration parameters related to the TDE wallet can cause backups to fail.

*To check configuration related to the TDE wallet*

Confirm that the wallet status is open and the wallet type is auto login by checking the `v$encryption_wallet` view. For example:

```
SQL> select status, wrl_parameter, wallet_type from v$encryption_wallet;
```

<table>
<thead>
<tr>
<th>STATUS</th>
<th>WRL_PARAMETER</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>/var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/</td>
<td>AUTOLOGIN</td>
</tr>
</tbody>
</table>
For pluggable databases (PDBs), ensure that you switch to the appropriate container before querying `v$encryption_wallet` view. For example:

```
[oracle@paulo ~]$ sqlplus / as sysdba
SQL> alter session set container=pdb1;
Session altered.
SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;
```

<table>
<thead>
<tr>
<th>WRL_TYPE</th>
<th>WRL_PARAMETER</th>
<th>STATUS</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>/var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/</td>
<td>OPEN</td>
<td>AUTOLOGIN</td>
</tr>
</tbody>
</table>

**Missing TDE Wallet File**

The TDE wallet file (`ewallet.p12`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[root@khdyygw-mpjxb1example /]# ls -altr /var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet/ewallet.p12
```

```
total 76
-rw------ 1 oracle oinstall 5467 Oct 1 20:17 ewallet.p12
```

The TDE wallet file should have file permissions with the octal value "600" (`-rw-------`), and the owner of this file should be a part of the `oinstall` operating system group.

**Missing Auto Login Wallet File**

The auto login wallet file (`cwallet.sso`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[root@khdyygw-mpjxb1example /]# ls -altr /var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet/cwallet.sso
```

```
total 76
-rw------ 1 oracle oinstall 5512 Oct 1 20:18 cwallet.sso
```

The auto login wallet file should have file permissions with the octal value "600" (`-rw-------`), and the owner of this file should be a part of the `oinstall` operating system group.

**Obtaining Further Assistance**

If you were unable to resolve the problem using the information in this topic, follow the instructions in Diagnostic Data Collection For Oracle Database Cloud Service Instances (OCI-C) (Doc ID 2219701.1) to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

**Deprecated Database Service APIs**

This topic lists deprecated APIs for the Database service.
**Deprecated Exadata Cloud Service APIs**

Oracle Cloud Infrastructure's Exadata DB system APIs were deprecated on November 15, 2020. Existing Exadata systems can be converted to the [new Exadata resource model](#) to use the new APIs. See [Switching an Exadata DB System to the New Resource Model and APIs](#) on page 1228 for more information.

**Important!** Support for the Exadata DB system APIs will end on **May 15, 2021**. Oracle recommends that you migrate your Exadata Cloud Service instances to the new resource model APIs as soon as possible. Converting to the new resource model does not involve any system downtime.

<table>
<thead>

**Deprecated Autonomous Data Warehouse APIs**

Oracle Cloud Infrastructure's Autonomous Data Warehouse APIs were deprecated on Feb. 15, 2019.

**Important!** Support for these Autonomous Data Warehouse APIs will end on **Jul. 1, 2020**. Oracle recommends that you migrate your database workloads to the replacement APIs as soon as possible.

<table>

</table>
This chapter explains how to create and manage your DNS zones and guide traffic to your endpoints based on various conditions.

DNS and Traffic Management

**DNS**
The DNS service helps you create and manage your DNS zones.

**Traffic Management Steering Policies**
Traffic Management helps you guide traffic to your endpoints based on various conditions, including endpoint health and the geographic origins of DNS requests.

**DDoS Protection**
DDoS Protection is an always-on detection and mitigation platform for common DDoS volumetric attacks. The service protects against common layer 3 and 4 attacks like SYN floods, UDP floods, ICMP floods, and NTP Amplification attacks. DDoS Protection is included with all Oracle Cloud Infrastructure accounts and no configuration or monitoring is required.

**Overview of the DNS Service**
The Oracle Cloud Infrastructure Domain Name System (DNS) service lets you create and manage your DNS zones. You can create zones, add records to zones, and allow Oracle Cloud Infrastructure's edge network to handle your domain's DNS queries.

See Supported Resource Records on page 1686 for additional information.

**DNS Service Components**
The following list describes the components used to build a DNS zone and make it accessible from the internet.

**DOMAIN**
Domain names identify a specific location or group of locations on the Internet as a whole. A common definition of "domain" is the complete portion of the DNS tree that has been delegated to a user's control. For example, example.com or oracle.com.

**ZONE**
A zone is a portion of the DNS namespace. A Start of Authority record (SOA) defines a zone. A zone contains all labels underneath itself in the tree, unless otherwise specified.
LABEL

Labels are prepended to the zone name, separated by a period, to form the name of a subdomain. For example, the "www" section of www.example.com or the "docs" and "us-ashburn-1" sections of docs.us-ashburn-1.oraclecloud.com are labels. Records are associated with these domains.

CHILD ZONE

Child zones are independent subdomains with their own Start of Authority and Name Server (NS) records. The parent zone of a child zone must contain NS records that refer DNS queries to the name servers responsible for the child zone. Each subsequent child zone creates another link in the delegation chain.

RESOURCE RECORDS

A record contains specific domain information for a zone. Each record type contains information called record data (RDATA). For example, the RDATA of an A or AAAA record contains an IP address for a domain name, while MX records contain information about the mail server for a domain. OCI normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input. For more information about RDATA, please see Supported DNS Resource Record Types.

DELEGATION

The name servers where your DNS is hosted and managed.

Ways to Access the DNS Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about available DNS service metrics and how to view them, see DNS Metrics on page 1704.

DNS Service Capabilities and Limits

The Oracle Cloud Infrastructure DNS service is limited to 1000 zones per account and 25,000 records per zone. Customers with zone and record size needs exceeding these values are encouraged to contact support at support.oracle.com. Zone file uploads are limited to 1 megabyte (MB) in size per zone file. If your zone file is larger than 1 MB, you will need to split the zone file into smaller batches to upload all of the zone information.
Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for DNS, see Details for the DNS Service.

Permissions are required for managing DNS. The level of access is cumulative as you go from inspect > read > use > manage. For example, the read verb covers permissions to read and inspect. The manage verb covers permissions for inspect, read, update, create, delete, and move.

Policy examples:

- To enable all operations on zones for a specific user group:
  
  Allow group <GroupName> to manage dns in tenancy <TenancyName>

- To enable a specific group to read zones:
  
  Allow group <GroupName> to read zones in tenancy <TenancyName>

- To create a read only DNS management group:
  
  Allow group <GroupName> to read dns in tenancy <TenancyName>

Using the DNS Management Overview to Manage DNS Services

This topic describes the Overview page in the DNS Management section of the Oracle Cloud Infrastructure Console. The Overview provides information on all of the available DNS services.

Manage DNS Services Section

The Manage DNS Services section provides you with details on Zones and Traffic Management Steering Policies and links to set them up.

Public DNS Zones hold the trusted DNS records that will reside on Oracle Cloud Infrastructure's nameservers. You can create public zones with publicly available domain names. Private DNS zones contain domain names that resolve DNS queries for private IP addresses within a VCN. You can create private zones to define your own domain name for private address resolution.

Traffic Management Steering Policies help you guide traffic to your endpoints based on various conditions, including endpoint health and the geographic origins of DNS requests.

Service Health and Documentation Section

The Service Health tile displays the availability status of all DNS zone management systems in the selected region, and allows you to easily navigate to the Console's Oracle Cloud Infrastructure status page to check the availability status of all Oracle Cloud Infrastructure services, by region.

The Documentation list provides quick access to information about DNS offerings.

Supporting Services Section

The Supporting Services section provides links to additional DNS Management services available in the Console.

- Private Views allows you to logically group a set of private DNS zones.
- HTTP Redirects allows you to redirect HTTP traffic to another URL.
- TSIG Keys ensures that DNS packets originate from an authorized sender.
Getting Started Section

To make it easier to set up DNS Management, the Console has the following quickstart links to set up DNS services.

- **Set Up a Zone** creates and publishes a zone, complete with the necessary records.
- **Private DNS** allows you to define your own domain name for private endpoints.
- **Set Up Steering Policies** allows you to define the traffic management behavior for your zones.

Getting Started with DNS

If you're new to Oracle Cloud Infrastructure DNS, this topic gives guidance on how to proceed.

**What is DNS?**

The Domain Name System (DNS) translates human-readable domain names to machine-readable IP addresses. A DNS nameserver stores the DNS records for a zone, and responds with answers to queries against its database. When you type a domain name into your browser, your operating system queries several DNS nameservers until it finds the authoritative nameserver for that domain. The authoritative nameserver then responds with an IP address or other requested record data. The answer is then relayed back to your browser and the DNS record is resolved to the web page.

**Creating a Zone**

In this step, you will create a zone. A zone holds the trusted DNS records that will reside on Oracle Cloud Infrastructure’s nameservers.

*To add a zone*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click **Create Zone**.
3. In the **Create Zone** dialog box, choose one of the following methods:
   - **Manual** - Enter the following:
     - **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
     - **Zone Type**: If you want to control the zone contents directly within Oracle Cloud Infrastructure, select **Primary**. If you want Oracle Cloud Infrastructure to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.
   - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file, see **Formatting a Zone File**.
4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.

**Delegating Your Zone**

In this step, you will delegate your domain with your registrar. Delegating your domain with your domain's registrar makes your Oracle Cloud Infrastructure hosted zone accessible through the internet.

*To delegate a zone*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.
5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

   **Note:**

   Once delegation has completed, allow 24 hours for your delegation to propagate across the internet.
To add a zone record

**Tip:**

There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the **Zone Name** in which you want to add a record. Zone details and a list of records appear.

**Tip:**

You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see **Supported Resource Records** on page 1686.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.
7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

**Common DNS Zone Record Types**

For a complete list of records supported by Oracle Cloud Infrastructure DNS, see **Supported Resource Records** on page 1686.

**A**

An address record used to point a hostname to an IPv4 address. For more information about A records, see **RFC 1035**.

**AAAA**

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see **RFC 3596**.

**CNAME**

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see **RFC 1035**.

**Note:**

Per **RFC 1912**, CNAMEs cannot be placed at the apex of the zone.

**MX**

A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see **RFC 1035**.

**TXT**

A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see **RFC 1035**.

**Testing DNS Using BIND's dig Tool**

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.
For more information on using dig to test your DNS, see Testing DNS Using BIND'S dig Tool on page 1696.

Managing DNS Service Zones

The Oracle Cloud Infrastructure DNS service enables you to manage zones within the Console.

Using the Console

Managing Zones and Zone Records

For information on creating private DNS zone, see Private DNS on page 1698.

To add a zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click Create Zone.
3. In the Create Public Zone dialog box, choose one of the following methods:
   - Manual - Enter the following:
     - Zone Name: Enter the name of a zone you want to create. Avoid entering confidential information.
     - Zone Type:
       - Primary - Select this option if you want to control the zone contents directly within Oracle Cloud Infrastructure.
       - Secondary - Select this option if you want Oracle Cloud Infrastructure to pull zone contents from an external server. Enter your Master Server IP address. Optionally, you can select an existing TSIG key in a specified compartment that is associated with the master server. For more information, see Managing TSIG Keys on page 1694.
   - Import - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File.
4. Click Create.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.

To update a secondary zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the secondary Zone Name you want to update.
   
   Tip:
   You can use the Zone Type sort filter to sort zone type alphanumerically in ascending or descending order.
3. Click Master Server IPs.
4. Select the checkbox for the Master Server IP you want to update, and then select Edit from the Actions drop-down menu.
5. Make the needed changes, and then click Submit.
6. (Optional) Click Add Master Server to add another Master Server IP address.
7. Click Publish Changes.
8. In the confirmation dialog box, click Publish Changes.

Tip:
For OCI to transfer data from your zone, your nameservers must be able to accept a transfer request from the following IP addresses: 208.78.68.65, 204.13.249.65, 2600:2001:0:1::65, 2600:2003:0:1::65
**To delete a zone**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deletion permanently removes a zone from your DNS service.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Select the checkbox for the zone you want to delete.
3. Click **Delete**. The zone is staged for deletion.
4. Click **Publish Changes** to delete the zone.
5. In the confirmation dialog box, click **Publish Changes**.

**To add a zone record**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the **Zone Name** in which you want to add a record. If you are adding a record to a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.</td>
</tr>
</tbody>
</table>

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see **Supported Resource Records** on page 1686.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.</td>
</tr>
</tbody>
</table>

7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

**To update a zone record**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protected Records</td>
</tr>
<tr>
<td>You can change various components of the records within your zones, such as time-to-live (TTL) and relevant RDATA. However, some records contain information that cannot be changed. You can attempt changes to such records through the <strong>Actions</strong> menu, but the system might not permit updates to some fields.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the **Zone Name** in which you want to update a record. If you are updating a record in a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

   **Tip:**

   To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. To help find a record, you can use the following filter options:
   - Enter the name of the record's domain in the **Search** field.
   - To find unpublished records, select the **Staged** check box.
   - To find published records, select the **Unstaged** check box.
   - Use the **Is Protected** sort filter to sort by records that are protected.
   - Use the **Record Type** sort filter to sort records.

4. Select the check box for the record you want to update, and select **Edit** from the **Actions** drop-down menu.

5. In the **Edit Record** dialog box, make the needed changes, and then click **Submit**.

   **Note:**

   When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.

6. Click **Publish Changes**.

7. In the confirmation dialog box, click **Publish Changes**.

**Reverting Changes Before Publishing**

You can revert records to their current published state before you publish changes. Once a record has been published, it cannot be reverted. Select the check box for the record you want to revert, and then select **Revert** from the **Actions** drop-down menu.

**To delete a zone record**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.

2. Click the **Zone Name** in which you want to delete a record. If you are deleting a record in a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

   **Tip:**

   To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. Select the check box for the record you want to delete, and then select **Delete** from the **Actions** drop-down menu.

4. Click **Publish Changes**.

5. In the confirmation dialog box, click **Publish Changes**.

**To delegate a zone**

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.

2. Click the **Zone Name** for the zone you want to delegate. Zone details and a list of records appear.

3. Use the **Type** sort filter to locate the NS records for your zone.

4. Note the name servers in the RDATA field within each NS record.

5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.
To move a zone to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. In the List Scope section, select a compartment.
3. Find the zone in the list, click the the Actions icon (three dots), and then click Choose New Compartment.
4. Choose the destination compartment from the list.
5. Click Move Resource.

For more information, see Managing Compartments on page 2431.

To add a TSIG key

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the secondary Zone Name you want to update. Zone details and a list of master server IPs appear.
3. Under Zone Information, click Add beside the TSIG field.
4. In the Add TSIG Key dialog box, select one of the following options:
   * Create New TSIG Key - Enter the following information:
     * Name: The name of the key used in domain name syntax. The name should reflect the names of the hosts and uniquely identify the key among a set of keys these two hosts may share at any given time.
     * Algorithm: Select the public key's algorithm used to encrypt or decrypt data. Applicable algorithms include hmac-md5, hmac-sha1, hmac-sha224, hmac-sha256, hmac-h384, and hmac-sha512.
     * Secret: The base64 string encoding the binary shared secret that corresponds to the key. A maximum value of 255 characters is allowed.
     * Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
   * Select Existing TSIG Key - Select a TSIG Key from the drop-down menu.
5. Click Add.
6. Click Publish.
7. In the confirmation dialog box, click Publish Changes.

For more information, see Managing TSIG Keys on page 1694.

To remove a TSIG key from a zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the secondary Zone Name you want to update. Zone details and a list of master server IPs appear.
3. Under Zone Information, click Remove beside the TSIG key name.
4. Click Publish.
5. In the confirmation dialog box, click Publish Changes. Changes cannot be made to this zone while it is updating.

For more information, see Managing TSIG Keys on page 1694.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage your DNS zones:

* GetZone
* ListZones
* CreateZone
* UpdateZone
* DeleteZone
* PatchZoneRecords (add or delete records)
Setting Up Reverse DNS Zones

Reverse DNS, or rDNS, maps an IP address to a hostname. Reverse DNS serves a number of different purposes from email to network troubleshooting. Some of the benefits include:

- Adding a label for network troubleshooting tools such as traceroute.
- Populating the “Received:” header field in an SMTP email.
- Checking for generic reverse DNS such as 1-2-3-4.example.com to identify spammers.
- Verifying a relationship between the owner of a domain name and the owner of the server (IP address).
- Writing a human readable hostname to the log files for system monitoring tools.
- Determining which hostname is affected when maintenance is performed on an IP address.

Before getting started with setting up reverse DNS within your Oracle Cloud Infrastructure account, contact your IP provider and confirm that they allow delegation of your reverse DNS zone. If they do not allow delegation, typically they can host your pointer record (PTR) for you and no reverse DNS configurations are required within your Oracle Cloud Infrastructure account. If they do allow delegation, confirm the exact syntax of the reverse DNS hostname with them, as some providers use slashes and some use dashes. Additionally, if you are delegating a reverse DNS zone, confirm that this zone matches exactly what you configure in your Oracle Cloud Infrastructure account as this is necessary in order for delegation to work properly.

After you create and publish your reverse DNS zone and PTR records, you can update your reverse DNS zone delegation with your IP provider. Delegation changes are not required with your domain registrar with a reverse DNS zone.

Setting up a reverse DNS zone is different for the two types of IP address blocks. Use the following procedures to set up a reverse DNS zone for your IP address block type.

Setting Up Reverse DNS for Classless Address Block (Partial Range of IP Addresses)

To find your reverse DNS zone name using classless address block

1. Make a note of your network IP address. For example, 192.168.15.224/27.
2. Remove the netmask portion of the address. This is the number after the slash (/). For example, remove the ‘27’ after your IP address, 192.168.15.224/27.
3. Reverse the order of the remaining octets. For example, 224.15.168.192.
4. Append ‘in-addr.arpa’ to the end of the IP address. For example, 224.15.168.192.in-addr.arpa.

5. Add the netmask back into the address. For example, 224-27.15.168.192.in-addr.arpa.

In this example, 224-27.15.168.192.in-addr.arpa is your reverse DNS zone name.

To create your DNS zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click Create Zone.
3. In the Create Zone dialog box, choose one of the following methods:

- **Manual** - Enter the following:
  
  a. **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
  
  b. **Zone Type**: If you want to control the zone contents directly within OCI, select **Primary**. If you want OCI to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.

- **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see **Formatting a Zone File** on page 1689.

4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

**To create a pointer record (PTR) for each host address**

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.

   **Tip:**
   
   You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the Add Record dialog box, select the **PTR – Pointer** record type from the drop-down list. Enter the following information:

   - **Name**: Optional. Name of the subdomain.
   - **TTL**: Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
   - **TTL Unit**: Select the unit of time used for the TTL value.
   - **RData Mode**: Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, *example.com*) that the record is going to point to in the RDATA field.
   - **Hostname**: The web address of your zone.

   For more information about the PTR record type, see **Supported Resource Records** on page 1686.

5. Click **Submit**.
6. Once your record has been added, click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

**To add CNAME records for each host at your ISP**

If your IP provider does not automatically configure the CNAME record on your behalf, you will need to add a CNAME record for each host at your ISP. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Make a note of the IP address and your desired CNAME for each host in your new reverse DNS zone.
2. Contact your ISP and request that they append a CNAME record for each host in your Oracle Cloud Infrastructure DNS zone to your account with them.
3. Test the reverse DNS path by running the following command:

   ```
   dig -x <insert any regular forward-formatted IP address from the zone> +trace
   ```

   See **Testing DNS Using BIND’S dig Tool** on page 1696 for more information.
The returned information should show that your reverse domain is now being resolved.

To update your zone delegation

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar (usually the website where you purchased your domain, such as GoDaddy.com or Bluehost.com).

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the Type sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

Setting Up Reverse DNS for Full Address Block

To find your reverse DNS zone name using full address block

1. Make a note of your network IP address. For example, 192.168.15.0.
2. Remove the netmask portion of the address (the last number in the set of 4). For example, 192.168.15.
3. Reverse the order of the remaining three octets. For example, 15.168.192.
4. Append ‘in-addr.arpa’ to the end. For example, 15.168.192.in-addr.arpa

In this example, 15.168.192.in-addr.arpa is your reverse DNS zone name.

To create your DNS zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click Create Zone.
3. In the Create Zone dialog box, choose one of the following methods:
   • Manual - Enter the following:
     a. Zone Name: Enter the name of a zone you want to create. Avoid entering confidential information.
     b. Zone Type: If you want to control the zone contents directly within OCI, select Primary. If you want OCI to pull zone contents from an external server, select Secondary and enter your Zone Master Server IP address.
   • Import - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File on page 1689.
4. Click Submit.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

To create a pointer record (PTR) for each host address

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.

   Tip:
   You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click Add Record.
4. In the Add Record dialog box, select the **PTR – Pointer** record type from the drop-down list. Enter the following information:

   a. **Name**: Optional. Name of the subdomain.
   
   b. **TTL**: Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
   
   c. **TTL Unit**: Select the unit of time used for the TTL value.
   
   d. **RData Mode**: Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, `example.com`) that the record is going to point to in the RDATA field.
   
   e. **Hostname**: The web address of your zone.

   For more information about the PTR record type, see [Supported Resource Records](#) on page 1686.

5. Click **Submit**.

6. Once your record has been added, click **Publish Changes**.

7. In the confirmation dialog box, click **Publish Changes**.

To update your zone delegation

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

**Supported Resource Records**

The Oracle Cloud Infrastructure DNS service supports many resource record types. The following list provides a brief explanation of the purpose of each supported record type. Avoid entering confidential information when entering record data. The RFC links direct you to further information about the record types and data structure.

**Note About RDATA**

Oracle Cloud Infrastructure normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input.

**Example:**

The RDATA for the ALIAS, CNAME, DNAME, MX, and NS record types may contain one or more absolute domain names. If the specified RDATA for one of these record types does not end in a dot or period to represent the root, the period will be added.

```
```

You can use various DNS libraries to normalize your RDATA before input.

<table>

DNS Resource Record Types

A
An address record used to point a hostname to an IPv4 address. For more information about A records, see RFC 1035.

AAAA
An address record used point a hostname at an IPv6 address. For more information about AAAA records, see RFC 3596.

ALIAS
A private pseudo-record that allows CNAME functionality at the apex of a zone.

CAA
A Certification Authority Authorization record allows a domain name holder to specify one or more Certification Authorities authorized to issue certificates for that domain. For more information about CAA records, see RFC 6844.

CDNSKEY
A Child DNSKEY moves a CDNSSEC key from a child zone to a parent zone. The information provided in this record must match the CDNSKEY information for your domain at your other DNS provider. This record is automatically created if you enable DNSSEC on a primary zone in Oracle Cloud Infrastructure DNS. For more information about CDNSKEY, see RFC 7344.

CDS
A Child Delegation Signer record is a child copy of a DS record, for transfer to a parent zone. For more information about CDS records, see RFC 7344.

CERT
A Certificate record stores public key certificates and related certificate revocation lists in the DNS. For more information about CERT records, see RFC 2538 and RFC 4398.

CNAME
A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see RFC 1035.

CSYNC
A Child-to-Parent Synchronization record syncs records from a child zone to a parent zone. For more information about CNAME records, see RFC 7477.

DHCID
A DHCP identifier record provides a way to store DHCP client identifiers in the DNS to eliminate potential hostname conflicts within a zone. For more information about DHCID, see RFC 4701.

DKIM
A Domain Keys Identified Mail is a special TXT record set up specifically to supply a public key used to authenticate arriving mail for a domain. For more information about DKIM records, see RFC 6376.

DNAME
A Delegation Name record has similar behavior to a CNAME record, but allows you to map an entire subtree beneath a label to another domain. For more information about DNAME records, see RFC 6672.

DNSKEY
A DNS Key record documents public keys used for DNSSEC. The information in this record must match the DNSKEY information for your domain at your other DNS provider. For more information about DNSKEY records, see RFC 4034.
DS
A Delegation Signer record resides at the top-level domain and points to a child zone's DNSKEY record. DS records are created when DNSSEC security authentication is added to the zone. For more information about DS records, see RFC 4034.

IPSECKEY
An IPSec Key record stores public keys for a host, network, or application to connect to IP security (IPSec) systems. For more information on IPSECKEY records, see RFC 4025.

KEY
A Key record stores a public key that is associated with a domain name. Currently only used by SIG and TKEY records. IPSECKEY and DNSKEY have replaced key for use in IPSec and DNSSEC, respectively. For more information about KEY records, see RFC 4025.

KX
A Key Exchanger record identifies a key management agent for the associated domain name with some cryptographic systems (not including DNSSEC). For more information about KX records, see RFC 2230.

LOC
A Location record stores geographic location data of computers, subnets, and networks within the DNS. For more information about LOC records, see RFC 1876.

MX
A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see RFC 1035.

NS
A Nameserver record lists the authoritative nameservers for a zone. Oracle Cloud Infrastructure DNS automatically generates NS records at the apex of each new primary zone. For more information about NS records, see RFC 1035.

PTR
A Pointer record reverse maps an IP address to a hostname. This behavior is the opposite of an A Record, which forward maps a hostname to an IP address. PTR records are commonly found in reverse DNS zones. For more information about PTR records, see RFC 1035.

PX
A resource record used in X.400 mapping protocols. For more information about PX records, see RFC 822 and RFC 2163.

SOA
A Start of Authority record specifies authoritative information about a DNS zone, including:
- The primary nameserver.
- The email of the domain administrator.
- The domain serial number.
- Several timers relating to refreshing the zone.

The Oracle Cloud Infrastructure DNS automatically generates an SOA record when a zone is created. For more information about SOA records, see RFC 1035.
DNS and Traffic Management

SPF
A Sender Policy Framework record is a special TXT record used to store data designed to detect email spoofing. For more information about SPF records, see RFC 4408.

SRV
A Service Locator record allows administrators to use several servers for a single domain. For more information about SRV records, see RFC 2782.

SSHFP
An SSH Public Key Fingerprint record publishes SSH public host key fingerprints using the DNS. For more information about SSHFP records, see RFC 6594.

TLSA
A Transport Layer Security Authentication record associates a TLS server certificate, or public key, with the domain name where the record is found. This relationship is called a TLSA certificate association. For more information about TLSA records, see RFC 6698.

TXT
A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Formatting a Zone File
A zone file is a text file that describes a DNS zone. The BIND file format is the industry preferred zone file format and has been widely adopted by DNS server software. The format is defined in RFC 1035.

Example of a Zone File
This is an example of a zone file downloaded from Oracle Cloud Infrastructure DNS.

```
$ORIGIN example.com.
@ 3600 SOA ns1.p30.oraclecloud.net. (zone-admin.dyndns.com. ; address of responsible party
  2016072701 ; serial number
  3600 ; refresh period
  600 ; retry period
  604800 ; expire time
  1800 ) ; minimum ttl
86400 NS ns1.p68.dns.oraclecloud.net.
86400 NS ns2.p68.dns.oraclecloud.net.
86400 NS ns3.p68.dns.oraclecloud.net.
86400 NS ns4.p68.dns.oraclecloud.net.
3600 MX 10 mail.example.com.
3600 MX 20 vpn.example.com.
3600 MX 30 mail.example.com.
60 A 204.13.248.106
3600 TXT "v=spf1 includespf.oraclecloud.net ~all"
mail 14400 A 204.13.248.106
vpn 60 A 216.146.45.240
webapp 60 A 216.146.46.10
webapp 60 A 216.146.46.11
www 43200 CNAME example.com.
```

Note:

Record Classes
DNS and Traffic Management

In the example zone file above, no record classes are displayed. Oracle Cloud Infrastructure DNS only works with Internet (IN) class records but omits the class information in zone files for efficiency purposes.

Anatomy of a Zone File

$ORIGIN indicates a DNS node tree and will typically start a DNS zone file. Any host labels below the origin will append the origin hostname to assemble a fully qualified hostname. Any host label within a record that uses a fully qualified domain terminating with an ending period will not append the origin hostname.

Example: With $ORIGIN example.com., any record where the host label field is not followed by a period, example.com. will be appended to them.

The “@” symbol is a special label that indicates the $ORIGIN should replace the “@” symbol. This is typically used for the apex of a zone.

SOA Record – The $ORIGIN is followed by the zone’s Start Of Authority (SOA) record. An SOA record is required for each zone. It contains the name of the zone, the e-mail address of the party responsible for administering the domain’s zone file, the current serial number of the zone, the primary nameserver of the zone, and various timing elements (measured in seconds).

SOA Record Format

```
@     IN     SOA    {primary-name-server}     {hostmaster-email} (
{serial-number}
{time-to-refresh}
{time-to-retry}
{time-to-expire}
{minimum-TTL} )
```

- **Primary Name Server** – The nameserver that contains the original zone file and not an AXFR transferred copy.
- **Hostmaster Email** – Address of the party responsible for the zone. A period “.” is used in place of an “@” symbol. For email addresses that contain periods, replace the periods with a slash “/”.
- **Serial Number** – Version number of the zone. The serial number will increase with each subsequent update to your zone.
- **Time To Refresh** – How long a nameserver should wait prior to checking for a serial number increase within the primary zone file, in seconds. An increased serial number detected by a secondary DNS nameserver means a transfer is needed to sync your records. Only applies to zones using secondary DNS.
- **Time To Retry** – How long a nameserver should wait prior to retrying to update a zone after a failed attempt, in seconds. Only applies to zones using secondary DNS.
- **Time To Expire** – How long a nameserver should wait prior to considering data from a secondary zone invalid and stop answering queries for that zone, in seconds. Only applies to zones using secondary DNS.
- **Minimum TTL** – Minimum Time To Live (TTL). How long a nameserver or resolver should cache a negative response, in seconds.

Anatomy of a Record Within a Zone File

A zone file is a collection of resource records with each record entry described in the following sequence:

<table>
<thead>
<tr>
<th>Format:</th>
<th>Host Label</th>
<th>TTL</th>
<th>Record Class</th>
<th>Record Type</th>
<th>Record Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>example.com.</td>
<td>60</td>
<td>IN</td>
<td>A</td>
<td>104.255.228.125</td>
</tr>
</tbody>
</table>

- **Host Label** – A host label helps to define the hostname of a record and whether the $ORIGIN hostname will be appended to the label. Fully qualified hostnames terminated by a period will not append the origin.
- **TTL** – The Time To Live (TTL) is the amount of time that a DNS record will be cached by an outside DNS server or resolver, in seconds.
- **Record Class** – There are three classes of DNS records: IN (Internet), CH (Chaosnet), and HS (Hesiod). Oracle Cloud Infrastructure DNS only uses the IN class of records.
• **Record Type** – The type of a record, such as CNAME, AAAA, or TXT.
• **Record Data** – The data within a DNS answer, such as an IP address, hostname, or other information. Different record types will contain different types of record data.

**Amending Zone Files Exported from GoDaddy.com for Import**

GoDaddy.com exports zone files in a proprietary format. To get the Oracle Cloud Infrastructure DNS service to correctly import a zone file exported from GoDaddy.com, you must directly alter the file. Follow these instructions to update the zone file.

1. Export your zone file from GoDaddy.com. Reference GoDaddy.com's documentation to see how this is done.
2. Open the file in your preferred text editor.
3. Prepend a new line to the file before the SOA record with the following information, including the trailing period: $ORIGIN [yourdomain].
4. Once the file has been amended, save the changes to the file and use the zone import function to import the file into your DNS configuration. For more information about zone import, see Managing DNS Zones.

**Note:**

If your zone file includes dynamic A records, such as @ 600 IN A GoCentral Published Site, you will need to amend these records with the correct IP addresses of your website. Please contact GoDaddy.com for information about how to obtain this information. Example: @ 600 IN A 192.0.2.255

**Example:**

This is an example of a zone file exported from GoDaddy.com. The code in bold is the code that needs to be removed from the file for it to be eligible for import into Oracle Cloud Infrastructure DNS.

**Tip:**

Placing a semi-colon at the beginning of a line is valid comment syntax for a zone file, per RFC 1035, but for ease of use and formatting it is recommended to remove the large section of comments from the beginning of the zone file provided by GoDaddy.com, as shown below.

```plaintext
Domain: example.com
; Exported (y-m-d hh:mm:ss): 2019-01-10 13:05:04
;
; This file is intended for use for informational and archival purposes ONLY and MUST be edited before use on a production DNS server.
;
; In particular, you must update the SOA record with the correct authoritative name server and contact e-mail address information, and add the correct NS records for the name servers which will be authoritative for this domain.
;
; For further information, please consult the BIND documentation located on the following website:
;
; http://www.isc.org/
;
; And RFC 1035:
;
; http://www.ietf.org/rfc/rfc1035.txt
;
; Please note that we do NOT offer technical support for any use of this zone data, the BIND name server, or any other third-party DNS software.
;```
Below is an example of an amended zone file ready to import into Oracle Cloud Infrastructure DNS. The code in bold needs to be prepended to your zone file before import.

$ORIGIN example.com.
example.com. 3600 IN SOA ns41.domaincontrol.com. dns.net. ( 2018122702 28800 7200 604800 3600 )

; A Records
@    600  IN     A   192.0.2.249
blog 10800 IN A 192.0.2.255
dev 1800 IN A 192.0.2.254
dev01 1800 IN A 192.0.2.253
dev02 1800 IN A 192.0.2.252
dev03 1800 IN A 192.0.2.251
dev04 1800 IN A 192.0.2.250

; CNAME Records
abc123b432dc7785b7ef31f04f25c3e71 1800 IN CNAME verify.bing.com.
akamai  600   IN     CNAME   www.example.com.edgekey.net.
email   3600 IN CNAME email.secureserver.net.

; MX Records

@     604800 IN MX 10 aplxe.l.google.com.

; TXT Records
@     3600 IN TXT "google-site-verification=3J82-80dbMyCo5Q5C1G11JszeOnZPGCSY1HcPcXg"

Below is an example of an amended zone file ready to import into Oracle Cloud Infrastructure DNS. The code in bold needs to be prepended to your zone file before import.
Managing HTTP Redirects

The HTTP Redirect service allows you to redirect HTTP traffic to another URL. You can use HTTP Redirect to:

- Redirect all HTTP traffic for an entire zone to another zone. For example, if a company owns example.net and example.com, HTTP Redirect lets the company redirect all HTTP traffic for example.net to example.com. This is a one-to-one mapping; wildcards are not supported.
- Redirect a specific subdomain to an HTTP URL. For example, test.example.com can be redirected to http://example.net/test/test.php.
- Redirect a subdomain to a URL with a port number. For example, camera.example.com can be redirected to http://office.example.com:8080 so a user can view their camera system without typing in the port number each time.
- Permanently redirect a domain name that has been deprecated by displaying a 301 response code. Permanently redirecting a domain name informs search engines and browsers what to do with the information.

Required IAM Policies

To work with HTTP Redirects, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions that follow. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would allow a specific group to manage HTTP Redirects:

```
Allow group <GroupName> to manage http-redirects in compartment <CompartmentName>
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for HTTP Redirect, see Details for the WAF Service on page 2353.

Using the Console

To create an HTTP redirect

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click HTTP Redirects.
2. Select a zone.
3. Click Create HTTP Redirect.
4. In the Create Redirect dialog box, enter the following information:
   - **Name:** (Optional) Enter the name of the redirect zone you want to create. Avoid entering confidential information.
   - **Select a Zone:** (Optional) Select a zone from a list of configured zones. If the Create DNS Record check box is selected, the zone will be used to build an alias record for the redirect.
   - **Domain:** Enter the domain name from which traffic is redirected.
   - **Target -** Enter the following information for the endpoint where the traffic will be redirected:
     - **Protocol:** The network protocol used to interact with the target.
     - **Host:** The hostname of the target.
     - **Port:** (Optional) The port used to connect to the endpoint. The default is 80 for HTTP and 443 for HTTPS.
     - **Path:** (Optional) The specific path on the target for the redirect. A value of `{path}` will copy the path from the incoming request.
     - **Query:** (Optional) The query component of the target URL (for example, "?redirected" in "https://target.example.com/path/to/resource?redirected"). Use of the "\" character is not permitted except to escape a following "\", "{", or "}". An empty value results in a redirection target URL with no query component. A static value must begin with a leading ", optionally followed by other query characters. A request-
copying value must exactly match "(query)", and will be replaced with the query component of the request URL (including a leading "?" if the request URL includes a query component).

- **Response Code**: The response code that is returned with the redirect. If your website was permanently moved to the redirection URL and you want it to be indexed by search engines, select **301 - Moved Permanently**. If you want to indicate that the URL has been temporarily changed to a different address, select **302 - Found**.

- **Create DNS Record**: Select this check box to create an associated ALIAS record for the redirect in the specified zone. If a record for the zone specified already exists, the DNS record will not be created.

- **ALIAS TTL in Seconds** - The Time to Live for the ALIAS record before a new ALIAS record is retrieved. The default value is 300.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**. The redirect zone is added to the redirects list.

**To edit an HTTP redirect**

1. Open the navigation menu. Under **Core Infrastructure**, go to Networking, DNS Management, and click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Edit**.
4. In the Edit Redirect dialog box, make the needed changes and then click **Save Changes**.

**To delete an HTTP redirect**

1. Open the navigation menu. Under **Core Infrastructure**, go to Networking, DNS Management, and click **HTTP Redirects**.
2. Select a redirect zone.
3. Click **Delete**.
4. In the Delete Resource dialog box, click **Delete HTTP Redirect**. Any attached records will need to be managed in DNS Zone Management.

**To move an HTTP redirect to another compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to Networking, DNS Management, and click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**Using the API**

Use the following operations to manage your HTTP redirect zones:

- **GetHttpRedirect**
- **ListHttpRedirects**
- **CreateHttpRedirect**
- **UpdateHttpRedirect**
- **DeleteHttpRedirect**
- **ChangeHttpRedirectCompartment**

**Managing TSIG Keys**

TSIG (Transaction Signature), also referred to as Secret Key Transaction Authentication, ensures that DNS packets originate from an authorized sender by using shared secret keys and one-way hashing to add a cryptographic signature to the DNS packets. TSIG keys are used to enable DNS to authenticate updates to secondary zones. TSIG keys provide an added layer of security for IXFR and AXFR transactions. A TSIG key consists of a key name, a
signing algorithm, and a secret. See RFC 2845 for more information. TSIG keys can also be managed in DNS Zone Management. See Managing DNS Service Zones on page 1679 for more information.

**Using the Console**

*To create a TSIG key*

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click TSIG Keys.
2. Click Create TSIG key.
3. In the Create TSIG Key dialog box, enter the following:
   - **Name:** The name of the key used in domain name syntax. The name should reflect the names of the hosts and uniquely identify the key among a set of keys these two hosts may share at any given time.
   - **Algorithm:** Select the public key's algorithm used to encrypt or decrypt data. Applicable algorithms include hmac-md5, hmac-sha1, hmac-sha224, hmac-sha256, hmac-h384, and hmac-sha512.
   - **Secret:** The base64 string encoding the binary shared secret that corresponds to the key. A maximum value of 255 characters is allowed.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create TSIG Key. The TSIG key details appear.

*To view the details of a TSIG key*

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click TSIG Keys.
2. Click the name of the TSIG key you want to view. TSIG key details and a list of associated zones appear.
3. To view the Secret assigned to the key, click Show beside the Secret field.
4. In the View Secret dialog box, click Close.

*To delete a TSIG key*

1. **Note:** A TSIG key attached to a zone must be removed from the zone in DNS Zone Management. See Managing DNS Service Zones on page 1679 for more information.

*To move a TSIG key to another compartment*

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click TSIG Keys.
2. Find the TSIG key in the list, click the Actions icon (three dots), and then click Delete.
3. In the confirmation dialog box, click Delete.

*Using the API*

Use the following operations to manage TSIG keys:

- ListTsigKeys
- CreateTsigKey
DNS and Traffic Management

- GetTsigKey
- UpdateTsigKey
- DeleteTsigKey
- ChangeTsigKeyCompartment

**Testing DNS Using BIND’S dig Tool**

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.

![Note:]

Windows users can download the tool from BIND’s [website](#). Use Terminal to access dig on Linux and Macintosh systems.

**Using dig**

Before using BIND’s dig tool, you must access or install dig on your system. Once you have access to dig, you can use dig to test your DNS.

*To access dig (Mac)*

1. From your Applications folder, open the Utilities folder, and then select **Terminal**.
2. When Terminal is open, type a dig command using a hostname you want to look up.

*To install dig (Windows)*

1. Go to [BIND’s website](#) and download the most current, stable version of BIND.

![Note:]

BIND supports both 32 and 64 bit Windows systems. Confirm which version of Windows you are using and download the correct version of BIND. View Microsoft’s [documentation](#) to determine which version of Windows you are using.

2. Extract the downloaded file and install BIND in the following directory: C:\Program Files\ISC BIND 9. Select the **Tools Only** check box.
3. Once BIND is installed, on the Windows menu open the Control Panel, and then open your System properties.
4. On the **Advanced** tab, click **Environment Variables**.
5. Under **System Variables**, select **Path**, and then click **Edit**.
6. At the end of the path in the Edit System Variable window, add C:\Program Files\ISC BIND 9\bin, and then click **OK**.
7. In the Edit Variables window, click **OK**. In the System properties window, click **OK**.

*To open the Command Prompt*

For Windows versions 8 -10:

1. Click the Windows menu icon.
2. In the **Search** field, type **CMD**.
3. Click **Command Prompt**.

For Windows version 7:

1. On the **Start** menu click **Run**.
2. Enter **CMD**, and then click **OK**.

*To use dig to test your DNS*

1. Open Terminal (Mac and Linux) or Command Prompt (Windows).
2. Type `dig <any hostname>`, and then press **Enter**.
The following information is returned:

```
$ dig oracle.com
+-------------------+---------------------------+
| Command            | Description               | Example                  |
+-------------------+---------------------------+--------------------------|
| dig [hostname]    | Returns any A record found within the queried hostname's zone. | dig oracle.com            |
|                   |                           |                          |
| dig [hostname] [record type] | Returns the records of that type found within the queried hostname's zone. | dig oracle.com MX         |
|                   |                           |                          |
| dig [hostname] +short | Provides a brief answer, usually just an IP address. | dig oracle.com +short     |
|                   |                           |                          |
| dig @[nameserver address] [hostname] | Queries the nameserver directly instead of your ISP's resolver. | dig @dnsmaster6.oracle.com |
+-------------------+---------------------------+--------------------------+
```

- **Question section**: The query made to the DNS. In this example, we asked for the first available A record for the hostname, oracle.com.
- **Answer section**: The first available answer for the query made to the DNS. In this example, we received the A record for the IP address 137.254.16.101.
- **Authority section**: The authoritative nameservers from which the answer to the query was received. These nameservers house the zones for a domain.
- **Additional section**: Additional information the resolver may need but not the answer to the query.
### DNS and Traffic Management

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dig [hostname] +trace</code></td>
<td>Adding <code>+trace</code> instructs <code>dig</code> to resolve the query from the root nameserver downwards and to report the results from each query step.</td>
<td><code>dig dyn.com +trace</code></td>
</tr>
<tr>
<td><code>dig -X [IP address]</code></td>
<td>Reverse lookup for IP addresses.</td>
<td><code>dig -X 137.254.16.101</code></td>

<tr>
<td><code>dig [hostname] any</code></td>
<td>Returns all records for a hostname.</td>
<td><code>dig oracle.com any</code></td>
</tr>
</tbody>
</table>

### Private DNS

This topic describes how to create and manage private DNS zones. Private DNS allows you to use your own private DNS domain names and fully manage the associated zones and records to provide hostname resolution for your applications running within and between VCNs, as well as your on-premises or other private network. Private DNS also provides DNS resolution across networks (for example, another VCN within the same region, cross region, or external network). Private DNS can be managed in the OCI DNS API and Console.

**Overview of Private DNS**

- **Private DNS Zones**: Private DNS zones contain DNS data only accessible from within a VCN, such as private IP addresses. A private DNS zone has similar capabilities to an internet DNS zone, but provides responses only for clients that can reach it through a VCN. Private DNS allows you to duplicate zones across multiple VCNs. A full or partial domain tree can be created. It also supports split-horizon DNS which allows you to use the same domain name for public and private zones. Different answers can be served for public queries versus private queries from within your VCN.

- **Private DNS Views**: A private DNS view is a collection of private zones. You can reference private views from a resolver to manage how DNS queries are answered. A zone can only belong to a single view. The same zone name can be used in multiple views, but the zones will have unique OCIDs to differentiate. You can use those views to create DNS resolvers configured to handle DNS queries from your VCNs. Any given view can be used by an arbitrary number of resolvers, allowing you to share private DNS data across VCNs.

- **Private DNS Resolver**: A private DNS resolver provides responses to DNS queries. It provides responses by checking each customer-referenced view in order, then the default view, then each rule in order, and finally by using internet DNS. The first item in that sequence able to provide an answer does so, and later items are not checked. Rules allow you to define the logic for how queries should be answered. The resolver listens on 169.254.169.254 by default, but also allows you to define endpoints for listening for queries and forwarding them to other resolvers in other VCNs, a customer's on-premises network, or other private network. Multiple views can be resolved within a VCN. You can specify an ordered list of views within a resolver. For more information, see [Private DNS resolvers](#)

**Required IAM Policies**

To work with private DNS, a user needs sufficient authority (by way of an IAM policy). If your user is in the Administrators group, you have the required authority. If your user is not in the Administrators group, then a policy like this will allow a specific group to manage private DNS:

```text
Allow group <GroupName> to manage dns in tenancy where target.dns.scope = 'private'
```

If you're new to policies, see [Getting Started with Policies](#) and [Common Policies](#). For more details about policies for private DNS, see [Details for the DNS Service](#) on page 2262.

**Using the Console**

To create a private zone with a private view

**Note:**

- Private zones can only be viewed in the region in which they are created.
1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the **Private Zones** tab.
3. Click **Create Zone**.
4. In the Create Private Zone dialog box, enter the following information:
   - **Zone Name**: Enter the name of the zone you want to create. Avoid entering confidential information. A domain name identifies a particular space within a zone for the purposes of naming systems and/or associating DNS records.
   - **Create in Compartment**: Select the compartment where you want to create the zone.
   - **Zone Type**: This field is read-only. The zone contents will be controlled directly within Oracle Cloud Infrastructure.
   - **DNS Private View**: A private zone must be created within a private view, which cannot be changed. When a private zone is attached to a private view, the private zone cannot be moved to a new private view.
     - **Select Existing Private DNS View**: To select an existing private view in the current compartment, select a private view from the drop-down menu. You can click **Change Compartment** to change the compartment where the private view exists.
     - **Create New Private DNS View**: Enter a name for the private view. Avoid entering confidential information. This resource is created in the compartment selected previously.
   - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

The system creates and publishes the zone, complete with the necessary SOA and NS records. The details for the zone appear. You can view the private view associated with this zone by clicking the Private View name in the Zone Information section. For information on adding a record to your zone, see **To add a zone record** on page 1680.

### To create a private view

**Note:** Private views can only be viewed in the region in which they are created.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Private Views**.
2. Click **Create Private View**.
3. In the Create Private View dialog box, enter the following:
   - **Name**: Enter the name of the private view you want to create. Avoid entering confidential information.
   - **Create in Compartment**: Select the compartment where you want to create the private view.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click **Create**.

### To create a private view with a new private zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Private Views**.
2. Click **Create Private View**.
3. In the Create Private Zone dialog box, enter the following information:
   • **Name**: Enter the name of the private view you want to create. Avoid entering confidential information.
   • **Create in Compartment**: Select the compartment where you want to create the private view.
   • **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

4. Click **Create**.
   The details for the private view appear.

5. Click **Create Zone**.

6. In the Create Private Zone dialog box, enter the following:
   • **Zone Name**: Enter the name of the zone you want to create. Avoid entering confidential information. A domain name identifies a particular space within a zone for the purposes of naming systems and/or associating DNS records.
   • **Create in Compartment**: Select the compartment where you want to create the zone.
   • **Zone Type**: This field is read-only. The zone contents will be controlled directly within Oracle Cloud Infrastructure.
   • **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create**.
   The new zone appears in the zone list associated with the private view you created.

To add a zone record

Tip:
There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Zones**.
2. Click the **Zone Name** in which you want to add a record. If you are adding a record to a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

   Tip:
   To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see Supported Resource Records on page 1686.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.

   Note:
   When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.

7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.
To update a zone record

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protected Records</td>
</tr>
</tbody>
</table>

You can change various components of the records within your zones, such as time-to-live (TTL) and relevant RDATA. However, some records contain information that cannot be changed. You can attempt changes to such records through the Actions menu, but the system might not permit updates to some fields.

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Zone Name in which you want to update a record. If you are updating a record in a private zone, click the Private Zones tab and then click the zone name. Zone details and a list of records appear.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.</td>
</tr>
</tbody>
</table>

3. To help find a record, you can use the following filter options:
   - Enter the name of the record's domain in the Search field.
   - To find unpublished records, select the Staged check box.
   - To find published records, select the Unstaged check box.
   - Use the Is Protected sort filter to sort by records that are protected.
   - Use the Record Type sort filter to sort records.
4. Select the check box for the record you want to update, and select Edit from the Actions drop-down menu.
5. In the Edit Record dialog box, make the needed changes, and then click Submit.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.</td>
</tr>
</tbody>
</table>

6. Click Publish Changes.
7. In the confirmation dialog box, click Publish Changes.

Reverting Changes Before Publishing

You can revert records to their current published state before you publish changes. Once a record has been published, it cannot be reverted. Select the check box for the record you want to revert, and then select Revert from the Actions drop-down menu.

To delete a zone record

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Zone Name in which you want to delete a record. If you are deleting a record in a private zone, click the Private Zones tab and then click the zone name. Zone details and a list of records appear.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.</td>
</tr>
</tbody>
</table>

3. Select the check box for the record you want to delete, and then select Delete from the Actions drop-down menu.
4. Click Publish Changes.
5. In the confirmation dialog box, click Publish Changes.
To edit a private view

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Private Views.
2. Click the name of the private view you want to update.
   
   **Tip:**
   You can use the Protected filter to sort private views by views that are protected (system generated).
3. Click Edit.
4. In the Edit Private DNS View dialog box, make the needed changes and then click Save Changes.

To edit a private zone

**Note:**
Private zones are only viewable in the region they are created.

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Private Zones tab.
3. Click the name of the zone you want to update.
   
   **Tip:**
   You can use filters to sort private zones by zones that are protected (system generated) or by associated private view names.
4. Click Edit.
5. In the Edit Zone dialog box, make the needed changes and then click Save Changes.

To delete a private zone

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Private Zones tab.
3. Click the Actions icon (three dots) for the zone you want to delete, and then click Delete.
4. In the Delete Private Zone dialog box, click Delete.
   
   **Caution:**
   Deletion removes associated resources.

To delete a private view

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Private Views.
2. Click the name of the private view that you want to delete.
3. Click Delete.
4. In the Delete DNS Private View dialog box, click Delete.
   
   **Caution:**
   Deletion removes any associated private zones.

To delete a private zone from a private view

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Private Views.
2. Click the private view that contains the zone you want to delete.
3. Click the the Actions icon (three dots) for the zone you want to delete, and then click Delete.
4. In the Delete Private Zone dialog box, click Delete.
To move a private zone to another compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Zones.
2. Click the Private Zones tab.
3. Click the name of the zone you want to move.
4. Find the zone in the list, click the the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move a private view to another compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Private Views.
2. Click the name of the view you want to move.
3. Click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To create a VCN with a dedicated DNS resolver

See To create a VCN on page 2825 and DNS in Your Virtual Cloud Network on page 2910 for more information.

Using the API

Use the following operations to manage private zones and records:

- ChangeZoneCompartment
- CreateZone
- DeleteZone
- GetZone
- ListZones
- UpdateZone
- DeleteDomainRecords
- GetDomainRecords
- PatchDomainRecords
- UpdateDomainRecords
- GetZoneRecords
- PatchZoneRecords (add or delete records)
- UpdateZoneRecords
- DeleteRRSet
- GetRRSet
- PatchRRSet
- UpdateRRSet

Use the following operations to manage private views:

- ChangeViewCompartment
- CreateView
- DeleteView
- GetView
- ListViews
- UpdateView

Use the following operations to manage resolvers and resolver endpoints:

- ChangeResolverCompartment
- GetResolver
- ListResolvers
• UpdateResolver
• CreateResolverEndpoint
• DeleteResolverEndpoint
• GetResolverEndpoint
• ListResolverEndpoints
• UpdateResolverEndpoint

Troubleshooting
This topic covers some common Private DNS issues and how to address them.

Querying for a private zone after creation returns an NXDOMAIN error message or Public IP address
• If a query is sent before the private zone is published, the query recurses to the internet. An error message stating that the domain doesn’t exist or a public name response will be returned for the query.
• Wait until the Time To Live (TTL) expires before querying.

Network connectivity issues when configuring DNS resolution between VCNs or between a VCN and your on-premises network
• Ensure that the local peering gateway is set up correctly between VCNs, and the remote peering connection, IPSec tunnel, or FastConnect network connectivity is set up correctly between resolvers.
• Ensure that DHCP is enabled as a protocol over the local peering gateway, remote peering connection, FastConnect or VPN and that the IP addresses of the endpoints are allowed. For more information, see DHCP Options on page 2917.

DNS Metrics
You can monitor the health, capacity, and performance of your DNS services by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_dns (the DNS service).

Overview of DNS Service Metrics
The DNS service metrics help you measure the number of queries for DNS zones and DNS zones with traffic management policies attached.

Prerequisites
• IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_dns
The metrics listed in the following table are automatically available. You do not need to enable monitoring on the resource to get these metrics.

Each metric includes the following dimensions:

RESOURCEID
The OCID of the zone to which the metric applies.
**Using the Console**

DNS service metrics are available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

*To view DNS metric charts*

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. For Metric Namespace, select oci_dns.
3. Select a metric to view from the Metric Name field.
4. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId is specified in the metric definition for DNSQueryCount.
5. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.
6. Click Update Chart.

The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Using the API**

Use the following APIs for monitoring:
- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Overview of the Traffic Management Steering Policies Service**

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is a critical component of DNS. Traffic Management Steering Policies enables you to configure policies to serve intelligent responses to DNS queries, meaning different answers (endpoints) may be served for the query depending on the logic the customer defines in the policy. Traffic Management Steering Policies can account for health of answers to provide failover capabilities, provide the ability to load balance traffic across multiple resources, and account for the location where the query was initiated to provide a simple, flexible and powerful mechanism to efficiently steer DNS traffic.

**Traffic Management Steering Policies Service Components**

The following list describes the components used to build a traffic management steering policy.

STEERING POLICIES

A framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

ATTACHMENTS

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.
DNS and Traffic Management

RULES

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

ANSWERS

Answers contain the DNS record data and metadata to be processed in a steering policy.

Ways to Access the Traffic Management Steering Policies Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Traffic Management Steering Policies Service Capabilities and Limits

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is limited to 100 policies and 1,000 attachments per tenant. See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Traffic Management Steering Policies, see Details for the Traffic Management Steering Policies Service.

Managing Traffic Management Steering Policies

Policy Types

FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the Secondary Answer.
LOAD BALANCER
Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be unhealthy.

GEOLOCATION STEERING
Geolocation steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region.

ASN STEERING
ASN steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint.

IP PREFIX STEERING
IP Prefix steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query.

Typical Traffic Steering Scenarios
This section describes several typical scenarios for using Traffic Management Steering Policies.

Basic Failover
You can leverage Traffic Management Steering Policies to provide automated failover between primary and secondary servers.

Cloud Migration
Weighted load balancing supports controlled migration from your data center to Oracle Cloud Infrastructure servers. You can steer a small amount of traffic (1%) to your new resources in the cloud to verify everything is working as expected. You can then increase the ratios until you are comfortable with fully migrating all DNS traffic to the cloud.

Load Balancing Across Multiple Servers for Scale
You can configure load balancing pools of multiple servers. Traffic Management Steering Policies can automatically distribute DNS traffic across the set of servers. Health Checks may also be used and traffic will be automatically redirected to healthy servers, if a server is determined to be unhealthy.

Hybrid Environments
Since Traffic Management Steering Policies is an agnostic service, it may be used to not only steer traffic to Oracle Cloud Infrastructure resources, but can also be used to steer traffic to any publicly exposed (internet resolvable) resources, including other cloud providers and enterprise data centers.

Worldwide Geolocation Treatment
You can divide your global users into geographically defined regions (for example, state/province level in NA, country level for rest of world) and steer customers to specified resources based on their location. This helps to ensure global, high performing internet resolution, and supports functions such as ring fencing. For example, keeping traffic from China in China and block traffic outside of China into China.

Canary Testing
Leveraging IP Prefix steering, you can configure policies to serve different responses for your internal users versus external users.
**Zero-Rating Services**

ASN steering conditional steering based on the originating enterprise, mobile operator or other communications provider in support of various commercial agreements that may be in place. Essentially, preferred ASNs can be directed to free resources, while all other traffic can be directed to paid resources.

**Using the Console**

**Managing Traffic Management Steering Policies**

*To create a Load Balancer policy*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Load Balancer**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy.
   - **Answer(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   - **Attach Domain(s)**: (Optional) The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.
5. Click **Create Policy**.

The system creates and publishes the policy.

*To create a Failover policy*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Failover**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select Mark pool answers eligible or Mark pool answers ineligible from the Actions drop-down menu.
     - **Pool Priority**: Failover priority rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
     - **Pool**: Select the priority in which the answers are served.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select None.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

*To create a Geolocation Steering policy*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Geolocation Steering**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the Actions drop-down menu.
   - **Geolocation Steering Rules**: Geolocation steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list. Additional rules and priorities can be added in this section.
     - **Geolocation**: Select a location that will be used to distribute DNS traffic.
     - **Pool Priority**: Select the priority in which the answers are served.
     - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

*To create an ASN Steering policy*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **ASN Steering**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
   - **ASN Steering Rules**: ASN steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
     - **ASN**: Enter an Autonomous System Number (ASN) that will be used to distribute DNS traffic.
     - **Pool Priority**: Select the priority in which the answers are served.
     - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To create an IP Prefix Steering policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **IP Prefix Steering**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
   - **IP Prefix Steering Rules**: IP prefix steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
     - **Subnet Address**: Enter a subnet address that will be used to distribute DNS traffic.
     - **Pool Priority**: Select the priority in which the answers are served.
     - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

**To update a policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click the **Policy Name** you want to update. Policy information and a list of attached domains appear.

   **Tip:**
   You can use search for a policy by name in the **Search** field. You can also use the **Time Created** sort filter to sort the policies chronologically in ascending or descending order.

3. Click **Edit**.
4. Make the needed changes, and then click **Save**.

**To attach a domain to an existing policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking, DNS Management**, and click **Traffic Management Steering Policies**.
2. Click the **Policy Name** you want to update. Policy information and a list of attached domains appear.

   **Tip:**
   You can use search for a policy by name in the **Search** field. You can also use the **Time Created** sort filter to sort the policies chronologically in ascending or descending order.

3. Click **Add Attached Domain(s)**.
4. In the Add Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click Submit.

To edit an attached domain

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Traffic Management Steering Policies.
2. Click the Policy Name you want to update. Policy information and a list of attached domains appear.

   Tip:
   You can use search for a policy by name in the Search field. You can also use the Time Created sort filter to sort the policies chronologically in ascending or descending order.

3. For the attached domain you want to edit, click the Actions icon (three dots), and then click Edit Attached Domain.
4. In the Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click Save.

To delete a policy

1. Open the navigation menu. Under Core Infrastructure, go to Networking, DNS Management, and click Traffic Management Steering Policies.
2. Select the check box for the policy you want to delete.
3. Click Delete. The policy is staged for deletion.
4. Click Publish Changes to delete the policy.
5. In the confirmation dialog box, click Publish Changes.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For more information about managing steering policies using the API, see Traffic Management Steering Policies API Guide.

Use the following operations to manage your steering policies:

- CreateSteeringPolicy
- ListSteeringPolicies
- GetSteeringPolicy
- UpdateSteeringPolicy
- DeleteSteeringPolicy

Use the following operations to manage your steering policy attachments:

- CreateSteeringPolicyAttachment
- ListSteeringPolicyAttachments
- GetSteeringPolicyAttachment
- UpdateSteeringPolicyAttachment
- DeleteSteeringPolicyAttachment

Traffic Management Steering Policies API Guide

Traffic Management Steering Policies allows you to build and configure traffic management policies using the Oracle Cloud Infrastructure DNS REST API. Use the following guide to learn how policies are constructed using the REST API.
**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Traffic Management Steering Policy Components**

The following list describes the components used to build a Traffic Management Steering Policy.

**STEERING POLICIES**

An overall framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

**ATTACHMENTS**

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.

**RULES**

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

**ANSWERS**

Answers contain the DNS record data and metadata to be processed in a steering policy.

**TEMPLATES**

Templates are predefined rule sequences that create a policy type and its intended behavior. Example: The FAILOVER template determines answers by checking DNS query against a FILTER rule first, then the following rules in succession: HEALTH, PRIORITY, and LIMIT. This gives the domain dynamic failover capability. Policies that define the template field with any policy other than CUSTOM, must follow the rule sequence outlined for that policy type, otherwise, a 400 status code error will be returned upon policy creation.

**CASES**

A rule may optionally include a sequence of cases defining alternate configurations for how it should behave during processing for any given DNS query. When a rule has no sequence of cases, it is always evaluated with the same configuration during processing. When a rule has an empty sequence of cases, it is always ignored during processing. When a rule has a non-empty sequence of cases, its behavior during processing is configured by the first matching case in the sequence. A rule case with no caseCondition always matches. A rule case with a caseCondition matches only when that expression evaluates to true for the given query.

**Create Steering Policies Using Templates**

The following section explains the rule configuration for each type of steering policy template followed by an example POST request (CreateSteeringPolicy) displaying how to configure each template.
FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the Secondary Answer. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a FAILOVER template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 1     | FILTER | • No cases are allowed.  
• Answer data must be defined in defaultAnswerData using the following JSON:  

```json
{
   "answerCondition": "answer.isDisabled != true",
   "shouldKeep": true
}
```
| Only included if healthCheckMonitorId is defined for the policy. |
| 2     | HEALTH | • No cases are allowed. |
| 3     | PRIORITY | • No cases are allowed.  
• Answer data must be defined in the defaultAnswerData property for the rule.  
• Every answer must have a pool property.  
• defaultAnswerData restrictions:  
  • Answers cannot be referenced by their name property in answerCondition expressions, they must be referenced by their pool property.  
  • Every answer pool must be referenced once and only once.  
  • Every answer pool must have a unique value property.  
  • Each answer pool reference must match the pool property on one or more answers defined in the answer list for the policy. |
| 4     | LIMIT | • No cases are allowed. |

Example of a POST /steeringPolicies policy using the FAILOVER template:

```json
{
   "compartmentId": "ocid1...",
   "displayName": "failover between endpoints",
   "ttl": 30,
   "healthCheckMonitorId": "ocid1...",
   "template": "FAILOVER",
   "answers": [
      {
         "name": "server-primary",
         "rtype": "A",
         "rdata": "192.168.0.2",
         "pool": "primary"
      }
   ]
}
```
LOAD_BALANCE

Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be unhealthy. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a LOAD_BALANCE template:
<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 1     | FILTER   | • No cases are allowed.  
• Answer data must be defined in defaultAnswerData using the following JSON: |                                                                           |
|       |          | {  
  "answerCondition": "answer.isDisabled != true",  
  "shouldKeep": true  
} | Only included if healthCheckMonitorId is defined for the policy.          |
| 2     | HEALTH   | • No cases are allowed.  
Only included if healthCheckMonitorId is defined for the policy. |                                                                           |
| 3     | WEIGHTED | • No cases are allowed.  
• Answer data must be defined in the defaultAnswerData property for the rule.  
• Answers cannot be referenced by their pool property in answerCondition expressions, they must be referenced by their name property. |                                                                           |
| 4     | LIMIT    | • No cases are allowed.                                                                 |                                                                           |

Example of a POST /steeringPolicies policy using the LOAD_BALANCE template:

```json
{
  "compartmentId": "ocid1...",  
  "displayName": "Weighted load balance for a set of answers with health checks",  
  "ttl": 30,  
  "healthCheckMonitorId": "ocid1...",  
  "template": "LOAD_BALANCE",  
  "answers": [  
    {  
      "name": "server1",  
      "rtype": "A",  
      "rdata": "192.168.0.2"  
    },  
    {  
      "name": "server2",  
      "rtype": "A",  
      "rdata": "192.168.0.3"  
    }  
  ],  
  "rules": [  
    {  
      "ruleType": "FILTER",  
      "defaultAnswerData": [  
        {  
          "answerCondition": "answer.isDisabled != true",  
          "shouldKeep": true  
        }  
      ]  
    }  
  ]
}
```
ROUTE_BY_GEO

Geolocation-based steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a ROUTE_BY_GEO template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;: &quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;shouldKeep&quot;: true</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>HEALTH</td>
<td>• No cases are allowed.</td>
<td>Only included if healthCheckMonitorId is defined for the policy.</td>
</tr>
</tbody>
</table>

```json
{
    "ruleType": "HEALTH"
},
{
    "ruleType": "WEIGHTED",
    "defaultAnswerData": [
        {
            "answerCondition": "answer.name == 'server1'",
            "value": 99
        },
        {
            "answerCondition": "answer.name == 'server2'",
            "value": 1
        }
    ]
},
{
    "ruleType": "LIMIT",
    "defaultCount": 1
}
```
### DNS and Traffic Management

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
</tr>
</thead>
</table>
| 3     | PRIORITY                                                                 | - The defaultAnswerData property cannot be used on this rule.  
- At least one case must be defined. If there are multiple cases, the final case can provide a "catch-all" case.  
- The caseCondition property on cases can only use query.client.geoKey in the conditional expression.  
- Answers cannot be referenced by their name property in answerCondition expressions, they must be referenced by their pool property.  
- Every answer must have a pool property.  
- For each case's answerData:  
  - Every answer pool must be referenced once and only once.  
  - Every answer pool must have a unique value property (within the case).  
  - Each answer pool reference must match the pool property on one or more answers defined in the answer list for the policy.  |
| 4     | LIMIT                                                                 | - No cases are allowed.                                                                                                                                                                                    |

Example of a POST `/steeringPolicies` request body using the ROUTE_BY_GEO template:

```json
{
  "compartmentId": "ocid1...",
  "displayName": "Geolocations mapped to answer pools",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "ROUTE_BY_GEO",
  "answers": [
    {
      "name": "US Server 1",
      "rtype": "A",
      "rdata": "192.168.0.2",
      "pool": "US"
    },
    {
      "name": "US Server 2",
      "rtype": "A",
      "rdata": "192.168.0.3",
      "pool": "US"
    },
    {
      "name": "EU Server 1",
      "rtype": "A",
      "rdata": "192.168.0.4",
      "pool": "EU"
    },
    {
      "name": "EU Server 2",
      "rtype": "A",
      "rdata": "192.168.0.5",
      "pool": "EU"
    },
    {
      "name": "rest of world 1",
      "rtype": "A",
      "rdata": "203.0.113.2",
      "pool": "Global"
    }
  ]
}```
},
  {
    "name": "rest of world 2",
    "rtype": "A",
    "rdata": "203.0.113.3",
    "pool": "Global"
  }
],
"rules": [
  {
    "ruleType": "FILTER",
    "defaultAnswerData": [
      {
        "answerCondition": "answer.isDisabled != true",
        "shouldKeep": true
      }
    ]
  },
  {
    "ruleType": "HEALTH"
  },
  {
    "ruleType": "PRIORITY",
    "cases": [
      {
        "caseCondition": "query.client.geoKey in (geoKey '6255149')",
        "answerData": [
          {
            "answerCondition": "answer.pool == 'US'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'EU'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Global'",
            "value": 3
          }
        ]
      },
      {
        "caseCondition": "query.client.geoKey in (geokey '6255148')",
        "answerData": [
          {
            "answerCondition": "answer.pool == 'EU'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'US'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Global'",
            "value": 3
          }
        ]
      },
      {
        "answerData": [
          {
            "answerCondition": "answer.pool == 'Global'",
            "value": 1
          }
        ]
      }
    ]
  }
]
ROUTE_BY_ASN

ASN-based steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a ROUTE_BY_ASN template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;: &quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;shouldKeep&quot;: true</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>HEALTH</td>
<td>• No cases are allowed.</td>
<td>Only included if healthCheckMonitorId is defined for the policy.</td>
</tr>
<tr>
<td>Order</td>
<td>Rule</td>
<td>Restrictions</td>
<td>Comments</td>
</tr>
<tr>
<td>-------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>3</td>
<td>PRIORITY</td>
<td>- The defaultAnswerData property cannot be used on this rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- At least one case must be defined. If there are multiple cases, the final</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>case can provide a &quot;catch-all&quot; case.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The caseCondition property on cases can only use query.client.asn in</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>the conditional expression.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Answers cannot be referenced by their name property in</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>answerCondition expressions, they must be referenced by their pool</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer must have a pool property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- For each case's answerData:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer pool must be referenced once and only once.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer pool must have a unique value property (within the case).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Each answer pool reference must match the pool property on one or</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>more answers defined in the answer list for the policy.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>LIMIT</td>
<td>- No cases are allowed.</td>
<td></td>
</tr>
</tbody>
</table>

Example of a POST /steeringPolicies request body using the ROUTE_BY_ASN template:

```json
{
   "compartmentId": "ocid1...",
   "displayName": "ASNs mapped to pools",
   "ttl": 30,
   "template": "ROUTE_BY_ASN",
   "answers": [
      {
         "name": "ABC Server",
         "rtype": "A",
         "rdata": "192.168.0.2",
         "pool": "ABC"
      },
      {
         "name": "DEF Server",
         "rtype": "A",
         "rdata": "192.168.0.3",
         "pool": "DEF"
      },
      {
         "name": "Other",
         "rtype": "A",
         "rdata": "203.0.113.2",
         "pool": "Other"
      }
   ],
   "rules": [
      {
         "ruleType": "FILTER",
         "defaultAnswerData": [
            {
               "answerCondition": "answer.isDisabled != true",
               "shouldKeep": true
            }

ROUTE_BY_IP

IP Prefix-based steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a ROUTE_BY_IP template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;shouldKeep&quot;: true</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>HEALTH</td>
<td>• No cases are allowed.</td>
<td>Only included if healthCheckMonitorId is defined for the policy.</td>
</tr>
<tr>
<td>3</td>
<td>PRIORITY</td>
<td>• The defaultAnswerData property cannot be used on this rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• At least one case must be defined. If there are multiple cases, the final</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>case can provide a &quot;catch-all&quot; case.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The caseCondition property on cases can only use query.client.address in</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>the conditional expression.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answers cannot be referenced by their name property in answerCondition</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>expressions, they must be referenced by their pool property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Every answer must have a pool property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For each case's answerData:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Every answer pool must be referenced once and only once.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Every answer pool must have a unique value property (within the case).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Each answer pool reference must match the pool property on one or more</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>answers defined in the answer list for the policy.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>LIMIT</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
</tbody>
</table>

Example of a POST /steeringPolicies request body using the ROUTE_BY_IP template:

```json
{
  "compartmentId": "ocid1...",
  "displayName": "IP subnets mapped to answer pools",
  "ttl": 30,
  "template": "ROUTE_BY_IP",
  "answers": [
    {
      "name": "ABC Server",
      "rtype": "A",
      "rdata": "192.168.0.2",
      "pool": "ABC"
    }
  ]
}```
{
    "name": "DEF Server",
    "rtype": "A",
    "rdata": "192.168.0.3",
    "pool": "DEF"
},
{
    "name": "Other",
    "rtype": "A",
    "rdata": "203.0.113.2",
    "pool": "Other"
}
],

{  "answerCondition": "answer.pool == 'DEF'",
   "value": 3
}
]
]
",
{  "ruleType": "LIMIT",
   "defaultCount": 1
}
]
}  

CUSTOM

Custom policies allow you to create complex policies combining the capabilities of failover, load balancing, geolocation, ASN and IP prefix steering. Custom templates do not require a regimented sequence of rules and it is recommended to contact Oracle Cloud Infrastructure support before creating a custom policy.

Rule Types

FILTER

Uses boolean data associated with answers, keeping answers only if the rule's shouldKeep value is true.

HEALTH

Utilizes Oracle Cloud Health Check monitors to determine the health of your endpoints and add and remove answers from your policy as needed. A health check monitor must be referenced in a health rule to have an effect on the policy. For more information about Health Checks, see Health Checks.

WEIGHTED

Uses a number between 0 and 255 used to determine how often an answer will be served in relation to other answers. Answers with higher values are more likely to be returned.

PRIORITY

Uses an integer associated with each answer to sort answers from lowest to highest value. Example: An answer with a priority value of 1 would be returned before an answer with a priority value of 10 in the list of answers. Answers that do not have a priority value assigned to them will be moved to the end of the list of answers.

LIMIT

Uses a count property to filter away all but the first answers in the list.

Traffic Management Steering Policy geokeys

Use these keys as values for the geokey fields of caseConditions in ROUTE_BY_GEO steering policies.
## Continent geokeys

<table>
<thead>
<tr>
<th>Continent Name</th>

This chapter explains how to send large volume email.

Overview of the Email Delivery Service

Oracle Cloud Infrastructure Email Delivery is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. Email Delivery provides the tools necessary to send application-generated email for mission-critical communications such as receipts, fraud detection alerts, multi-factor identity verification, and password resets.

Oracle Cloud Infrastructure's Email Deliverability team manages the platform using key deliverability metrics to ensure the best sending reputation possible for your emails.

The following items are provided to you when you send email using the Email Delivery service:

- Unique mailbox provider SMTP configurations on our Mail Transfer Agents (MTA)
- Bounce collection
- User complaint collection
- Email authentication standards
- Deliverability performance

Email Delivery Service Components

Email Delivery uses the components described in this section.

APPROVED SENDERs

An Approved Sender is a resource that equates to the "From" address. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. If you need to have the same approved sender in another region, it must be created in the other region. For example, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region.

SUPPRESSION LIST

The Suppression List is included on your Email Delivery console user interface and from the API. Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future.

Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests
SPF AUTHENTICATION

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

Regions and Availability Domains

SMTP credentials can be used for any region, as identities are global assets. However, approved senders (your "From" address) must be configured within each region you plan to use for Email Delivery. To configure approved senders within each region, select a region from the Region menu in the Console and create an approved sender. Configure your application to send email to the endpoint of that region where you created the approved sender, using the global SMTP credentials. The sending application is not required to be located in the region where email is sent from, however, we recommend that it is local or as close as possible for performance reasons.

For more information, see Regions and Availability Domains on page 180.

Configuring a New Region

If you want to start sending email from a new region, keep the following in mind:

- An approved sender must be created in the new region.
- SMTP credentials are global, however, it is recommended that you generate SMTP credentials for a new user (without console access) in the new region so that the credentials are not shared with other regions. Ensure that the user has the correct privileges.
- Email must be sent to the new regional SMTP connection endpoint.
- The suppression list and approved senders are regional Email Delivery assets.

For example, if an email sent from the US West (Phoenix) region bounces, the recipient email address will be added to the US West (Phoenix) region suppression list. This recipient would not be added to other region suppression lists. If you are sending email from different regions, approved senders must be created in each region.

- SPF must be set up on each subdomain. For example, in your DNS setup, create a TXT record for notification.eu-frankfurt-1.oraclecloud.com and paste the following information from the dialog box into the record: v=spf1 include:eu.rp.oracleemaildelivery.com ~all

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see SDKs and Other Tools.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You are prompted to enter your cloud tenant, your user name, and your password. For general information about using the API, see About the API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more
information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Email Delivery supports the following authentication types for control plane operations (management endpoint):

- **Instance Authorization:** The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

- **Cross-Tenancy:** Cross-tenancy authorization allows customers to share resources between tenancies. To authorize a cross-tenancy request, the request must be endorsed by the requester’s tenancy and permitted by the target tenancy.

- **Federated:** Federated authentication enables an administrator to configure a relationship between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure’s IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

**Note:** Instance authorization, cross-tenancy, and federated authentication types do not apply to SMTP email sending. An approved sender and SMTP credentials are required and must be associated with the same tenancy for SMTP email sending.

**SMTP Authentication and Connection Endpoints**

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

Use the following regional endpoints for establishing SMTP connections for sending.

- South Korea North (Chuncheon): smtp.email.ap-chuncheon-1.oci.oraclecloud.com
- India South (Hyderabad): smtp.email.ap-hyderabad-1.oci.oraclecloud.com
- Australia Southeast (Melbourne): smtp.email.ap-melbourne-1.oci.oraclecloud.com
- India West (Mumbai): smtp.email.ap-mumbai-1.oci.oraclecloud.com
- Japan Central (Osaka): smtp.email.ap-osaka-1.oci.oraclecloud.com
- South Korea Central (Seoul): smtp.email.ap-seoul-1.oci.oraclecloud.com
- Australia East (Sydney): smtp.email.ap-sydney-1.oci.oraclecloud.com
- Japan East (Tokyo): smtp.email.ap-tokyo-1.oci.oraclecloud.com
- Canada Southeast (Montreal): smtp.email.ca-montreal-1.oci.oraclecloud.com
- Canada Southeast (Toronto): smtp.email.ca-toronto-1.oci.oraclecloud.com
- Netherlands Northwest (Amsterdam): smtp.email.eu-amsterdam-1.oci.oraclecloud.com
- Germany Central (Frankfurt): smtp.email.eu-frankfurt-1.oci.oraclecloud.com
- Switzerland North (Zurich): smtp.email.eu-zurich-1.oci.oraclecloud.com
- UAE East (Dubai): smtp.email.me-dubai-1.oci.oraclecloud.com
- Saudi Arabia West (Jeddah): smtp.email.me-jeddah-1.oci.oraclecloud.com
- Chile (Santiago): smtp.email.sa-santiago-1.oci.oraclecloud.com
- Brazil East (Sao Paulo): smtp.email.sa-saopaulo-1.oci.oraclecloud.com
- UK West (Newport): smtp.email.uk-cardiff-1.oci.oraclecloud.com
- UK South (London): smtp.email.uk-london-1.oci.oraclecloud.com
- US East (Ashburn): smtp.email.us-ashburn-1.oci.oraclecloud.com
- US West (Phoenix): smtp.email.us-phoenix-1.oci.oraclecloud.com
• US West (San Jose): smtp.email.us-sanjose-1.oci.oraclecloud.com

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about available Email Delivery service metrics and how to view them, see Email Delivery Metrics on page 1756.

Email Delivery Service Capabilities and Limits

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Customers that sign up for a free Oracle Cloud trial are limited to:

• A volume of 200 unique recipients among all emails sent per day.

  Note:
  
  This limit applies to unique recipients among all emails sent. For example, a single email sent to 100 recipients would count the same as 100 individual emails each sent to a single recipient.

• 2,000 approved senders.
• Each user is limited to a maximum of two SMTP credentials.
• Sending rates are limited to 10 emails per minute.
• Inline attachments.

  Note:
  
  Customers that start with a Free Trial and transition to a paid account must request a limit increase.

Enterprise accounts are limited to:

• A volume of 50,000 unique recipients among all emails sent per day.

  Note:
  
  This limit applies to unique recipients among all emails sent. For example, a single email sent to 100 recipients would count the same as 100 individual emails each sent to a single recipient.

• 10,000 approved senders.
• Sending rates are limited to 18,000 emails per minute.
• Inline attachments.

Email Delivery, by default, supports messages up to 2 MB, inclusive of message headers, body, and attachments. Based on requirement, you can request a limit increase up to a maximum of 60 MB. To open a service request to increase the limit, see Requesting a Service Limit Increase on page 217. Your increase request is evaluated by the following information you provide:

• What are your current sending domains?
• Do your sending practices meet the requirements of CAN-SPAM and CASL?
• Briefly describe the type of email you will be sending. For example, are the emails marketing/bulk/newsletters, transactional, notifications, and so on?
• Do you send emails related to payday loans or credit card offers?
• Do you send email on behalf of other companies?
• How do the recipients sign up to receive these emails? Specify any domains they might sign up on.
• Are there any other methods that are used to collect email addresses?
• How many emails do you want to send per month?
• Which ESP supplier are you currently using to send your emails?
• What is the maximum number of messages you need to send in a burst capacity (within a specific timeframe)?
• What is the maximum size of your messages?
• What is the number of emails sent per day that is over 2 MB?
• Are your recipients Oracle email addresses (for example, test.user@oracle.com)?
• Which email delivery region do you intend to use to send email through?

**Note:**
The Email Delivery platform supports higher volumes. Limits are set as a safeguard for our customers' reputation. To open a service request to increase the email sending limit, see Requesting a Service Limit Increase on page 217.

### Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Service.

Permissions are required for managing and using approved senders and the suppression list. For example:

• To enable all operations on approved senders for a specific user group:
  
  Allow group <Your Group Name> to manage approved-senders in tenancy

• To enable all operations on suppressions for a specific user group:
  
  Allow group <Your Group Name> to manage suppressions in tenancy

### Dedicated IP Addresses

When you create an Email Delivery service account, by default, your emails are sent from IP addresses shared with other Oracle customers.

Email Delivery supports IPs addresses dedicated to you, for complete control over your reputation. Both a shared IP or dedicated IP strategy can provide excellent delivery depending on your needs and mail stream characteristics.

When using a dedicated pool of Oracle owned IP addresses, only your mail is sent from them.

**Note:**
Our deliverability experts review all dedicated IP requests to ensure the best deliverability for your situation. Dedicated IP addresses may not be advised for lower volume or more sporadic email sending, as this does not support a good sending reputation and therefore can cause an impact to your email deliverability.

Dedicated IP addresses are ideal for senders who:

• **Send large volumes of mail on a consistent basis to sustain their own IP reputation.** Sending a large volume of mail consistently is what Internet Service Providers (ISPs) automated filters use to assign a reputation to your IP address. This is one of the key inputs into whether your messages are delivered into the inbox, spam folder, or temporarily rejected.

• **Want complete control of their sending reputation AND understand email delivery best practices.** When you are the only sender on an IP, it insulates your reputation from other senders. This can be good or bad depending on your sending practices and consistent hygiene.
• **Have large volumes, different mail streams, and want to build unique reputations for each.** Dedicated IPs enable you to build separate IP reputations based on different types of mail streams like transactional messages versus bulk marketing mail. If you have the volume to support it, isolating these mail streams can reduce the risk of delivery challenges for more critical message types.

Dedicated IP addresses are likely not a good fit for senders who:

• **Send mail inconsistently at low volumes preventing an ISP reputation from being assigned.** To build an IP reputation, ISPs prefer a predictable mail cadence with enough email volume to assign a reputation. Failing to meet this requirement could lead to delivery challenges. Sending in a shared IP pool with many smaller senders will provide the ISP with a large volume of consistent mail.

• **Do not understand email best practices, which could lead to poor-reputation delivery challenges.** Sending in a shared IP pool with other customers that is managed by Oracle can be less risky for an email novice.

Your mail characteristics (volume, burst rates, reputation, and so on) will vary your dedicated IP strategy. Our teams are trained on dedicated IP strategies and ready to support your needs. If you need help with your configuration, you can go to My Oracle Support and create a service request.

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Email Delivery supports applying tags to approved senders.

### Integration with Oracle Cloud Infrastructure Services

Email Delivery audits the following events:

- Creating a sender (CreateSender)
- Deleting a sender (DeleteSender)
- Retrieving details about a sender (ListSenders)

To view logs for events in the Email Delivery service, your user must be in a group with the ability to view all of the Audit event logs in the tenancy. For more information, see Viewing Audit Log Events on page 494.

### Getting Started with Email Delivery

You can set up the Email Delivery service within the Console. To begin sending email with Email Delivery, complete the following steps:

1. Generate SMTP credentials for a user.
2. Set up permissions.
3. Create an approved sender.
4. Configure SPF on the approved sender domain.
5. Configure the SMTP connection.

For more information, see Getting Started with Email Delivery on page 1743.

### Getting Started with Email Delivery

Email Delivery provides a highly scalable, cost effective, and reliable way to send email from your applications. Email Delivery includes developer-friendly tools to quickly send application-generated email for mission-critical communications such as receipts, programmatic notifications, or password reset emails.
Email Delivery Basics

When you use Email Delivery, we become your outbound email server. If you have an existing email server, you can keep it and configure it to send through Email Delivery. The Email Delivery service will take care of the feedback loops and platform reputation automatically.

Getting Started

This topic gives guidance on how to get started with Email Delivery. For complete details about the service and its components, see Overview of the Email Delivery Service on page 1738.

Email Configuration Options

You can configure Oracle Cloud Infrastructure using the Console (a browser-based interface), REST API, SDKs, CLI or Terraform.

Using the Email Delivery SDK

The Email Delivery SDK is available in several programming languages. For information on installing and configuring the Oracle Cloud Infrastructure SDKs, see Developer Resources on page 4178.

Examples of SDK usage can be found on GitHub, including:

- Example: Email Delivery SDK for Java
- Example: Email Delivery SDK for Python
- Example: Email Delivery SDK for Ruby
- Example: Email Delivery SDK for Go

Configuring Third-Party Applications

The following information describes how you can configure third-party applications to send email through Email Delivery:

- Integrating Oracle Application Express with Email Delivery on page 1758
- Integrating Postfix with Email Delivery on page 1759
- Integrating Oracle Enterprise Manager with Email Delivery on page 1760
- Integrating Mailx with Email Delivery on page 1761
- Integrating Swaks with Email Delivery on page 1763
Email Delivery

- Integrating Sendmail with Email Delivery on page 1767
- Integrating JavaMail with Email Delivery on page 1764
- Integrating PeopleSoft with Email Delivery on page 1770
- Integrating Python with Email Delivery on page 1773

Sending Email

To begin sending email with Email Delivery, complete the following steps:

**Generate SMTP credentials for a user.**

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated that are associated with another existing user or more users must be created.

**Best Practice:** A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating a user, see Adding Users.

**To generate SMTP credentials for a user.**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list that has permissions to manage email, and then click the user's name to view the details.

   **Tip:** If your user does not have permissions to view or create users, you can create SMTP credentials under your user.

   Open the Profile menu and click User Settings.

2. Click SMTP Credentials.
3. Click Generate SMTP Credentials.
4. Enter a Description of the SMTP Credentials in the dialog box.
5. Click Generate SMTP Credentials. A user name and password is displayed.
6. Copy the user name and password for your records and click Close.

**Set up permissions.**

The new user must be assigned to a group with permissions to manage approved-senders and suppressions.

**To create a policy to allow a group to manage approved senders and suppressions**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed.
2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Overview of Policies on page 2136).
3. Click Create Policy.
4. Enter the following:
   - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Policy Versioning:** Select Keep Policy Current if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the
Email Delivery

definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see **Advanced Policy Features** on page 2160.

- **Statement**: Enter the following policy statement:

  ```
  Allow group <group name> to use approved-senders in compartment <compartment name>
  ```

  For more information about policies and policy syntax, see **Policy Basics** on page 2137.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

The new policy will go into effect typically within 10 seconds.

**To add the new user to the group**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.

2. Locate the user in the list.

3. Click the user. Its details are displayed.

4. Click **Groups**.

5. Click **Add User to Group**.

6. Select the group from the drop-down list, and then click **Add**.

Make sure to let the user know which compartment(s) they have access to.

**Create an approved sender.**

You must set up an approved sender for all “From:” addresses sending mail via Oracle Cloud Infrastructure or mail will be rejected. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. That is, if you create an approved sender in the Phoenix (PHX) region, you cannot send email through the Ashburn (IAD) region.

**Best Practice**: Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

**To create an approved sender using the Console**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage approved-senders in this compartment.

2. Click **Create Approved Sender** within the **Approved Senders** view.

3. Enter the email address you want to list as an approved sender in the **Add Sender** dialog box.

4. Click **Add**. The email address is added to your Approved Senders list.

**Tip:**

Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

**To create an approved sender using the API**

The following example shows how to create an approved sender. For more information about creating an approved sender, see **CreateSender**.

```bash
POST /20170907/senders
```
Configure SPF on the approved sender domain.

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be "spoofed" to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders.

To configure SPF

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders.
2. Select the checkbox for the approved sender you want to view SPF details for and click View SPF.
3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.

- If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.
- In your DNS setup, create a TXT record and paste the following information into the record based on the sending location:

<table>
<thead>
<tr>
<th>Sending Location</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>Americas</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>Asia/Pacific</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:ap.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>Europe</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:eu.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>All Commercial Regions</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:ap.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>include:eu.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
</tbody>
</table>
Configure the SMTP connection.

Set up and test your SMTP connection using an SMTP library or product such as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

SMTP Connection Endpoints

Use the following regional endpoints for establishing SMTP connections for sending.

- YNY: smtp.email.ap-chuncheon-1.oci.oraclecloud.com
- HYD: smtp.email.ap-hyderabad-1.oci.oraclecloud.com
- MEL: smtp.email.ap-melbourne-1.oci.oraclecloud.com
- BOM: smtp.email.ap-mumbai-1.oci.oraclecloud.com
- KIX: smtp.email.ap-osaka-1.oci.oraclecloud.com
- ICN: smtp.email.ap-seoul-1.oci.oraclecloud.com
- SYD: smtp.email.ap-sydney-1.oci.oraclecloud.com
- NRT: smtp.email.ap-tokyo-1.oci.oraclecloud.com
- YUL: smtp.email.ca-montreal-1.oci.oraclecloud.com
- YYZ: smtp.email.ca-toronto-1.oci.oraclecloud.com
- AMS: smtp.email.eu-amsterdam-1.oci.oraclecloud.com
- FRA: smtp.email.eu-frankfurt-1.oci.oraclecloud.com
- ZRH: smtp.email.eu-zurich-1.oci.oraclecloud.com
- DXB: smtp.email.me-dubai-1.oci.oraclecloud.com
- JED: smtp.email.me-jeddah-1.oci.oraclecloud.com
- SCL: smtp.email.sa-santiago-1.oci.oraclecloud.com
- GRU: smtp.email.sa-saopaulo-1.oci.oraclecloud.com
- CWL: smtp.email.uk-cardiff-1.oci.oraclecloud.com
- LHR: smtp.email.uk-london-1.oci.oraclecloud.com
- IAD: smtp.email.us-ashburn-1.oci.oraclecloud.com
- PHX: smtp.email.us-phoenix-1.oci.oraclecloud.com
- SJC: smtp.email.us-sanjose-1.oci.oraclecloud.com

TLS Requirements

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

To access SMTP sending information to configure the connection in your system

Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Configuration.

The following information is displayed:

- **Public Endpoint**: The public endpoint used to send email to for this region.
- **SMTP Ports**: The SMTP ports used to accept email. Email Delivery supports TLS on port 25 or 587.
• **Security:** This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

  **Tip:**

  Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle’s supported security policies and ciphers.

**Begin sending email.**

Use Email Delivery to begin sending email.

**Suppression List**

As you begin to send email, Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future. Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests

**To manually add an email address to the suppression list using the Console**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Suppression List**.
2. Click **Add Suppression**.
3. In the Add Suppression dialog box, enter the email address.
4. Click **Add**. The email address is added to the suppression list.

For more information, see **Managing the Suppression List** on page 1755.

**To manually add an email address to the suppression list using the API**

The following example shows how to add an email address to the suppression list. For more information about managing the suppressions list, see **GetSuppression** and **DeleteSuppression**.

```
POST /20170907/suppressions
{
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaat7uqcb6zoxvzoga4d4vh4dtweciauepcacd3skz56atf3qp73d7fx",
    "emailAddress": "user@example.com",
}
```

**Using the API**

You can access Oracle Cloud Infrastructure using the **REST API**. Instructions for the API are included in topics throughout this guide. For a list of available SDKs, see **SDKs and Other Tools**.

**Regions**

See **Regions and Availability Domains** on page 1739 for more information.

**Limits**

See **Email Delivery Service Capabilities and Limits** for information on new account and enterprise account limits.
Best Practices

This section describes best practices for using Email Delivery.

Volume Testing - In order to maintain our sender reputation and yours, testing at volume needs to be done using the following best practice.

- Use a recipient address at the email-blackhole.com domain, such as example@email-blackhole.com. Email Delivery will accept the mail but will not deliver it to an inbox.
- If large volume emails are sent to valid email addresses, these will get rejected by receivers and will result in a large amount of hard bounces. This will negatively affect IP reputation. For testing bounce processing, send small amounts of emails to a domain that does not have an MX record, in other words, the domain does not exist.

Deliverability - To help you learn and manage the habits that affect your sending reputation, see Deliverability Best Practices on page 1780.

Sending to Email Aliases - When sending email to an alias, the alias is considered one recipient. When sending email to a distribution group or list set up in an email client such as Apple Mail or Outlook, a separate email is sent for each recipient in the group.

Generate SMTP Credentials for a User

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated on other existing users or more users must be created.

A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating a user, see Adding Users. The new user must be assigned to a group with permissions to manage approved-senders and suppressions. For example:

```
Allow group <group name> to use approved-senders in compartment <compartment name>
```

Using the Console

To generate SMTP credentials for a user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list that has permissions to manage email, and then click the user's name to view the details.

   **Tip:**
   If your user does not have permissions to view or create users, you can create SMTP credentials under your user.

   Open the **Profile** menu () and click **User Settings**.

2. Click SMTP Credentials.
3. Click Generate SMTP Credentials.
4. Enter a Description of the SMTP Credentials in the dialog box.
5. Click Generate SMTP Credentials. A user name and password is displayed.
6. Copy the user name and password for your records and click Close.

Managing Approved Senders

An approved sender must be set up for all “From:” addresses sending mail through Oracle Cloud Infrastructure, or mail will be rejected. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. That is, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region with that sender.

The approved senders that you add must use a domain name that you own and control. The following sending domains cannot be used to create approved senders:
Email Delivery

- @oracle.com - This sending domain name is reserved for Oracle employee and corporate system use.
- @*.oraclevcn.com - This domain name is reserved for private use within an Oracle Cloud Infrastructure VCN. Email sending domains must have SPF and DKIM records that can be resolved on the public internet, and oraclevcn.com is only reachable within private Oracle Cloud Infrastructure networks. Use of this sending domain results in delivery delays, failures, and a possible blocklist addition.
- @gmail.com, @hotmail.com, @yahoo.com, and other public mailbox service providers - You cannot use a sending domain from a public mailbox service provider such as gmail, hotmail, icloud, yahoo, and so on. These providers tend to have restrictive DMARC records and will not delegate permission to third-party Email Delivery services (through SPF and DKIM records). Use of these sending domains results in delivery delays, failures, and a possible blocklist addition.

The following sending domain is problematic for use as an approved sender:
- @oraclecloud.com - This sending domain name is reserved for Oracle Cloud system use.

Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

Moving Approved Senders to a Different Compartment

You can move approved senders from one compartment to another. To manage approved senders and use approved senders to send mail, user groups must have an associated identity policy in the new compartment. For more information, see Managing Compartments on page 2431.

Using the Console

To create an approved sender

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage approved senders in this compartment.
2. Click Create Approved Sender within the Approved Senders view.
3. Enter the email address you want to list as an approved sender in the Create Approved Sender dialog box.

   Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click Create Approved Sender. The email address is added to your Approved Senders list.

   Tip:
   Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

To delete an approved sender

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click Delete.
3. In the confirmation dialog box, click Confirm. The email address is removed from the Approved Senders list.

To move an approved sender to a different compartment

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders.
2. In the List Scope section, select a compartment.
3. Find the approved sender in the list, click the the Actions icon (three dots), and then click Choose New Compartment.
4. Choose the destination compartment from the list.
5. Click Move Approved Sender.

   For more information, see Managing Compartments on page 2431.

To manage tags for an approved sender

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click View Tags to view or edit existing tags. Or click Apply tag(s) to add new ones.

   For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use the following operations to manage your approved senders:

- CreateSender
- GetSender
- ListSenders
- DeleteSender

Configure SPF

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders. SPF is required for subdomains of oraclegovcloud.com and recommended in other cases.

Using the Console

To configure SPF:

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Approved Senders.
2. Select the checkbox for the approved sender you want to view SPF details for and click View SPF.

   Tip:

   You can search for an approved sender by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.

   If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle...
Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.

- In your DNS setup, create a TXT record and paste the following information into the record based on the sending region:

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>Americas</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>Asia/Pacific</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:ap.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>Europe</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:eu.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
<tr>
<td>All Commercial Regions</td>
<td>v=spf1</td>
</tr>
<tr>
<td></td>
<td>include:rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>include:ap.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>include:eu.rp.oracleemaildelivery.com</td>
</tr>
<tr>
<td></td>
<td>-all</td>
</tr>
</tbody>
</table>

- For US Government Cloud with FedRAMP Authorization, see SPF Record Syntax on page 161.
- For US Federal Cloud with DISA Impact Level 5, see SPF Record Syntax on page 167.
- For United Kingdom Government Cloud, see SPF Record Syntax on page 176.

- If your domain currently has an SPF DNS record, you must update your record in order to successfully use Email Delivery.
- The following is an example of a command used to view an SPF record:

```
dig -t TXT +short syd1.rp.oracleemaildelivery.com
```

Example output:

```
"v=spf1 ip4:192.168.0.25 -all"
```

- If you're using other email providers in addition to Email Delivery, you'll need to combine the include statements from your other providers with Email Delivery.

### Configure SMTP Connection

Set up and test your SMTP connection using an SMTP library or product, such as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

Open Email Configuration to access SMTP sending information to configure the connection in your system. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Configuration. The following information is displayed:

- **Public Endpoint:** The public endpoint used to send email to for this region.
- **SMTP Ports:** The SMTP ports used to accept email. Email Delivery supports TLS on port 25 or 587.
• **Security:** This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

```
<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle’s supported security policies and ciphers.</td>
</tr>
</tbody>
</table>
```

**SMTP Connection Endpoints**

Use the following regional endpoints for establishing SMTP connections for sending.

- YNY: smtp.email.ap-chuncheon-1.oci.oraclecloud.com
- HYD: smtp.email.ap-hyderabad-1.oci.oraclecloud.com
- MEL: smtp.email.ap-melbourne-1.oci.oraclecloud.com
- BOM: smtp.email.ap-mumbai-1.oci.oraclecloud.com
- KIX: smtp.email.ap-osaka-1.oci.oraclecloud.com
- ICN: smtp.email.ap-seoul-1.oci.oraclecloud.com
- SYD: smtp.email.ap-sydney-1.oci.oraclecloud.com
- NRT: smtp.email.ap-tokyo-1.oci.oraclecloud.com
- YUL: smtp.email.ca-montreal-1.oci.oraclecloud.com
- YYZ: smtp.email.ca-toronto-1.oci.oraclecloud.com
- AMS: smtp.email.eu-amsterdam-1.oci.oraclecloud.com
- FRA: smtp.email.eu-frankfurt-1.oci.oraclecloud.com
- ZRH: smtp.email.eu-zurich-1.oci.oraclecloud.com
- DXB: smtp.email.me-dubai-1.oci.oraclecloud.com
- JED: smtp.email.me-jeddah-1.oci.oraclecloud.com
- SCL: smtp.email.sa-santiago-1.oci.oraclecloud.com
- GRU: smtp.email.sa-sao paulo-1.oci.oraclecloud.com
- CWL: smtp.email.uk-cardiff-1.oci.oraclecloud.com
- LHR: smtp.email.uk-london-1.oci.oraclecloud.com
- IAD: smtp.email.us-ashburn-1.oci.oraclecloud.com
- PHX: smtp.email.us-phoenix-1.oci.oraclecloud.com
- SJC: smtp.email.us-sanjose-1.oci.oraclecloud.com

**TLS Requirements**

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

Managing the Suppression List

Manually add an email address to the suppression list to prevent it from being part of your sending list.

Users are required to have correct permissions to manage the suppression list. Currently, identity policies for suppression must be at the tenant level (not at the compartment level). The following is an example of the permission policy statement.

```
Allow group <group name> to manage suppressions in tenancy
```

Suppressions are stored at the tenancy level. Therefore any request requiring a `compartmentId` must provide the `tenancyId` as the `compartmentId`. For example:

```
Allow group <ordinary users> to inspect approved-senders in tenancy
Allow group <power users> to read approved-senders in tenancy
Allow group <sender admins> to manage approved-senders in tenancy
Allow user <mail user> to use approved-senders in tenancy where target.approved-sender.senderId = <senderId>
```

```
Allow group <ordinary users> to inspect suppressions in tenancy
Allow group <power users> to read suppressions in tenancy
Allow group <sender admins> to manage suppressions in tenancy
```

Using the Console

To manually add an email address to the suppression list

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Suppression List.
2. Click Add Suppression.
3. In the Add Suppression dialog box, enter the email address.
4. Click Add. The email address is added to the Suppression List.

To delete an email address from the suppression list

1. Open the navigation menu. Under Solutions and Platform, go to Email Delivery and click Email Suppression List.
2. Select the checkbox for the email address you want to delete and then click Delete.
3. In the confirmation dialog box, click OK. The email address is removed from the Suppression List.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use the following operations to manage your suppressions:

- CreateSuppression
- GetSuppression
- ListSuppressions
- DeleteSuppression
Email Delivery Metrics

You can monitor the health, capacity, and performance of your Email Delivery by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_emaildelivery` (the Email Delivery service).

Overview of the Email Delivery Service Metrics

Oracle Cloud Infrastructure Email Delivery (Email Delivery) is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. The Email Delivery service metrics help you measure counts for accepted mail, email complaints, emails hard bounced, and emails soft bounced. Accepted mail consists of the unique emails accepted by the Email Delivery service to send. Emails are defined by the number of unique emails, as well as the number of unique recipients per message attempted to be delivered, resulting in successful delivery and blocked email. For example, sending an email with 10 recipients means 10 emails accepted. Email complaints consists of the number of email complaints for a sender by the Email Delivery service. Emails hard bounced consists of the number of emails hard bounced (permanent failure) for a sender by the recipient domain's email service. Emails soft bounced consists of the number of emails soft bounced (persistent transient failure) by the recipient domain's email service or due to an inability to reach that service.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email Delivery is billed for every 1,000 emails accepted.</td>
</tr>
</tbody>
</table>

For more information, see Overview of the Email Delivery Service on page 1738.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_emaildelivery

The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However, your tenancy must have Email Delivery configured and must send mail to make the `oci_emaildelivery` metric space available in the Metrics Explorer feature.

Each metric includes the following dimensions:

- **RESOURCEID**
  
  The OCID of the policy to which the metric applies.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>EmailsAccepted</td>
<td>Emails Accepted</td>
<td>count</td>
<td>The number of unique emails accepted by the Email Delivery service.</td>
<td>resourceID (The OCID of the approved sender to which the metric applies.)</td>
</tr>
<tr>
<td>EmailComplaints</td>
<td>Email Complaints</td>
<td>count</td>
<td>The number of email complaints for a sender by the Email Delivery service.</td>
<td>resourceDomain (The domain name of the approved sender email address to which the metric applies.)</td>
</tr>
<tr>
<td>EmailsHardBounced</td>
<td>Emails Hard Bounced</td>
<td>count</td>
<td>The number of emails hard bounced (permanent failure) for a sender by the recipient domain's email service.</td>
<td></td>
</tr>
<tr>
<td>EmailsSoftBounced</td>
<td>Emails Soft Bounced</td>
<td>count</td>
<td>The number of emails soft bounced (persistent transient failure) by the recipient domain's email service or due to an inability to reach that service.</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

Email Delivery service metrics are currently only available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

**To view Email Delivery metric charts**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
   For Metric Namespace, select `oci_emaildelivery`.
2. Select a metric to view from the Metric Name field.
3. Select a qualifier specified in the Dimension Name field. For example, the dimension `resourceId` is specified in the metric definition for `EmailsAccepted`.
4. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.
5. Click Update Chart.
   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Using the API**

Use the following APIs for monitoring:
- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Integrating Oracle Application Express with Email Delivery

Configure Oracle Application Express to Send Email Through Email Delivery

You can use the APEX_MAIL package to send emails from Oracle Application Express applications deployed in Autonomous Transaction Processing. See Creating an Autonomous Database on Shared Exadata Infrastructure on page 1157 and Autonomous Transaction Processing for more information.

Before you use APEX_MAIL you must configure Oracle Cloud Infrastructure Email Delivery in your Application Express instance.

To enable APEX_MAIL functionality in your Application Express instance in Autonomous Transaction Processing:

1. Identify the SMTP connection endpoint for Email Delivery. You configure the endpoint as the SMTP Host in your Application Express instance in Step 4. See Configure SMTP Connection on page 1753 for more information.

2. Generate SMTP credentials for Email Delivery. Your Application Express instance uses credentials to authenticate with Email Delivery servers when you send email. See Generate SMTP Credentials for a User on page 1750 for more information.

3. Create an approved sender for Email Delivery. You need to complete this step for all email addresses you use as the "From" with APEX_MAIL.SEND calls, as the Application Email From Address in your apps, or in the SMTP_FROM instance parameter. See Managing Approved Senders on page 1750 for more information.

4. Connect to your Autonomous Transaction Processing as ADMIN user using a SQL client and configure the following SMTP parameters using APEX_INSTANCE_ADMIN.SET_PARAMETER:
   - **SMTP_HOST_ADDRESS**: Specifies the SMTP connection endpoint from Step 1.
   - **SMTP_USERNAME** Specifies the SMTP credential user name from Step 2.
   - **SMTP_PASSWORD** Specifies the SMTP credential password from Step 2.

   For example:

   ```sql
   BEGIN
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_ADDRESS', 'smtp.us-phoenix-1.oraclecloud.com');
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_USERNAME', 'ocid1.user.oc1.username');
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_PASSWORD', 'password');
   COMMIT;
   END;
   /
   ```

5. Send a test email using APEX SQL Workshop, SQL Commands specifying one of the approved senders from Step 3 as "From". For example:

   ```sql
   BEGIN
   APEX_MAIL.SEND(p_from => 'alice@example.com',
   p_to   => 'bob@example.com',
   p_subj => 'Email from Oracle Autonomous Database',
   p_body => 'Sent using APEX_MAIL');
   END;
   /
   ```

6. To monitor email delivery in your Application Express instance:
   a. Sign in to APEX Administration Services.
   b. Open the Manage Instance page.
   c. Click the Mail Queue link in the Manage Meta Data section.

   Alternatively, query APEX_MAIL_QUEUE and APEX_MAIL_LOG views using a SQL client.

More Information

- Creating Applications with Oracle Application Express in Autonomous Database
Integrating Postfix with Email Delivery

Configure Postfix to Send Email Through Email Delivery

You can use Postfix to send emails through Email Delivery. Before you use Postfix you must configure Oracle Cloud Infrastructure Email Delivery in your Postfix application.

**Note:**
The paths and commands used below for specifying file locations are specific to Ubuntu/Debian; your file paths or editing commands may differ depending on the operating system you are using. The changes to the configuration files are the same.

To enable Postfix to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

   **Note:**
The SMTP credentials are required to configure Postfix to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. To open the `main.cf` file, run the following command:

   ```
sudo vi /etc/postfix/main.cf
   ```

   Add the following information to the end of the file:

   ```
smtp_tls_security_level = may
smtp_sasl_auth_enable = yes
smtp_sasl_password_maps = hash:/etc/postfix/sasl_passwd
smtp_sasl_security_options =
   ```

3. Update the Postfix `main.cf` file.

   If the following line is present, either remove the line or turn it off:

   ```
smtpd_use_tls = yes
   ```

4. Update `relayhost` to include your SMTP connection endpoint and port. For example:

   ```
relayhost = smtp.us-ashburn-1.oraclecloud.com:587
   ```

5. Create the `sasl_passwd` file in the same directory as `main.cf`.

   Run the following command:

   ```
sudo vi /etc/postfix/sasl_passwd
   ```

6. Add your relay host and port by entering:

   ```
server:port user:pass
   ```

   where:

   - `server` is your relay host and `port` is 25 or 587.
   - `user` is the user name and `pass` is the password you received when you generated your SMTP credentials.
7. Enter the permissions in the password file.
   Run the following command:
   ```bash
   sudo chown root:root /etc/postfix/sasl_passwd & & sudo chmod 600 /etc/postfix/sasl_passwd
   ```

8. Generate the password hash.
   Run the following command:
   ```bash
   sudo postmap hash:/etc/postfix/sasl_passwd
   ```

   Run the following command:
   ```bash
   sudo postfix reload
   ```

10. Test the configuration by sending a test email.
    Run the following command:
    ```bash
    echo "This is a test message" | mail -s "Test" -r "<approved sender email address>" <recipient email address>
    ```
    If you want to monitor the log while you send the test email, open a separate Terminal window and run the following command before running the test command:
    ```bash
    log stream --predicate ' (process == "smtpd") || (process == "smtp")' --info
    ```
    A status=sent (250 Ok) message in the log indicates the email was sent successfully.

    **Note:**
    If you are using SASL authentication, you must use the following RPM package: cyrus-sasl-plain. See the PostFix website for further documentation on configuring SASL authentication.

**More Information**
- See the Postfix website for more information on Postfix configuration.
- See TLS errors when integrating with Postfix on page 1776 for troubleshooting techniques related to Email Delivery.

**Integrating Oracle Enterprise Manager with Email Delivery**

**Configure Oracle Enterprise Manager to Send Email Through Email Delivery**

You can use Oracle Enterprise Manager to send emails through Email Delivery. Before you use Oracle Enterprise Manager, you must configure Oracle Cloud Infrastructure Email Delivery in your Oracle Enterprise Manager application.

**Note:**
For information on installing Oracle Enterprise Manager, see Setting Up Oracle Enterprise Manager on Oracle Cloud Infrastructure.

To enable Oracle Enterprise Manager to integrate with Email Delivery:
1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

   Note:

   The SMTP credentials are required to configure Oracle Enterprise Manager to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. In Oracle Enterprise Manager, go to the Setup menu and click Initial Setup Console.
3. In the Initial Setup Console section, click Configure Mail Servers in the navigation pane.
4. In the Sender Identify section, click Edit.
5. Enter the name of the administrator or system that should send the email notifications and the email address from which the notifications should be sent, and then click OK.
6. In the Outgoing Mail (SMTP) Servers section, click Create.
7. Enter the mail server host name, the mail server credentials, and the encryption method to be used, and then click OK.
8. Select the outgoing mail server you wish to test and select Test Mail Server. Note the confirmation message in the console and verify that you received the test email in your inbox.

   Note:

   If you configure multiple outgoing mail servers, automatic failover and load balancing is performed in round robin fashion.

Integrating Mailx with Email Delivery

Configure Mailx to Send Email Through Email Delivery

You can use Mailx to send emails through Email Delivery. Before you use Mailx, you must configure Oracle Cloud Infrastructure Email Delivery in your Mailx application.

Use these instructions only if no mail transfer agent (MTA), such as Postfix or Sendmail, is in use on the system. If you are configuring an MTA, follow the configuration instructions for that program and leave the Mailx settings at their defaults. This makes Mailx use the local MTA program to send outbound mail.

   Note:

   These steps assume you are logged into an Oracle Linux instance. Other distributions of Linux might have different commands and file locations.

To enable Mailx to integrate with Email Delivery:

1. Ensure that Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

   Note:

   The SMTP credentials are required to configure Mailx to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Update the Mailx mail.rc file.

   To open the mail.rc file, run the following command:

   ```
   sudo vi ~/etc/mail.rc
   ```

   Add the following information to the end of the file:

   ```
   #smtp config
   set nss-config-dir=/etc/pki/nssdb/
   set smtp-use-starttls
   ```
set smtp-auth=plain
set smtp=<SMTP_connection_endpoint>:25
set from=<from_email_address>
set smtp-auth-user=<OCID from smtp credentials>
set smtp-auth-password=<password from smtp credentials>

#write and quit file
:wq!

3. Test the configuration by sending a test email.

Run the following command:

```bash
echo "Test Email" | mail -v -s "Send an email via mailx" -r "from_name<from_email_address>" -S replyto="from_name<from_email_address>" -S smtp="SMTP_connection endpoint:25" -S smtp-use-starttls -S smtp-auth=plain -S smtp-auth-user='"<ocid from smtp credentials>"' -S smtp-auth-password='"<password from smtp credentials>"' -S ssl-verify=ignore <recipient_email_address>
```

**Troubleshooting**

"Error in certificate: Peer's certificate issuer has been marked as not trusted" occurs when sending email

To troubleshoot this issue, complete the following steps:

1. Run the following command to view the certificate chain:

   ```bash
echo | openssl s_client -starttls smtp -crlf -connect <SMTP-endpoint>:587
```

Example output:

```
[root@ociuvddatg01 ~]# echo | openssl s_client -starttls smtp -crlf -connect smtp.email.us-ashburn-1.oci.oraclecloud.com:587
CONNECTED(00000003)
depth=2 C = US, O = DigiCert Inc, OU = www.digicert.com, CN = DigiCert Global Root G2
  verify return:1
depth=1 C = US, O = DigiCert Inc, CN = DigiCert Global CA G2
  verify return:1
depth=0 C = US, ST = California, L = Redwood City, O = Oracle Corporation, OU = Oracle OCI-PROD ASHBURN, CN = smtp.email.us-ashburn-1.oci.oraclecloud.com
  verify return:1
  ---
Certificate chain
0 s:/C=US/ST=California/L=Redwood City/O=Oracle Corporation/OU=Oracle OCI-PROD ASHBURN/CN=smtp.email.us-ashburn-1.oci.oraclecloud.com
  i:/C=US/O=DigiCert Inc/CN=DigiCert Global CA G2
1 s:/C=US/O=DigiCert Inc/CN=DigiCert Global CA G2
  i:/C=US/O=DigiCert Inc/CN=www.digicert.com/CN=DigiCert Global Root G2
2 s:/C=US/O=DigiCert Inc/CN=www.digicert.com/CN=DigiCert Global Root G2
  i:/C=US/O=DigiCert Inc/CN=www.digicert.com/CN=DigiCert Global Root G2
  ---
Server certificate
-----BEGIN CERTIFICATE-----
.......-----END CERTIFICATE-----
.......```

2. Extract the certificate that signed your domain. In this example, this is the last certificate (2 s:/C=US/O=DigiCert Inc/CN=www.digicert.com/CN=DigiCert Global Root G2). Copy and paste the
certificate into a separate DigiCert.pem file, including the BEGIN CERTIFICATE and END CERTIFICATE fields.

3. Install the certificate into the Centos NSSDB database. Replace "DigiCert Global Root G2" in the following example with your certificate:

```bash
sudo certutil -A -t "C,r," -n "DigiCert Global Root G2" -d /etc/pki/nssdb/ -i DigiCert.pem
```

To view the certificate, use the following command:

```bash
sudo certutil -L -d /etc/pki/nssdb/
```

More Information

- For network security services, see the Mailx documentation.

Integrating Swaks with Email Delivery

Swaks (Swiss Army Knife SMTP) is a transaction-based tool you can use to test SMTP configurations in Email Delivery. Before you use Swaks, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials.

**Note:**
Many options and parameters can be used to test various scenarios with Swaks. When Swaks evaluates an option (that is, a flag with parameters), it does so in three steps:
- First, it looks for a configuration file (default location or specified with --config).
- Next, it looks for options in environment variables.
- Finally, it looks at command line options. At each step, any options set earlier are overridden.

Assumptions

The following procedures assume the following:
- The following example supplies options to Swaks via the command line in long form, for example, --server as opposed to the short form, -s.
- The following example assumes the default behavior to connect through network sockets.
- A local certificate is not required for a TLS connection to be negotiated. The following example assumes the default behavior where Swaks does not attempt certificate verification.
- Swaks is primarily intended for use on UNIX-like operating systems with functionality based on known standards so it should work on most modern mail servers.

Configure Swaks to Send Email Through Email Delivery

To enable Swaks to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

**Note:**
The SMTP credentials are required to configure Swaks to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.
2. Ensure Swaks is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Swaks on Oracle Linux:

```
sudo yum install swaks -y
```

3. To send a test email with Swaks, run the following command:

```
swaks --pipeline -tls --server <smtp.region.oraclecloud.com> --port <587 or 25> --auth-user '<username OCID from SMTP credentials>' --auth-pass '<password>' --from '<sender email address>' --to '<recipient email address>' --data '<email message>'
```

For example:

```
swaks --pipeline -tls --server smtp.us-ashburn-1.oraclecloud.com --port 25 --auth-user 'ocid1.user.oc1..<unique_ID>' --auth-pass '<password>' --from 'sender@example.com' --to 'recipient@example.com' --data 'From: sender@example.com
Date: Thu, 13 Sep 2019
Subject: Test Send

Test email'
```

Note the following when sending email with Swaks:

- The `-tls` parameter is required.
- The `--pipeline` parameter is supported to make use of SMTP pipelining.
- The `--port <number>` parameter or `:<port number>` syntax can be used to specify the port.

**More Information**

- See the Swaks documentation for more information.

**Integrating JavaMail with Email Delivery**

JavaMail provides a platform-independent and protocol-independent framework to build mail and messaging applications. Before you use JavaMail, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials. This guide uses the Eclipse IDE and the JavaMail API to send email through Email Delivery.

**Important:**

Java applications (including JavaMail) must be updated to the latest version to ensure that the latest protocols, ciphers, and security patches are in compliance with Oracle's supported security policies and ciphers.

**Configure JavaMail to Send Email Through Email Delivery**

To enable JavaMail to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

```
Note:

The SMTP credentials are required to configure JavaMail to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.
```

2. Open a browser and go to https://github.com/javaee/javamail/releases.

3. Under Downloads, select `javax.mail.jar` to download the latest version of JavaMail.
4. Create a project in Eclipse by performing the following steps:
   
   a. In Eclipse, open the **File** menu. Select **New**, and then click **Java Project**.
   
   b. In the Create a Java Project dialog box, enter a project name, and then click **Next**.
   
   c. In the Java Settings dialog box, select the **Libraries** tab.
   
   d. Click **Add External JARs**.
   
   e. In the JAR Selection dialog box, browse to the folder in which you downloaded JavaMail. Select the `javax.mail.jar` file, and then click **Open**.
   
   f. In the Java Settings dialog box, click **Finish**.
   
5. In Eclipse, in the Package Explorer window, expand your project.

6. Under your project, right-click the src directory, select **New**, and then click **Class**.

7. In the New Java Class dialog box, enter "OCIemail" in the **Name** field and then click **Finish**.

8. Enter the following code in **OCIemail.java** to send a test email with JavaMail:

```java
import java.util.Properties;
import javax.mail.Message;
import javax.mail.Session;
import javax.mail.Transport;
import javax.mail.internet.InternetAddress;
import javax.mail.internet.MimeMessage;

public class OCIemail {

    public static void main(String[] args) throws Exception {

    // Replace FROM with your "From" address.
    // This address must be added to Approved Senders in the console.
    static final String FROM = "<sender email address>";
    static final String FROMNAME = "<sender name>";

    // Replace TO with a recipient address.
    static final String TO = "<recipient email address>";

    // Replace smtp_username with your Oracle Cloud Infrastructure SMTP username generated in console.
    static final String SMTP_USERNAME = "<username OCID from SMTP credentials>";

    // Replace smtp_password with your Oracle Cloud Infrastructure SMTP password generated in console.
    static final String SMTP_PASSWORD = "<SMTP password>";

    // Oracle Cloud Infrastructure Email Delivery hostname.
    static final String HOST = "<SMTP endpoint>";

    // The port you will connect to on the SMTP endpoint. Port 25 or 587 is allowed.
    static final int PORT = 587;

    static final String SUBJECT = "<subject of your email>";
    static final String BODY = String.join(
        System.getProperty("line.separator"),
        "<h1>OCI Email Delivery test</h1>",
        "<p>This email was sent with OCI Email Delivery using the ",
        "<a href='javamail'>https://github.com/javaee/javamail</a>'s Javamail Package</a>",
    )

    }

```
Properties props = System.getProperties();
props.put("mail.transport.protocol", "smtp");
props.put("mail.smtp.port", PORT);
//props.put("mail.smtp.ssl.enable", "true"); //the default value is
false if not set
props.put("mail.smtp.auth", "true");
props.put("mail.smtp.auth.login.disable", "true"); //the default
authorization order is "LOGIN PLAIN DIGEST-MD5 NTLM". 'LOGIN' must be
disabled since Email Delivery authorizes as 'PLAIN'
props.put("mail.smtp.starttls.enable", "true"); //TLSv1.2 is
required
props.put("mail.smtp.starttls.required", "true"); //Oracle Cloud
Infrastructure required

// Create a Session object to represent a mail session with the
specified properties.
Session session = Session.getDefaultInstance(props);

// Create a message with the specified information.
MimeMessage msg = new MimeMessage(session);
msg.setFrom(new InternetAddress(FROM,FROMNAME));
msg.setRecipient(Message.RecipientType.TO, new
InternetAddress(TO));
msg.setSubject(SUBJECT);
msg.setContent(BODY,"text/html");

// Create a transport.
Transport transport = session.getTransport();

// Send the message.
try {
    System.out.println("Sending Email now...standby...");

    // Connect to OCI Email Delivery using the SMTP credentials
    specified.
    transport.connect(HOST, SMTP_USERNAME, SMTP_PASSWORD);
    // Send email.
    transport.sendMessage(msg, msg.getAllRecipients());
    System.out.println("Email sent!");
}
catch (Exception ex) {
    System.out.println("The email was not sent.");
    System.out.println("Error message: " + ex.getMessage());
}
finally
{
    // Close & terminate the connection.
9. In the OCIemail.java file, replace the following with your own values:

```
transport.close();
}
}
}
```

**Note:**

Email addresses are case-sensitive. Ensure that the addresses are the same as the ones you entered in Approved Senders in the console.

- **FROM** - Replace with your sender email address. This email address must be added to the Approved Senders list in Email Delivery first.
- **TO** - Replace with your recipient email address.
- **SMTP credentials** - Replace smtp_username and smtp_password with your Oracle Cloud Infrastructure SMTP username and password generated in the console.
- **HOST** - Replace with the Email Delivery SMTP endpoint. For example, smtp.us-ashburn-1.oraclecloud.com.

10. Refer to the requirements for configuring an SMTP connection with Email Delivery. TLSv1.2 is required for Email Delivery. Some default settings of Javamail need to be disabled. For example, JavaMail authorizes in a certain order. The default authorization order is "LOGIN PLAIN DIGEST-MD5 NTLM". Since Email Delivery authorizes as "PLAIN", "LOGIN" needs to be disabled. For example, the following code is entered in OCIemail.java file to configure the SMTP connection:

```
//props.put("mail.smtp.ssl.enable", "true"); //default is false if not set
props.put("mail.smtp.auth", "true");
props.put("mail.smtp.auth.login.disable", "true");
props.put("mail.smtp.starttls.enable", "true");
props.put("mail.smtp.starttls.required", "true");
```

11. Open the File menu and click **Save**.
12. To build the project, open the **Project** menu and then select **Build Project**. If this option is disabled, you may have automatic building enabled.
13. To start the program and send the email, open the **Run** menu and then click **Run**.
14. Review the output. If the email was successfully sent, the console displays "Email sent successfully!" Otherwise, it displays an error message.
15. Log into the recipient inbox to verify receipt of the email.

**More Information**

- See the JavaMail documentation for more information.
- There is a known issue that can cause an error. See **JavaMail issues occur when multiple recipients are set in an email and one or more of the email addresses are suppressed.**

**Integrating Sendmail with Email Delivery**

**Configure Sendmail to Send Email Through Email Delivery**

You can use Sendmail to send emails through Email Delivery. Before you use Sendmail you must configure Oracle Cloud Infrastructure Email Delivery in your Sendmail application.
To enable Sendmail to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

2. Run the following update and install commands:

   ```
   sudo apt update
   sudo apt install sendmail
   sudo apt install m4
   ```

3. In a file editor such as vi, update `/etc/mail/authinfo`. Run the following command:

   ```
   sudo vi /etc/mail/authinfo
   ```

   Add the following line:

   ```
   AuthInfo:<SMTP connection endpoint> "U:root" "I:<username from smtp credentials>" "P:<password from smtp credentials>" "M:PLAIN"
   #write and quit file
   :wq!
   ```

4. Generate the `/etc/mail/authinfo.db` file.

   Run the following command:

   ```
   sudo sh -c 'makemap hash /etc/mail/authinfo.db < /etc/mail/authinfo'
   ```

5. Add support for relaying to the Oracle Cloud Infrastructure Email Delivery SMTP endpoint.

   Run the following command:

   ```
   sudo sh -c 'echo "Connect:<SMTP connection endpoint> RELAY" >> /etc/mail/access'
   ```

6. Regenerate `/etc/mail/access.db`.

   Run the following command:

   ```
   sudo sh -c 'makemap hash /etc/mail/access.db < /etc/mail/access'
   ```

7. Create a backup of the `sendmail.cf` and `sendmail.mc` files.

   Run the following command:

   ```
   sudo sh -c 'cp /etc/mail/sendmail.cf /etc/mail/sendmail_cf.backup && cp /etc/mail/sendmail.mc /etc/mail/sendmail_mc.backup'
   ```
8. Update the `/etc/mail/sendmail.mc` file.

   Run the following command:

   ```sh
sudo vi /etc/mail/sendmail.mc
   ```

   Find the MAILER() definitions.

   Type `/MAILER` and press ENTER.

   In Insert mode, add the following settings before any MAILER() definitions:

   ```
   define(`SMART_HOST', `<SMTP connection endpoint>')
   define(`RELAY_MAILER_ARGS', `TCP $h 25')
   define(`confAUTH_MECHANISMS', `LOGIN PLAIN')
   FEATURE(`authinfo', `hash -o /etc/mail/authinfo.db')
   MASQUERADE_AS(`<sending_domain>')
   FEATURE(`masquerade_envelope')
   FEATURE(`masquerade_entire_domain')
   ```

   Disable Insert mode.

   Run the following command:

   ```sh
   #write and quit file
   :wq!
   ```

   Run the following command:

   ```sh
   sudo chmod 666 /etc/mail/sendmail.cf
   ```

10. Regenerate `sendmail.cf`.

    Run the following command:

    ```sh
    sudo sh -c 'm4 /etc/mail/sendmail.mc > /etc/mail/sendmail.cf'
    ```

    **Note:**

    If you receive an error, such as "Command not found" or "No such file or directory," confirm that the `m4` and `sendmail` packages are installed on your system.

11. Reset permissions for `sendmail.cf` to read only.

    Run the following command:

    ```sh
    sudo chmod 644 /etc/mail/sendmail.cf
    ```

12. Restart Sendmail.

    Run the following command:

    ```sh
    sudo /etc/init.d/sendmail restart
    ```
13. Test the configuration by sending a test email.
   Run the following command:
   
   ```
   /usr/sbin/sendmail -vf <from_email_address> <recipient_email_address>
   ```
   
Enter the details of the email. After each line press `Enter`.
   For example:
   
   ```
   From: <from_email_address>
   To: <recipient_email_address>
   Subject: OCI Email Delivery test email
   This is a test message sent from OCI Email Delivery using Sendmail.
   ```
   
   Press `Ctrl + D` to send the email.

14. Verify receipt of the test email.

   **Note:**
   You can troubleshoot an issue by reviewing the Sendmail log on your mail server, located at `/var/log/mail.log`.

**More Information**

- For more information, see the [Sendmail Installation and Operation Guide](#).

### Integrating PeopleSoft with Email Delivery

#### Configure PeopleSoft to Send Email Through Email Delivery

You can use PeopleSoft to send emails through Email Delivery. Before you use PeopleSoft, you must configure Oracle Cloud Infrastructure Email Delivery in your PeopleSoft application.

**Note:**

The following steps require familiarity with人民Soft documentation. (This link points to PeopleTools 8.57, which is the latest version at the time this article was published. Please refer to the documentation for your specific PeopleTools version.)

To enable PeopleSoft to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See [Getting Started with Email Delivery](#) on page 1743.

   **Note:**
   SMTP credentials are required to configure PeopleSoft to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Run the following command to view the certificate chain:

   ```
   echo | openssl s_client -starttls smtp -crlf -connect <SMTP-endpoint>:587
   ```

   Example output:

   ```
   [root@ociuvddatg01 ~]# echo | openssl s_client -starttls smtp -crlf -connect smtp.email.us-ashburn-1.oci.oraclecloud.com:587
   CONNECTED(00000003)
   depth=2 C = US, O = DigiCert Inc, OU = www.digicert.com, CN = DigiCert Global Root G2
   verify return:1
   ```
3. Extract the certificate that signed your domain. In this example, this is the last certificate (2 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2). Copy and paste the certificate into a separate DigiCert.pem file, including the BEGIN CERTIFICATE and END CERTIFICATE fields.

4. Add the certificates to the PeopleSoft application.
   Log into the Pure Internet Architecture (PIA) as user "PS" and import the certificates into the target environment. See Installing Application Server-Based Digital Certificates and refer to the Adding CA Authorities and Installing Root Certificates section.

5. Encrypt the SMTP password in the config file.
   You can encrypt the SMTP password using the PIA or the PSCipher utility.

   **Using the PIA**
   a. Open the navigation menu on the PeopleSoft dashboard. Go to PeopleTools, and then select Integration Broker.
   b. Select Configuration, and then click Gateways. Select the default LOCAL gateway.
   c. Click Gateway Setup Properties. The default user ID is administrator and the default password is the password selected during setup.
   d. Click the Advanced Properties Page link.
   e. Click Password Encryption at the bottom of the page. This is where you will encrypt your password.

   **Using PSCipher**
   The PSCipher utility can be found under $PS_CFG_HOME/webserv/<DOMAIN>/piabin where <DOMAIN> is your web server domain.
   Run the following command:

   ```bash
   ./PSCipher.sh <password>
   ```

   **Note:**
   The password can have special characters so you will need to enclose the password in single quotes. For example: ./PSCipher.sh
   ```bash
   '#rpassword$){'
   ```
6. Update the SMTP settings on the PeopleSoft Application server. For more information, see SMTP Settings in the PeopleSoft documentation.

Establish an ssh connection to the PeopleSoft Application server machine (as username "opc") and do the following:

a. Switch user to psadm2 (for example, sudo su - psadm2).

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>psadm2 is the PeopleTools domain user who creates and configures the Application Server domain.</td>
</tr>
</tbody>
</table>

b. Navigate to the Appserver configuration directory.

Run the following command:

```
$ cd $PS_CFG_HOME/appserv/APPDOM
```

c. Back up the original psappsrv.cfg file.

d. Add the following information to the psappsrv.cfg file:

```
SMTPServer=<SMTP connection endpoint>
SMTPUserName=<username from SMTP credentials>
SMTPUserPassword=<encrypted SMTP password>
SMTPPort=587
SMTPUseSSL=N
SMTPSSLPort=587
SMTPTLSEnable=true
SMTPTLSRequired=true
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not include a space between the &quot;=&quot; and the values because the space could be counted in the value for the password, causing an authentication failure.</td>
</tr>
</tbody>
</table>

7. Add the primary email address for the PeopleSoft application user who is trying to send notification from within the application. In this example, the user is "PS".

Log in as "PS" and do the following:

a. Open the navigation menu on the PeopleSoft dashboard. Go to PeopleTools, and then select Security.

b. Select User Profiles, and then click user Profiles. Find the profile for "PS".

c. On the General tab, click Edit Email Addresses.

d. Enter the approved sender email address as the primary email address.

8. Log out of the PeopleSoft application.

9. Reboot the application server using the PSADMIN utility. See Using the Application Server Administration Menu.

10. Test the email notification delivery.

Log into the PIA as "PS", and select Notify anywhere in the console. For example, you can do the following:

a. Go to Peopletools, and then select Web Profile.

b. Select Web Profile Configuration.

c. Click Search, and then click PROD in the search results.

d. Click Notify, enter the notification details, and then click OK.

Confirm receipt of the test email.

To debug SMTP errors (optional):
1. You can add the following parameter to help with SMTP debugging: `SMTPTrace=1`
   
   LogFence should be set to 5 to use this parameter. The system writes the log information to SMTP<DDMM>.log in `%PS_SERVDIR%/LOGS` by default, or the custom value set for Log Directory.
   
   For example:
   ```
   $PS_CFG_HOME\APPSERV\domain\LOGS\SMTP6_27.log
   ```

2. After you set this parameter, you will need to reboot the Application server. Once this parameter is set, you can monitor the SMTP log.

3. Type `ls` and find the SMTP file for the date you sent the email.

4. Run the following command:
   ```
   tail -f <smtp log file and date>
   ```
   
   For example,
   ```
   tail -f SMTP9_17.log
   ```
   
   Search for any errors in the output.

**Troubleshooting**

*535 authentication required error occurs when sending email*

To troubleshoot this issue, complete the following steps:

1. Use the following method to re-encrypt the SMTP user password, and enter it in the PeopleSoft application server or process scheduler configuration file's SMTP settings.
   
   a. Open any Integration Broker node by navigating to **PeopleTools, Integration Broker, Integration Setup**, and then click **Nodes**.
   
   b. Click on the **Connectors** tab. Ensure it is using the HTTPTARGET Connector.
   
   c. Expand the encryption section and encrypt the SMTP user password again.
   
   d. Enter the new encrypted password in the SMTPUserPassword settings.

2. Verify that the optional parameters below are set in the SMTP settings section of the configuration file even if they are not being used.
   ```
   SMTPUseSSL1=N
   SMTPSSLPor1t1=587
   SMTPTLSEnable1=true
   SMTPTLSRequired1=true
   SMTPClientCertAlias1=
   ```

**More Information**

- **SMTP Settings (PeopleSoft)**
- **Encrypting Passwords in the PeopleSoft Pure Internet Architecture**
- **My Oracle Support: Is There a Way to Both Authenticate And Secure Emails From PeopleSoft?**

**Integrating Python with Email Delivery**

You can use Python to send emails through Email Delivery. Before you can send email you must configure Email Delivery in Python.

**Note:**

These steps assume you are logged into an Oracle Linux instance. Other distributions of Linux may have different commands and file locations.
Configure Python to Send Email Through Email Delivery

To enable Python to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 1743.

   **Note:**
   The SMTP credentials are required to configure Python to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Ensure Python is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Python on Oracle Linux:

   ```bash
   sudo yum install python3 -y
   ```

3. In a file editor such as vi, create a python script to test Email Delivery.

   Run the following command:

   ```bash
   sudo vi ociemail.py
   ```

4. In the `ociemail.py` file, replace the variables with your own values.

   For example:

   ```python
   # python script for sending SMTP configuration with Oracle Cloud Infrastructure Email Delivery
   import smtplib
   import email.utils
   from email.message import EmailMessage
   import ssl

   # Replace sender@example.com with your "From" address.
   # This address must be verified.
   # this is the approved sender email
   SENDER = 'sender@example.com'
   SENDERNAME = 'Sender Name'

   # Replace recipient@example.com with a "To" address. If your account
   # is still in the sandbox, this address must be verified.
   RECIPIENT = 'recipient@example.com'

   # Replace the USERNAME_SMTP value with your Email Delivery SMTP username.
   USERNAME_SMTP = '
ocid1.user.oc1..<unique_ID>@ocid1.tenancy.oc1..<unique_ID>.vf.com'

   # Put the PASSWORD value from your Email Delivery SMTP password into the
   # following file.
   PASSWORD_SMTP_FILE = 'ociemail.config'

   # If you're using Email Delivery in a different region, replace the HOST
   # value with an appropriate SMTP endpoint.
   # Use port 25 or 587 to connect to the SMTP endpoint.
   HOST = "smtp.us-ashburn-1.oraclecloud.com"
   PORT = 587

   # The subject line of the email.
   SUBJECT = 'Email Delivery Test (Python smtplib)'

   # The email body for recipients with non-HTML email clients.
   BODY_TEXT = "Email Delivery Test\r\n" "This email was sent through the Email Delivery SMTP " "Interface using the Python smtplib package."
   ```
Email Delivery

# The HTML body of the email.
BODY_HTML = """"<html>
<head></head>
<body>
<h1>Email Delivery SMTP Email Test</h1>
<p>This email was sent with Email Delivery using the
<a href='https://www.python.org/'>Python</a>
<a href='https://docs.python.org/3/library/smtplib.html'>smtplib</a> library.</p>
</body>
</html>"

# get the password from a named config file ociemail.config
with open(PASSWORD_SMTP_FILE) as f:
    password_smtp = f.readline().strip()

# create message container
msg = EmailMessage()
msg['Subject'] = SUBJECT
msg['From'] = email.utils.formataddr((SENDERNAME, SENDER))
msg['To'] = RECIPIENT

# make the message multi-part alternative, making the content the first part
msg.add_alternative(BODY_TEXT, subtype='text')
# this adds the additional part to the message
# According to RFC 2046, the last part of a multipart message, in this case
# the HTML message, is best and preferred.
msg.add_alternative(BODY_HTML, subtype='html')

# Try to send the message.
try:
    server = smtplib.SMTP(HOST, PORT)
    server.ehlo()
    # most python runtimes default to a set of trusted public CAs that will include the CA used by OCI Email Delivery.
    # However, on platforms lacking that default (or with an outdated set of CAs), customers may need to provide a capath that includes our public CA.
    server.starttls(context=ssl.create_default_context(purpose=ssl.Purpose.SERVER_AUTH, cafile=None, capath=None))
    # smtplib docs recommend calling ehlo() before & after starttls()
    server.ehlo()
    server.login(USERNAME_SMTP, password_smtp)
    # our requirement is that SENDER is the same as From address set previously
    server.sendmail(SENDER, RECIPIENT, msg.as_string())
    server.close()
except Exception as e:
    print(f"Error: {e}")
else:
    print("Email successfully sent!")

Note:
Python 2 and legacy email APIs should not be used with Email Delivery.
5. In a file editor such as vi, create a file that contains the SMTP password. Run the following command and replace the contents with your SMTP password:

```bash
sudo vi ociemail.config
```

6. To send a test email with Python, run the following command from the directory the script is located in:

```bash
python3 ociemail.py
```

**More Information**

- More Python script examples can be found on [GitHub](https://github.com).

**Troubleshooting Email Delivery**

This topic provides troubleshooting solutions for problems you might encounter using Email Delivery.

**TLS errors when integrating with Postfix**

- If you are encountering TLS errors when attempting to integrate Postfix with Email Delivery, ensure that the following setting is removed from the Postfix `main.cf` file, as it has been deprecated:

  ```
  smtp_use_tls = yes
  ```

- Use the following setting instead to turn on TLS:

  ```
  smtp_tls_security_level = may
  ```

  Using this setting, the Postfix SMTP server announces STARTTLS support to remote SMTP clients, but does not require that clients use TLS encryption.

- If you want to enforce the use of TLS, so that the Postfix SMTP server announces STARTTLS and accepts no mail without TLS encryption, use the following setting:

  ```
  smtp_tls_security_level = encrypt
  ```

  For more information, see [Postfix TLS Support](https://www.postfix.org/tls.html).

**Connectivity Issues**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email Delivery does not prohibit connectivity from any source IP range. Any IP that attempts to connect to Email Delivery will be accepted.</td>
</tr>
</tbody>
</table>

Refer to [Configure SMTP Connection](https://docs.oracle.com/en-us/iaas/Content/Email FAMILY/Concepts/ociemail.htm#ociemail_connection) on page 1753 for a list of regional endpoints to establish SMTP connections for sending.

**To troubleshoot a problem connecting to endpoint network ports**

- Ensure that you have the correct endpoint DNS name or IP address for the region and that you have been allowlisted to use the endpoint.
Email Delivery

- Test connectivity to the endpoint using port 25 or 587. Use a utility such as Telnet or netcat to attempt to connect to the port manually.
  
  1. Open a command prompt.
  2. Use the following command to test the network connection.

```
telnet <SMTP endpoint> <port>
```

For example:

```
telnet smtp.us-ashburn-1.oraclecloud.com 25
```

The port is open and the test is successful if a blank screen appears. If you are unable to connect to the ports using telnet, you are experiencing a network connectivity issue.

**To troubleshoot a problem connecting to an external mail transfer agent (MTA)**

Use the following steps to determine whether you are able to communicate with an external service on the required ports 25 or 587. If you are unable to connect successfully, you are experiencing a network connectivity issue. If you are able to connect to an external MTA, the network connectivity issue is within Oracle Cloud Infrastructure.

- Connect to an external MTA such as Google's mail exchangers.
  
  1. Open a command prompt.
  2. Use the following command to retrieve one of Google's MX server records.

```
dig MX google.com
```

3. Use the following command to test connectivity to the endpoint port 25 or 587 against Google's MX servers.

```
telnet <IP address> <port>
```

If you are unable to connect to Google's MX servers, this confirms that you are having issues connecting to mail servers (port 25 or 587). It is possible that your egress rules are filtering traffic at the VCN.

If you can connect to an external MTA (that is, you are able to communicate with a public SMTP endpoint on the correct ports) but you cannot connect to Email Delivery public SMTP endpoints on those ports, create a service request with My Oracle Support with this information.

**Common Errors Returned by Email Delivery**

**API Errors**

For a complete list of common errors returned by all the services for Oracle Cloud Infrastructure, see API Errors.

**Common SMTP Errors Returned by Email Delivery**

The following table lists the common errors returned by the Email Delivery SMTP service.

<table>
<thead>
<tr>
<th>SMTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>254</td>
<td>4.7.1</td>
<td>Message has been accepted but a status code was returned indicating suppression. Enhanced Status Code 4.7.1 indicated a persistent transient failure (RFC3463).</td>
</tr>
<tr>
<td></td>
<td>Suppression for user &lt;user ocid&gt; to &lt;recpt&gt;</td>

</tr>
</tbody>
</table>

**Service Limits**

For Email Delivery limits issues, see Email Delivery Service Capabilities and Limits and Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

**Troubleshooting Undelivered Emails**

The following issues can cause an email to be undelivered:

- The recipient is on the Suppression List.
- An authentication failure or an issue with the format of the email message occurred. For example, if the SMTP "From" address is not the same as the "From" address in the email body, the email is rejected. The addresses must match and be an Approved Sender. Refer to your sending application’s logs to review any issues.
Refer to Deliverability Best Practices to learn about recommendations that can help lower your email bounce rate, stay off blocklists, lower your complaint rate, and improve your email sender reputation.

If you are unable to resolve the issue, you can go to My Oracle Support and create a service request. See 4. Open a support service request on page 126 for more information.

Deliverability Best Practices

Deliverability Best Practices help you to learn and manage the habits that affect your sending reputation. These recommendations can help lower your email bounce rate, stay off blocklists, lower your complaint rate, and improve your email sender reputation.

Implement an Opt-in Process

An opt-in process is a method for your users to subscribe to your mailing list, which gives you permission to send messages. Only send messages to subscribers who have opted-in to your mailing list. There are two types of opt-in procedures.

- **Single opt-in (unconfirmed):** A user provides their email address and gives permission to receive relevant messages. Once the address is provided, messages can be sent without confirming the email address belongs to the user who provided it.

- **Double opt-in (confirmed):** A user provides their email address, but before the first mailing, a confirmation email is sent to the account owner. The email requires action from the account owner to confirm that future messages are wanted. An account can be verified by having the owner click a link for reply to the email. The confirmation email ensures that the address was not added to a third-party mailing list without consent.

Purge Unengaged Users

Remove unengaged users by implementing a process. If a recipient is not engaging with your mail by either opening or clicking the email, this might be an indication that the email account is not in use or that the recipient is no longer interested in your content. If the recipient does not use the email account, eventually the mailbox provider terminates the account or transforms the account into a spam trap. Remove recipients who have not engaged with your email in a time frame defined by your business model. Purging unengaged users helps your deliverability by increasing your user engagement rate.

Review Your Subscriber List

When reviewing your subscriber list, keep these things in mind:

- Eliminate duplicate addresses before sending. If addresses that do not exist are mailed to multiple times, your hard bounce rate could be inflated.
- Ensure that a previous suppression list (possibly from another email service provider) was not accidentally included.
- Verify that subscribers have opted-in. Do not send to an old list that you found.
- Restrict users from uploading their email client’s contact list in a “select all” fashion. Forcing users to select addresses individually prevents users from accidentally including potentially out of date or expired addresses.

Evaluate Your Sending Frequency

Sending too many emails in a short time might aggravate recipients, causing the recipients to mark your messages as spam. This is called list fatigue. Ensure that your message cadence aligns with the expected frequency of your content. Reducing frequency might reduce spam complaints. Ensure that your content is relevant to your subscribers. Keep your email messages consistent to your audience. A person who subscribed to a list for coupon updates might not want regular emails about auto loan finance rates. These unexpected messages are likely to be marked as spam, which decreases your sender reputation.
Easily Accessible Unsubscribe URL

Unsubscribing helps your inbox success by sending only to recipients that engage by opening or clicking. When people complain, your sending reputation is harmed. Make it easy for recipients to be removed from the list. Do not hide the unsubscribe URL at the bottom of the message. A small percentage of users scroll to the bottom of the email and search for a small URL. Most users mark the email as spam.

Canadian Anti-Spam Law (CASL) Guide

Canada's Anti-Spam Law (CASL) is one of the best guides to ensuring your compliance with the law, users’ desire, and the intended filtering that most mailbox providers use. If you are a Canadian email sender or you send email to Canadian residents, you must comply with CASL. The following information is intended to help provide you with some guidance for complying with CASL. This article does not constitute legal advice, nor is it intended supplement or otherwise affect your rights or obligations under your service agreement with Oracle, including your obligations under Oracle’s Acceptable Use Policy. If you have questions about CASL or the legality of your sending practices, we encourage you to speak with an attorney who specializes in that subject matter.

What is covered by CASL?

CASL and its related regulations apply to any “commercial electronic message” sent from or to Canadian computers and devices in Canada. Electronic messages that are merely routed through Canadian computer systems are not subject to CASL.

A “commercial electronic message” is any message that:

- Is in an electronic format, including emails, instant messages, text messages, and some social media communications.
- Is sent to an electronic address, including email addresses, instant message accounts, phone accounts, and social media accounts; and
- Contains a message encouraging recipients to take part in some type of commercial activity, including the promotion of products, services, people/personas, companies, or organizations.

Are there any types of messages that are exempt from CASL?

These types of electronic messages are exempt from CASL for various reasons.

- Messages to family or a person with established personal relationship.
- Messages to an employee, consultant, or person associated with your business.
- Responses to a current customer, or someone who has inquired in the last six months.
- Messages that will be opened or accessed in a foreign country, including the U.S., China, and most of Europe.
- Messages sent on behalf of a charity or political organization for the purposes of raising funds or soliciting contributions.
- Messages attempting to enforce a legal right or court order.
- Messages that provide warranty, recall, safety, or security information about a product or service purchased by the recipient.
- Messages that provide information about a purchase, subscription, membership, account, loan, or other ongoing relationship, including delivery of product updates or upgrades.
- A single message to a recipient without an existing relationship based on a referral. The full name of the referring person must be disclosed in the message. The referrer might be family or have another relationship with the person to whom you are sending.

If your message does not meet one of these criteria, consent is required under CASL. Not all of the previous messages listed are permitted under the Oracle Cloud Hosting and Delivery Policy.

What is “express consent”?

Under CASL, “express consent” means a written or oral agreement to receive specific types of messages. For example, “You want to receive monthly newsletters and weekly discount notifications from Oracle”.

Express consent is only valid if your request for consent clearly and simply describes the following information:
Email Delivery

- Your purpose in obtaining consent.
- A description of messages you will be sending.
- The name and contact information (physical mailing address and telephone number, email address, or website URL) of the requestor.
- A statement that the recipient can unsubscribe at any time.

The requestor can be you or someone for whom you are asking. If you are requesting consent on behalf of a client, the name and contact information of the client must be included with the consent request.

What is “implied consent”?
Under CASL, you can only obtain implied consent when certain circumstances exist, including when:

- A recipient has purchased a product, service or made another business deal, contract, or membership with your organization in the last 24 months.
- You are a registered charity or political organization, and the recipient has made a donation or gift, has volunteered, or attended a meeting organized by you.
- A professional message is sent to someone whose email address was given to you, or is conspicuously published, and who has not published or told you that unsolicited messages are not wanted.

What type of consent is required?
After July 1, 2017, you can only send to recipients with express consent or whose implied consent is valid under CASL.

Some additional requirements
In addition to understanding what qualifies as CASL-regulated message, and what type of consent is needed, there are a few other details to keep in mind.

- Retention of a record of consent confirmations is required.
- When requesting consent, checkboxes cannot be pre-filled to suggest consent. Each subscriber must check the box themselves for consent to be valid.
- All messages sent must include the following:
  - your name
  - the person on whose behalf you are sending (if any)
  - your physical mailing address and telephone number
  - your email address or website URL
- All messages sent after consent must also include an unsubscribe mechanism, and unsubscribes must be processed within ten days.

Where can I find more information on CASL?
The full text of the law can be found on the website for the Canadian Justice Department. The Canadian Radio and Telecommunications Commission has also set up an FAQ page and some guidelines for obtaining consent. If you have any questions, we encourage you to contact an attorney who is familiar with the law.

Oracle Cloud Hosting and Delivery Policy
Often, the Oracle Cloud Hosting and Delivery Policy is more stringent than CASL requirements. It is important that you review Oracle policies before using the service.

Troubleshooting Undelivered Emails
The following issues can cause an email to be undelivered:

- The recipient is on the Suppression List.
- An authentication failure or an issue with the format of the email message occurred. For example, if the SMTP "From" address is not the same as the "From" address in the email body, the email is rejected. The addresses must match and be an Approved Sender. Refer to your sending application’s logs to review any issues.
If you are unable to resolve the issue, you can go to My Oracle Support and create a service request. See Creating a Service Request Using the Console for more information.
Chapter 17

Events

This chapter explains how to create automation in your tenancy.

Overview of Events

Oracle Cloud Infrastructure Events enables you to create automation based on the state changes of resources throughout your tenancy. Use Events to allow your development teams to automatically respond when a resource changes its state.

Here are some examples of how you might use Events:

- Send a notification to a DevOps team when a database backup completes.
- Convert files of one format to another when files are uploaded to an Object Storage bucket.

How Events Works

Oracle Cloud Infrastructure services emit events, which are structured messages that indicate changes in resources. Events (the messages, not the service) follow the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF). This standard allows for interoperability between various cloud providers or on-premises systems and cloud providers. An event could be a create, read, update, or delete (CRUD) operation, a resource lifecycle state change, or a system event impacting a resource. For example, an event can be emitted when a backup completes or fails, or a file in an Object Storage bucket is added, updated, or deleted.

Services emit events for resources or data. For example, Object Storage emits events for buckets and objects. Services emit different types of events for resources, which are distinguished as event types. Buckets and objects have event types of create, update, and delete, for example. Event types are the changes that produce events by a given resource. For a list of services that produce events and the event types that those services track, see Services that Produce Events on page 1817.

You work with events by creating rules. Rules include a filter you define to specify events produced by the resources in your tenancy. The filter is flexible:

- You can define filters that match only certain events or all events.
- You can define filters based on the way resources are tagged or the presence of specific values in attributes from the event itself.

Rules must also specify an action to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions (more on these select services follows). The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
Events Concepts

The following concepts are essential to working with Events.

**EVENTS**

An automatic notification of a state change as reported by an event-emitting Oracle Cloud Infrastructure resource. For example, an database resource emits a `backup.begin` event when a backup begins.

**EVENT TYPES**

A distinction between the different types of events. For more information, see Services that Produce Events on page 1817.

**RULES**

A JSON object you create to subscribe to an event type and trigger an action should that event occur. For example, a rule might specify that `backup.end` event types from databases trigger the Notifications service to send an email to a particular DevOps engineer. For more information, see Matching Events with Filters on page 1796.

**ACTIONS**

Rules must also specify an action to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions. The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions
Events

Region Availability

Events is currently available in all regions of the commercial realm. Events is currently not available in regions within the Government Cloud realm.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: You must write IAM policy that authorize users to work with rules. For more information, see Events and IAM Policies on page 1801.

Limits on Events Resources

The Events service has a limitation of 50 rules per tenancy.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Service Gateway and Events

The Events service also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Events public endpoints from private IP addresses in private subnets. For example, you can manage rules over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Events. See Access to Oracle Services: Service Gateway on page 3256 for details.

Getting Started with Events

This topic introduces you to creating automation with Events. You create a simple rule that sends a notification whenever someone creates a bucket in a particular compartment in your tenancy.

Setting Up for Events

To try out the Events service for this tutorial, you must have these things set up first:

- Create IAM policy for Events
Events

- Create a topic and subscription to use as an action

**Important:**

A tenancy administrator must configure your tenancy for Events. These configurations give you access to an Oracle Cloud Infrastructure tenancy with the necessary IAM policy and a resource to use as an action.

Create Users, Groups, and Compartments

You can use existing users, groups, and compartments or make new ones.

**To create groups and users**

If suitable users and groups for assigning users permissions to work with rules don't already exist, log in to the Console as a tenancy administrator and create them.

1. Log in to the Console as a tenancy administrator.
2. If you need a group for Events, perform these steps:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list of the groups in your tenancy is displayed.
   b. Click Create Group and create a new group (see To create a group on page 2420). Give the group a meaningful name and description. Avoid entering confidential information.
3. If you need user accounts for Events, perform these steps:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of
      the users in your tenancy is displayed.
   b. Click Create User and create one or more new users (see To create a user on page 2417).

4. If users haven't been added to groups already, perform these steps:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list
      of the groups in your tenancy is displayed.
   b. Click the group you want to use for Events.
   c. Click Add User to Group.
   d. Select the users from the drop-down list, and then click Add.

To create a compartment

If suitable compartment for rules and the resources that emit events doesn't already exist, log in to the Console as a
tenancy administrator and create it.

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A
   list of the compartments in your tenancy is displayed.
3. Click **Create Compartment** and create a new compartment (see To create a compartment on page 2442). Give the compartment a meaningful name and description. Avoid entering confidential information.

### Create IAM Policy for Events

Before users can start using Events to create automation, as a tenancy administrator you must create IAM policy:

**To create a policy that allows users to create and manage rules**

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
3. Select the root compartment.
4. Click **Create Policy**.
5. Enter the following:
   - **Name**: A meaningful name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A meaningful description. You can change this later if you want to.
   - **Statement**: Enter the following policy statements to give users in the group the ability to manage and create rules:
     - This line gives the user inspect access to resources in compartments to select actions.
     ```plaintext
     allow group <RuleAdmins> to inspect compartments in tenancy
     ```
     - This line gives the user access to defined tags to apply filter tags to rules.
     ```plaintext
     allow group <RuleAdmins> to use tag-namespaces in tenancy
     ```
     - These lines give the user access to Streaming resources for actions
     ```plaintext
     allow group <RuleAdmins> to inspect streams in tenancy
     allow group <RuleAdmins> to use stream-push in tenancy
     allow group <RuleAdmins> to use stream-pull in tenancy
     ```
     - These lines give the user access to Functions resources for actions.
     ```plaintext
     allow group <RuleAdmins> to use virtual-network-family in tenancy
     ```
allow group <RuleAdmins> to manage function-family in tenancy

This line gives the user access to Notifications topics for actions.

allow group <RuleAdmins> to use ons-topic in tenancy

This line gives the user manage access to rules for Events.

allow group <RuleAdmins> to manage cloudevents-rules in tenancy

6. Click Create.

Create Notifications Topic and Subscription

If a suitable Notifications topic doesn't already exist, then you must log in to the Console as a tenancy administrator and create it. Whether you use an existing topic or create a new one, add an email address as a subscription so that you can monitor that email account for notifications.

To create a topic

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Click Create Topic at the top of the topic list.

3. In the Create Topic dialog box, configure your topic.
   - Name: Required. Specify a friendly name for the topic. It must be unique; validation is case-sensitive. Avoid entering confidential information.
   - Description: Optional. Enter a description for the topic.
4. Click Create.

To create a subscription

1. Open the navigation menu. Under Solutions and Platform, go to Application Integration and click Notifications.
2. Click the name of the topic that you created in the previous step or the topic you intend to use for this tutorial.
3. On the topic detail page, click **Create Subscription**.

![Create Subscription Dialog Box](image)

4. In the **Create Subscription** dialog box, select **Email**, and then type an email address.

5. Click **Create**.

The subscription has been created and a subscription confirmation URL will be sent. The subscription remains in "Pending" status until it has been confirmed.

To confirm a subscription

- In the confirmation email sent to the address you specified in the previous procedure, click the confirmation URL.

Using the Console to Create a Rule

Use the Console to create a rule with a pattern that matches bucket creation events emitted by Object Storage. Specify the Notifications topic you created as an action to deliver matching events. To test your rule, create a bucket. Object Storage emits an event which triggers the action. Check the email specified in the subscription to receive your notification.

To create a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.
   
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.

3. Enter the following.
   
   - **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description**: Specify a description of what the rule does. You can change this description later.

4. In **Event Matching**, select **Event Type**.
   
   a. In **Service Name**, select **Object Storage**.
   b. In **Event Type**, select **Object Storage - Create Bucket**.

5. In **Actions**, specify the actions to trigger when the filter finds a match:
   
   a. In **Action Type**, select **Notifications**.
   b. In **Notifications Compartment**, select the compartment that contains the topic.
   c. In **Topic**, select the topic.

6. Click **Create Rule**.

**To create a bucket**

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.

4. In the **Create Bucket** dialog, specify the attributes of the bucket:
   
   - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     
     - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it’s accessible.

5. Click **Create Bucket**.
To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

Tip:
You will receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Using the CLI to Create a Rule

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

To create an action file

1. Create a file and add the following content.

```json
{
   "actions": [
   {
      "actionType": "ONS",
```
Tip: You can specify functions, streams, or topics as an action.

Example action file template

```
{
  "actions": [
    {
      "actionType": "FAAS",
      "description": "string",
      "functionId": "<function_OCID>",
      "isEnabled": true
    },
    {
      "actionType": "ONS",
      "description": "string",
      "isEnabled": true,
      "topicId": "<topic_OCID>
    },
    {
      "actionType": "OSS",
      "description": "string",
      "isEnabled": true,
      "streamId": "<stream_OCID>
    }
  ]
}
```

2. Fill in `<topic_OCID>` with actual topic OCID value from your tenancy.

3. Add a description.

4. Save the file with `action.json` as the file name.

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether the rule is evaluated.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

**Examples**

- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any child compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name CLI-created_rule
--is-enabled true --condition "{"eventType": ["com.oraclecloud.objectstorage.createbucket"]}"
--compartment-
```
id <compartment_OCID> --actions <path_to_json_formatted_actions_file> --
wait-for-state=ACTIVE

Note:
Replace the values in <compartment_OCID> and
<path_to_json_formatted_actions_file> with the actual values from your
tenancy and local file system.

When you run the preceding command, the CLI prompts you about the rule and its display:

```
Action completed. Waiting until the resource has entered state: ACTIVE
{
    "data": {
        "actions": [
            {
                "action-type": "ONS",
                "description": "Notifications action",
                "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
                "lifecycle-message": null,
                "lifecycle-state": "ACTIVE",
                "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
            }
        ],
        "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
        "condition": "{"eventType": ["com.oraclecloud.objectstorage.createbucket"]}",
        "defined-tags": {},
        "description": null,
        "display-name": "CLI-created_rule",
        "freeform-tags": {},
        "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
        "is-enabled": true,
        "lifecycle-message": null,
        "lifecycle-state": "ACTIVE",
        "time-created": "2019-04-25T01:32:56.855000+00:00"
    },
    "etag": "<unique_ID>--gzip"
}
```

To create a bucket

1. Open the navigation menu. Under Core Infrastructure, click Object Storage.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click Create Bucket.
4. In the Create Bucket dialog, specify the attributes of the bucket:
   - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the Archive tier is not immediate. You must restore archived data before it’s accessible.
5. Click Create Bucket.
To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

Tip:

You receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Matching Events with Filters

This topic describes how to match events with pattern filters in rules to build automation.

Background

To understand filtering, it’s helpful to review the structure of an actual event message. Events uses JSON objects to represent events. This is an event:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.deletebucket",
  "source": "objectstorage",
  "eventTypeVersion": "1.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceId": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "NfHZ:PHX-AD-2",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

Two key points to remember about all events:

- Events all have the same set of top-level attributes, which are known as the event envelope. With one exception, most of these top-level attributes are not that useful for creating filters. The exception is eventType, which identifies the type of event included in the payload.

- The payload of the event appears within the data attribute. The information in this field depends on which service produced the event and the event type requested. The information in the payload is useful for isolating one event from another with a filter.
For more information about the envelope, see Contents of an Event Message on page 1814. For a list of all the services that produce events, see Services that Produce Events on page 1817.

**Event Matching with Filters**

Rules use filters to select events and route them for delivery to action resources. A rule is represented as a JSON object, similar to an event. The filter is an attribute of the rule, and the attribute is named `condition`. A filter either matches an event or it does not.

A few important things to remember about filters:

- Fields not mentioned in a filter are ignored. You can create a valid filter that matches all event messages with two curly brackets.
- For a filter to match an event, the event must contain all the field names listed in the filter. Field names must appear in the filter with the same nesting structure used in the event.
- Rules apply to events in the compartment in which you create them and any child compartments. This means that a filter specified by a rule only matches events emitted from resources in the same compartment or any child compartments.
- Wildcard matching is supported with the asterisk (*) character. See Examples of Wildcard Matching in Filters on page 1799.

**Examples of Simple Filters**

The following filter matches every event in the compartment and any child compartments where you create the rule.

```json
{
  ...
  "condition": "{ }"
}
```

When you add fields to the filter, you limit the events that the filter can match. For example, the following filter matches only `deletebucket` events.

```json
{
  ...
  "condition": "{
    "eventType": "com.oraclecloud.objectstorage.deletebucket"
  }"
}
```

To create a filter for more than one event type, use an array in `eventType`. The following filter matches `deletebucket` and `createbucket` events.

```json
{
  ...
  "condition": "{
    "eventType": [
      "com.oraclecloud.objectstorage.deletebucket",
      "com.oraclecloud.objectstorage.createbucket"
    ]
  }"
}
```
Examples of Filters with Event Payload Attributes

Both of the following filters would match the event at the top of the page. The first because filter specifies two fields and both fields appear in the event, the second because the "NoPublicAccess" type appears in the event.

The important thing to note is how the field names in the filter match the nesting structure of the event.

```json
{
...
"condition": "{
"data": {
  "compartmentName": "example_name",
  "resourceName": "my_bucket"
}
}""
}
```

Neither of the following filters would match the event at the top of this page. The first because the filter specifies a PublicAccessType not found in the event. The second because the event specifies a name for different bucket.

```json
{
...
"condition": "{
"data": {
  "additionalDetails": {
    "publicAccessType": "NoPublicAccess"
  }
}
}""
}
```

```json
{
...
"condition": "{
"data": {
  "compartmentName": "example_name",
  "resourceName": "my_bucket",
  "additionalDetails": {
    "publicAccessType": "PublicAccess"
  }
}
}""
}
```

```json
{
...
"condition": "{
"data": {
  "additionalDetails": {
    "publicAccessType": "NoPublicAccess"
  }
}
}""
}
```
Examples of Arrays in Filters

Arrays in filters match events if any of the values in the filter match a value in an event. The following filter would match the event at the top of the page because the name of the bucket in the event is included in an array in the filter.

```json
{
  ...
  "condition": 
  "data": 
  "resourceName": [
    "my_bucket_2",
    "my_bucket_1",
    "my_bucket"
  ],
  "additionalDetails": 
  "namespace": "example_namespace",
  "publicAccessType": "NoPublicAccess"
}
```

You can use an array in `eventType` (or any of the top-level fields), the event payload as shown in the preceding example, or both the event payload and a top-level field.

```json
{
  ...
  "condition": 
  "eventType": [
    "com.oraclecloud.objectstorage.deletebucket",
    "com.oraclecloud.objectstorage.createbucket"
  ],
  "data": 
  "resourceName": [
    "my_bucket_2",
    "my_bucket_1",
    "my_bucket"
  ],
  "additionalDetails": 
  "namespace": "example_namespace",
  "publicAccessType": "NoPublicAccess"
}
```

Examples of Wildcard Matching in Filters

The following are a few things to consider about wildcard matching with filters.

- Use the wildcard only in attribute values. You cannot use the asterisk for matching in keys.
- An attribute value with only an asterisk matches all values for the associated attribute name, but not null.
- The period character has no special meaning in a filter.

You can add the asterisk at the start of a string, in the middle, or at the end. All of the filters that follow match the event at the top of the page.

- The first matches because the wildcard in `displayName` matches the bucket naming pattern.
- The second one matches because the `publicAccessType` uses a wildcard. Because of the use of the wildcard, these first two filters would also match events from buckets with a similar naming pattern and would include events from buckets with or without public access.
- The third one matches because the event type includes all types of bucket events.

```json
{
...
"condition": "{
    "data": {
        "resourceName": "my_bucket*",
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess"
        }
    }
}
}
```

```json
{
...
"condition": "{
    "data": {
        "resourceName": ["my_bucket_2", "my_bucket_1", "my_bucket"],
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "*
        }
    }
}
}
```

```json
{
...
"condition": "{
    "eventType": "com.oraclecloud.objectstorage.*bucket",
    "data": {
        "resourceName": ["my_bucket_2", "my_bucket_1", "my_bucket"],
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess"
        }
    }
}
}
```
Events and IAM Policies

This topic describes how an administrator must write IAM policy for the Events service. If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more details about how to write IAM policy for Events, see Details for the Events Service on page 2272.

Allow Users to Work with Rules

These IAM policies allow users to manage or list rules.

**Let users list rules in a compartment**

*Type of access:* Ability to list Events rules.

*Where to create the policy:* In the tenancy.

Allow group RuleReaders to read cloudevents-rules in tenancy

The preceding policy allows RuleReaders to list rules in the tenancy.

**Let admins manage rules in a compartment**

*Type of access:* Ability to manage Events rules, including creating, deleting, updating or moving rules to a different compartment.

*Where to create the policy:* In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

allow group <RuleAdmins> to inspect compartments in tenancy

This line gives the user access to defined tags to apply filter tags to rules.

allow group <RuleAdmins> to use tag-namespaces in tenancy

These lines give the user access to Streaming resources for actions.

allow group <RuleAdmins> to inspect streams in tenancy
allow group <RuleAdmins> to use stream-push in tenancy
allow group <RuleAdmins> to use stream-pull in tenancy

These lines give the user access to Functions resources for actions.

allow group <RuleAdmins> to use virtual-network-family in tenancy
allow group <RuleAdmins> to manage function-family in tenancy

This line gives the user access to Notifications topics for actions.

allow group <RuleAdmins> to use ons-topic in tenancy

This line gives the user manage access to rules for Events.

allow group <RuleAdmins> to manage cloudevents-rules in tenancy

Managing Rules for Events

This topic describes how to manage rules for the Events service. For more information about Events, see Overview of Events on page 1784.
Prerequisites for Creating Rules

- Action resources: You must have resources already set up to specify as an action. The Events service invokes the action specified in the rule by delivering the event message to action resources, which can include topics, streams, or functions. Every rule must have at least one action. The Events service can invoke any of the following services by delivering an event message for processing:
  - Notifications
  - Streaming
  - Functions
- IAM policies: To manage or list rules, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform a task and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information, see Events and IAM Policies on page 1801.
- Event messages: To create rules, the resources you want to monitor with the rule must emit events. For more information, see Services that Produce Events on page 1817.

Working with Rules

**Note:** Each rule can have a maximum of 10 actions.

A typical workflow for setting up rule might follow this pattern:

1. **Identify action resources**
   
   Set up or identify whatever action resources you intend to use with the rule. For example, you might set up a Notifications topic and create subscriptions for the DevOps team so that they are notified when backups complete. If a topic already exists, you can use it instead of creating a topic. The resources you specify for actions do not have to be in the same compartment as the rule.

2. **Plan filtering**
   
   Ensure the resources that you want to monitor emit events to the Events service and plan your pattern matching strategy. For example, you might want to monitor backups on Autonomous Data Warehouse instances in the ABC compartment. Ensure Autonomous Data Warehouse instances emit an event type you can use to create the automation you require. Review the example JSON event to determine the best way to identify those resources in filters. See Matching Events with Filters on page 1796 and Services that Produce Events on page 1817.

3. **Create the rule**
   
   Rules apply to events in the compartment in which you create them and any child compartments. Create a rule in the compartment with the resource you want to monitor and specify where to deliver matching events. For example, in the ABC compartment, you might create a rule that filters for Autonomous Data Warehouse backup events. Since Events has no requirement about the location of action resources, you could specify a topic in the XYZ compartment as the resource to deliver any matching events.

Managing Tags for Rules

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

Tags and Event Filtering

With Events, you can also use tags to target resources in your tenancy. You target resources by adding the tag to a filter in a rule. A filter tag helps you hone automation by targeting only resources that contain a particular tag. For example, let's say you have dozens of Database instances in your tenancy, but only a few of the most critical of these instances have the tag "Operations." You could create a rule that triggers a particular action for resources that only contain the "Operations" tag.
Policy for working with filter tags is no different from policy for working with tags.

To manage filter tags

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click rule's name.
3. In the Resources menu, click Event Matching.
4. In the Filter Tags section, you can view or edit existing filter tags, or click Add Filter Tag to add new ones.

To manage tags for rules

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click rule's name.
3. Click the Tags tab to view or edit existing tags, or click Add Tags to add new ones.

For more information, see Resource Tags on page 211.

Move Rules to a Different Compartment

You can move rules from one compartment to another. When you move a rule to a new compartment, you stop monitoring events from resources in the current compartment and begin monitoring events in the new compartment (and any child compartments). After you move the rule to the new compartment, inherent policies apply immediately and affect access to the rules through the Console. Moving rules doesn't affect access by the Events service to actions defined in rules. For more information, see Working with Compartments on page 2432.

Monitoring Rules

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For more information about monitoring the rules you create, see Events Metrics on page 1917.

Object Events and the Events Service

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Using the Console

To create a rule

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click Create Rule.
   
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   
   - Display Name: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - Description: Specify a description of what the rule does. You can change this description later.
4. In **Rule Conditions**, create a filter:

**To add an event type**

a. Select **Event Type**.

b. Select a **Service Name**.

c. In **Event type**, select one or more event types for this service.

d. Click **+ Another Condition** and select **Event Type** to add event types for a different service.

This filter will match events of the event types you specify.

**To add an attribute**

You must first select an event type to add an attribute.

a. Select **Attribute**.

b. Select an **Attribute Name**. Attribute values are optional.

c. Enter an **Attribute Value**. Attribute values are optional.

d. Click **+ Another Condition** and select **Attribute** to add another attribute.

This filter will match events of the event types with the attributes you specify.

**To add a filter tag**

a. Select **Filter Tag**

b. Select a **Tag Namespace**.

To specify a free-form tag, select **None (apply a free-form tag)**.

c. Select a **Tag Key**.

d. Enter a **Tag Value**. Tag values are optional.

e. Click **+ Another Condition** and select **Filter Tag** to add another filter tag.

This filter will match events with the tags you specify.

Filter tags help you to hone automation by targeting only resources that contain a particular tag. If you want to use tags to organize your rules, use resource tags instead. For more information, see [Managing Tags for Rules](#) on page 1802.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can leave this field entirely blank to match all events. See <a href="#">Matching Events with Filters</a> on page 1796.</td>
</tr>
</tbody>
</table>

**To validate this rule**

You can only evaluate a rule against one event type at a time. To test different event types, repeat these steps as necessary.

a. Click **Validate Rule**. The **Test Rule** panel opens.

b. In **Service Name**, select a service if necessary.

c. In **Event Type**, select an event type, if necessary. A example event appears based on the selections you made. Edit the values in the event to match the values for any attributes and tags you added to your rule. For more information, see [Contents of an Event Message](#) on page 1814.

d. Click **Check if Example Event Matches Rule**. If the rule doesn't match, use the rule editor to modify any of the following:

   - Add or remove event types
   - Add or remove values or attributes
   - Add or remove tags
   - Insert wildcards

   For more information, see [Matching Events with Filters](#) on page 1796.

e. Click **Close**.
To view reference events

a. Click View example events (JSON). The View Example Events panel opens.
b. In Service Name, select a service if necessary.
c. In Event Type, select an event type, if necessary. An example event appears based on the selections you made. Use the events viewer to browse reference events.
d. Click Done.

For more information, see Contents of an Event Message on page 1814 and Matching Events with Filters on page 1796.

To add an attribute

5. In Actions, specify the actions resources to trigger when the filter finds a match:

To select a topic

a. Select Notifications.
b. Select the Notifications Compartment.
c. Select the Topic.
d. Click + Another Action and select Notifications to add another topic.

To select a stream

a. Select Streaming.
b. Select the Stream Compartment.
c. Select the Stream.
d. Click + Another Action and select Streaming to add another stream.

To select a function

a. Select Functions.
b. Select the Function Compartment.
c. Select a Function Application.
d. Select the Function.
e. Click + Another Action and select Functions to add another function.

6. Click Create Rule.

To edit a rule

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment that has the rule you want to edit.
3. For the rule you want to edit, click the Actions icon (three dots), and then click Edit.
4. Make your changes and click Save Changes.

To disable or enable a rule

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment that has the rule you want to work with.
3. For the rule, you want change, click the Actions icon (three dots), and then take one of the following actions:
   a. Click Disable
   b. Click Enable
4. Confirm when prompted.

To move a rule to a different compartment

1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. In the Scope section, select a compartment.
3. Find the rule in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To validate a rule**

You can only evaluate a rule against one event type at a time. Repeat as necessary to test different event types.

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to test.
3. Click **Validate Rule**.
4. Take one or more of the following actions:
   - If there are no event types in the rule, select the service and event type you want to test.
   - If you want to test a different event type than the one selected by default, select the service and event type you want to test.
   - If you added attribute values or filter tags to the rule, edit the example data in the event to match the values in your rule.
5. Click **Check if Example Event Matches Rule**.

For more information, see **Matching Events with Filters** on page 1796 and **Contents of an Event Message** on page 1814.

**To delete a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose the **Compartment** that has rule you want to delete.
3. For the rule you want to delete, click the Actions icon (three dots) , and then click **Delete**.
4. Confirm when prompted.

**To add an action to a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Click **Add**.
   - The **Add Action** box appears. Configure the action resources:
     - **To select a topic**
       a. Select **Notifications**.
       b. Select the **Notifications Compartment**.
       c. Select the **Topic**.
     - **To select a stream**
       a. Select **Streaming**.
       b. Select the **Stream Compartment**.
       c. Select the **Stream**.
     - **To select a function**
       a. Select **Functions**.
       b. Select the **Function Compartment**.
       c. Select a **Function Application**.
       d. Select the **Function**.
   - **Action State**: Select to enable the action. Clear to disable.
5. Click Add Action.

To edit an action
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and click Edit. The Edit Action box appears.
6. Make your changes and click Save Changes.

To enable or disable an action
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and specify Enable or Disable.
6. Confirm when prompted.

To remove an action
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and click Remove.
6. Confirm when prompted.

Each rule must have one action.

To add event types to a rule
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Click Add Event Type.
5. In Service Name, select a service.
6. In Event Type, select an event type for this service.
7. Click Add Event Type.

To edit event types for a rule
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Select an event type.
5. Click Edit. The Edit Event Type box appears.
6. Make your changes and click Save Changes.

To remove event types for a rule
1. Open the navigation menu. Under the Solutions and Platform group, go to Application Integration and click Events Service.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the event types you want to remove.

   **Tip:**
   To select the entire list, select the check box in the header row.
5. Click **Remove**.
6. Confirm when prompted.

### To add attributes to a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Attribute**. The **Add Attribute** box appears. Configure the attribute:

   - **Attribute Name**: Specify an attribute or tag to narrow matching results.
     - Select an attribute name. The list of attribute names is based on the event types you selected. If you select no event types, you cannot add an attribute.
     - If you specify an attribute here, you limit the events that match this rule.
   - **Attribute Values**: Specify one or more values for the attribute name.
     a. Enter a value. As you type, the value appears under the field with (New) appended. Select the value with (New) appended to add the value to **Attribute Values**.

![ATTRIBUTE VALUES](image)

b. Enter more values for attribute name in the same manner as before.

![ATTRIBUTE VALUES](image)

Here are some things to consider about attribute values:

- Use an asterisk to create a wildcard. See Examples of Wildcard Matching in Filters on page 1799.
- Multiple values for an attribute name broaden your results. If any of the values you enter here match a value in an event, the rule matches. See Examples of Arrays in Filters on page 1799.
5. Click **Add attribute**.
**To edit attributes for a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select an attribute.
5. Click **Edit**. The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

**To remove attributes for a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the attributes you want to remove.
5. Click **Remove**.
6. Confirm when prompted.

**To add filter tags to a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Filter Tag**.
5. In **Tag Namespace**, do one of the following:
   - Select a namespace to add a defined tag as a filter.
   - Select **None (apply a free-form tag)** to add a free-form tag as a filter.
6. In **Tag Key**, do one of the following:
   - Select the tag key for the defined tag.
   - Enter the tag key for the free-form tag.
7. Enter a **Value**.
8. Click **Add Filter Tag**.

**To edit filter tags for a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select a filter tag.
5. Click **Edit**. The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

**To remove filter tags for a rule**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the filter tags you want to remove.

   Tip:
   To select the entire list, select the check box in the header row.

5. Click Remove.
6. Confirm when prompted.

**Using the Command Line Interface (CLI)**

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**To create an action JSON file**

To specify the actions for your rule, use a JSON formatted file. For more information, see Advanced JSON Options on page 4214.

1. Create a file and add the following content. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   {
   "actions": [
   {
   "actionType": "FAAS",
   "description": "string",
   "functionId": "<function_OCID>",
   "isEnabled": true
   },
   {
   "actionType": "ONS",
   "description": "string",
   "isEnabled": true,
   "topicId": "<topic_OCID>"
   },
   {
   "actionType": "OSS",
   "description": "string",
   "isEnabled": true,
   "streamId": "<stream_OCID>"
   }
   ]
   }
   ```

2. Edit the file and remove any objects you don't want to use as an action. For example, if you wanted to only use Notifications as an action, then you would delete all the other objects.

   ```json
   { 
   "actions": [
   {
   "actionType": "ONS",
   "description": "string",
   "isEnabled": true,
   "topicId": "<topic_OCID>"
   }
   ]
   }
3. Edit the file and fill in any variables with actual values from your tenancy, as shown in the following example.

```json
{
  "actions": [
    {
      "actionType": "ONS",
      "description": "string",
      "isEnabled": true,
      "topicId": "<topic_OCID>"
    }
  ]
}
```

4. Add a description.
5. Save the file as action.json
6. To create a rule and specify Notifications as an action, run the following command.

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json
```

**To create a rule**

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether Events should evaluate the rule.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

**Examples**

The following example shows how to pass a simple condition that matches all events. Everything between the double quotes (" ") is a string, while the brackets { } indicate JSON:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

To pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character. For example:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{"eventType": ["com.oraclecloud.objectstorage.createobject"]}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

In PowerShell, to escape double quotes, you must use two characters: The backslash (\) and the back tick (`). For example, in Windows PowerShell:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{"eventType": ["com.oraclecloud.objectstorage.createobject"]}" --compartment-id <compartment_OCID> --actions file://action.json
```
Tip:
The condition option does not support using a file to pass the JSON formatted string.

For information on creating filters, see Matching Events with Filters on page 1796.

- **compartment-id** indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any subordinate compartments.
- **actions** indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- **wait-for-state=** when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition <json_formatted_string> --compartment-id <compartment_OCID> --actions <json_formatted_file> --wait-for-state=ACTIVE
```

**Note:**
Replace the values in `<compartment_OCID>` and `<json_formatted_file>` with the actual values from your tenancy and the local file system.

To delete a rule

Open a command prompt and run `oci events rule delete` to delete a single rule. For example:

```bash
oci events rule delete --rule-id <rule_OCID>
```

The command returns a prompt, asking for confirmation. Type y to delete the rule.

To get rule metadata

You can get rule metadata using the CLI. The Console displays this metadata in the Rule Details tab.

Open a command prompt and run `oci events rule get` to get information about a single rule. For example:

```bash
oci events rule get --rule-id <rule_OCID>
```

The command returns the following information:

```json
{
  "data": {
    "actions": {
      "actions": [
        {
          "action-type": "ONS",
          "description": null,
          "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
          "lifecycle-message": null,
          "lifecycle-state": "ACTIVE",
          "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
        }
      ],
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
```
To get a list of rules

Open a command prompt and run `oci events rule list` to list the rules in a compartment. For example:

```
oci events rule list --compartment-id <compartment_OCID>
```

The command returns the following information:

```json
{
  "data": [
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": "Example_Rule",
      "display-name": "rule_1",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:10:53.562000+00:00"
    },
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": null,
      "display-name": "rule_2",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:27:25.099000+00:00"
    },
    ...
  ]
}
```
To update a rule

Open a command prompt and run `oci events rule update` to update a rule.

To update the condition for a rule:

```
oci events rule update --rule-id <rule_OCID> --
condition <json_formatted_string>
```

For example:

```
oci events rule update --rule-id ocid1.eventrule.oc1.phx.<unique_ID> --
condition "{}" --wait-for-state=ACTIVE
```

The previous command would update the condition of the rule to use an empty JSON string. The CLI updates the rule, waits for the rule to update and change to the active state (only if you used the --wait-for-state option), then displays the updated rule.

Use the following options to update a rule:

- `display-name`
- `description`
- `is-enabled`
- `condition`
- `actions`
- `freeform-tags`
- `defined-tags`

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage rules:

- `ChangeRuleCompartment`
- `CreateRule`
- `DeleteRule`
- `GetRule`
- `UpdateRule`
- `ListRules`

Contents of an Event Message

This topic describes the contents of an event message. Every event message includes two main parts:

- Envelope: a container for all event messages
- Payload: the data from the resource emitting the event message

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).
### Property | Description
--- | ---
**cloudEventsVersion** | The version of the CloudEvents specification.  
  Note:  
  Events uses version 0.1 specification of the CloudEvents event envelope.
**contentType** | Set to *application/json*. The content type of the data contained in the data attribute.
**data** | The payload of the event. All of the information within data comes from the resource emitting the event. See the following table for more detail on the structure of the payload.
**eventID** | The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.
**eventTime** | The time of the event, expressed in RFC 3339 timestamp format.
**eventType** | The type of event that happened. For a list of all services that produce events and the even types that those services track, see Services that Produce Events on page 1817.  
  Note:  
  The service that produces the event can also add, remove, or change the meaning of a field by publishing a new version of an eventType and revising the eventTypeVersion field.
**eventTypeVersion** | The version of the event type.
**extensions** | The OCID of the compartment from which the event originates. If the event originates from the root compartment of the tenancy, then this attribute specifies a tenancy OCID. This attribute is mandatory in the Oracle Cloud Infrastructure implementation of the CloudEvents specification.
**source** | The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.

### Payload
The data in these fields depends on which service produced the event and the event type it defines.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compartmentId</strong></td>
<td>The OCID of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td><strong>compartmentName</strong></td>
<td>The name of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td><strong>resourceName</strong></td>
<td>The name of the resource emitting the event.</td>
</tr>
<tr>
<td><strong>resourceId</strong></td>
<td>An OCID or an ID for the resource emitting the event.</td>
</tr>
<tr>
<td><strong>availabilityDomain</strong></td>
<td>The availability domain of the resource emitting the event.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>freeFormTags</td>
<td>Free-form tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>definedTags</td>
<td>Defined tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>additionalDetails</td>
<td>A container for attributes unique to the resource emitting the event. In the example bucket event that follows, the payload includes three Object Storage attributes:</td>
</tr>
<tr>
<td></td>
<td>• namespace</td>
</tr>
<tr>
<td></td>
<td>• publicAccessType</td>
</tr>
<tr>
<td></td>
<td>• eTag</td>
</tr>
</tbody>
</table>
|                  | To determine what attributes are included for other resources, retrieve an event or consult the reference samples listed on Services that Produce Events on page 1817.

## Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

## An Example Event

The following is an example bucket event emitted by Object Storage.

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.deletebucket",
  "source": "objectstorage",
  "eventTypeVersion": "1.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "NfHz:PHX-AD-2",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```
Services that Produce Events

This topic lists the Oracle Cloud Infrastructure services that emit events:

- Analytics Cloud
- API Gateway
- Application Migration
- Big Data
- Block Volume
- Blockchain Platform
- Budgets
- Cloud Guard on page 1830
- Compute
- Container Engine for Kubernetes
- Content and Experience
- Database
- Data Catalog on page 1863
- Data Safe
- Data Science
- Data Transfer
- Digital Assistant
- File Storage
- Functions
- Health Checks
- IAM
- Integration
- Networking
- NoSQL Database Cloud
- Notifications
- Object Storage
- Operations Insights on page 1909
- OS Management
- Resource Manager
- WAF

About Event Types and Example Reference Events

Services emit event messages by resource type. Event messages use a combination of an event type and a data payload (from the resource) to identify state changes.

In this section:

- Event types are organized by service, then by resource type
- There is one reference example per resource type if the payload contains the same attributes for all event types

See Matching Events with Filters on page 1796 and Contents of an Event Message on page 1814.

Analytics Cloud

For details about events emitted by Analytics Cloud, see Service Events.
API Gateway

API Gateway resources that emit events:

- **API Gateway Certificate Event Types** on page 1818
- **API Deployment Event Types** on page 1819
- **API Gateway Event Types** on page 1820
- **API Event Types** on page 1821

**API Gateway Certificate Event Types**

These are the event types that API Gateway certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.begin</td>
</tr>
<tr>
<td>Change Certificate Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.end</td>
</tr>
<tr>
<td>Create Certificate Begin</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.begin</td>
</tr>
<tr>
<td>Create Certificate End</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.end</td>
</tr>
<tr>
<td>Delete Certificate Begin</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.begin</td>
</tr>
<tr>
<td>Delete Certificate End</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.end</td>
</tr>
<tr>
<td>Update Certificate Begin</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.begin</td>
</tr>
<tr>
<td>Update Certificate End</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.end</td>
</tr>
</tbody>
</table>

**API Gateway Certificate Example**

This is an example event for API Gateway certificates:

```json
{
    "eventType": "com.oraclecloud.apigateway.creategatewaycertificate.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_Certificate",
        "resourceId": "ocid1.apigatewaycertificate.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
API Deployment Event Types

These are the event types that API deployments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Deployment Compartment Begin</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.begin</td>
</tr>
<tr>
<td>Change Deployment Compartment End</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.end</td>
</tr>
<tr>
<td>Create Deployment Begin</td>
<td>com.oraclecloud.apigateway.createdeployment.begin</td>
</tr>
<tr>
<td>Create Deployment End</td>
<td>com.oraclecloud.apigateway.createdeployment.end</td>
</tr>
<tr>
<td>Delete Deployment Begin</td>
<td>com.oraclecloud.apigateway.deletedeployment.begin</td>
</tr>
<tr>
<td>Delete Deployment End</td>
<td>com.oraclecloud.apigateway.deletedeployment.end</td>
</tr>
<tr>
<td>Update Deployment Begin</td>
<td>com.oraclecloud.apigateway.updatedeployment.begin</td>
</tr>
<tr>
<td>Update Deployment End</td>
<td>com.oraclecloud.apigateway.updatedeployment.end</td>
</tr>
</tbody>
</table>

API Deployment Example

This is an example event for API deployments:

```json
{
  "eventType": "com.oraclecloud.apigateway.createdeployment.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "apigateway",
  "eventTime": "2019-08-16T15:09:04.550Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "My_Deployment",
    "resourceId": "ocid1.apideployment.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"  
  }
}
```
**API Gateway Event Types**

These are the event types that API gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Gateway Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.begin</td>
</tr>
<tr>
<td>Change Gateway Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.end</td>
</tr>
<tr>
<td>Create Gateway Begin</td>
<td>com.oraclecloud.apigateway.creategateway.begin</td>
</tr>
<tr>
<td>Create Gateway End</td>
<td>com.oraclecloud.apigateway.creategateway.end</td>
</tr>
<tr>
<td>Delete Gateway Begin</td>
<td>com.oraclecloud.apigateway.deletegateway.begin</td>
</tr>
<tr>
<td>Delete Gateway End</td>
<td>com.oraclecloud.apigateway.deletegateway.end</td>
</tr>
<tr>
<td>Update Gateway Begin</td>
<td>com.oraclecloud.apigateway.updategateway.begin</td>
</tr>
<tr>
<td>Update Gateway End</td>
<td>com.oraclecloud.apigateway.updategateway.end</td>
</tr>
</tbody>
</table>

**Gateway Example**

This is an example event for API gateways:

```json
{
    "eventType": "com.oraclecloud.apigateway.creategateway.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "eventID": "<unique_ID>"
}
```
## API Event Types

These are the event types that API resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change API Compartment Begin</td>
<td>com.oraclecloud.apigateway.changeapicompartment.begin</td>
</tr>
<tr>
<td>Change API Compartment End</td>
<td>com.oraclecloud.apigateway.changeapicompartment.end</td>
</tr>
<tr>
<td>Create API Begin</td>
<td>com.oraclecloud.apigateway.createapi.begin</td>
</tr>
<tr>
<td>Create API End</td>
<td>com.oraclecloud.apigateway.createapi.end</td>
</tr>
<tr>
<td>Delete API Begin</td>
<td>com.oraclecloud.apigateway.deleteapi.begin</td>
</tr>
<tr>
<td>Delete API End</td>
<td>com.oraclecloud.apigateway.deleteapi.end</td>
</tr>
<tr>
<td>Update API Begin</td>
<td>com.oraclecloud.apigateway.updateapi.begin</td>
</tr>
<tr>
<td>Update API End</td>
<td>com.oraclecloud.apigateway.updateapi.end</td>
</tr>
</tbody>
</table>

### API Example

This is an example event for API resources:

```json
{
    "eventType": "com.oraclecloud.apigateway.createapi.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2020-09-09T12:00:00.000Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_API",
        "resourceId": "ocid1.apigatewayapi.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

### Application Migration

For details about events emitted by Application Migration, see Service Events.
Big Data
For details about events emitted by Big Data, see Service Events.

Block Volume
Block Volume resources that emit events:
- Block Volume Event Types on page 1822 and Block Volume Backup Event Types on page 1824
- Boot Volume Event Types on page 1825 and Boot Volume Backup Event Types on page 1826
- Volume Groups and Volume Group Backups on page 1827

Block Volume Event Types
These are the event types that block volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changevolumecompartmentbegin</td>
</tr>
<tr>
<td>Change Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changevolumecompartmentend</td>
</tr>
<tr>
<td>Create Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createvolume.begin</td>
</tr>
<tr>
<td>Create Volume End</td>
<td>com.oraclecloud.blockvolumes.createvolume.end</td>
</tr>
<tr>
<td>Delete Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolume.begin</td>
</tr>
<tr>
<td>Delete Volume End</td>
<td>com.oraclecloud.blockvolumes.deletevolume.end</td>
</tr>
<tr>
<td>Delete Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumekmskey.begin</td>
</tr>
<tr>
<td>Update Volume</td>
<td>com.oraclecloud.blockvolumes.updatevolume</td>
</tr>
<tr>
<td>Update Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolumebegin</td>
</tr>
<tr>
<td>Update Volume End</td>
<td>com.oraclecloud.blockvolumes.updatevolume.end</td>
</tr>
<tr>
<td>Update Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.begin</td>
</tr>
<tr>
<td>Update Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.end</td>
</tr>
</tbody>
</table>

Block Volume Example
This is a reference event for block volumes:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createvolume.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_volume",
        "resourceId": "ocid1.volume.oc1..<unique_ID>",
        "availabilityDomain": "<availability_domain>"
    }
}
```

# Block Volume Backup Event Types

These are the event types that block volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumebackupcompartment</td>
</tr>
<tr>
<td>Copy Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.begin</td>
</tr>
<tr>
<td>Copy Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.begin</td>
</tr>
<tr>
<td>Create Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.createvolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Delete Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.begin</td>
</tr>
<tr>
<td>Delete Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.end</td>
</tr>
<tr>
<td>Delete Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Update Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackup</td>
</tr>
<tr>
<td>Update Volume Backup Policy</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackuppolicy</td>
</tr>
</tbody>
</table>

## Block Volume Backup Example

This is a reference event for block volume backups:

```json
{
  "eventType": "com.oraclecloud.blockvolumes.createvolumebackup.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "BlockVolumes",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_volumebackup via policy:gold",
    "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
    "additionalDetails": {
      "sourceType": "SCHEDULED",
      "volumeId": ""ocid1.volume.oc1..<unique_ID>"
    }
  }
}```
Boot Volume Event Types

These are the event types that boot volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.begin</td>
</tr>
<tr>
<td>Change Boot Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.end</td>
</tr>
<tr>
<td>Create Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.begin</td>
</tr>
<tr>
<td>Create Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.begin</td>
</tr>
<tr>
<td>Delete Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume</td>
</tr>
<tr>
<td>Update Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.begin</td>
</tr>
<tr>
<td>Update Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.end</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.end</td>
</tr>
</tbody>
</table>

Boot Volume Example

This is a reference event for boot volumes:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createbootvolume.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
```
"eventTime": "2019-01-10T21:19:24Z",
"contentType": "application/json",
"data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"",
    "compartmentName": "example_name",
    "resourceName": "my_volume",
    "resourceId": "ocid1.volume.oc1..<unique_ID>"",
    "availabilityDomain": "<availability_domain>"
}
"eventID": ":<unique_ID>"",
"extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}

Boot Volume Backup Event Types

These are the event types that boot volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changebootvolumebackup.compartment</td>
</tr>
<tr>
<td>Create Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackup.begin.</td>
</tr>
<tr>
<td>Create Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackup.end.</td>
</tr>
<tr>
<td>Delete Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackup.begin.</td>
</tr>
<tr>
<td>Delete Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackup.end.</td>
</tr>
<tr>
<td>Update Boot Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumebackup.</td>
</tr>
</tbody>
</table>

Boot Volume Backup Example

This is a reference event for boot volume backups:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createbootvolume.end",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"",
        "compartmentName": "example_name",
        "resourceName": "my_volumebackup via policy:gold",
        "resourceId": "ocid1.volumebackup.oc1..<unique_ID>"",
        "additionalDetails": {
            "sourceType": "SCHEDULED",
            "volumeId": "ocid1.volume.oc1..<unique_ID>"
        }
    }
}
```
Volume Groups and Volume Group Backups

These are the event types that volume groups and volume group backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Group Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupcompartment</td>
</tr>
<tr>
<td>Change Volume Group Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupbackupcompartment</td>
</tr>
<tr>
<td>Create Volume Group</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup</td>
</tr>
<tr>
<td>Create Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.begin</td>
</tr>
<tr>
<td>Create Volume Group End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.end</td>
</tr>
<tr>
<td>Create Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.begin</td>
</tr>
<tr>
<td>Create Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.end</td>
</tr>
<tr>
<td>Delete Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.begin</td>
</tr>
<tr>
<td>Delete Volume Group End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.end</td>
</tr>
<tr>
<td>Delete Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.begin</td>
</tr>
<tr>
<td>Delete Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.end</td>
</tr>
<tr>
<td>Update Volume Group</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroup</td>
</tr>
<tr>
<td>Update Volume Group Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroupbackup</td>
</tr>
</tbody>
</table>

Volume Group Example

This is a reference event for volume groups:

```json
{
  "eventType": "com.oraclecloud.blockvolumes.createvolumegroup",
  "cloudEventsVersion": "0.1",
}
### Blockchain Platform

For details about events emitted by Blockchain Platform, see [Service Events](#).

### Budgets

Budgets resources that emit events:

- [Alert Rule Event Types](#) on page 1828
- [Budget Event Types](#) on page 1829
- [Create Triggered Alert Event Types](#) on page 1830

#### Alert Rule Event Types

These are the event types that alert rule emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Alert Rule</td>
<td>com.oraclecloud.budgets.createalertrule</td>
</tr>
<tr>
<td>Update Alert Rule</td>
<td>com.oraclecloud.budgets.updatealertrule</td>
</tr>
<tr>
<td>Delete Alert Rule</td>
<td>com.oraclecloud.budgets.deletealertrule</td>
</tr>
</tbody>
</table>

#### Alert Rule Example

This is a reference event for creating an alert:

```json
{
    "eventType": "com.oraclecloud.budgets.createalertrule",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "budgets",
    "eventID": "<unique_ID>",
    "eventTime": "2020-02-02T20:20:02.002Z",
    "contentType": "application/json",
    "data": {
        "eventName": "CreateAlertRule",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
Budget Event Types

These are the event types that budget emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Budget</td>
<td>com.oraclecloud.budgets.createbudget</td>
</tr>
<tr>
<td>Update Budget</td>
<td>com.oraclecloud.budgets.updatebudget</td>
</tr>
<tr>
<td>Delete Budget</td>
<td>com.oraclecloud.budgets.deletebudget</td>
</tr>
</tbody>
</table>

Budget Example

This is a reference event for updating a budget:

```json
{
    "eventType": "com.oraclecloud.budgets.updatebudget",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "budgets",
    "eventID": "<unique_ID>",
    "eventTime": "2020-02-02T20:20:02.002Z",
    "contentType": "application/json",
    "data": {
        "eventName": "UpdateBudget",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My test budget",
        "resourceId": "ocid1.budget.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain",
        "additionalDetails": {
            "targetCompartmentId": "ocid1.tenancy.oc1..<unique_ID>",
            "targetType": "COMPARTMENT"
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
Events

Create Triggered Alert Event Types
This is the event type that the create triggered alert emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Triggered Alert</td>
<td>com.oraclecloud.budgets.createtriggeredalert</td>
</tr>
</tbody>
</table>

Create Triggered Alert Example
This is a reference event for creating a triggered alert:

```json
{
   "eventType": "com.oraclecloud.budgets.createtriggeredalert",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "budgets",
   "eventID": "<unique_ID>",
   "eventTime": "2020-02-02T20:20:02.002Z",
   "contentType": "application/json",
   "data": {
      "eventName": "CreateTriggeredAlert",
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceId": "ocid1.triggeredalert.oc1.phx.<unique_ID>",
      "availabilityDomain": "availability_domain",
      "additionalDetails": {
         "budgetId": "ocid1.budget.oc1.phx.<unique_ID>",
         "alertRuleId": "ocid1.alertrule.oc1.phx.<unique_ID>"
      }
   }
}
```

Cloud Guard
Cloud Guard resources that emit events:
- Problems
- Targets

Problem Event Types
These are the event types that problems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detected-Problem</td>
<td>com.oraclecloud.cloudguard.problemdetected</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>com.oraclecloud.cloudguard.problemremediated</td>
</tr>
</tbody>
</table>

Detected-Problem Example
This is a reference event for detected problems:

```json
{
}
```
Events

```
"eventType" : "com.oraclecloud.cloudguard.problemdetected",
"cloudEventsVersion" : "0.1",

            "firstDetected" : "2020-09-02T18:44:44.145Z",
```
Target Event Types
These are the event types that targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target-Information</td>
<td>com.oraclecloud.cloudguard.targetinformation</td>
</tr>
</tbody>
</table>

Target-Information Example
This is a reference event for target information:

```json
{
  "eventType": "com.oraclecloud.cloudguard.targetinformation",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "CloudGuard",
  "eventTime": "2020-02-11T01:29:51.404Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Compute
Compute resources that emit events:
- [Autoscaling Event Types](#) on page 1833
- [Cluster Network Event Types](#) on page 1834
Autoscaling Event Types

These are the event types that autoscaling configurations and autoscaling policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Autoscaling Configuration Compartment</td>
<td>com.oraclecloud.autoscaling.changeautoscalingconfigurationcompartment</td>
</tr>
<tr>
<td>Create Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.createautoscalingconfiguration</td>
</tr>
<tr>
<td>Delete Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.deleteautoscalingconfiguration</td>
</tr>
<tr>
<td>Scaling Action</td>
<td>com.oraclecloud.autoscaling.scalingaction</td>
</tr>
<tr>
<td>Update Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.updateautoscalingconfiguration</td>
</tr>
<tr>
<td>Update Autoscaling Policy</td>
<td>com.oraclecloud.autoscaling.updateautoscalingpolicy</td>
</tr>
</tbody>
</table>

Autoscaling Example

This is a reference event for autoscaling:

```json
{
    "eventType": "com.oraclecloud.autoscaling.scalingaction",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "autoscaling",
    "eventTime": "2019-08-21T04:00:10.046Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example autoscaling configuration",
        "resourceId": "ocid1.autoscalingconfiguration.oc1.phx.<unique_ID>",
        "additionalDetails": {
            "policyName": "my_policy_name",
            "ruleName": "my_scale_up_condition",
            "actionType": "SCALE_OUT",
            "previousSize": 1,
            "newSize": 2
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
Cluster Network Event Types

These are the event types that cluster networks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Cluster Network Compartment</td>
<td>com.oraclecloud.computemanagement.changeclusternetwork_compartment</td>
</tr>
<tr>
<td>Create Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.begin</td>
</tr>
<tr>
<td>Create Cluster Network End</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.end</td>
</tr>
<tr>
<td>Terminate Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.begin</td>
</tr>
<tr>
<td>Terminate Cluster Network End</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.end</td>
</tr>
</tbody>
</table>

Cluster Networks Example

This is a reference event for most cluster network events:

```json
{
   "eventType": "com.oraclecloud.computemanagement.createclusternetwork.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "ComputeManagement",
   "eventTime": "2019-09-12T21:45:09.036Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "my_cluster_network",
      "resourceId": "ocid1.clusternetwork.oc1.uk-london-1.<unique_ID>",
      "availabilityDomain": "<availability_domain>",
   },
   "eventId": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Create cluster network end and terminate cluster network end don't include the availability domain.
## Console History Event Types

These are the event types that console histories emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capture Console History Begin</td>
<td>com.oraclecloud.computeapi.captureconsolehistory.begin</td>
</tr>
<tr>
<td>Capture Console History End</td>
<td>com.oraclecloud.computeapi.captureconsolehistory.end</td>
</tr>
<tr>
<td>Delete Console History</td>
<td>com.oraclecloud.computeapi.deleteconsolehistory</td>
</tr>
<tr>
<td>Update Console History</td>
<td>com.oraclecloud.computeapi.updateconsolehistory</td>
</tr>
</tbody>
</table>

### Console History Example

This is a reference event for console histories:

```json
{
    "eventType": "com.oraclecloud.computeapi.captureconsolehistory.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-20T21:58:13.554Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceId": "ocid1.consolehistory.oc1.iad.<unique_ID>",
        "availabilityDomain": "SoSC:PHX-AD-3"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
Image Event Types

These are the event types that images emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.addimageshapecompatibility</td>
</tr>
<tr>
<td>Change Image Compartment</td>
<td>com.oraclecloud.computeapi.moveimage</td>
</tr>
<tr>
<td>Create Image Begin</td>
<td>com.oraclecloud.computeapi.createimage.begin</td>
</tr>
<tr>
<td>Create Image End</td>
<td>com.oraclecloud.computeapi.createimage.end</td>
</tr>
<tr>
<td>Delete Image</td>
<td>com.oraclecloud.computeapi.deleteimage</td>
</tr>
<tr>
<td>Export Image Begin</td>
<td>com.oraclecloud.computeapi.exportimage.begin</td>
</tr>
<tr>
<td>Export Image End</td>
<td>com.oraclecloud.computeapi.exportimage.end</td>
</tr>
<tr>
<td>Remove Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.removeimageshapecompatibility</td>
</tr>
<tr>
<td>Update Image</td>
<td>com.oraclecloud.computeapi.updateimage</td>
</tr>
</tbody>
</table>

Image Example

This is a reference event for most image events:

```json
{
    "eventType": "com.oraclecloud.computeapi.exportimage.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-27T04:12:37.397Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.tenancy.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_image",
        "resourceId": "ocid1.image.oc1.iad.<unique_ID>",
        "availabilityDomain": "SoSC:PHX-AD-3"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.tenancy.oc1..<unique_ID>"
    }
}
```

Change image compartment doesn't include the resource name or availability domain.
### Instance Event Types

These are the event types that Compute instances and instance attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.attachbootvolume.begin</td>
</tr>
<tr>
<td>Attach Boot Volume End</td>
<td>com.oraclecloud.computeapi.attachbootvolume.end</td>
</tr>
<tr>
<td>Attach Secondary VNIC Begin</td>
<td>com.oraclecloud.computeapi.attachvnic.begin</td>
</tr>
<tr>
<td>Attach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.attachvnic.end</td>
</tr>
<tr>
<td>Attach Volume Begin</td>
<td>com.oraclecloud.computeapi.attachvolume.begin</td>
</tr>
<tr>
<td>Attach Volume End</td>
<td>com.oraclecloud.computeapi.attachvolume.end</td>
</tr>
<tr>
<td>Change Instance Compartment Begin</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.begin</td>
</tr>
<tr>
<td>Change Instance Compartment End</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.end</td>
</tr>
<tr>
<td>Detach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.detachbootvolume.begin</td>
</tr>
<tr>
<td>Detach Boot Volume End</td>
<td>com.oraclecloud.computeapi.detachbootvolume.end</td>
</tr>
<tr>
<td>Detach Secondary VNIC Begin</td>
<td>com.oraclecloud.computeapi.detachvnic.begin</td>
</tr>
<tr>
<td>Detach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.detachvnic.end</td>
</tr>
<tr>
<td>Detach Volume Begin</td>
<td>com.oraclecloud.computeapi.detachvolume.begin</td>
</tr>
<tr>
<td>Detach Volume End</td>
<td>com.oraclecloud.computeapi.detachvolume.end</td>
</tr>
<tr>
<td>Instance Action Begin</td>
<td>com.oraclecloud.computeapi.instanceaction.begin</td>
</tr>
<tr>
<td>Instance Action End</td>
<td>com.oraclecloud.computeapi.instanceaction.end</td>
</tr>
<tr>
<td>Launch Instance Begin</td>
<td>com.oraclecloud.computeapi.launchinstance.begin</td>
</tr>
<tr>
<td>Launch Instance End</td>
<td>com.oraclecloud.computeapi.launchinstance.end</td>
</tr>
<tr>
<td>Terminate Instance Begin</td>
<td>com.oraclecloud.computeapi.terminateinstance.begin</td>
</tr>
<tr>
<td>Terminate Instance End</td>
<td>com.oraclecloud.computeapi.terminateinstance.end</td>
</tr>
<tr>
<td>Update Instance</td>
<td>com.oraclecloud.computeapi.updateinstance</td>
</tr>
</tbody>
</table>
Events

Compute Instance Example

This is a reference event for most instance events (attach/detach volume and boot volume events don’t include additional details):

```
{
  "eventType": "com.oraclecloud.computeapi.launchinstance.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3",
    "additionalDetails": {
      "imageId": "ocid1.image.oc1.phx.<unique_ID>",
      "shape": "VM.Standard2.1",
      "type": "CustomerVmi"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for attach/detach VNIC events:

```
{
  "eventType": "com.oraclecloud.computeapi.attachvnic.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3",
    "additionalDetails": {
      "subnetId": "ocid1.subnet.oc1.phx.<unique_ID>"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for instance action events:

```
{
  "eventType": "com.oraclecloud.computeapi.instanceaction.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-16T12:07:14.623Z",
```
Events

```
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_compartment",
  "resourceName": "my_instance",
  "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
  "availabilityDomain": "SoSC:PHX-AD-3",
  "additionalDetails": {
    "imageId": "ocid1.image.oc1.phx.<unique_ID>",
    "instanceActionType": "start",
    "shape": "VM.Standard2.1",
    "type": "CustomerVmi"
  }
},
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}
```

**Instance Configuration Event Types**

These are the event types that Compute instance configurations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Instance Configuration Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstanceconfiguration</td>
</tr>
<tr>
<td>Create Instance Configuration</td>
<td>com.oraclecloud.computemanagement.createinstanceconfiguration</td>
</tr>
<tr>
<td>Delete Instance Configuration</td>
<td>com.oraclecloud.computemanagement.deleteinstanceconfiguration</td>
</tr>
<tr>
<td>Launch Instance Configuration Begin</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.begin</td>
</tr>
<tr>
<td>Launch Instance Configuration End</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.end</td>
</tr>
<tr>
<td>Update Instance Configuration</td>
<td>com.oraclecloud.computemanagement.updateinstanceconfiguration</td>
</tr>
</tbody>
</table>

**Compute Instance Configuration Example**

This is a reference event for most instance configuration events:

```
{
  "eventType": 
    "com.oraclecloud.computemanagement.createinstanceconfiguration",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeManagement",
  "eventTime": "2019-08-12T22:52:01.062Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance_configuration",
```
Launch instance configuration end doesn't include the availability domain.

**Instance Console Connection Event Types**

These are the event types that Compute instance console connections emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Instance Console Connection Begin</td>
<td><code>com.oraclecloud.computeapi.createinstanceconsoleconnection.begin</code></td>
</tr>
<tr>
<td>Create Instance Console Connection End</td>
<td><code>com.oraclecloud.computeapi.createinstanceconsoleconnection.end</code></td>
</tr>
<tr>
<td>Delete Instance Console Connection Begin</td>
<td><code>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.begin</code></td>
</tr>
<tr>
<td>Delete Instance Console Connection End</td>
<td><code>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.end</code></td>
</tr>
<tr>
<td>Update Instance Console Connection Begin</td>
<td><code>com.oraclecloud.computeapi.updateinstanceconsoleconnection.begin</code></td>
</tr>
<tr>
<td>Update Instance Console Connection End</td>
<td><code>com.oraclecloud.computeapi.updateinstanceconsoleconnection.end</code></td>
</tr>
</tbody>
</table>

**Compute Instance Console Connection Example**

This is a reference event for instance console connections:

```json
{
    "eventType": "com.oraclecloud.computeapi.createinstanceconsoleconnection.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-12T14:47:35.762Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceId": "ocid1.instanceconsoleconnection.oc1.phx..<unique_ID>",
        "availabilityDomain": "soSc:PHX-AD-3"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
## Instance Pool Event Types

These are the event types that Compute instance pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer.begin</td>
</tr>
<tr>
<td>Attach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer.end</td>
</tr>
<tr>
<td>Change Instance Pool Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstancepoolcompartment</td>
</tr>
<tr>
<td>Create Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.createinstancepool.begin</td>
</tr>
<tr>
<td>Create Instance Pool End</td>
<td>com.oraclecloud.computemanagement.createinstancepool.end</td>
</tr>
<tr>
<td>Detach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer.begin</td>
</tr>
<tr>
<td>Detach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer.end</td>
</tr>
<tr>
<td>Reset Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.begin</td>
</tr>
<tr>
<td>Reset Instance Pool End</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.end</td>
</tr>
<tr>

</table>
**Compute Instance Pools Example**

This is a reference event for most instance pool events:

```json
{
    "eventType": "com.oraclecloud.computemanagement.createinstancepool.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeManagement",
    "eventTime": "2019-08-12T22:52:01.343Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance_pool",
        "resourceId": "ocid1.instancepool.oc1.phx..<unique_ID>",
        "availabilityDomain": "<availability_domain>",
    },
    "eventId": "<unique_id>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

These instance pool events don’t include the availability domain: create instance pool end, detach load balancer end, reset instance pool end, soft reset instance pool end, start instance pool end, stop instance pool end, terminate instance pool end, and update instance pool end.

**Container Engine for Kubernetes**

Container Engine for Kubernetes resources that emit events:

- **Cluster Event Types** on page 1842
- **Node Pool Event Types** on page 1843

**Cluster Event Types**

These are the event types that clusters emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Cluster Begin</td>
<td><code>com.oraclecloud.clustersapi.createcluster.begin</code></td>
</tr>
<tr>
<td>Delete Cluster Begin</td>
<td><code>com.oraclecloud.clustersapi.deletecluster.begin</code></td>
</tr>
<tr>
<td>Update Cluster Begin</td>
<td><code>com.oraclecloud.clustersapi.updatecluster.begin</code></td>
</tr>
</tbody>
</table>

**Cluster Example**

This is an example event for clusters:

```json
{
    "eventType": "com.oraclecloud.clustersapi.createcluster.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ClustersAPI",
    "eventId": "<unique_ID>",
    "eventTime": "2020-04-15T16:26:56.848Z",
```
Node Pool Event Types

These are the event types that node pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.createnodepool.begin</td>
</tr>
<tr>
<td>Delete Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.deletenodepool.begin</td>
</tr>
<tr>
<td>Update Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.updatenodepool.begin</td>
</tr>
</tbody>
</table>

Node Pool Example

This is an example event for node pools:

```json
{
  "eventType": "com.oraclecloud.clustersapi.createnodepool.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ClustersAPI",
  "eventID": "<unique_ID>",
  "eventTime": "2020-04-15T16:26:59.418Z",
  "contentType": "application/json",
  "data": {
    "eventGroupingId": "<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_cluster",
    "resourceId": "ocid1.cluster.oc1.iad.<unique_ID>",
    "availabilityDomain": "my_availability_domain",
    "freeformTags": null,
    "definedTags": null
  }
}
```

Content and Experience

For details about events emitted by Content and Experience, see Service Events.

Database

# Database Service: Autonomous Database Control Plane Event Types

These are the event types that Autonomous Databases emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic Failover Begin <em>(Emitted if database connection attempts fail for 5 minutes.)</em></td>
<td>com.oraclecloud.databaseservice.automaticfailoverautonomousdatabase.begin</td>
</tr>
<tr>
<td>Automatic Failover End <em>(Emitted after failover completes successfully or unsuccessfully. Unsuccessful automatic failovers may result in data loss. Check the Autonomous Database details page in the Oracle Cloud Infrastructure Console for additional information in the event of an unsuccessful automatic failover.)</em></td>
<td>com.oraclecloud.databaseservice.automaticfailoverautonomousdatabase.end</td>
</tr>
<tr>
<td>Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.begin</td>
</tr>
<tr>
<td>Change Compartment End</td>
<td>com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.end</td>
</tr>
<tr>
<td>Create Backup Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.database.backup.begin</td>
</tr>
<tr>
<td>Create Backup End</td>
<td>com.oraclecloud.databaseservice.autonomous.database.backup.end</td>
</tr>
<tr>
<td>Create Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.database.instance.create.begin</td>
</tr>
<tr>
<td>Create End</td>
<td>com.oraclecloud.databaseservice.autonomous.database.instance.create.end</td>
</tr>
<tr>
<td>Disable Data Guard Begin</td>
<td>com.oraclecloud.databaseservice.disableautonomousdataguard.begin</td>
</tr>
<tr>
<td>Disable Data Guard End</td>
<td>com.oraclecloud.databaseservice.disableautonomousdataguard.end</td>
</tr>
<tr>
<td>Enable Data Guard Begin</td>
<td>com.oraclecloud.databaseservice.enableautonomousdataguard.begin</td>
</tr>
<tr>
<td>Enable Data Guard End</td>
<td>com.oraclecloud.databaseservice.enableautonomousdataguard.end</td>
</tr>
<tr>
<td>Free Database Automatic Stop Reminder <em>(emitted 48 hours prior to database stop)</em></td>
<td>com.oraclecloud.databaseservice.freeautonomousdatabase.stop.reminder</td>
</tr>
<tr>
<td>Free Database Automatically Stopped</td>
<td>com.oraclecloud.databaseservice.freeautonomousdatabase.stopped</td>
</tr>
<tr>
<td>Free Database Automatic Termination Reminder <em>(emitted 48 hours prior to database termination)</em></td>
<td>com.oraclecloud.databaseservice.freeautonomousdatabase.termination.reminder</td>
</tr>
<tr>
<td>Free Database Automatically Terminated</td>
<td>com.oraclecloud.databaseservice.freeautonomousdatabase.terminated</td>
</tr>
<tr>
<td>Manual Failover Begin</td>
<td>com.oraclecloud.databaseservice.failoverautonomousdatabase.begin</td>
</tr>
<tr>
<td>Manual Failover End <em>(Emitted after failover completes successfully or unsuccessfully. Unsuccessful manual failovers may result in data loss. Check the Autonomous Database details page in the Oracle Cloud Infrastructure Console for additional information in the event of an unsuccessful manual failover.)</em></td>
<td>com.oraclecloud.databaseservice.failoverautonomousdatabase.end</td>
</tr>
<tr>
<td>Peer Database Provisioning Begin</td>
<td>com.oraclecloud.databaseservice.standbyinstance.create.begin</td>
</tr>
<tr>
<td>Peer Database Provisioning End</td>
<td>com.oraclecloud.databaseservice.standbyinstance.create.end</td>
</tr>
<tr>
<td>Restore Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.database.restore.begin</td>
</tr>
<tr>
<td>Restore End</td>
<td>com.oraclecloud.databaseservice.autonomous.database.restore.end</td>
</tr>
<tr>
<td>Start Begin</td>
<td>com.oraclecloud.databaseservice.startautonomousdatabase.begin</td>
</tr>
<tr>
<td>Start End</td>
<td>com.oraclecloud.databaseservice.startautonomousdatabase.end</td>
</tr>
<tr>
<td>Stop Begin</td>
<td>com.oraclecloud.databaseservice.stopautonomousdatabase.begin</td>
</tr>
<tr>
<td>Stop End</td>
<td>com.oraclecloud.databaseservice.stopautonomousdatabase.end</td>
</tr>
<tr>
<td>Switchover Begin</td>
<td>com.oraclecloud.databaseservice.switchoverautonomousdatabase.begin</td>
</tr>
<tr>
<td>Switchover End</td>
<td>com.oraclecloud.databaseservice.switchoverautonomousdatabase.end</td>
</tr>
<tr>
<td>Terminate Begin</td>
<td>com.oraclecloud.databaseservice.deleteautonomousdatabase.begin</td>
</tr>
<tr>
<td>Terminate End</td>
<td>com.oraclecloud.databaseservice.deleteautonomousdatabase.end</td>
</tr>
<tr>
<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.updateautonomousdatabase.begin</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.updateautonomousdatabase.end</td>
</tr>
<tr>
<td>Upgrade Begin</td>
<td>com.oraclecloud.databaseservice.upgradeautonomousdatabasedbversion.begin</td>
</tr>
<tr>
<td>Upgrade End</td>
<td>com.oraclecloud.databaseservice.upgradeautonomousdatabasedbversion.end</td>
</tr>
</tbody>
</table>
Autonomous Database Example

This is a reference event for Autonomous Databases:

```json
{
    "cloudEventsVersion": "0.1",
    "eventId": 
        "<unique_ID>"
    
    "eventType":
    "com.oraclecloud.databasemanager.autonomous.database.backup.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T14:06:23Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_database",
        "resourceId": "ocid1.autonomousdatabase.oc1.phx.<unique_ID>",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeFormTags": {},
        "definedTags": {},
        "additionalDetails": {
            "cpuCoreCount": 1,
            "lifecycleState": "PROVISIONING",
            "dataStorageSizeInTBs": 1,
            "timeCreated": "2019-07-10T14:06:10.905Z",
            "timeUpdated": "2019-07-10T14:06:10.905Z",
            "serviceConsoleUrl": null,
            "licenseType": null,
            "workloadType": "<Data Warehouse | Transaction Processing>",
            "autonomousDatabaseType": 
                "<Dedicated Infrastructure | Shared Infrastructure>",
        }
    }
}
```

Database Service: Autonomous Database Data Plane Event Types

Autonomous Databases emit "critical" and "information" data plane events. Information events provide important details about the database lifecycle, such as the time when maintenance begins and maintenance ends, or notifications of connections from a new IP address.

Critical events on Autonomous Database are issues that cause disruption to the database.

Both the "information" and "critical" event types use an additionalDetails section of the event message to provide specific details about what is happening within the Autonomous Database emitting the event. Details about the conditions and operations that trigger these two event types follow below.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>com.oraclecloud.databasemanager.autonomous.database.backup.begin</td>
</tr>
<tr>
<td>Information</td>
<td>com.oraclecloud.databasemanager.autonomous.database.backup.begin</td>
</tr>
</tbody>
</table>
In the following example of a "critical" event, you can see within the **additionalDetails** section of the event message that this particular message concerns a "database down" condition that has just ended. The **eventName** and **description** fields provide information regarding the critical situation within the "adwfinance" database:

```json
{
   "cloudEventsVersion": "0.1",
   "eventID": "<unique_ID>",
   "eventType": "com.oraclecloud.databaseservice.autonomous.database.critical",
   "source": "DatabaseService",
   ...
   "additionalDetails": {
      "eventName": "DatabaseDownEnd",
      "dbName": "adwfinance",
      "description": "adwfinance is up and ready for user operations.",
      "workloadType": "Data Warehouse",
      "autonomousDatabaseType": "Shared Infrastructure"
   }
}
```

In the tables below, you can read about the conditions and operations that trigger "critical" and "information" event types. Each condition or operation is identified by a unique **eventName** value.

<table>
<thead>
<tr>
<th>Critical Event - EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AdminPasswordWarning</strong></td>
<td>Generated when Autonomous Database determines that the ADMIN password will expire after a 30 day grace period is complete. ADMIN passwords should be reset after no more than 360 days. The 30 day grace period begins after a password has been in use for 360 days. If the password is not reset during the grace period, the event is generated a second time, 30 days after the first event notification, to notify you that the password has expired and needs to be reset.</td>
</tr>
</tbody>
</table>
| **DatabaseDownBegin**      | The Autonomous Database instance cannot be opened, or the services such as high, low, medium, tp, or tpurgent are not started or available. The following conditions do not trigger **DatabaseDownBegin**:  
   • Operations performed during the maintenance window  
   • Load balancer, network, or backup related issues  
   • A user stopping the instance  
   This event will not be triggered if you are using Autonomous Data Guard and the standby database is not available due to any of the above conditions. |
### Critical Event - EventName

<table>
<thead>
<tr>
<th>EventName</th>
<th>Description</th>
</tr>
</thead>
</table>
| DatabaseDownEnd   | The database is recovered from the down state, meaning the Autonomous Database instance is opened with its services, following a DatabaseDownBegin event. DatabaseDownEnd is triggered only if there was a preceding DatabaseDownBegin event. The following conditions do not trigger DatabaseDownEnd:  
  - Operations performed during the maintenance window  
  - A user starting the instance  
  If you are using Autonomous Data Guard and the primary database goes down, this triggers a DatabaseDownBegin event. If the system fails over to the standby database, this triggers a DatabaseDownEnd event. |
| WalletExpirationWarning | Generated when Autonomous Database determines that a wallet is due to expire in less than six (6) weeks. This event is reported at most once per week.                                                                                                                                   |

### Information Event - EventName

<table>
<thead>
<tr>
<th>EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DatabaseConnection</td>
<td>Generated if a connection is made to the database from a new IP address. A new IP address is defined as an address that has not connected to the database in the last 30 days.</td>
</tr>
<tr>
<td>MaintenanceBegin</td>
<td>Triggered when the maintenance starts and provides the start timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled start time.</td>
</tr>
<tr>
<td>MaintenanceEnd</td>
<td>Triggered when the maintenance ends and provides the end timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled end time.</td>
</tr>
<tr>
<td>NewMaintenanceSchedule</td>
<td>Generated when the maintenance date is updated and the new date is shown on the Oracle Cloud Infrastructure Console.</td>
</tr>
<tr>
<td>ScheduledMaintenanceWarning</td>
<td>Generated when the instance is 24 hours from a scheduled maintenance operation, and again when the instance is 1 hour (60 minutes) from the scheduled maintenance.</td>
</tr>
</tbody>
</table>

**Note:**

If you are using Autonomous Data Guard for shared Exadata infrastructure, any of the above listed events that occurs on the standby database does not trigger an Information event.
**Database Service: Autonomous Container Database Event Types**

These are the event types that Autonomous Container Databases emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment</td>
<td>com.oraclecloud.databaseservice.changeautonomouscontainerdatabase.begin</td>
</tr>
<tr>
<td>Create Backup Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.backup.begin</td>
</tr>
<tr>
<td>Create Backup End</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.backup.end</td>
</tr>
<tr>
<td>Create Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.instance.create.begin</td>
</tr>
<tr>
<td>Create End</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.instance.create.end</td>
</tr>
<tr>
<td>Maintenance Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.maintenance.begin</td>
</tr>
<tr>
<td>Maintenance End</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.maintenance.end</td>
</tr>
<tr>
<td>Maintenance Reminder</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder</td>
</tr>
<tr>
<td>Maintenance Scheduled</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.maintenance.scheduled</td>
</tr>
<tr>
<td>Restart Begin</td>
<td>com.oraclecloud.databaseservice.restartautonomouscontainerdatabase.begin</td>
</tr>
<tr>
<td>Restart End</td>
<td>com.oraclecloud.databaseservice.restartautonomouscontainerdatabase.end</td>
</tr>
<tr>
<td>Restore Begin</td>

</tr>
<tr>
<td>Restore End</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.restore.end</td>
</tr>
<tr>
<td>Terminate Begin</td>
<td>com.oraclecloud.databaseservice.terminateautonomouscontainerdatabase.begin</td>
</tr>
<tr>
<td>Terminate End</td>
<td>com.oraclecloud.databaseservice.terminateautonomouscontainerdatabase.end</td>
</tr>
<tr>
<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.instance.update.begin</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.autonomous.container.database.instance.update.end</td>
</tr>
</tbody>
</table>
Events

**Autonomous Container Database Example**

This is a reference event for Autonomous Container Databases:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.autonomous.container.database.backup.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_container_database",
        "resourceId": "<unique_ID>",
        "availabilityDomain": "all",
        "freeFormTags": {},
        "definedTags": {},
        "additionalDetails": {
            "cpuCoreCount": null,
            "lifecycleState": "ACTIVE",
            "dataStorageSizeInTBs": null,
            "timeCreated": "2019-06-27T21:15:59.000Z",
            "dbUniqueName": "dwrrdtsr_phx289",
            "dbHomeId": "ocid1.autonomoushome.oc1.phx.<unique_ID>",
            "dbName": "dwrrdtsr"
        }
    }
}
```
Database Service: Autonomous Exadata Infrastructure Event Types

These are the event types that Autonomous Exadata Infrastructure instances emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment</td>
<td>com.oraclecloud.databaseservice.changeautonomousexadatainfrastructurebegin</td>
</tr>
<tr>
<td>Create Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin</td>
</tr>
<tr>
<td>Create End</td>
<td>com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.end</td>
</tr>
<tr>
<td>Maintenance Begin</td>
<td>com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.maintenance.begin</td>
</tr>

<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.updateautonomousexadatainfrastructure.begin</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.updateautonomousexadatainfrastructure.end</td>
</tr>
</tbody>
</table>

Autonomous Exadata Infrastructure Example

This is a reference event for Autonomous Exadata Infrastructure instances:

```json
{
    "cloudeventsVersion": "0.1",
    "eventId": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T23:28:12Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "resourceName": "my_exadata_infrastructure_name",
        "compartmentName": "example_compartment_name"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "my_exadata_infrastructure_name"
    }
}
```
Database Service: DB System Event Types

These are the event types that DB systems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changedbsystemcompartment.begin</td>
</tr>
<tr>
<td>Change Compartment End</td>
<td>com.oraclecloud.databaseservice.changedbsystemcompartment.end</td>
</tr>
<tr>
<td>Create Begin</td>
<td>com.oraclecloud.databaseservice.launchdbsystem.begin</td>
</tr>
<tr>
<td>Create End</td>
<td>com.oraclecloud.databaseservice.launchdbsystem.end</td>
</tr>
<tr>
<td>Terminate Begin</td>
<td>com.oraclecloud.databaseservice.terminatedbsystem.begin</td>
</tr>
<tr>
<td>Terminate End</td>
<td>com.oraclecloud.databaseservice.terminatedbsystem.end</td>
</tr>
<tr>
<td>Update IORM Begin</td>
<td>com.oraclecloud.databaseservice.updateiormconfig.begin</td>
</tr>
<tr>
<td>Update IORM End</td>
<td>com.oraclecloud.databaseservice.updateiormconfig.end</td>
</tr>
</tbody>
</table>

DB System Example

This is a reference event for DB Systems:

```json
{
    "cloudEventsVersion": "0.1",
    "contentType": "application/json",
    "data": {
        "additionalDetails": {
            "cpuCoreCount": 1,
            "dataStoragePercentage": 80,
            "dataStorageSizeInGBs": 256,
            "exadataIormConfig": "null",
            "dataStorageSizeInTBs": null,
            "timeCreated": "2019-07-10T23:13:43.136Z",
            "timeUpdated": "2019-07-10T23:28:12.390Z",
            "lifecycleState": "PROVISIONING",
            "availabilityDomain": "XXIT:PHX-AD-3",
            "resourceId": "ocid1.autonomousexainfrastructure.oc1.phx.<unique_ID>",
            "additionalDetails": {
                "cpuCoreCount": 92,
                "lifecycleState": "PROVISIONING",

                "licenseType": null,
                "dbName": null
            }
        }
    }
}
```
Database Service: Node (Virtual Machine) Event Types

These are the event types that database nodes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.dbnodeaction.end</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.dbnodeaction.end</td>
</tr>
</tbody>
</table>

DB System Node Example

This is a reference event for DB system nodes:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.db.node.reboot.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-29T04:43:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "",
        "resourceId": "ocid1.dbnode.oc1.phx.<unique_ID>",
        "availabilityDomain": "TGjA:PHX-AD-2",
        "freeFormTags": null,
        "definedTags": null,
        "additionalDetails": {
            "cpuCoreCount": null,
            "lifecycleState": "STARTING",
        }
    }
}
```
Database Service: Database Home Event Types

These are the event types that Database Homes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Begin</td>
<td>com.oraclecloud.databaseservice.createdbhome.begin</td>
</tr>
<tr>
<td>Create End</td>
<td>com.oraclecloud.databaseservice.createdbhome.end</td>
</tr>
<tr>
<td>Terminate Begin</td>
<td>com.oraclecloud.databaseservice.deletedbhome.begin</td>
</tr>
<tr>
<td>Terminate End</td>
<td>com.oraclecloud.databaseservice.deletedbhome.end</td>
</tr>
<tr>
<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.updatedbhome.begin</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.updatedbhome.end</td>
</tr>
</tbody>
</table>

Database Home Example

This is a reference event for Database Homes:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
    "eventType": "com.oraclecloud.databaseservice.createdbhome.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-08-29T21:16:04Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_dbhome",
        "resourceId": "DbHome-unique_ID",
        "availabilityDomain": "all",

        "definedTags": {},
        "additionalDetails": {
```
Database Service: Database Event Types

These are the event types that databases in bare metal DB systems, virtual machine DB systems, and Exadata Cloud Service instances emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic Backup Begin</td>
<td>com.oraclecloud.databaseservice.automaticbackupdatabase.begin</td>
</tr>
<tr>
<td>Automatic Backup End</td>
<td>com.oraclecloud.databaseservice.automaticbackupdatabase.end</td>
</tr>
<tr>
<td>Create Backup Begin</td>
<td>com.oraclecloud.databaseservice.backupdatabase.begin</td>
</tr>
<tr>
<td>Create Backup End</td>
<td>com.oraclecloud.databaseservice.backupdatabase.end</td>
</tr>
<tr>
<td>Delete Backup Begin</td>
<td>com.oraclecloud.databaseservice.deletebackup.begin</td>
</tr>
<tr>
<td>Delete Backup End</td>
<td>com.oraclecloud.databaseservice.deletebackup.end</td>
</tr>
<tr>
<td>Restore Begin</td>
<td>com.oraclecloud.databaseservice.restoredatabase.begin</td>
</tr>
<tr>
<td>Restore End</td>
<td>com.oraclecloud.databaseservice.restoredatabase.end</td>
</tr>
<tr>
<td>Update Begin</td>
<td>com.oraclecloud.databaseservice.updatedatabase.begin</td>
</tr>
<tr>
<td>Update End</td>
<td>com.oraclecloud.databaseservice.updatedatabase.end</td>
</tr>
<tr>
<td>Upgrade Begin</td>
<td>com.oraclecloud.databaseservice.upgradedatabase.begin</td>
</tr>
<tr>
<td>Upgrade End</td>
<td>com.oraclecloud.databaseservice.upgradedatabase.end</td>
</tr>
</tbody>
</table>

Database Example
This is a reference event for databases:

```json
{
  "eventType": "com.oraclecloud.databaseservice.backupdatabase.begin",
  "udEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "DatabaseService",
  "eventTime": "2020-01-08T17:31:43.666Z",
  "contentType": "application/json",

    },
    "definedTags": {
      "My_example_tag_name": {
        "Example_key": "Example_value"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
    }
  }
}
```

Database Service: Cloud Exadata Infrastructure Events

**Note:**

See Database Service: DB System Event Types on page 1852 for additional events related to Exadata DB systems. The events in this section are emitted for systems using the [new Exadata resource model](https://docs.oracle.com/en/cloud/middleware/database/oracle-cloud-infrastructure/userguide/cloud-exadata-resource-model.html).

These are the event types that cloud Exadata infrastructure resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Exadata Infrastructure - Create Begin</td>
<td>com.oraclecloud.databaseservice.createcloudexadatainfrastructure.begin</td>
</tr>
<tr>
<td>Cloud Exadata Infrastructure - Create End</td>
<td>com.oraclecloud.databaseservice.createcloudexadatainfrastructure.end</td>
</tr>
<tr>
<td>Cloud Exadata Infrastructure - Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changecloudexadatainfrastructurecompartment.begin</td>
</tr>
<tr>
<td>Cloud Exadata Infrastructure - Change Compartment End</td>
<td>com.oraclecloud.databaseservice.changecloudexadatainfrastructurecompartment.end</td>
</tr>
<tr>
<td>Cloud Exadata Infrastructure - Update Begin</td>
<td>com.oraclecloud.databaseservice.updatecloudexadatainfrastructure.begin</td>
</tr>
<tr>
<td>Cloud Exadata Infrastructure - Update End</td>
<td>com.oraclecloud.databaseservice.updatecloudexadatainfrastructure.end</td>
</tr>
</tbody>
</table>
This is a reference event for a Cloud Exadata Infrastructure resource:

```json
{
  "cloudEventsVersion": "0.1",
  "eventId": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.cloudexadatainfrastructuremaintenance.end",
  "source": "DatabaseService",
  "eventTypeVersion": "1.0",
  "eventTime": "2019-06-27T21:16:04.000Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_exadata_infrastructure",
    "resourceId": "ocid1.dbsystem.oc1.eu-frankfurt-1.<unique_ID>",
    "availabilityDomain": "tXPJ:EU-FRANKFURT-1-AD-3",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "subnetId": "ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>",
      "lifecycleState": "MAINTENANCE_IN_PROGRESS",
      "sshPublicKeys": "...",

      "patchHistoryEntries": "null",
      "lifecycleMessage": "The underlying infrastructure of this system (cell storage) is being updated and this will not impact database availability.",
      "exadataIormConfig": "ExadataIormConfigCache(lifecycleState=DISABLED, lifecycleDetails=null, objective=Auto",
```

Oracle Cloud Infrastructure User Guide 1857
Database Service: Exadata Cloud VM Cluster Events

Note:

See Database Service: DB System Event Types on page 1852 for additional events related to Exadata DB systems. The events in this section are emitted for systems using the new Exadata resource model.
These are the event types that Exadata Cloud VM cluster resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud VM Cluster - Create Begin</td>
<td>com.oraclecloud.databaseservice.createcloudvmcluster.begin</td>
</tr>
<tr>
<td>Cloud VM Cluster - Create End</td>
<td>com.oraclecloud.databaseservice.createcloudvmcluster.end</td>
</tr>
<tr>
<td>Cloud VM Cluster - Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changecloudvmclustercompartment.begin</td>
</tr>
<tr>
<td>Cloud VM Cluster - Change Compartment End</td>
<td>com.oraclecloud.databaseservice.changecloudvmclustercompartment.end</td>
</tr>
<tr>
<td>Cloud VM Cluster - Update Begin</td>
<td>com.oraclecloud.databaseservice.updatecloudvmcluster.begin</td>
</tr>
<tr>
<td>Cloud VM Cluster - Update End</td>
<td>com.oraclecloud.databaseservice.updatecloudvmcluster.end</td>
</tr>
<tr>
<td>Cloud VM Cluster - Update IORM Configuration Begin</td>
<td>com.oraclecloud.databaseservice.updatecloudvmclusteriormconfig.begin</td>
</tr>
<tr>
<td>Cloud VM Cluster - Update IORM Configuration End</td>
<td>com.oraclecloud.databaseservice.updatecloudvmclusteriormconfig.end</td>
</tr>
<tr>
<td>Cloud VM Cluster - Delete Begin</td>
<td>com.oraclecloud.databaseservice.deletecloudvmcluster.begin</td>
</tr>
<tr>
<td>Cloud VM Cluster - Delete End</td>
<td>com.oraclecloud.databaseservice.deletecloudvmcluster.end</td>
</tr>
</tbody>
</table>

This is a reference event for a cloud VM cluster resource:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.updatecloudvmclusteriormconfig.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2022-06-27T21:16:04.000Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "UpdateCloudVmClusterIormConfig",
        "compartmentName": "example_compartment",
        "resourceName": "my_container_database",
        "resourceId": "ocid1.cloudvmcluster.oc1.<unique_ID>",
        "resourceVersion": null,
        "additionalDetails": {
            "cloudExadataInfrastructureId": "ocid1.cloudexadatainfrastructure.oc1.<unique_ID>",
            "freeFormTags": {},
            "definedTags": {},
            "licenseType": "BRING_YOUR_OWN_LICENSE",
            "lifecycleState": "AVAILABLE",
```
Database Service: Data Guard Association Event Types

These are the event types that Data Guard associations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Guard Association - Create Begin</td>
<td>com.oraclecloud.databaseservice.createdataguardassociation.begin</td>
</tr>
<tr>
<td>Data Guard Association - Create End</td>
<td>com.oraclecloud.databaseservice.createdataguardassociation.end</td>
</tr>
<tr>
<td>Data Guard Association - Failover Begin</td>
<td>com.oraclecloud.databaseservice.failoverataguardassociation.begin</td>
</tr>
<tr>
<td>Data Guard Association - Failover End</td>
<td>com.oraclecloud.databaseservice.failoverataguardassociation.end</td>
</tr>
<tr>
<td>Data Guard Association - Reinstate Begin</td>
<td>com.oraclecloud.databaseservice.reinstatedataguardassociation.begin</td>
</tr>
<tr>
<td>Data Guard Association - Reinstate End</td>
<td>com.oraclecloud.databaseservice.reinstatedataguardassociation.end</td>
</tr>
<tr>
<td>Data Guard Association - Switchover Begin</td>
<td>com.oraclecloud.databaseservice.switchoverataguardassociation.begin</td>
</tr>
<tr>
<td>Data Guard Association - Switchover End</td>
<td>com.oraclecloud.databaseservice.switchoverataguardassociation.end</td>
</tr>
</tbody>
</table>

Data Guard Association Example

This is a reference event for Data Guard associations:

```json
{
   "cloudEventsVersion": "0.1",
   "contentType": "application/json",
   "data": {
      "additionalDetails": {
         "ApplyLag": null,
         "DGConfigId": "7e8eff2b-a4cd-474a-abd5-940b05c0b1fd",
         "DGConfigState": "null",
         "DatabaseId": "ocid1.database.oc1.iad.<unique_ID>",
         "DbHomeId": "ocid1.dbhome.oc1.iad.<unique_ID>",
         "DbSystemId": "ocid1.dbsystem.oc1.iad.<unique_ID>",
         "LastSyncedTime": null,
         "SyncState": "null",
         "dcsDgUpdateTimestamp": null,
         "lastUpdatedIdentifier": null,
         "lifeCycleMessage": null,
         "lifecycleState": "PROVISIONING",
      }
   }
}```
    
    "availabilityDomain": "XXIT:US-ASHBURN-AD-1",
    "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceId": "ocid1.dgassociation.oc1.iad.<unique_ID>
},
    "eventId": "5<unique_ID>-4730-9761-e52715b7bc79",

    }
}
```

Data Catalog

For details about events emitted by Data Catalog, see Data Catalog Events.

Data Safe

For details about events emitted by Data Safe, see Oracle Data Safe Events in Oracle Cloud Infrastructure.
Data Science

Data Science resources that emit events:

- Project Event Types on page 1864
- Notebook Session Event Types on page 1865
- Model Event Types on page 1866

Project Event Types

These are the event types that projects emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Project</td>
<td>com.oraclecloud.datascience.createproject</td>
</tr>
<tr>
<td>Delete Project Begin</td>
<td>com.oraclecloud.datascience.deleteproject.begin</td>
</tr>
<tr>
<td>Delete Project End</td>
<td>com.oraclecloud.datascience.deleteproject.end</td>
</tr>
<tr>
<td>Update Project</td>
<td>com.oraclecloud.datascience.deleteproject.end</td>
</tr>
</tbody>
</table>

Project Example

This is a reference event for projects:

```json
{
  "eventType": "com.oraclecloud.datascience.createproject",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "datascience",
  "eventTime": "2019-11-22T01:43:35.246Z",
  "eventID": "<unique_ID>",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example_project",
    "resourceId": "ocid1.datascienceproject.oc1.iad.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
  }
}
```
Notebook Session Event Types

These are the event types that notebook sessions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate Notebook Session Begin</td>
<td>com.oraclecloud.datascience.activatenotebooksession.begin</td>
</tr>
<tr>
<td>Activate Notebook Session End</td>
<td>com.oraclecloud.datascience.activatenotebooksession.end</td>
</tr>
<tr>
<td>Create Notebook Session Begin</td>
<td>com.oraclecloud.datascience.createnotebooksession.begin</td>
</tr>
<tr>

    }
  }
}
```
Data Transfer

Data Transfer resources that emit events:

- Jobs Event Types on page 1867
- Appliances Event Types on page 1868
- Packages Event Types on page 1869
- Devices Event Types on page 1870
- Appliance Entitlements Event Types on page 1871
- Appliance Export Jobs Event Types on page 1872

Jobs Event Types

These are the event types that job events emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Job</td>
<td>com.oraclecloud.datatransferservice.addtransferjob</td>
</tr>
<tr>
<td>Update Transfer Job</td>
<td>com.oraclecloud.datatransferservice.updatetransferjob</td>
</tr>
<tr>
<td>Delete Transfer Job</td>
<td>com.oraclecloud.datatransferservice.deletetransferjob</td>
</tr>
<tr>
<td>Move Transfer Job</td>
<td>com.oraclecloud.datatransferservice.movetransferjob</td>
</tr>
</tbody>
</table>

Jobs Examples

```json
{
  "eventType": "com.oraclecloud.datatransferservice.addtransferjob",
  "source": "datatransferservice",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",

<tr>
<td>Delete Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
<tr>
<td>Attach Devices To Transfer Package</td>
<td>com.oraclecloud.datatransferservice.addtransferpackage</td>
</tr>
<tr>
<td>Detach Devices From Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
</tbody>
</table>

**Packages Example**

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferpackage",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "transfer_job",
        "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "packageLabel": "example_label",
            "lifecycleState": "example_state"
        }
    }
}
```
Events

**Devices Event Types**

These are the event types that devices emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Device</td>
<td>com.oraclecloud.datatransferservice.addtransferdevice</td>
</tr>
<tr>
<td>Update Transfer Device</td>
<td>com.oraclecloud.datatransferservice.updatetransferdevice</td>
</tr>
<tr>
<td>Delete Transfer Device</td>
<td>com.oraclecloud.datatransferservice.deletetransferdevice</td>
</tr>
</tbody>
</table>

**Devices Example**

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferdevice",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
        "compartmentName": "example_compartment",
        "resourceName": "transfer_job",
        "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>"
        "availabilityDomain": "<availability_domain>"
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "deviceLabel": "example_label",
            "lifecycleState": "example_state"
        }
    }
}
```
## Appliance Entitlements Event Types

These are the event types that appliance entitlements emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.createtransferapplianceentitlement</td>
</tr>
<tr>
<td>Update Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.updateapplianceentitlement</td>
</tr>
<tr>
<td>Delete Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.updateapplianceentitlement</td>
</tr>
</tbody>
</table>

## Appliance Entitlements Example

```json
{
  "eventType": "com.oraclecloud.datatransferservice.createtransferapplianceentitlement",
  "source": "datatransferservice",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "transfer_appliance_entitlement",
    "resourceId": "ocid1.datatransferapplianceentitlement.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "requestorName": "Sample User",
      "requestorEmail": "sample.user@oracle.com",
      "lifecycleState": "example_state",
      "lifecycleStateDetails": "example_details"
    }
  }
}
```
**Appliance Export Jobs Event Types**

These are the event types that appliance export jobs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Appliance Export Job</td>
<td>com.oraclecloud.datatransferservice.addapplianceexportjob</td>
</tr>
<tr>
<td>Update Appliance Export Job</td>
<td>com.oraclecloud.datatransferservice.updateapplianceexportjob</td>
</tr>
<tr>
<td>Delete Appliance Export Job</td>
<td>com.oraclecloud.datatransferservice.deleteapplianceexportjob</td>
</tr>
<tr>
<td>Move Appliance Export Job</td>
<td>com.oraclecloud.datatransferservice.moveapplianceexportjob</td>
</tr>
</tbody>
</table>

**Appliance Export Jobs Example**

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addapplianceexportjob",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "export_job",
        "resourceId": "ocid1.datatransferapplianceexportjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "bucketName": "example_bucket",
            "lifecycleState": "example_state",
            "lifecycleStateDetails": "example_details"
        }
    }
}
```

**Digital Assistant**

For details about events emitted by Digital Assistant, see [Events for Digital Assistant Instances](#).

**File Storage**

File Storage resources that emit events:

- File System Event Types on page 1873 and Snapshot Event Types on page 1874
Events

- **Mount Target Event Types** on page 1875
- **Export Event Types** on page 1876 and **Export Set Event Types** on page 1876

**File System Event Types**

These are the event types that file systems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change File System Compartment</td>
<td>com.oraclecloud.filestorage.changefilesystemcompartment</td>
</tr>
<tr>
<td>Create File System</td>
<td>com.oraclecloud.filestorage.createfilesystem</td>
</tr>
<tr>
<td>Delete File System</td>
<td>com.oraclecloud.filestorage.deletefilesystem</td>
</tr>
<tr>
<td>Update File System</td>
<td>com.oraclecloud.filestorage.updatefilesystem</td>
</tr>
</tbody>
</table>

**File System Example**

This is a reference event for file systems:

```json
{
    "eventType": "com.oraclecloud.filestorage.createfilesystem",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_filesystem",
        "resourceId": "ocid1.filesystem.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Snapshot Event Types

These are the event types that snapshots emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Snapshot</td>
<td>com.oraclecloud.filestorage.createsnapshot</td>
</tr>
<tr>
<td>Delete Snapshot</td>
<td>com.oraclecloud.filestorage.deletesnapshot</td>
</tr>
</tbody>
</table>

Snapshot Example

This is a reference event for snapshots:

```json
{
    "eventType": "com.oraclecloud.filestorage.createsnapshot",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_snapshot",
        "resourceId": "ocid1.snapshot.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Mount Target Event Types

These are the event types that mount targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Mount Target Compartment</td>
<td>com.oraclecloud.filestorage.changemounttargetcompartment</td>
</tr>
<tr>
<td>Create Mount Target</td>
<td>com.oraclecloud.filestorage.createmounttarget</td>
</tr>
<tr>
<td>Delete Mount Target</td>
<td>com.oraclecloud.filestorage.deletemounttarget</td>
</tr>
<tr>
<td>Update Mount Target</td>
<td>com.oraclecloud.filestorage.updatemounttarget</td>
</tr>
</tbody>
</table>

Mount Target Example

This is a reference event for mount targets:

```json
{
    "eventType": "com.oraclecloud.filestorage.createmounttarget",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_mounttarget",
        "resourceId": "ocid1.mounttarget.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
### Export Event Types

These are the event types that exports emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Export</td>
<td>com.oraclecloud.filestorage.createexport</td>
</tr>
<tr>
<td>Delete Export</td>
<td>com.oraclecloud.filestorage.deleteexport</td>
</tr>
<tr>
<td>Update Export</td>
<td>com.oraclecloud.filestorage.updateexport</td>
</tr>
</tbody>
</table>

#### Export Example

This is a reference event for exports:

```json
{
    "eventType": "com.oraclecloud.filestorage.createexport",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_export",
        "resourceId": "ocid1.export.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    },
    "eventID": "unique_ID",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>"
    }
}
```

### Export Set Event Types

These are the event types that export sets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete Export Set</td>
<td>com.oraclecloud.filestorage.deleteexportset</td>
</tr>
<tr>
<td>Update Export Set</td>
<td>com.oraclecloud.filestorage.updateexportset</td>
</tr>
</tbody>
</table>

#### Export Set Example

---

---
This is a reference event for export sets:

```
{
    "eventType": "com.oraclecloud.filestorage.updateexportset",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_exportset",
        "resourceId": "ocid1.exportset.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    },
    "eventID": "unique_ID",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>"
    }
}
```

### Functions

Functions resources that emit events:

- Application Event Types on page 1877
- Function Event Types on page 1878

#### Application Event Types

These are the event types that applications emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Application Compartment</td>
<td>com.oraclecloud.functions.changeapplicationcompartment</td>
</tr>
<tr>
<td>Create Application</td>
<td>com.oraclecloud.functions.createapplication</td>
</tr>
<tr>
<td>Delete Application</td>
<td>com.oraclecloud.functions.deleteapplication</td>
</tr>
<tr>
<td>Update Application</td>
<td>com.oraclecloud.functions.updateapplication</td>
</tr>
</tbody>
</table>

#### Application Example

This is an example event for applications:

```
{
    "eventType": "com.oraclecloud.functions.createapplication",
}
Events

```
"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "functions",
"eventTime": "2019-07-22T09:33:44.754Z",
"contentType": "application/json",
"data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my-application",
    "resourceId": "ocid1.fnapp.oc1.phx.<unique_ID>",
    "availabilityDomain": "AD3"
},
"eventID": "<unique_ID>",
"extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
}
}
```

**Function Event Types**

These are the event types that functions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Function</td>
<td><code>com.oraclecloud.functions.createfunction</code></td>
</tr>
<tr>
<td>Delete Function</td>
<td><code>com.oraclecloud.functions.deletefunction</code></td>
</tr>
<tr>
<td>Update Function</td>
<td><code>com.oraclecloud.functions.updatefunction</code></td>
</tr>
</tbody>
</table>

**Function Example**

This is an example event for functions:

```
{
    "eventType": "com.oraclecloud.functions.createfunction",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "functions",
    "eventTime": "2019-07-22T09:33:44.754Z",
    "contentType": "application/json",
    "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my-function",
    "resourceId": "ocid1.fnfunc.oc1.phx.<unique_ID>",
    "availabilityDomain": "AD3"
    },
    "eventID": "<unique_ID>",
    "extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
}
}
```

**Health Checks**

Health Checks resources that emit events:
HTTP Monitors Event Types

These are the event types that HTTP monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.createhttpmonitor</td>
</tr>
<tr>
<td>Delete HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.deletehttpmonitor</td>
</tr>
<tr>
<td>Update HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.updatehttpmonitor</td>
</tr>
</tbody>
</table>

HTTP Monitor Example

This is an example event for HTTP monitors:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createhttpmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:06:29.451Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_monitor",
    "resourceId": "ocid1.httpmonitor.oc1..<unique_ID>",
    "availabilityDomain": "AD1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```
### Ping Monitor Event Types

These are the event types that ping monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Ping Monitor</td>
<td>com.oraclecloud.healthchecks.createpingmonitor</td>
</tr>
<tr>
<td>Delete Ping Monitor</td>
<td>com.oraclecloud.healthchecks.deletepingmonitor</td>
</tr>
<tr>
<td>Update Ping Monitor</td>
<td>com.oraclecloud.healthchecks.updatepingmonitor</td>
</tr>
</tbody>
</table>

### Ping Monitor Example

This is an example event for ping monitors:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createpingmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:08:11.242Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_monitor",
    "resourceId": "ocid1.pingmonitor.oc1..<unique_ID>",
    "availabilityDomain": "AD1",
    "freeFormTags": { 
      "Department": "Finance"
    },
    "definedTags": { 
      "Operations": { 
        "CostCenter": "42"
      }
    }
  }
}
```

### IAM

IAM resources that emit events:

- [Authentication Policy Event Types](#) on page 1881
- [Credentials Event Types](#) on page 1882
- [Dynamic Group Event Types](#) on page 1883
- [Group Event Types](#) on page 1884
- [Identity Provider Event Types](#) on page 1886
- [Multi-Factor Authentication TOTP Device Event Types](#) on page 1888
- [Policy Event Types](#) on page 1889
- [User Event Types](#) on page 1890
**Authentication Policy Event Types**

This is the event type that authentication policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update Authentication Policy</td>
<td><code>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</code></td>
</tr>
</tbody>
</table>

**Authentication Policy Example**

This is a reference event for authentication policy events:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_compartment",
        "resourceId": "ocid1.compartment.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
        }
    }
}
```
## Credentials Event Types

These are the event types that credentials emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Auth Token</td>
<td>com.oraclecloud.identityControlPlane.CreateAuthToken</td>
</tr>
<tr>
<td>Create Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.CreateCustomerSecretKey</td>
</tr>
<tr>
<td>Create or Reset Password</td>
<td>com.oraclecloud.identityControlPlane.CreateOrResetPassword</td>
</tr>
<tr>
<td>Create SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.CreateSmtpCredential</td>
</tr>
<tr>
<td>Create Swift Password</td>
<td>com.oraclecloud.identityControlPlane.CreateSwiftPassword</td>
</tr>
<tr>
<td>Delete API Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteApiKey</td>
</tr>
<tr>
<td>Delete Auth Token</td>
<td>com.oraclecloud.identityControlPlane.DeleteAuthToken</td>
</tr>
<tr>
<td>Delete Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteCustomerSecretKey</td>
</tr>
<tr>
<td>Delete SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.DeleteSmtpCredential</td>
</tr>
<tr>
<td>Delete Swift Password</td>
<td>com.oraclecloud.identityControlPlane.DeleteSwiftPassword</td>
</tr>
<tr>
<td>Update Auth Token</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthToken</td>
</tr>
<tr>
<td>Update Authentication Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</td>
</tr>
<tr>
<td>Update SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.UpdateSmtpCredential</td>
</tr>
<tr>
<td>UpdateSwift Password</td>
<td>com.oraclecloud.identityControlPlane.UpdateSwiftPassword</td>
</tr>
<tr>
<td>Upload API KEY</td>
<td>com.oraclecloud.identityControlPlane.UploadApiKey</td>
</tr>
</tbody>
</table>

### Credentials Example
Events

This is a reference event for most credential events (create or reset password don't include additional details):

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.DeleteApiKey",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>"
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
  }
}
```

Dynamic Group Event Types

These are the event types that dynamic groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.CreateDynamicGroup</td>
</tr>
<tr>
<td>Delete Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteDynamicGroup</td>
</tr>
<tr>
<td>Update Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.UpdateDynamicGroup</td>
</tr>
</tbody>
</table>

Dynamic Group Example

This is a reference event for dynamic groups:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateDynamicGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
```
### Group Event Types

These are the event types that groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to Group</td>
<td><code>com.oraclecloud.identityControlPlane.AddUserToGroup</code></td>
</tr>
<tr>
<td>Create Group</td>
<td><code>com.oraclecloud.identityControlPlane.CreateGroup</code></td>
</tr>
<tr>
<td>Delete Group</td>
<td><code>com.oraclecloud.identityControlPlane.DeleteGroup</code></td>
</tr>
<tr>
<td>Remove User From Group</td>
<td><code>com.oraclecloud.identityControlPlane.RemoveUserFromGroup</code></td>
</tr>
<tr>
<td>Update Group</td>
<td><code>com.oraclecloud.identityControlPlane.UpdateGroup</code></td>
</tr>
</tbody>
</table>

### Group Example

This is a reference event for some groups (create, delete, and update events don't include additional details):

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.AddUserToGroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_group",
        "resourceId": "ocid1.groupmembership.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        }
    }
}
```
"definedTags": {
  "Operations": {
    "CostCenter": "42"
  }
},
"additionalDetails": {
  "userId": "ocid1.user.oc1..<unique_ID>",
  "groupId": "ocid1.group.oc1..<unique_ID>"
},
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
### Identity Provider Event Types

These are the event types that identity providers emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to IdP Group</td>
<td>com.oraclecloud.identityControlPlane.AddUserToIdpGroup</td>
</tr>
<tr>
<td>Create Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProvider</td>
</tr>
<tr>
<td>Create Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup</td>
</tr>
<tr>
<td>Create IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpGroupMapping</td>
</tr>
<tr>
<td>Create IdP User</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpUser</td>
</tr>
<tr>
<td>Delete Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProvider</td>
</tr>
<tr>
<td>Delete Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProviderGroup</td>
</tr>
<tr>
<td>Delete IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpGroupMapping</td>
</tr>
<tr>
<td>Delete IdP User</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpUser</td>
</tr>
<tr>
<td>Remove User From IdP Group</td>
<td>com.oraclecloud.identityControlPlane.RemoveUserFromIdpGroup</td>
</tr>
<tr>
<td>Reset IdP SCIM Client</td>
<td>com.oraclecloud.identityControlPlane.ResetIdpScim</td>
</tr>
<tr>
<td>Update Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdentityProvider</td>
</tr>
<tr>
<td>Update IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdpGroupMapping</td>
</tr>
</tbody>
</table>

### Identity Provider Example

The following reference events are for identity provider events that include additional details. Some identity providers events do not include additional details. These events are create, delete, and update identity providers, as well as delete identity provider group, delete IdP user, and reset IdP SCIM.

This is a reference event for adding and removing users from IdP groups:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.AddUserToIdpGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "entity": {
    "type": "USER",
    "id": "<unique_ID>",
    "name": "<unique_name>",
    "email": "<unique_email>",
    "firstName": "<unique_firstName>",
    "lastName": "<unique_lastName>",
    "organization": "<unique_organization>",
    "profile": {
      "attributes": {
        "preferred_language": "en",
        "locale": "en",
        "timezone": "America/Los_Angeles"
      }
    }
  }
}
```
This is a reference event for create, update, and delete IdP group mapping:

```
{
"eventType": "com.oraclecloud.identityControlPlane.CreateIdpGroupMapping",
"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "identityControlPlane",
"eventID": "<unique_ID>",
"eventTime": "2019-10-21T17:23:54.095Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "my_group",
  "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
  "availabilityDomain": "availability_domain",
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  },
  "additionalDetails": {
    "userId": "ocid1.user.oc1..<unique_ID>
  }
},
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}
```

This is a reference event for create IdP user and create IdP group:

```
{
"eventType": "com.oraclecloud.identityControlPlane.CreateIdpGroupMapping",
"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "identityControlPlane",
"eventID": "<unique_ID>",
"eventTime": "2019-10-21T17:23:54.095Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "my_identityprovider",
  "resourceId": "ocid1.idpmapping.oc1..<unique_ID>",
  "availabilityDomain": "availability_domain",
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  },
  "additionalDetails": {
    "idpGroupName": "my_group",
    "groupId": "ocid1.group.oc1..<unique_ID>
  }
},
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}
```

This is a reference event for create, update, and delete IdP group mapping:
Multi-Factor Authentication TOTP Device Event Types

These are the event types that MFA TOTP devices emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.ActivateMfaTotpDevice</td>
</tr>
<tr>
<td>Create MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.CreateMfaTotpDevice</td>
</tr>
<tr>
<td>Delete MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.DeleteMfaTotpDevice</td>
</tr>
<tr>
<td>Generate MFA TOTP Device Seed</td>
<td>com.oraclecloud.identityControlPlane.GenerateTotpSeed</td>
</tr>
</tbody>
</table>

Multi-Factor Authentication TOTP Devices Example

This is a reference event for MFA TOTP Devices:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateMfaTotpDevice",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_idpgroup",
        "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "externalIdentifier": "my_externalidentifier"
        },
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
        }
    }
}
```
Events

```
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "my_user",
  "resourceId": "ocid1.credential.oc1..<unique_ID>",
  "availabilityDomain": "availability_domain",
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  },
  "additionalDetails": {
    "userId": "ocid1.user.oc1..<unique_ID>
  }
},
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>
}
```

Policy Event Types

These are the event types that policies emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Policy</td>
<td>com.oraclecloud.identityControlPlane.CreatePolicy</td>
</tr>
<tr>
<td>Delete Policy</td>
<td>com.oraclecloud.identityControlPlane.DeletePolicy</td>
</tr>
<tr>
<td>Update Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdatePolicy</td>
</tr>
</tbody>
</table>

Policy Example

This is a reference event for policies:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreatePolicy",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_policy",
    "resourceId": "ocid1.policy.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
```
User Event Types

These are the event types that users emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create User</td>
<td>com.oraclecloud.identityControlPlane.CreateUser</td>
</tr>
<tr>
<td>Delete User</td>
<td>com.oraclecloud.identityControlPlane.DeleteUser</td>
</tr>
<tr>
<td>Update User</td>
<td>com.oraclecloud.identityControlPlane.UpdateUser</td>
</tr>
<tr>
<td>Update User Capabilities</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserCapabilities</td>
</tr>
<tr>
<td>Update User State</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserState</td>
</tr>
</tbody>
</table>

User Example

This is a reference event for users:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateUser",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_user",
        "resourceId": "ocid1.user.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
        }
    }
}
```
Integration

For details about events emitted by Oracle Integration, see Automating with Events.

Networking

Networking resources that emit events:

- DHCP Options Event Types on page 1891
- Dynamic Routing Gateway (DRG) Event Types on page 1892
- DRG Attachment Event Types on page 1893
- Internet Gateway Event Types on page 1894
- Local Peering Gateway (LPG) Event Types on page 1895
- NAT Gateway Event Types on page 1896
- Network Security Group (NSG) Event Types on page 1897
- Private IP Event Types on page 1898
- Public IP Event Types on page 1899
- Route Table Event Types on page 1900
- Security List Event Types on page 1901
- Service Gateway Event Types on page 1902
- Subnet Event Types on page 1903
- VCN Event Types on page 1904
- Virtual Network Interface Card (VNIC) Event Types on page 1904
- VLAN Event Types on page 1905

DHCP Options Event Types

These are the event types that sets of DHCP options emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change DHCP Options Compartment</td>
<td>com.oraclecloud.virtualnetwork.changedhcpoptions</td>
</tr>
<tr>
<td>Create DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.createdhcpoptions</td>
</tr>
<tr>
<td>Delete DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.deletedhcpoptions</td>
</tr>
<tr>
<td>Update DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.updatedhcpoptions</td>
</tr>
</tbody>
</table>

DHCP Options Example

This is a reference event for a set of DHCP options:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createdhcpoptions",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {  
```
Dynamic Routing Gateway (DRG) Event Types

These are the event types that DRGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG</td>
<td>com.oraclecloud.virtualnetwork.createdrg</td>
</tr>
<tr>
<td>Delete DRG</td>
<td>com.oraclecloud.virtualnetwork.deletedrg</td>
</tr>
<tr>
<td>Update DRG</td>
<td>com.oraclecloud.virtualnetwork.updatedrg</td>
</tr>
</tbody>
</table>

DRG Example

This is a reference event for a DRG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createdrg",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.drg.oci.phx.<unique_ID>"
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": { "Department": "Finance"
        },
        "definedTags": { "Operations": { "CostCenter": "42"
        } },
        "eventID": "<unique_ID>",
        "extensions": { "compartmentId": "ocid1.compartment.oci..<unique_ID>" }
    }
}
```
DRG Attachment Event Types

These are the event types that DRG attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.createdrgattachment</td>
</tr>
<tr>
<td>Delete DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.deletedrgattachment</td>
</tr>
<tr>
<td>Update DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.updatedrgattachment</td>
</tr>
</tbody>
</table>

DRG Attachment Example

This is a reference event for a DRG attachment:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createdrgattachment",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>"",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.drgattachment.oci.phx.<unique_ID>"",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```
Internet Gateway Event Types

These are the event types that internet gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Internet Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeinternetgateway</td>
</tr>
<tr>
<td>Create Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.createinternetgateway</td>
</tr>
<tr>
<td>Delete Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.deleteinternetgateway</td>
</tr>
<tr>
<td>Update Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.updateinternetgateway</td>
</tr>
</tbody>
</table>

Internet Gateway Example

This is a reference event for an internet gateway:

```json
{
   "eventType": "com.oraclecloud.virtualnetwork.createinternetgateway",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "virtualNetwork",
   "eventTime": "2019-08-12T17:51:42.789Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "ocid1.internetgateway.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "eventID": "<unique_ID>",
      "extensions": {
         "compartmentId": "ocid1.compartment.oci..<unique_ID>"
      }
   }
}
```
### Local Peering Gateway (LPG) Event Types

These are the event types that LPGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Local Peering Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changelocalpeeringgateway_compartment</td>
</tr>
<tr>
<td>Create Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.createlocalpeeringgateway</td>
</tr>
<tr>
<td>Delete Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.deletelocalpeeringgateway</td>
</tr>
<tr>
<td>Update Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.updatelocalpeeringgateway</td>
</tr>
</tbody>
</table>

### LPG Example

This is a reference event for an LPG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createlocalpeeringgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.localpeeringgateway.oci.phx..<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
NAT Gateway Event Types

These are the event types that NAT gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change NAT Gateway Compartment</td>
<td>com.oraclecloud.natgateway.changenatgatewaycompartment</td>
</tr>
<tr>
<td>Create NAT Gateway</td>
<td>com.oraclecloud.natgateway.createnatgateway</td>
</tr>
<tr>
<td>Delete NAT Gateway</td>
<td>com.oraclecloud.natgateway.deletenatgateway</td>
</tr>
<tr>
<td>Update NAT Gateway</td>
<td>com.oraclecloud.natgateway.updatenatgateway</td>
</tr>
</tbody>
</table>

NAT Gateway Example

This is a reference event for NAT gateways:

```json
{
   "eventType": "com.oraclecloud.natgateway.createnatgateway",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "natgateway",
   "eventTime": "2019-08-12T17:51:42.789Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oci.<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "ocid1.natgateway.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      }
   },
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oci.<unique_ID>"
   }
}
```
### Network Security Group (NSG) Event Types

These are the event types that NSGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Network Security Group Compartment</td>
<td>com.oraclecloud.virtualnetwork.changenetworksecuritygrouppanagement</td>
</tr>
<tr>
<td>Create Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.createnetworksecuritygroup</td>
</tr>
<tr>
<td>Delete Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.deletenetworksecuritygroup</td>
</tr>
<tr>
<td>Update Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.updatenetworksecuritygroup</td>
</tr>
</tbody>
</table>

### NSG Example

This is a reference event for an NSG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createnetworksecuritygroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.networksecuritygroup.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Private IP Event Types

These are the event types that private IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Private IP</td>
<td>com.oraclecloud.virtualnetwork.createprivateip</td>
</tr>
<tr>
<td>Delete Private IP</td>
<td>com.oraclecloud.virtualnetwork.deleteprivateip</td>
</tr>
<tr>
<td>Update Private IP</td>
<td>com.oraclecloud.virtualnetwork.updateprivateip</td>
</tr>
</tbody>
</table>

Private IP Example

This is a reference event for a private IP:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createprivateip",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
      "compartmentId": "oci1.compartment.oci..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "oci1.privateip.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
        "Department": "Finance"
      },
      "definedTags": {
        "Operations": {
          "CostCenter": "42"
        }
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "oci1.compartment.oci..<unique_ID>"
    }
}
```
Public IP Event Types

These are the event types that public IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Public IP Compartment</td>
<td>com.oraclecloud.virtualnetwork.changepublicipcompartment</td>
</tr>
<tr>
<td>Create Public IP</td>
<td>com.oraclecloud.virtualnetwork.createpublicip</td>
</tr>
<tr>
<td>Delete Public IP</td>
<td>com.oraclecloud.virtualnetwork.deletepublicip</td>
</tr>
<tr>
<td>Update Public IP</td>
<td>com.oraclecloud.virtualnetwork.updatepublicip</td>
</tr>
</tbody>
</table>

Public IP Example

This is a reference event for a public IP:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createpublicip",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.publicip.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
**Route Table Event Types**

These are the event types that route tables emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Route Table Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeroutetable</td>
</tr>
<tr>
<td>Create Route Table</td>
<td>com.oraclecloud.virtualnetwork.createroutetable</td>
</tr>
<tr>
<td>Delete Route Table</td>
<td>com.oraclecloud.virtualnetwork.deleteroutetable</td>
</tr>
<tr>
<td>Update Route Table</td>
<td>com.oraclecloud.virtualnetwork.updateroutetable</td>
</tr>
</tbody>
</table>

**Route Table Example**

This is a reference event for route tables:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createroutetable",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.routetable.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Security List Event Types

These are the event types that security lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Security List Compartment</td>
<td><code>com.oraclecloud.virtualnetwork.changesecuritylist</code></td>
</tr>
<tr>
<td>Create Security List</td>
<td><code>com.oraclecloud.virtualnetwork.createsecuritylist</code></td>
</tr>
<tr>
<td>Delete Security List</td>
<td><code>com.oraclecloud.virtualnetwork.deletesecuritylist</code></td>
</tr>
<tr>
<td>Update Security List</td>
<td><code>com.oraclecloud.virtualnetwork.updatesecuritylist</code></td>
</tr>
</tbody>
</table>

Security List Example

This is a reference event for security lists:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createsecuritylist",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci.<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.securitylist.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci.<unique_ID>"
        }
    }
}
```
Service Gateway Event Types

These are the event types that service gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Service</td>
<td>com.oraclecloud.servicegateway.attachserviceid</td>
</tr>
<tr>
<td>Change Service Gateway Compartment</td>
<td>com.oraclecloud.servicegateway.changeservicegatewaycompartment</td>
</tr>
<tr>
<td>Create Service Gateway</td>
<td>com.oraclecloud.servicegateway.createservicegateway</td>
</tr>
<tr>
<td>Delete Service Gateway End</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.end</td>
</tr>
<tr>
<td>Delete Service Gateway Start</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.begin</td>
</tr>
<tr>
<td>Detach Service</td>
<td>com.oraclecloud.servicegateway.detachserviceid</td>
</tr>
<tr>
<td>Update Service Gateway</td>
<td>com.oraclecloud.servicegateway.updateservicegateway</td>
</tr>
</tbody>
</table>

Service Gateway Example

This is a reference event for service gateways:

```json
{
  "eventType": "com.oraclecloud.servicegateway.createservicegateway",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "servicegateway",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.servicegateway.oci.phx.<unique_ID>>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventId": "<unique_ID>>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>>"
  }
}
```
Subnet Event Types

These are the event types that subnets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subnet</td>
<td>com.oraclecloud.virtualnetwork.createsubnet</td>
</tr>
<tr>
<td>Delete Subnet</td>
<td>com.oraclecloud.virtualnetwork.deletesubnet</td>
</tr>
<tr>
<td>Update Subnet</td>
<td>com.oraclecloud.virtualnetwork.updatesubnet</td>
</tr>
</tbody>
</table>

Subnet Example

This is a reference event for a subnet:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createsubnet",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.subnet.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```

VCN Event Types

These are the event types that VCNs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VCN</td>
<td><code>com.oraclecloud.virtualnetwork.createvcn</code></td>
</tr>
<tr>
<td>Delete VCN</td>
<td><code>com.oraclecloud.virtualnetwork.deletevcn</code></td>
</tr>
<tr>
<td>Update VCN</td>
<td><code>com.oraclecloud.virtualnetwork.updatevcn</code></td>
</tr>
</tbody>
</table>

VCN Example

This is a reference event for VCNs:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createvcn",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.vcn.oci.phx..<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
}
```

Virtual Network Interface Card (VNIC) Event Types

These are the event types that VNICs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update VNIC</td>
<td><code>com.oraclecloud.virtualnetwork.updatevnic</code></td>
</tr>
</tbody>
</table>

VNIC Example

This is a reference event for a VNIC:

```json
{
```

Oracle Cloud Infrastructure User Guide 1904
Events

```
"eventType": "com.oraclecloud.virtualnetwork.updatevnic",
"cloudEventsVersion": "0.1",

}
```

### VLAN Event Types

These are the event types that VLANs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VLAN</td>
<td>com.oraclecloud.virtualnetwork.createvlan</td>
</tr>
<tr>
<td>Update VLAN</td>
<td>com.oraclecloud.virtualnetwork.updatevlan</td>
</tr>
<tr>
<td>Delete VLAN</td>
<td>com.oraclecloud.virtualnetwork.deletevlan</td>
</tr>
</tbody>
</table>

### VLAN Example

This is a reference event for a VLAN:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createvlan",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2020-04-16T17:44:31.116Z",
  "contentType": "application/json",
  "eventId": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    ...  
  }
}
```
NoSQL Database Cloud

For details about events emitted by Oracle NoSQL Database Cloud, see Service Events.

Notifications

Notifications resources that emit events:

- Subscriptions Event Types on page 1906
- Topics Event Types on page 1907

Subscriptions Event Types

These are the event types that subscriptions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subscription</td>
<td>com.oraclecloud.notification.createsubscription</td>
</tr>
<tr>
<td>Delete Subscription</td>
<td>com.oraclecloud.notification.deletesubscription</td>
</tr>
<tr>
<td>Move Subscription</td>
<td>com.oraclecloud.notification.movesubscription</td>
</tr>
<tr>
<td>Resend Subscription Confirmation</td>
<td>com.oraclecloud.notification.resendsubscription</td>
</tr>
<tr>
<td>Update Subscription</td>
<td>com.oraclecloud.notification.updatesubscription</td>
</tr>
</tbody>
</table>

Subscription Example

This is a reference event for subscriptions:

```json
{
    "eventType": "com.oraclecloud.notification.createsubscription",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "notification",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data":{
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "my_compartment",
    }
}
```
Topics Event Types

These are the event types that topics emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Topic</td>
<td>com.oraclecloud.notification.createtopic</td>
</tr>
<tr>
<td>Delete Topic</td>
<td>com.oraclecloud.notification.deletetopic</td>
</tr>
<tr>
<td>Move Topic</td>
<td>com.oraclecloud.notification.movetopic</td>
</tr>
<tr>
<td>Update Topic</td>
<td>com.oraclecloud.notification.updatetopic</td>
</tr>
</tbody>
</table>

Topic Example

This is a reference event for topics:

```
{
  "eventType": "com.oraclecloud.notification.createtopic",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "notification",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my_topic",
    "resourceId": "ocid1.onstopic.oc1..<unique_ID>",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Object Storage

Object Storage resources that emit events:

- Buckets Event Types on page 1908
- Objects Event Types on page 1908
Buckets Event Types

These are the event types that buckets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Bucket</td>
<td>com.oraclecloud.objectstorage.createbucket</td>
</tr>
<tr>
<td>Delete Bucket</td>
<td>com.oraclecloud.objectstorage.deletebucket</td>
</tr>
<tr>
<td>Update Bucket</td>
<td>com.oraclecloud.objectstorage.updatebucket</td>
</tr>
</tbody>
</table>

Bucket Example

This is an example event for buckets:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.createbucket",
  "source": "objectstorage",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ff6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

Objects Event Types

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.
These are the event types that objects emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Object</td>
<td>com.oraclecloud.objectstorage.createobject</td>
</tr>
<tr>
<td>Delete Object</td>
<td>com.oraclecloud.objectstorage.deleteobject</td>
</tr>
<tr>
<td>Update Object</td>
<td>com.oraclecloud.objectstorage.updateobject</td>
</tr>
</tbody>
</table>

**Object Example**

This is an example event for objects:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.objectstorage.createobject",
    "source": "objectstorage",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T13:37:11Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "Example_Compartment",
        "resourceName": "v1/log/10.0.6.166",
        "resourceId": "",
        "availabilityDomain": "all",
        "additionalDetails": {
            "eTag": "8162db5b-50d7-4947-a576-4401798ed2fa",
            "namespace": "my_namespace",
            "archivalState": null,
            "bucketName": "my_bucket",
            "bucketId": "ocid1.bucket.oc1.<unique_ID>"
        }
    }
}
```

**Operations Insights**

Operations Insights resources that emit events:

- Database insights
## Database Insight Event Types

These are the event types that database insights emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingest SQL Text</td>
<td>com.oraclecloud.OperationsInsights.IngestSqlText</td>
</tr>
<tr>
<td>List SQL Searches</td>
<td>com.oraclecloud.OperationsInsights.ListSqlSearches</td>
</tr>
</tbody>
</table>
Database Insight Example 1: Read Event

Following is a reference read event for database insights:

```json
{
    "eventType": "com.oraclecloud.OperationsInsights.SummarizeDatabaseInsightResourceCapacityTrend",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T00:05:46.370Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "SummarizeDatabaseInsightResourceCapacityTrend",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "resourceCapacityTrend",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeformTags": null,
        "definedTags": null
    }
}
```

Database Insight Example 2: Ingest Event

Following is a reference ingest event for database insights:

```json
{
    "eventType": "com.oraclecloud.OperationsInsights.IngestSqlText",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T01:09:00.688Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "IngestSqlText",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "actions",
        "availabilityDomain": "AD1",
        "freeformTags": null,
        "definedTags": null
    }
}
```

OS Management

For details about events emitted by OS Management, see Creating Automation with Events.

Resource Manager

Resource Manager resources that emit events:

- Job Event Types on page 1912
- Stack Event Types on page 1913
### Job Event Types

These are the event types that jobs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cancel Job</td>
<td>com.oraclecloud.oracleresourcemanager.canceljob</td>
</tr>
<tr>
<td>Create Job Begin</td>
<td>com.oraclecloud.oracleresourcemanager.createjob.begin</td>
</tr>
<tr>
<td>Create Job End</td>
<td>com.oraclecloud.oracleresourcemanager.createjob.end</td>
</tr>
<tr>
<td>Update Job</td>
<td>com.oraclecloud.oracleresourcemanager.updatejob</td>
</tr>
</tbody>
</table>

This is a reference event for jobs:

```json
{
    "eventType": "com.oraclecloud.oracleresourcemanager.updateJob",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OracleResourceManager",
    "eventTime": "2019-07-23T01:46:37.606Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example_name",
        "resourceId": "ocid1.ormjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
**Stack Event Types**

These are the event types that stacks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment Begin</td>
<td>com.oraclecloud.oracleresourcemanager.changestackcompartment.begin</td>
</tr>
<tr>
<td>Change Compartment End</td>
<td>com.oraclecloud.oracleresourcemanager.changestackcompartment.end</td>
</tr>
<tr>
<td>Create Stack</td>
<td>com.oraclecloud.oracleresourcemanager.createstack</td>
</tr>
<tr>
<td>Delete Stack</td>
<td>com.oraclecloud.oracleresourcemanager.deletestack</td>
</tr>
<tr>
<td>Update Stack</td>
<td>com.oraclecloud.oracleresourcemanager.updatestack</td>
</tr>
</tbody>
</table>

This is a reference event for stacks:

```json
{
    "eventType": "com.oraclecloud.oracleresourcemanager.createstack",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OracleResourceManager",
    "eventTime": "2019-07-23T01:32:10.866Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example_name",
        "resourceId": "ocid1.ormstack.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

**WAF**

WAF resources that emit events:

- [Waas Policy Event Types](page 1914)
- [Address List Event Types](page 1915)
- [Custom Protection Rule Event Types](page 1916)
- [Certificate Event Types](page 1917)
**Waas Policy Event Types**

These are the event types that Waas policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Waas Policy Compartment</td>
<td>com.oraclecloud.waf.changewaaspolicycompartment</td>
</tr>
<tr>
<td>Create Waas Policy Begin</td>
<td>com.oraclecloud.waf.createwaaspolicy.begin</td>
</tr>
<tr>
<td>Create Waas Policy End</td>
<td>com.oraclecloud.waf.createwaaspolicy.end</td>
</tr>
<tr>
<td>Delete Waas Policy Begin</td>
<td>com.oraclecloud.waf.deletewaaspolicy.begin</td>
</tr>
<tr>
<td>Delete Waas Policy End</td>
<td>com.oraclecloud.waf.deletewaaspolicy.end</td>
</tr>
<tr>
<td>Update Waas Policy Begin</td>
<td>com.oraclecloud.waf.updatewaaspolicy.begin</td>
</tr>
<tr>
<td>Update Waas Policy End</td>
<td>com.oraclecloud.waf.updatewaaspolicy.end</td>
</tr>
</tbody>
</table>

**Waas Policy Example**

This is an example event for a Waas policy:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updatewaaspolicy.begin",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_policy",
    "resourceId": "ocid1.waaspolicy.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "domain": "example.com"
    }
  }
}
```
**Address List Event Types**

These are the event types that address lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Address List Compartment</td>
<td>com.oraclecloud.waf.changeaddresslistcompartment</td>
</tr>
<tr>
<td>Create Address List</td>
<td>com.oraclecloud.waf.createaddresslist</td>
</tr>
<tr>
<td>Delete Address List</td>
<td>com.oraclecloud.waf.deleteaddresslist</td>
</tr>
<tr>
<td>Update Address List</td>
<td>com.oraclecloud.waf.updateaddresslist</td>
</tr>
</tbody>
</table>

**Address List Example**

This is an example event for address lists:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updateaddresslist",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_address_list",
    "resourceId": "ocid1.waasaddresslist.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```
Custom Protection Rule Event Types

These are the event types that protection rules emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Custom Protection Rule Compartment</td>
<td>com.oraclecloud.waf.changecustomprotectionrulecom.oraclecloud.waf.changecustomprotectionrulecompartment</td>
</tr>
<tr>
<td>Create Custom Protection Rule</td>
<td>com.oraclecloud.waf.createcustomprotectionrulecom.oraclecloud.waf.createcustomprotectionrulecom.oraclecloud.waf.createcustomprotectionrule</td>
</tr>
<tr>
<td>Delete Custom Protection Rule</td>
<td>com.oraclecloud.waf.deletecustomprotectionrulecom.oraclecloud.waf.deletecustomprotectionrulecom.oraclecloud.waf.deletecustomprotectionrule</td>
</tr>
<tr>
<td>Update Custom Protection Rule</td>
<td>com.oraclecloud.waf.updatecustomprotectionrulecom.oraclecloud.waf.updatecustomprotectionrulecom.oraclecloud.waf.updatecustomprotectionrule</td>
</tr>
<tr>
<td>Update Waas Policy Custom Protection Rules</td>
<td>com.oraclecloud.waf.updatewaaspolicycustomprotectionrulecom.oraclecloud.waf.updatewaaspolicycustomprotectionrulecom.oraclecloud.waf.updatewaaspolicycustomprotectionrule</td>
</tr>
</tbody>
</table>

Protection Rule Example

This is an example event for custom protection rules:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.waf.updatecustomprotectionrule",
    "source": "waf",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-10-11T13:40:54.931962577Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_waas_custom_protection_rule",
        "resourceId": "ocid1.waascustomprotectionrule.oc1..<unique_ID>",
        "availabilityDomain": "all",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```
**Certificate Event Types**

These are the event types that certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment</td>
<td>com.oraclecloud.waf.changecertificatecompartment</td>
</tr>
<tr>
<td>Create Certificate</td>
<td>com.oraclecloud.waf.createcertificate</td>
</tr>
<tr>
<td>Delete Certificate</td>
<td>com.oraclecloud.waf.deletecertificate</td>
</tr>
<tr>
<td>Update Certificate</td>
<td>com.oraclecloud.waf.updatecertificate</td>
</tr>
</tbody>
</table>

**Certificate Example**

This is an example event for certificates:

```
{
    "cloudEventsVersion": "0.1",
    "eventId": "<unique_ID>",
    "eventType": "com.oraclecloud.waf.updatecertificate",
    "source": "waf",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-10-11T13:40:54.931962577Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    }
}
```

**Events Metrics**

You can monitor performance of your rules by using metrics, alarms, and notifications. This topic describes the metrics emitted by the metric namespace `oci_cloudevents` (the Events service).

Resources: rules. Also measures data for events, which are not resources.

**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must
Events give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Overview of the Events Service Metrics

You create rules that specify which events should be delivered to other services for processing. This delivery creates the automation in your tenancy. A rule identifies an event pattern to match and specifies other services to deliver matching events to. Metrics help you measure the success of the rules you create (in terms of pattern matching and delivery) and the quality and scope of the emitted events in your tenancy. For more information, see Overview of Events on page 1784.

Available Metrics: oci_cloudevents

The metrics listed in the following table are automatically available for rules you create. You do not need to enable monitoring to get these metrics.

Each metric includes one or more of the following dimensions:

**RESOURCEID**

The OCID of the rule or compartment to which the metric applies.

**EVENTTYPE**

The type of event emitted by a resource.

**RESOURCEDISPLAYNAME**

The name of the rule.

**ACTIONTYPE**

One or more of the following types of resources that receives an event from the Events service.

- Notifications
- Streaming
- Functions

<table>
<thead>

<td>If you view the default chart from a rule, this metric provides the total number of successful deliveries to actions for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of successful deliveries to actions for all the rules in a compartment.</td>
<td>actionType, resourceDisplayName, resourceId</td>
</tr>
<tr>
<td>DeliveryFailedEvents</td>
<td>Delivery Failure</td>
<td>count</td>
<td>If you view the default chart from a rule, this metric provides the total number of unsuccessful deliveries to actions for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of unsuccessful deliveries to actions for all the rules in a compartment.</td>
<td>actionType, resourceDisplayName, resourceId</td>
</tr>
</tbody>
</table>

### Using the Console

#### To view default metric charts for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose the **Compartment** that contains the rule you want to view, and then click the rule's name.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current rule.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

#### To view default metric charts for a compartment

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose the **Compartment** that contains the rules you want to monitor.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current compartment.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

### Using the API

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
Chapter 18

File Storage

This chapter explains how to create file systems, how to manage them, and how to mount them to write files.

Overview of File Storage

Oracle Cloud Infrastructure File Storage service provides a durable, scalable, secure, enterprise-grade network file system. You can connect to a File Storage service file system from any bare metal, virtual machine, or container instance in your Virtual Cloud Network (VCN). You can also access a file system from outside the VCN using VCN peering, Oracle Cloud Infrastructure FastConnect, and Internet Protocol security (IPSec) virtual private network (VPN).

Large Compute clusters of thousands of instances can use the File Storage service for high-performance shared storage. Storage provisioning is fully managed and automatic as your use scales from a single byte to exabytes without upfront provisioning.

The File Storage service supports the Network File System version 3.0 (NFSv3) protocol. The service supports the Network Lock Manager (NLM) protocol for file locking functionality.

Oracle Cloud Infrastructure File Storage employs 5-way replicated storage, located in different fault domains, to provide redundancy for resilient data protection. Data is protected with erasure encoding.

The File Storage service uses the "eventual overwrite" method of data eradication. Files are created in the file system with a unique encryption key. When you delete a single file, its associated encryption key is eradicated, making the file inaccessible. When you delete an entire file system, the file system is marked as inaccessible. The service systematically traverses deleted files and file systems, frees all the used space, and eradicates all residual files.

Use the File Storage service when your application or workload includes big data and analytics, media processing, or content management, and you require Portable Operating System Interface (POSIX)-compliant file system access semantics and concurrently accessible storage. The File Storage service is designed to meet the needs of applications and users that need an enterprise file system across a wide range of use cases, including the following:

- **General Purpose File Storage:** Access to an unlimited pool of file systems to manage growth of structured and unstructured data.
- **Big Data and Analytics:** Run analytic workloads and use shared file systems to store persistent data.
- **Lift and Shift of Enterprise Applications:** Migrate existing Oracle applications that need NFS storage, such as Oracle E-Business Suite and PeopleSoft.
- **Databases and Transactional Applications:** Run test and development workloads with Oracle, MySQL, or other databases.
- **Backups, Business Continuity, and Disaster Recovery:** Host a secondary copy of relevant file systems from on premises to the cloud for backup and disaster recovery purposes.
- **MicroServices and Docker:** Deliver stateful persistence for containers. Easily scale as your container-based environments grow.

Tip:

Watch a video introduction to the service and its capabilities.
File Storage Concepts

Using the File Storage service requires an understanding of the following concepts, including some that pertain to Oracle Cloud Infrastructure Networking:

**MOUNT TARGET**

An NFS endpoint that lives in a subnet of your choice and is highly available. The mount target provides the IP address or DNS name that is used in the mount command when connecting NFS clients to a file system. File systems are exported (made available) through mount targets. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

Mount target limitations:

- Each mount target can accept up to 100,000 NFS client connections.
- If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 1942 for more information.
- By default, you can create two mount targets per account per availability domain. See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

See Managing Mount Targets on page 1980 for more information about working with this resource.

**EXPORT**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter,

- You can create as many exports in a mount target for different file systems as you wish.
- You can create as many exports in a mount target for a single file system as you wish.
- You can delete and re-create exports in a mount target as often as you need to.
- You can add export options to an export to control access to the file system.

For more information, see Managing Mount Targets on page 1980 and Working with NFS Export Options on page 1934.

**EXPORT SET**

Collection of one or more exports that control what file systems the mount target exports using NFSv3 protocol and how those file systems are found using the NFS mount protocol. Each mount target has an export set. Each file system associated with the mount target has at least one export in the export set.

**EXPORT PATH**

A path that is specified when an export is created. It uniquely identifies the file system within the mount target, letting you associate many file systems to a single mount target. This path is unrelated to any path within the file system itself, or the client mount point path.

The File Storage service adds an export that pairs the file system's Oracle Cloud Identifier (OCID) and path. See Paths in File Systems on page 2006 for more information.
EXPORT OPTIONS

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export. For more information, see Working with NFS Export Options on page 1934.

VIRTUAL CLOUD NETWORK (VCN)

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice. For more information about VCNs, see VCNs and Subnets on page 2821 in the Oracle Cloud Infrastructure Networking documentation.

You can set up a service gateway and give your VCN private access to the File Storage service. A service gateway can be used only by resources in the gateway's own VCN. Traffic to the service will not travel through the internet. When creating the service gateway, enable the service label called All <region> Services in Oracle Services Network. It includes the File Storage service. Be sure to update route tables for any subnets that need to access File Storage through the service gateway.

For more information and detailed instructions, see Setting Up a Service Gateway in the Console on page 3260.

SUBNETS

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual network interface cards (VNICs), which attach to instances. A subnet can span a region or exist in a single availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing rules and security lists that apply to it. For more information about subnets, see VCNs and Subnets on page 2821 in the Oracle Cloud Infrastructure Networking documentation.

SECURITY RULES

Virtual firewall rules for your VCN. Your VCN comes with a default security list, and you can add more. These security lists provide ingress and egress rules that specify the types of traffic allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. Security list rules must be set up so that clients can connect to file system mount targets.

Network security groups (NSGs). Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

SNAPSHOTS

Snapshots provide a consistent, point-in-time view of your file system, and you can take as many snapshots as you need. You pay only for the storage used by your data and metadata, including storage capacity used by snapshots. Each snapshot reflects only data that changed from the previous snapshot. For more information, see Managing Snapshots on page 1990.

Encryption

The File Storage service encrypts all file system and snapshot data at rest. By default all file systems are encrypted using Oracle-managed encryption keys. You have the option to encrypt all of your file systems using the keys that you own and manage using the Vault service.

Note:

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.
For more information, see Overview of Vault on page 3952.

For information about how to use your own key for new file systems, see Creating File Systems on page 1948. See To update the key for a file system on page 1978 for how to assign or change the key for an existing file system.

Data Transfers

FastConnect offers you the ability to accelerate data transfers. You can leverage the integration between FastConnect and the File Storage service to perform initial data migration, workflow data transfers for large files, and disaster recovery scenarios between two regions, among other things.

File Storage Space Allocation

The File Storage service allocates space in blocks of variable size in a way that is fine-tuned to minimize total customer cost and optimize performance for modern workloads. The minimum block size used is 8192 bytes. For example, if you create a 1-byte file, we allocate 8192 bytes. We use larger blocks to store larger files. To learn more about file system and snapshot usage, see File System Usage and Metering on page 2007.

How File Storage Permissions Work

File Storage service resources include file systems, mount targets, and export sets. The AUTH_UNIX style of authentication and permission checking is supported for remote NFS client requests. You use Oracle Cloud Infrastructure Identity and Access Management (IAM) policy language to define access to Oracle Cloud Infrastructure resources. You can consider exports and snapshots subsidiary resources of export sets and file systems, respectively. As such, they do not need their own permissions. Related resources include Oracle Cloud Infrastructure Compute instances and Oracle Cloud Infrastructure Networking virtual cloud networks (VCNs).

Oracle Cloud Infrastructure users require resource permissions to create, delete, and manage resources. Without the appropriate IAM permissions, you cannot export a file system through a mount target. Until a file system has been exported, Compute instances cannot mount it. For more information about creating an IAM policy, see Let users create, manage, and delete file systems on page 2148.

If you have successfully exported a file system on a subnet, then you use Networking security lists to control traffic to and from the subnet and, therefore, the mount target. Security lists act as a virtual firewall, allowing only the network traffic you specify to and from the IP addresses and port ranges configured in your ingress and egress rules. The security list you create for the subnet lets hosts send and receive packets and mount the file system. If you have firewalls on individual instances, use FastConnect, or use a virtual private network (VPN), the settings for those might also impact security at the networking layer. For more information about creating a security list for the File Storage service, see Creating File Systems on page 1948. See About Security on page 1925 for more information on how different types of security work together in your file system.

Regions and Availability Domains

You can use the File Storage service in all regions. For a list of supported regions, see Regions and Availability Domains on page 180.

When you create file systems and mount targets, you specify the availability domain they are created in. All file system data is then stored entirely within the availability domain the file system resides in. Within an availability domain, the File Storage service uses synchronous replication and high availability failover to keep your data safe and available.

You cannot move a file system to a different availability domain or region. However, you can take a snapshot of your data and use a tool such as rsync to copy your data to a different availability domain or region. To maximize performance for data protection operations, you can use the File Storage Parallel Tools suite. The Parallel File Tools suite provides parallel versions of tar, rm, and cp. See Managing Snapshots on page 1990 for more information on using snapshots to protect your data.

While it is possible to access mount targets from any availability domain in a region, for optimal performance, place File Storage resources in the same availability domain as the Compute instances that access them.
Subnets can be either AD-specific or regional. You can create File Storage resources in either type of subnet. Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet. For more information, see Overview of VCNs and Subnets on page 2822.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

The following File Storage resources emit events:

- File systems
- Snapshots
- Mount targets
- Exports
- Export sets

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Your File Storage Components

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

To set compartment-specific limits on file systems or mount targets, administrators can use compartment quotas.
Additional Documentation Resources

The following Oracle Cloud Infrastructure File Storage service solution playbooks and white papers are available:

- **Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service**
  Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business Suite.

- **Learn about deploying Oracle E-Business Suite on Oracle Cloud Infrastructure**
  Learn how file storage is part of a multihost, secure, high-availability topology for Oracle E-Business Suite.

- **Design a pilot-light disaster recovery (DR) topology**
  Learn how to use file storage in your disaster recovery topology.

About Security

Access Control

The File Storage service uses four different layers of access control. Each layer has its own authorization entities and methods which are separate from the other layers.

| Tip: Watch a video about security in File Storage. |

The **Oracle Cloud Infrastructure (OCI) policy** layer uses policies to control what users can do within Oracle Cloud Infrastructure, such as creating instances, a VCN and its security rules, mount targets, and file systems.

The **Network security** layer controls which instance IP addresses or CIDR blocks can connect to a host file system. It uses VCN security list rules to allow or deny traffic to the mount target, and therefore access to any associated file system.

The **NFS export option** layer is a method of applying access control per-file system export based on source IP address that bridges the Network Security layer and the NFS v.3 Unix Security layer.

The **NFS v.3 Unix security** layer controls what users can do on the instance, such as installing applications, creating directories, mounting external file systems by a local mount point, and reading and writing files.

<table>

</tr>
</tbody>
</table>
This security layer... | Uses these... | To control actions like...
--- | --- | ---
NFS export options | File system exports, IP addresses, Unix users | Privileged source port connection, reading and writing files, and limiting root user access on a per-file system basis.

**Oracle Cloud Infrastructure Identity and Access Management**

You can create users and groups in Oracle Cloud Infrastructure. Then, you can use policies to specify which users and groups can create, access, or modify resources such as file systems, mount targets, snapshots, and export options within. See [Overview of Oracle Cloud Infrastructure Identity and Access Management](#) on page 2124 to learn more about how to set up access.

**Network Security**

The network security layer allows you to use VCN network security groups (NSGs) and security rules to block the appropriate ports from specific IP addresses and CIDR blocks and restrict host access. However, it’s on an ‘all or nothing’ basis - the client either can or cannot access the mount target, and therefore all file systems associated with it. See [Ways to Secure Your Network](#) on page 2830 for general information about VCN security groups, security lists, and rules. See [Configuring VCN Security Rules for File Storage](#) on page 1927 for specific information about the security rules necessary for File Storage.

**NFS v.3 Unix security**

File Storage service supports the AUTH_UNIX style of authentication and permission checking for remote NFS client requests. When mounting file systems, we recommend that you use the `-nosuid` option. This option disables set-user-identifier or set-group-identifier bits. Remote users are prevented from gaining higher privileges using a `setuid` program. For more information, see [Mounting File Systems](#) on page 1954.

Remember that users in UNIX aren’t the same as users in Oracle Cloud Infrastructure - they’re not linked or associated in any way. The Oracle Cloud Infrastructure policy layer doesn’t govern anything that happens inside the file system, the UNIX security layer does. Conversely, the UNIX security layer doesn’t govern creating file systems or mount targets in Oracle Cloud Infrastructure.

File Storage does not support file level Access Control Lists (ACLs). Only `user`, `group`, and `world` permissions are supported. File Storage uses the NFSv3 protocol, which doesn’t include support for ACLs. `setfacl` fails on mounted file systems. `getfacl` returns only standard permissions.

**Note:**

Some implementations might extend the NFSv3 protocol and add support for ACLs as part of a separate `rpc` program.

**SETFAACL error example**

This example shows an example of a `setfacl` error:

```
[opc@example setfacl_testing]$ ls -ld test
drwxr--r--. 2 opc opc 0 Jul 2 10:31 test
[opc@example setfacl_testing]$ setfacl -m u:applmgr:r test
setfacl: test: Operation not supported
```

Oracle Cloud Infrastructure User Guide 1926
NFS export options

NFS export options are a method of applying access control at both the network security layer and the NFS v.3 Unix security layer. You can use NFS export options to limit access levels by IP addresses or CIDR blocks connecting to multiple file systems through exports of an associated mount target. Access can be restricted so that each client’s file system is inaccessible and invisible to the other, allowing for managed hosted environment security. Moreover, you can set NFS v.3 Unix security permissions for read-only, read/write, or root-squash for your file systems. See Working with NFS Export Options on page 1934 for more information.

Encryption

Within Oracle Cloud Infrastructure

All data is encrypted at rest. You can leave all encryption-related matters to Oracle, or you can choose to manage your own encryption using the Oracle Cloud Infrastructure Vault (KMS) service. You can use KMS to create master encryption keys and data encryption keys, rotate keys to generate new cryptographic material, enable or disable keys for use in cryptographic operations, assign keys to file systems, and use keys for encryption and decryption.

Note:
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 3952.

Between Instances and Mounted File Systems

In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v. 1.2 (Transport Layer Security) encryption.

In-transit encryption is enabled by installing a client package on your instance. The package creates an NFS endpoint, network namespace, and network interface. A forwarder process receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

For more information, see Using In-transit Encryption on page 1942.

Configuring VCN Security Rules for File Storage

Before you can mount a file system, you must configure security rules to allow traffic to the mount target’s VNIC using specific protocols and ports. Security rules enable traffic for the following:

- Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility protocol
- Network File System (NFS) protocol
- Network File System (MOUNT) protocol
- Network Lock Manager (NLM) protocol

File Storage Security Rule Scenarios

There are three basic scenarios that require different security rules for File Storage:
Scenario A: Mount target and instance in the same subnet

In this scenario, the mount target that exports the file system is in the same subnet as the instance you want to mount the file system to.

- Stateful ingress from ALL ports in source CIDR block to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress from ALL ports in source CIDR block to UDP ports 111 and 2048.
- Stateful egress from TCP ALL ports to ports 111, 2048, 2049, and 2050 in destination CIDR block.
- Stateful egress from UDP ALL ports to port 111 in destination CIDR block.

Important:
Oracle recommends that NFS clients be limited to reserved ports. To do this, set the Source Port range to 1-1023. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options on page 1934.

Here's an example of the rules for Scenario A set up for a single subnet that contains both the mount target and the instance. In this example, both the mount target and the instance are in CIDR block 10.0.0.0/24:

<table>
<thead>
<tr>
<th>Stateless</th>
<th>Source</th>
<th>IP Protocol</th>
<th>Source Port Range</th>
<th>Destination Port Range</th>
<th>Type and Code</th>
<th>Allows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>10.0.0.0/24</td>
<td>TCP</td>
<td>All</td>
<td>2048-2050</td>
<td>TCP traffic for ports: 2048-2050</td>
<td></td>
<td></td>
</tr>
<tr>
<td>No</td>
<td>10.0.0.0/24</td>
<td>TCP</td>
<td>All</td>
<td>111</td>
<td>TCP traffic for ports: 111</td>
<td></td>
<td></td>
</tr>
<tr>
<td>No</td>
<td>10.0.0.0/24</td>
<td>UDP</td>
<td>All</td>
<td>2048</td>
<td>UDP traffic for ports: 2048</td>
<td></td>
<td></td>
</tr>
<tr>
<td>No</td>
<td>10.0.0.0/24</td>
<td>UDP</td>
<td>All</td>
<td>111</td>
<td>UDP traffic for ports: 111</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to the resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 1931 for an overview of these methods and instructions about how to use them to set up security rules.

Scenario B: Mount target and instance in different subnets

In this scenario, the mount target that exports the file system is in a different subnet than the instance you want to mount the file system to. Security rules must be configured for both the mount target and the instance either in a security list for each subnet, or a network security group (NSG) for each resource.

Set up the following the following security rules for the mount target. Specify the instance IP address or CIDR block as the source for ingress rules and the destination for egress rules:
• Stateful ingress from ALL ports in the source instance CIDR block to TCP ports 111, 2048, 2049, and 2050.
• Stateful ingress from ALL ports in the source instance CIDR block to UDP ports 111 and 2048.
• Stateful egress from TCP ports 111, 2048, 2049, and 2050 to ALL ports in the destination instance CIDR block.
• Stateful egress from UDP port 111 ALL ports in the destination instance CIDR block.

**Important:**

Oracle recommends that NFS clients be limited to reserved ports. To do this, set the **Source Port** range to **1-1023**. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see [Working with NFS Export Options](#) on page 1934.

Next, set up the following security rules for the **instance**. Specify the mount target IP address or CIDR block as the **source** for ingress rules and the **destination** for egress rules:

• Stateful ingress from source mount target CIDR block TCP ports 111, 2048, 2049, and 2050 to ALL ports.
• Stateful ingress from source mount target CIDR block UDP port 111 to ALL ports.
• Stateful egress from ALL ports to destination mount target CIDR block TCP ports 111, 2048, 2049, and 2050.
• Stateful egress from ALL ports to destination mount target CIDR block UDP ports 111 and 2048.

Here's an example of the rules for Scenario B set up in security list rules for the instance and mount target. This example shows rules for specific source and destination CIDR blocks.

**Ingress** rules for the mount target's NSG or subnet security list. The instance CIDR block **10.0.0.0/24** is the source:

<table>
<thead>
<tr>
<th>Stateless</th>

</table>

### Using a Security List

Security lists are associated with subnets. If you use security lists to set up your security rules, you need to set up the mount target rules in the mount target subnet, and the instance rules in the instance subnet. You can add the rules to the default security list for each subnet, or create new security lists.
Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target and instance to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 1931 for an overview of these methods and instructions about how to use them to set up security rules.

**Scenario C: Mount target and instance use in-transit encryption**

In this scenario, in-transit encryption secures your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. See Using In-transit Encryption on page 1942 for more information.

You can limit the source or destination to the IP address or CIDR block of your choice. Alternatively, you can allow traffic from all sources or destinations.

Set up the following security rules for the **mount target**:

- **Stateful ingress** from ALL ports in the source CIDR block to TCP port **2051**.
- **Stateful egress** from TCP port **2051** to ALL ports in the destination CIDR block.

<table>

</tbody>
</table>

Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 1931 for an overview of these methods and instructions about how to use them to set up security rules.

**Ways to Enable Security Rules for File Storage**

The Networking service offers two virtual firewall features that both use security rules to control traffic at the packet level. The two features are:

- **Security lists**: The original virtual firewall feature from the Networking service. When you create a VCN, a default security list is also created. Add the required rules to the security list for the subnet that contains the mount target. (If you're setting up Scenario B: Mount target and instance in different subnets on page 1928, you have to add rules for both subnets.) See Setting Up Required Rules in a Security List on page 1932 for instructions.

- **Network security groups (NSGs)**: A subsequent feature designed for application components that have different security postures. Create an NSG that contains the required rules, and then add the mount target to the NSG. Alternatively, you can add the required rules to a previously existing NSG, and add the mount target to the NSG. Each mount target can belong to up to five (5) NSGs. (If you're setting up Scenario B: Mount target and instance in different subnets on page 1928, you have to add both the mount target and instance to an NSG that contains the required security rules.) See Setting Up Required Rules in a Network Security Group (NSG) on page 1933 for instructions.
Important:

You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you choose to use both security lists and network security groups, the set of rules that applies to a given mount target VNIC is the combination of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

It doesn't matter which method you use to apply security rules to the mount target VNIC, as long as the ports for protocols necessary for File Storage are correctly configured in the rules applied.

See Security Rules on page 2833, Security Lists on page 2850, and Network Security Groups on page 2841 for more information, examples, and scenarios about how these features interact in your network. Networking Overview on page 2748 provides general information about networking. See About Security on page 1925 for information about how security rules work with other types of security in File Storage.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let network admins manage a cloud network on page 2143 covers management of all networking components, including security lists and NSGs. See the Policy Reference on page 2167 for more information.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Using the Console

Setting Up Required Rules in a Security List

You can add the required rules to a pre-existing security list associated with a subnet, such as the default security list that is created along with the VCN. See To create a security list on page 2853 for more information.

To add required rules to a security list

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. In the Scope section, select the compartment that contains the VCN the subnet is in.
3. Click the name of the VCN.
4. On the details page for the cloud network, in Resources, and then click Security Lists.
5. Click the name of the security list used by the subnet.
7. Click Add Ingress Rules.

- Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 2839). By default, rules are stateful unless you specify otherwise.
- To allow traffic from the subnet of the cloud network, click Source Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
- Click IP Protocol, and then choose the protocol. For example, TCP.
- In Source Port Range, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of All to allow traffic from any source port.
- Click Destination Port Range, and then enter individual ports or a port range. For example, 2048-2050.
8. Click + Additional Ingress Rule to create more ingress rules.
9. When you're done, click Add Ingress Rules.
11. Click Add Egress Rules.
   • Specify that it's a stateful rule by leaving the check box clear.
   • Click Destination Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   • Click IP Protocol, and then choose the protocol. For example, TCP.
   • In Source Port Range, and then enter individual ports or a port range. For example, 2048-2050.
   • In Destination Port Range, accept the default of All to allow traffic to any destination port.
12. Click + Additional Egress Rule to create more egress rules.
13. When you're done, click Add Egress Rules.

**Setting Up Required Rules in a Network Security Group (NSG)**

The general process for setting up NSGs that work with File Storage is:

1. Create an NSG with the required security rules. (Alternatively, you can add them to a previously existing NSG.)
2. Add the mount target (or more specifically, the mount target's VNIC) to the NSG. You can do this when you create the mount target, or you can update the mount target and add it to one or more NSGs that contain the required security rules.
3. If you're setting up Scenario B: Mount target and instance in different subnets on page 1928, you'll have to add both the mount target and instance to an NSG that contains the required security rules.

To create an NSG with the required security rules

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
5. Enter the following:
   • **Name**: A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   • **Create in Compartment**: The compartment where you want to create the network security group, if different from the compartment you're currently working in.
   • **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
6. Click Next.
7. Enter ingress rules.
   • Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 2839). By default, rules are stateful unless you specify otherwise.
   • In **Direction**, choose Ingress.
   • To allow traffic from the subnet of the cloud network, click **Source Type**, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   • Click IP Protocol, and then choose the protocol. For example, TCP.
   • In **Source Port Range**, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of All to allow traffic from any source port.
   • Click **Destination Port Range**, and then enter individual ports or a port range. For example, 2048-2050.
8. Click + Another Rule to create more ingress rules.
9. Enter egress rules.
   • Specify that it's a stateful rule by leaving the check box clear.
   • In Direction, choose Egress.
   • Click Destination Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   • Click IP Protocol, and then choose the protocol. For example, TCP.
   • In Source Port Range, and then enter individual ports or a port range. For example, 2048-2050.
   • In Destination Port Range, accept the default of All to allow traffic to any destination port.
10. Click + Another Rule to create more egress rules.
11. When you're done, click Create.

To add a mount target to an NSG

• When creating a mount target along with a file system: See To create a file system on page 1948.
• When creating only the mount target: See To create a mount target on page 1983.
• For an existing mount target:
  1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
  2. In the List Scope section, select a compartment.
  3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount Target Details.
  4. In the Mount Target Information tab, click the Edit link next to Network Security Groups.
  5. Select a Compartment and NSG from the list.
  6. Click Save.

To add an instance to an NSG

See To add or remove a resource from an NSG on page 2848 for instructions on how to add an instance to an NSG.

Working with NFS Export Options

This topic describes the basic features of NFS export options, and how to control client access to your file system.

Overview

NFS export options enable you to create more granular access control than is possible using just security list rules to limit VCN access. You can use NFS export options to specify access levels for IP addresses or CIDR blocks connecting to file systems through exports in a mount target. Access can be restricted so that each client's file system is inaccessible and invisible to the other, providing better security controls in multi-tenant environments.

Using NFS export option access controls, you can limit clients' ability to connect to the file system and view or write data. For example, if you want to allow clients to consume but not update resources in your file system, you can set access to Read Only. You can also reduce client root access to your file systems and map specified User IDs (UIDs) and Group IDs (GIDs) to an anonymous UID/GID of your choice. For more information about how NFS export options work with other security layers, see About Security on page 1925.

Tip:
Watch a video about working with NFS export options in File Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to manage NFS export options.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.
Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

See To create an export for a file system on page 1972 for more information.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

Each separate client IP address or CIDR block you want to define access for needs a separate export options entry in the export. For example, if you want to set options for NFS client IP addresses 10.0.0.6, 10.0.0.8, and 10.0.0.10, you need to create three separate entries, one for each IP address.

File Storage service considers the listed order of each export options entry for the export. During an NFS request by a client, File Storage service applies the first set of options that matches the client Source IP address. Only the first set is applied; the rest are ignored.

For example, consider the following two export options entries specifying access for an export:

Entry 1: Source: 10.0.0.0/16, Access: Read Only
Entry 2: Source: 10.0.0.8, Access: Read/Write

In this case, clients who connect to the export from IP address 10.0.0.8 have Read Only access. The request Source IP address is contained in the CIDR block specified in the first entry, and File Storage Service applies the options in the first match.

**Important:** File systems can be associated with one or more exports, contained within one or more mount targets. If the client source IP address does not match any entry on the list for a single export, then that export is not visible to the client. However, the file system could be accessed through other exports on the same or other mount targets. To completely deny client access to a file system, be sure that the client source IP address or CIDR block is not included in any export for any mount target associated with the file system.

The following options can be set to control export access:

- **Source**: The IP address or CIDR block of a connecting NFS client.
- **Require Privileged Source Port (true/false)**: This setting determines whether the NFS clients specified in source are required to connect from a privileged source port. Privileged ports are any port including 1-1023. On Unix-like systems, only the root user can open privileged ports. Setting this value to true disallows requests from unprivileged ports. The default for this setting is different depending on how the export is created. Creating an export without an explicit ClientOption array sets the requirePrivilegedSourcePort attribute of the client option to false. When you create a ClientOption array explicitly, requirePrivilegedSourcePort defaults to true.

For example, creating an export in the Console using the default selections sets requirePrivilegedSourcePort to false. Creating an export in the API along with a ClientOption array sets requirePrivilegedSourcePort to true.
Important:

When **Require Privileged Source Port** is set to **true**, you also have to follow these additional configuration steps:

1. When mounting the file system from a Unix-like system, include the `resvport` option in your mount command when mounting. For example:

   ```
   sudo mount -o resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```

   For more information, see [Mounting File Systems From Unix-Style Instances](#) on page 1957.

2. When mounting the file system from a Windows system, be sure the `UseReserverdPort` registry key value is set to **1**.

   For more information, see [Mounting File Systems From Windows Instances](#) on page 1964.

- **Access (Read Only, Read_Write):** This setting specifies the source NFS client access. If unspecified, defaults to **Read_Write**.
- **Identity Squash: (All, Root, None):** This setting determines whether the source clients accessing the file system have their User ID (UID) and Group ID (GID) remapped to `anonymousUid` and `anonymousGid`. If you choose **All**, all users and groups are remapped. If **Root**, only the root user UID/GID combination 0/0 is remapped. If **None**, no users are remapped. If unspecified, defaults to **None**.
- **anonymousUid:** This setting is used along with the **Identity Squash** option. When remapping users, you can use this setting to change the default `anonymousUid` of **65534** to any user ID of your choice.
- **anonymousGid:** This setting is used along with the **Identity Squash** option. When remapping groups, you can use this setting to change the default `anonymousGid` of **65534** to any group ID of your choice.

**Typical Access Control Scenarios**

When you create file system and export, the NFS export options for that file system are set to the following defaults, which allow full access for all NFS client source connections. These defaults must be changed if you want to restrict access:

- **Source:** 0.0.0.0/0 (All)
- **Require Privileged Source Port:** False
- **Access:** Read_Write
- **Identity Squash:** None

**Scenario A: Control Host Based Access**

Provide a managed hosted environment for two clients. The clients share a mount target, but each has their own file system, and cannot access each other's data. For example:

- Client A, who is assigned to CIDR block 10.0.0.0/24, requires Read/Write access to file system A, but not file system B.
- Client B, who is assigned to CIDR block 10.1.1.0/24, requires Read/Write access to file system B, but not file system A.
- Client C, who is assigned to CIDR block 10.2.2.0/24, has no access of any kind to file system A or file system B.
- Both file systems A and B are associated to a single mount target, MT1. Each file system has an export contained in the export set of MT1.

Since Client A and Client B access the mount target from different CIDR blocks, you can set the client options for both file system exports to allow access to only a single CIDR block. Client C is denied access by not including its IP address or CIDR block in the NFS export options for any export of either file system.
**Console Example**

Set the export options for file system A to allow Read/Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image)

Set the export options for file system B to allow Read/Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image)

**CLI Example**

Set the export options for file system A to allow Read_Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_A_export_ID> --export-options '[["source":"10.0.0.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"]]
```

Set the export options for file system B to allow Read_Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_B_export_ID> --export-options '[["source":"10.1.1.0/24 ","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"]]
```

**API Example**

Set the export options for file system A to allow READ_WRITE access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{"exportOptions": [
]}
```
Set the export options for file system B to allow READ_WRITE access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```json
{
    "source": "10.1.1.0/24",
    "requirePrivilegedSourcePort": true,
    "access": "READ_WRITE",
    "identitySquash": "NONE",
    "anonymousUid": 65534,
    "anonymousGid": 65534
}
}
```

**Scenario B: Limit the Ability to Write Data**

Provide data to customers for consumption, but don't allow them to update the data.

For example, you'd like to publish a set of resources in file system A for an application to consume, but not change. The application connects from IP address 10.0.0.8.

**Console Example**

Set the source IP address 10.0.0.8 to Read Only in the export for file system A:

```bash
oci fs export update --export-id <File_System_A_export OCID> --export-options '{"source":"10.0.0.8","require-privileged-source-port":"true","access":"READ_ONLY","identitysquash":"NONE","anonymousuid":65534,"anonymousgid":65534}
```

**CLI Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:
**API Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```plaintext
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
   "exportOptions": [
   {
      "source": "10.0.0.8",
      "requirePrivilegedSourcePort": true,
      "access": "READ_ONLY",
      "identitySquash": "NONE",
      "anonymousUid": 65534,
      "anonymousGid": 65534
   }
   ]
}
```

**Scenario C: Improve File System Security**

To increase security, you'd like to limit the root user's privileges when connecting to File System A. Use Identity Squash to remap root users to UID/GID 65534. In Unix-like systems, this UID/GID combination is reserved for 'nobody', a user with no system privileges.

**Console Example**

```
```

**CLI Example**

```
oci fs export update --export-id <File_System_A_export_OCID> --export-options '[]{"source": "0.0.0.0/0","require-privileged-source-port": "true","access": "READ_WRITE","identitysquash": "ROOT","anonymousuid": "65534","anonymousgid": "65534"}]
```

**API Example**

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
   "exportOptions": [
   {
      "source": "0.0.0.0/0",
      "requirePrivilegedSourcePort": true,
      "access": "READ_WRITE",
      "identitySquash": "ROOT",
      "anonymousUid": 65534,
      "anonymousGid": 65534
   }
   ]
}
```
File Storage

Tip:

If you don't want a file system to be visible to any clients, you can set all of the properties in the `exportOptions` array to empty values. For example,

```
{
    "exportOptions": [
        {
            "source": "",
            "requirePrivilegedSourcePort": "",
            "access": "",
            "identitySquash": ""
        }
    ]
```

Using the Console

To set export options for a file system

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment. All of the file systems in the selected compartment are displayed.
3. Find the file system you want to set export options for, click the Actions icon (three dots), and then click View File System Details.
4. In the Exports list, find the export you want to set export options in, click the Actions icon (three dots), and then click View Export Details. If there is no export listed for the file system, you can create one. See To create an export for a file system on page 1972 for more information.

Tip:

To be sure you be sure that you select the correct export, check the following:

- **The export path**: This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name**: File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

5. Click Edit Export Options.
6. Make one or more of these changes:
   - Change an export option entry in the list.
   - Click +Another Option to create a new export option entry.
   - Click the Actions icon (three dots) for an entry and move it up or down in the list.
7. When you're done, click Update.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 4192.

To create an export

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set. This example creates an export along with its NFS export options.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>" --export-options '{"source":"10.0.0.0/16","requireprivilegedsourceport":"true","access":"READWRITE","identitysquash":null,"access":null,"identitysquash":null}'
```
Important:

Export Path Names

The path must start with a slash (/) followed by a sequence of zero or more
slash-separated elements. For any two export resources associated with the
same export set, the path sequence for the first export resource can’t contain
the complete path element sequence of the second export sequence. Paths
can’t end in a slash. No path element can be a period (.) or two periods in
sequence (...). Lastly, no path can exceed 255 bytes.

Examples:

Acceptable:

/example and /path
/example1 and /example2

Not Acceptable:

/example and /example/path
/ and /example
/example/
/example/path/.. /example1

To update export options

Open a command prompt and run `oci fs export update` to update export options for a specified file system, use `--export-options`.

For example:

```
oci fs export update --export-id <export_OCID> --export-options '[["source":"<0.0.0.0/0>"],"require-privileged-source-port":"true","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"]'
```

WARNING: Updates to export-options will replace any existing values. Are you sure you want to continue? [y/N]: y

Tip:

If you don’t want a file system to be visible to any clients, you can set all of
the properties in Client Options to empty values. For example,

```
oci fs export update --export-id <export_OCID> --export-options '[["source":"","require-privileged-source-port":"true","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"]]
```

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id <target_compartment_id>
```
To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id <export_OCID>
```

Caution:
When you delete an export, you can no longer mount the file system using the file path specified in the deleted export.

Using the API

- CreateExport
- UpdateExport
- ListExports
- GetExport
- DeleteExport

Using In-transit Encryption

In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. Together with other methods of security such as Oracle Cloud Infrastructure Vault (KMS) and File Storage's encryption-at-rest, in-transit encryption provides for end-to-end security.

- For general information about getting started with file systems, see Overview of File Storage on page 1920.
- For more information on the Vault service, see Overview of Vault on page 3952.
- For more information on securing your file system, see About Security on page 1925 and the Securing File Storage on page 3687 reference in the Security Guide.

How In-transit Encryption is Enabled

In-transit encryption doesn't require any updates to your file system's mount target or export configuration. To enable in-transit encryption, you install a package called `oci-fss-utils` on your instance. The `oci-fss-utils` package creates a network namespace and virtual network interface on your instance and provides a local NFS endpoint. The `oci-fss-utils` package also runs a forwarder process in the background called `oci-fss-forwarder`.

The network namespace isolates the forwarder process from your instance's networking environment. The virtual network interface provides the forwarder process a unique IP address. The local NFS endpoint provides NFS connection capability.

The file system is mounted using a special command that initiates encryption. After the file system is mounted, the `oci-fss-forwarder` process connects the local NFS client to the NFS endpoint. The process then receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

Here are the general steps for setting up In-transit encryption:

1. Download the `oci-fss-utils` package. For instructions, see Task 1: Download the OCI-FSS-UTILS package on page 1943
2. Install the `oci-fss-utils` package on the instance. For instructions, see Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 1944
3. Use the in-transit encryption command to mount the file system. For instructions, see Task 3: Mount the file system with the encryption command on page 1944

Limitations and Considerations

- The in-transit encryption installation package is distributed as an RPM for Oracle Linux and CentOS and can be downloaded at cloud-infrastructure-file-storage-downloads.html
• You must install the `oci-fss-utils` package on every instance that requires encrypted access to a mount target.
• The number of encrypted NFS/TLS connections for a single mount target is limited to 64. This limitation is caused by TLS memory requirements. Unlike NFS connections, TLS connections do not share memory buffers. So, once a TLS connection has been established, the allocated memory stays dedicated to it.
• DNS hostnames are not supported for mounting encrypted file systems with `oci-fss-forwarder`. Use the mount target IP address to mount encrypted file systems.

**Setting up In-transit Encryption**

**Prerequisites**

• Add the following new rules to the security list for the mount target subnet. Alternatively, you can add the following rules to a Network Security Group (NSG) and then add the mount target to the NSG. For more information and instructions about adding security list rules for File Storage, see Configuring VCN Security Rules for File Storage on page 1927.
  - A stateful **ingress** rule allowing TCP traffic to a **Destination Port Range** of 2051.
  - A stateful **egress** rule allowing TCP traffic from a **Source Port Range** of 2051.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard (unencrypted) access to File Storage mount targets requires access to the following ports:</td>
</tr>
<tr>
<td>• Stateful ingress to TCP ports 111, 2048, 2049, and 2050.</td>
</tr>
<tr>
<td>• Stateful ingress to UDP ports 111 and 2048.</td>
</tr>
<tr>
<td>• Stateful egress from TCP ports 111, 2048, 2049, and 2050.</td>
</tr>
<tr>
<td>• Stateful egress from UDP port 111.</td>
</tr>
</tbody>
</table>

If you have previously set up rules for standard access, and you want to enforce encrypted access only, then you can disable the standard access ports.

---

Only the rules for TCP port 2051 are required for encrypted access.

**Setup Tasks**

**Task 1: Download the OCI-FSS-UTILS package**

Internet access is required to download the RPM installation package. If the destination instance doesn't have internet access, you can download the RPM to a staging instance on your network and then use the `scp` command to securely copy the RPM from the staging instance to the destination instance.

The `scp` command requires an SSH key pair to authenticate a remote user. If your instances are UNIX-style systems, you probably already have the `ssh-keygen` utility installed. To determine if it's installed, open a shell or terminal and type `ssh-keygen` on the command line. If it's not installed, you can obtain OpenSSH for UNIX from [http://www.openssh.com/portable.html](http://www.openssh.com/portable.html).

1. (Optional) Create a directory for the RPM installation package on the destination instance. For example:

   ```bash
   sudo mkdir -p /<rpm_directory_name>
   ```

2. Download the `oci-fss-utils` package from [cloud-infrastructure-file-storage-downloads.html](http://cloud-infrastructure-file-storage-downloads.html) to the directory on the destination instance or to a staging instance on your network.

   If you've downloaded the package directly to the destination instance, skip the next step and proceed directly to **Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS** on page 1944.

   If you've downloaded the package to a staging instance, proceed to the next step in these instructions.
3. Open a terminal window on the staging instance, and use the `scp` command to securely copy the RPM from the staging instance to the destination instance. For example:

```
scp -i <private_key> <path_to_.rpm> <username>@<destination-public-ip-address>:/<rpm_directory_name>
```

After the RPM package is downloaded to the target instance, proceed to **Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS** on page 1944.

**Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS**

1. Open a terminal window on the destination instance.
2. Install the package using the following command:

```
sudo yum localinstall oci-fss-utils-<version>.rpm
```

The package creates a namespace called `ns1` in your instance, which contains a default network interface for ethernet traffic. A network interface pair is created for each mount target.

After the package has finished installing, proceed to **Task 3: Mount the file system with the encryption command** on page 1944.

**Task 3: Mount the file system with the encryption command**

1. Open a terminal window in your instance.
2. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```

3. Mount the file system using the following command:

```
sudo mount -t oci-fss 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint`
with the path to the local mount point. The export path is the path to the file system (relative to the mount target IP address).

**Important:**

DNS hostnames are not currently supported for mounting file systems with the `mount -t oci-fss` command. You must use the mount target IP address.

Example output from the `mount -t oci-fss` command:

```
```

Each time you mount a file system using this command, a new `oci-fss` service is initiated with an incrementing sequence number between 2 and 255. For example, `oci-fss-2.service`, `oci-fss-3.service`, and so on.

**Tip:**

You can use the `resvport` option to restrict the client to using a specific reserved port. For example:

```
sudo mount -t oci-fss -o resvport=900 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

### Managing In-transit Encryption

**To auto-mount a file system**

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a terminal window on the instance. Mount the file system as described in.
2. Open the `/etc/fstab` file for editing:

   ```
cd /etc

vi fstab
```
   
3. Add the following line to the `fstab` file:

   ```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-systemd.requires=oci-fss-init.service,defaults,nofail 0 0
```

Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with the path to the local mount point.

**Tip:**

You can use the `resvport` option to restrict the client to using a specific reserved port. For example:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-systemd.requires=oci-fss-init.service,defaults,nofail,resvport=900 0 0
```
To unmount a file system

When you unmount a file system, you must use another oci-fss-utils command to ensure that the associated local network namespace is removed:

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

   ```
   sudo umount -t oci-fss /mnt/yourmountpoint
   ```

   Replace `yourmountpoint` with the path to the local mount point.

To uninstall the OCI-FSS-UTILS package

1. First, unmount all mounted file systems. For instructions, see To unmount a file system on page 1946.
2. Open a terminal window on the instance.
3. Type the following command to uninstall the oci-fss package:

   ```
   sudo yum remove oci-fss-utils
   ```

Troubleshooting

If you experience issues with in-transit encryption, try the following techniques:

Verify that you have all the security list rules set up correctly for the mount target subnet.

In-transit encryption requires the following security list rules:

- A stateful **ingress** rule allowing **TCP** traffic to a **Destination Port Range** of **2051**.
- A stateful **egress** rule allowing **TCP** traffic from a **Source Port Range** of **2051**.

For more information and instructions, see Security Rules on page 2833.

Verify that the oci-fss service is running for the mounted file system.

If it is not, restart the service.

To verify the service is running

When you mount a file system using the `mount.oci-fss` command, it creates a systemd-managed service called `oci-fss<sequence_number>.service`. `<sequence_number>` is an incrementing value between 2-255. An `oci-fss` service is created for every file system mounted using the command. The exact name of the service is displayed as output when the file system is mounted.

For example:

   ```
   ```

1. Open a terminal window on the instance.
2. Verify that the service is running using the following command:

   ```
   systemctl status oci-fss-<sequence_number>
   ```

To start the service

1. Open a terminal window on the instance.
2. Use the following command to start the service:

   ```
   systemctl start oci-fss-<sequence_number>
   ```
Verify that the namespace ns1 has been created and contains a network interface.

To verify the network namespace

1. Open a terminal window on the instance.
2. Use the following command to verify the namespace and see the network interface:

   ```bash
   sudo ip netns exec ns1 ip link list
   ```

   You should see output displaying all the ethernet devices within namespace ns1. For example:

   ```
   1: lo: <LOOPBACK> mtu 65536 qdisc noop state DOWN mode DEFAULT group default qlen 1000
   default qdisc noop state DOWN mode DEFAULT group default qlen 1000
   link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
   3: v-peer1@if4: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP mode DEFAULT group default qlen 1000
   link/ether be:5b:35:2d:e9:54 brd ff:ff:ff:ff:ff:ff link-netnsid 0
   ```

Verify that IP forwarding is running on the instance.

Installing oci-fss-utils automatically turns on IP forwarding. However, you may have other processes running on the instance that disable it.

To verify that IP forwarding is running on the instance

1. Open a terminal window on the instance.
2. Use the following command to view the status of IP forwarding:

   ```bash
   # sysctl net.ipv4.ip_forward
   net.ipv4.ip_forward = 1
   ```

   An output value of 1 means that IP forwarding is enabled. This value is read from the /proc/sys/net/ipv4/ip_forward file.

   If the output value is 0, then IP forwarding is not enabled for the instance. Enable IP forwarding by following the instructions in To enable IP forwarding on the instance on page 1947.

To enable IP forwarding on the instance

If IP forwarding is not currently enabled on the instance, you must enable it and make the change permanent.

1. Open a terminal window on the instance.
2. Type the following command to open the /etc/sysctl.conf file:

   ```bash
   sudo vi /etc/sysctl.conf
   ```

   3. Remove the # to uncomment this line: # net.ipv4.ip_forward=1. If the value is 0, change it to 1.
   4. Type :wq to save the file and exit the editor.

Use the tcpdump utility to analyze traffic between the oci-fss service and the NFS client.

To obtain information using TCPDUMP

1. Open a terminal window on the instance.
2. Type the following command:

   ```bash
   sudo ip netns exec ns1 tcpdump -i v-peer2 "port 2049"
   ```

Use the journalctl command to view any messages that may have been logged by systemd regarding the service.

To obtain information from the SYSTEMD journal

1. Open a terminal window on the instance.
2. Type the following command:

```
journalctl -f -u oci-fss-<version>
```

- `f` displays the most recent journal entries, and prints new entries as they are appended to the journal.
- `-u` specifies a specific `systemd` service unit. In this case, `oci-fss-<sequence_number>` is the specified unit. If no unit is specified, `journalctl` returns all `systemd` entries.

## Creating File Systems

You can create a shared file system in the cloud using the File Storage service. Network access to your file system is provided through a mount target. Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in one mount target for any instance to mount and use the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

### Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to create file systems. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 2167 for more information.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

### Prerequisites

Before you create a file system, you need:

- At least one Virtual Cloud Network (VCN) in a compartment. For more information, see VCNs and Subnets on page 2821.
- Correctly configured security rules for the file system mount target. Security rules can be created in the security list for the mount target subnet, or in a Network Security Group (NSG) that you add the mount target to. See Security Rules on page 2833 for information about how security rules work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security Rules for File Storage on page 1927 to set up security rules correctly for your file systems.

### Using the Console

#### To create a file system

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the left-hand navigation, in the List Scope section, under Compartment, select a compartment.
3. Click Create File System.

**Note:**

File systems are encrypted by default. You cannot turn off encryption.
4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.

**File System Information:**

- **Name:** File Storage service creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system. Avoid entering confidential information.

- **Availability domain:** The first availability domain selected in the left panel list is used as default.

- **Encryption:** File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

**Note:**

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

To use Vault for your encryption needs, select **Encrypt using customer-managed keys** check box. Then, select the **Vault compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master encryption key compartment** and **Master encryption key**. For more information about encryption, see **Overview of Vault** on page 3952.

**Caution:**

*Be sure to back up your vaults and keys.* Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see **Backing Up Vaults and Keys** on page 4003.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

**Export Information**

Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.

- **Export Path:** The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

/example and /path
/example and /example2

Not Acceptable:

/example and /example/path
/ and /example
Caution:

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note:

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2006.

- **Use Secure Export Options**: Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options on page 1934 for more information.

Caution:

Leaving the "Use Secure Export Options" setting disabled allows unprivileged users to read and modify any file or directory on the target file system.

- **Mount Target Information**:

File systems must be associated with a mount target to be mounted by an instance.

If you have one or more previously created mount targets in the availability domain, the File Storage service automatically chooses the most recently created mount target in the list. If you don't have a mount target in the selected availability domain, the File Storage service creates one using the following defaults.

- **Mount Target Name**: File Storage service creates a default mount target name using "Mount-YYYYMMDD-HHMM".
- **Compartment**: The compartment you're currently working in.
- **Virtual Cloud Network**: The first VCN listed in the current compartment is used as default.
- **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list. Each mount target can belong to up to five (5) NSGs.

Important:

Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 1927.

- **Subnet**: The most recently created subnet listed in the selected availability domain is used as default. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 2821.

5. If you want to accept the defaults for the mount target, click Create. The file system is created with the information displayed. If you want to choose another mount target or change the default information, click the Edit Details link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:

- **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

  **Tip:**

  If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

  - Choose a different compartment.
  - Choose a different availability domain in the **File System Information** section.
  - Create a new mount target.

- **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

  **Important:**

  The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances that access them. For more information, see **Regions and Availability Domains** on page 1923.

- **Create in Compartment:** Specify the compartment you want to create the mount target in.

- **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

  **Note:**

  The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.

- **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.

- **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

  **Important:**

  Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see **Configuring VCN Security Rules for File Storage** on page 1927.

- **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.

- **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see **VCNs and Subnets** on page 2821.

  **Caution:**

  Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation.
because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.

- **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
- **Hostname:** You can specify a hostname you want to assign to the mount target.

**Note:**
The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example,
myhostname.subnet123.dnslabel.oraclevcn.com.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 1980 for more information.

8. Click **Create**.

The File Storage service typically creates the file system and mount target within seconds. Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 1954 for instructions about obtaining mount commands for your operating system type and mounting your file system.

### Using the command line interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192.

#### To create a file system

Open a command prompt and run `oci fs file-system create` to create a file system. For example:

```
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id>
```

Avoid entering confidential information.

The file system is created.

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key. For more information, see Overview of Vault on page 3952.

For example:

```
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.phx.<unique_id>
```

#### To create a file system that is encrypted with a Key Management Key

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.
Note:
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 3952.

Caution:
Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 4003.

Open a command prompt and run `oci fs file-system create` to create a file system that is encrypted with a key management key.

```
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
```

For example:

```
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id ocid1.key.oc1.iad.<unique_id>
```

To create a mount target
You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

Caution:
Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

To create an export
An export is a file system together with the path that can be used to mount it. Each export resource belongs to one export set.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "<pathname>"
```
Important:

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:
/example and /path
/example and /example2

Not Acceptable:
/example and /example/path
/ and /example
/example/
/example/path/../../example1

Caution:

If one file system associated to a mount target has ‘/’ specified as an export path, you can't associate another file system with that mount target.

Note:

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2006.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to create file systems:

- CreateFileSystem
- CreateMountTarget
- CreateExport

Mounting File Systems

Users of Unix-style operating systems and Windows Server 2012 R2 and later versions can connect to a file system and write files. Mount targets serve as file system network access points for file systems. After your mount target is assigned an IP address, you can use it together with the file system export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client. For Unix-style operating systems, you create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. Windows operating systems use a drive letter assignment instead of a mount point to represent root access.
Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 1948 for more information.

Mounting File Systems From an Instance

Mounting File Systems From Unix-Style Instances on page 1957 (Including Oracle Linux DB instances)
Mounting File Systems From Windows Instances on page 1964

Obtaining Mount Command Samples

Mount command samples that include mount information for a specific mount target and file system are available in the Console. Samples are available for the following operating system images:

- Oracle Linux
- CentOS
- Debian
- Red Hat Linux
- Ubuntu

Here’s an example of the information contained in a mount command sample. The file system name is used to create directory names:

If you specified a hostname for the mount target, the sample uses the FQDN in the commands. If you didn't specify a hostname, the sample uses the mount target IP address. Using a FQDN to mount your file system is optional; even if you specified a hostname, you can edit the command to use the IP address instead. If you use an FQDN to mount the
file system, ensure that the the FQDN correctly resolves to the mount target's IP address. For more information, see DNS in Your Virtual Cloud Network on page 2910.

Mount command samples mount the file system at the file system root directory. Mount command samples don't include subdirectory information for the file system. If you want to mount a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information on mounting subdirectories in Linux-type instances, see To mount a file system subdirectory (Linux). For more information on mounting subdirectories in Windows instances, see To mount a file system subdirectory (Windows).

Caution:

When mounting file systems, the following mount option combination is not supported by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). This combination can cause corruption of your data.

The following mount options or mount option combinations are not recommended for use with the File Storage service:

- `soft` when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than 300 seconds. This combination can cause a profusion of I/O error responses.
- `rsize`, or `wsize`. These options cause issues with performance.

Note:

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to obtain mount commands.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Using the Console

To get mount command samples

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment.
   
   The Console displays a list of file systems that have already been created in the compartment, if any.
3. Find the file system you want to mount, click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Exports.
5. Find the export in the mount target you want to use to mount the file system, click the Actions icon (three dots), and then click **Mount Commands**.

**Tip:**

To be sure that you select the correct export, check the following:

- **The export path:** This path uniquely identifies the file system within the mount target. **No two exports in a mount target can have the same export path, even if the exports are for the same file system.**
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

6. In **Image**, choose the image of the Compute instance you want to mount the file system to.
7. Click the **Copy** link to copy the commands.

Next, mount the file system from a **Unix-style** or **Windows** instance.

### Mounting File Systems From Unix-Style Instances

Users of Ubuntu and Linux operating systems can use the command line to connect to a file system and write files. **Mount targets** serve as network access points for file systems. After your mount target is assigned an IP address, you can use it together with the **export path** to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client and create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. You can mount to any directory within the file system.

### Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See **Creating File Systems** on page 1948 for more information.
- Correctly configured security rules for the mount target. See **Security Rules** on page 2833 for information about how security rules work in Oracle Cloud Infrastructure. Use the instructions in **Configuring VCN Security Rules for File Storage** on page 1927 to set up security rules correctly for your file systems.

### Mounting File Systems

You can use the following instructions to construct your mount commands, or use the Console to get mount command samples that include all the information for a specific mount target and file system. For more information, see **Obtaining Mount Command Samples** on page 1955.

Mount command samples mount the file system at the file system root directory. Mount command samples don’t include subdirectory information for the file system. If you want to mount your Linux-type instance at a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information, see **To mount a file system subdirectory** on page 1963.

**Caution:**

When mounting file systems, the following mount option combination is **not supported** by the File Storage service:

- **soft** when the file system is mounted with the read/write mount option (\(-o\) **rw**). **This combination can cause corruption of your data.**

The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- **soft** when the file system is mounted with the read-only mount option (\(-o\) **ro**), and the **timeo** has been specified as less than 300 seconds. **This combination can cause a profusion of I/O error responses.**
- **rsize**, or **wsize**. **These options cause issues with performance.**
Note:

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

To mount a file system from Ubuntu or Debian

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or type the following:

   ```
sudo apt-get install nfs-common
   ```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

   ```
sudo mkdir -p /mnt/yourmountpoint
   ```

3. Mount the file system by copying and pasting the Mount Command from the Console or type the following:

   ```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```

   - Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
   - Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
   - Replace `yourmountpoint` with the path to the local mount point.

   **Tip:**

   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 1984 for more information.

   **Caution:**

   Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to ‘root’. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

   **Note:**

   The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options on page 1934 for more information.

4. View the file system.

   ```
df -h
   ```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

   ```
sudo touch /mnt/yourmountpoint/helloworld
   ```
6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```bash
cd /mnt/yourmountpoint
ls
```

See [Mount Command Fails](page 2012) in [Troubleshooting Your File System](page 2010) on page 2010 for more information about common issues you may encounter.

**To mount a file system from Linux, Red Hat, or CentOS**

1. Open a command window. Then, get the NFS client by copying and pasting the **Install Command** from the Console or typing the following:

```bash
sudo yum install nfs-utils
```

2. Create a mount point by copying and pasting the **Create Mount Point Command** from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```bash
sudo mkdir -p /mnt/yourmountpoint
```

3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```bash
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See [To view details of a mount target](page 1984) on page 1984 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [Working with NFS Export Options](page 1934) on page 1934 for more information.

4. View the file system.

```bash
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```bash
sudo touch /mnt/yourmountpoint/helloworld
```
6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
ls
```

See Mount Command Fails on page 2012 in Troubleshooting Your File System on page 2010 for more information about common issues you may encounter. See if you want to mount a subdirectory of the file system.

To mount a file system from a Database VM instance

Database VM instances are built on Oracle Linux 6.8, unlike Oracle Linux Compute instances, which run on version 7.4. The NFS Utilities package is pre-installed on DB instances, but the Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility is disabled by default. Oracle Linux 6.8 does not have systemd, so DB instances are managed differently than OL compute instances. An Oracle DB instance comes with a set of iptables rules that excludes any non-database ports and need to be updated to allow mount target traffic.

1. SSH to the DB system.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Start the rpcbind service by typing the following:

```
sudo service rpcbind start
```

3. Use the chkconfig command to enable starting rpcbind service at system startup.

```
sudo chkconfig rpcbind on
```

4. Change the default configuration of iptables to include the mount target IP address and allow traffic by typing the following. Replace `10.x.x.x` with the local subnet address assigned to the mount target for the file system. Save the new iptables entries.

```
sudo iptables -A INPUT -p tcp -s 10.x.x.x -j ACCEPT
sudo iptables -A OUTPUT -p tcp -s 10.x.x.x -j ACCEPT
sudo service iptables save
```

5. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```
6. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```bash
sudo mount -t nfs -o nosuid,resvport,tcp,vers=3 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See [*To view details of a mount target*](#) on page 1984 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The **nosuid** option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [*Working with NFS Export Options*](#) on page 1934 for more information.

See [*Mount Command Fails*](#) on page 2012 in [*Troubleshooting Your File System*](#) on page 2010 for more information about common issues you may encounter.

### To auto-mount a file system

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a command window. Then, mount the file system using the steps described in the previous section.
2. Type the following command to get the file system entry point:

```bash
sudo cat /etc/mtab |grep -i nfs
```

3. Copy the file system entry point, and open the `/etc/fstab` file:

```bash
cd /etc
vi fstab
```

4. Add the following line to the `fstab` file:

```bash
<file_system_ip_address>:<file_system_path_name><your_local_mount_point>
nfs defaults,nofail,nosuid,resvport 0 0
```

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The **nosuid** option disables set-user-identifier
or set-group-identifier bits within the mounted system, which are rarely used.

**Important:**

Be sure to add the `nofail` option to each entry. This option ensures that an unavailable file system does not cause the instance reboot process to fail.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See *Working with NFS Export Options* on page 1934 for more information.

5. Save the `/etc/fstab` file.

See *Mount Command Fails* on page 2012 in *Troubleshooting Your File System* on page 2010 for more information about common issues you may encounter.

**Mounting File System Subdirectories**

If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of `/FileSystem1` and a directory structure like this:

```
(MountTarget1)
10.0.0.16: /FileSystem1
```

```
/rootdirectory
```

```
/directoryA
```

```
/FileA
```

```
/directoryB
```

```
/FileB
```

The file system is exported from "MountTarget1" which has an IP address of `10.0.0.16`.

The following command mounts `directoryA` to the instance mount point `/mnt/mymountpoint`:

```
sudo mount -o nosuid,resvport 10.0.0.16:/FileSystem1/rootdirectory/directoryA /mnt/mymountpoint
```
Neither directoryB or FileB would be accessible from the instance mount point.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 1925.</td>
</tr>
</tbody>
</table>

To mount a file system subdirectory

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or typing the following:

   ```bash
   sudo yum install nfs-utils
   ```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing yourmountpoint with the local directory from which you want to access your file system.

   ```bash
   sudo mkdir -p /mnt/yourmountpoint
   ```

3. Mount the file system by copying and editing the Mount Command from the Console or type the following:

   ```bash
   sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path/directory-path /mnt/yourmountpoint
   ```

   - Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
   - Replace fs-export-path with the export path you specified when associating the file system with the mount target.
   - Replace directory-path with the path from the root directory to subdirectory you want to mount.
   - Replace yourmountpoint with the path to the local mount point.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 1984 for more information.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Omitting the -o nosuid option may allow unprivileged users to escalate their permissions to 'root'. The nosuid option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.</td>
</tr>
</tbody>
</table>

<table>

</tr>
</tbody>
</table>

4. View the file system.

   ```bash
   df -h
   ```

5. Write a file to the file system by typing the following. Replace yourmountpoint with the path to the local mount point and helloworld with your file name.

   ```bash
   sudo touch /mnt/yourmountpoint/helloworld
   ```
6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
ls
```

To unmount a file system

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

```
sudo umount /mnt/yourmountpoint
```

Replace `yourmountpoint` with the path to the local mount point.

Writing to File Systems

When a file system is created, its root directory is owned by the root user. If you're connecting from an Oracle-provided Linux or CentOS instance, the default user is opc. If you're connecting from an Oracle-provided Ubuntu instance, the default user is ubuntu. These default users are not root users, so you can't initially write a file or directory to a new file system with these users. Depending on your security requirements, there are several ways to proceed:

- Connect as the root user. Then, create files or directories in the new file system.
- Connect as the root user. Then, change the ownership or permissions of the file system root directory to allow other users (such as opc or ubuntu) to write to the file system.
- Connect as the root user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

Learn more about updating file and directory ownership and permissions.

- Connect as the default user. Then, use the `sudo` command to write or to change permissions or ownership of files or directories. The `sudo` command temporarily provides a regular user with root user permissions. Here's an example of using the `sudo` command to write to the file system:

```
sudo touch /mnt/yourmountpoint/helloworld
```

Learn more about the `sudo` command.

For more information on accessing Oracle-provided instances, see Connecting to an Instance on page 733.

Mounting File Systems From Windows Instances

Users of Windows Server 2012 R2 and later versions can mount a file system on any available drive letter using the mount target IP address and the file system export path.

The Windows NFS client must be installed on the instance from which you want to mount the file system.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installing the Windows NFS client may require a restart of your system.</td>
</tr>
</tbody>
</table>

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using AnonymousGid and AnonymousUid. On brand new file systems, write permissions are only granted to the root user. The AnonymousGid and AnonymousUid identity values must be configured to allow write access.
After you have installed the NFS client and correctly mapped user identities, you can mount the file system to any available drive letter using the command line or Map network drive. You can access your file system through the chosen drive letter to write files.

**Prerequisites**

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See [Creating File Systems](page 1948) for more information.
- Correctly configured security rules for the mount target. See [Security Rules](page 2833) for information about how security rules work in Oracle Cloud Infrastructure. Use the instructions in [Configuring VCN Security Rules for File Storage](page 1927) to set up security rules correctly for your file systems.

**Caution:**

- Updating the 'AnonymousGid' and 'AnonymousUid' values require registry changes to your system.

**Caution:**

- When mounting file systems, the following mount option combination is **not supported** by the File Storage service:
  - `soft` when the file system is mounted with the read/write mount option `-o rw`. **This combination can cause corruption of your data.**

**Caution:**

- The following mount options or mount option combinations are **not recommended** for use with the File Storage service:
  - `soft` when the file system is mounted with the read-only mount option `-o ro` and the `timeo` has been specified as less than 300 seconds.
    - **This combination can cause a profusion of I/O error responses.**
  - `rsize`, or `wsize`. These options cause issues with performance.

**Note:**

- When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.
- Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

### Using Windows Command Prompt

**To mount a file system from Windows Server Command Prompt**

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 4.

1. **Open Windows PowerShell and run as Administrator:**
   
   a. Go to **Start** and click the **Windows PowerShell** icon.
   
   b. In Windows PowerShell, type the following to run as Administrator:

   ```bash
   Start-Process powershell -Verb runAs
   ```

   c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. **In Administrator: PowerShell, get the NFS client by typing the following:**

   ```bash
   Install-WindowsFeature -Name NFS-Client
   ```
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousUid -Value 0
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousGid -Value 0
Stop-Service -Name NfsClnt
Restart-Service -Name NfsRdr
Start-Service -Name NfsClnt

**Important:**

If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the `UseReservedPorts` registry key to 1.

For example:

Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name UseReservedPorts -Value 1

For more information, see [Working with NFS Export Options](#) on page 1934.

3. **Close** the Administrator: PowerShell window.

   Open a **standard Command Prompt Window**:

   a. Click **Start**, then click **Command Prompt**.

   **Important:**

   NFS file systems mounted as Administrator are not available to standard users.

4. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X:` with the drive letter of any available drive you want to map the file system to.

   ```bash
   mount 10.x.x.x:/fs-export-path X:
   ```

   **Tip:**

   IP address and export path information is available in the **Details** page of the mount target associated with your file system. See [To view details of a mount target](#) on page 1984 for more information.

   **Important:**

   The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "/" represents the full extent of the mount target. In that case, you must use a "!" when mounting the file system. For example: `mount 10.0.0.0://! X:

5. Write a file to the file system by typing the following. Replace `X:` with the drive letter you used in step 10 and `helloworld` with your file name.

   ```bash
   X:
   echo > helloworld.txt
   ```
6. Verify that you can view the file by typing the following.

```
  dir
```

See Troubleshooting Windows NFS Connections on page 2026 for more information about common issues you might encounter.

**Using Windows File Explorer**

To mount a file system from Windows Server File Explorer

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 9.

1. Open **Windows PowerShell** and run as **Administrator**:
   
   a. Go to **Start** and click the **Windows PowerShell** icon.
   
   b. In Windows PowerShell, type the following to run as Administrator:

   ```
   Start-Process powershell -Verb runAs
   ```
   
   c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. In Administrator: PowerShell, get the NFS client by typing the following:

   ```
   Install-WindowsFeature -Name NFS-Client
   ```

3. If necessary, restart your system.

4. Open the registry editor (regedit) to map the AnonymousGid and AnonymousUid to the root user.

   **Caution:**
   
   User identity mapping requires changes to your system registry.

   a. Click **Windows Search**.
   
   b. Enter `regedit` in the **Search** field and press **Enter**.
   
   c. Click **Yes** to allow changes to your device.
   
   d. Click **HKEY_LOCAL_MACHINE**. Then, browse to: `Software\Microsoft\ClientForNFS\CurrentVersion\Default`.

5. Add a new DWORD32 registry entry for **AnonymousGid**:

   a. Click **Edit**, and select **New DWORD (32 bit) Value**.
   
   b. In the **Name** field, enter **AnonymousGid**. Leave the value at 0.
6. Repeat step 5 to add a second DWORD32 registry entry named `AnonymousUid` with a value of 0.

   ![Registry Editor](image)

   **Important:**

   If you’ve set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the `UseReservedPorts` registry key to 1.

   For more information, see Working with NFS Export Options on page 1934.

7. Open Windows Command Line (CMD) and run as Administrator:

   a. Go to Start and scroll down to Apps.
   b. In the Windows System section, press Ctrl+Shift and click Command Prompt.

8. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

   ```
   nfsadmin client stop
   nfsadmin client start
   ```

9. Open File Explorer and select This PC. In the Computer tab, select Map network drive.

10. Select the Drive letter that you want to assign to the file system.

11. In the Folder field, enter the following. Replace `10.x.x.x` with the local subnet IP address assigned to your mount target, and `fs-export-path` with the export path you specified when associating the file system with the mount target.

   ```
   \10.x.x.x\fs-export-path
   ```

   **Tip:**

   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 1984 for more information.

   **Important:**

   The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "\" represents the full extent of the file system.
mount target. In that case, you must use a "!" when entering the file system folder path. For example: `\10.0.0.0\!`

12. Click the Finish button when complete.

See Troubleshooting Windows NFS Connections on page 2026 for more information about common issues you might encounter.

**Mounting File System Subdirectories**

If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of `/FileSystem1` and a directory structure like this:

![Diagram of file system structure]

The file system is exported from "MountTarget1" which has an IP address of 10.0.0.16.

The following command mounts `directoryA` to drive letter X:

```
mount 10.0.0.16:/rootdirectory/directoryA X:
```

Neither `directoryB` or `FileB` would be accessible from drive X.

**Caution:**

Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 1925.

To mount a file system subdirectory

1. Choose the method you want to use to mount the file system Using Windows Command Prompt on page 1965 or Using Windows File Explorer on page 1967.
2. Follow the instructions to install the NFS client and add the registry entries for AnonymousGid and AnonymousUid.

3. After the NFS client is installed and registry entries are added, both mounting methods describe how to enter the mount information for the file system. Depending on which method you use, edit the mounting information to append the subdirectory path to the export path:

   a. If you're Using Windows Command Prompt on page 1965, type the following command (step 4):
      - Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
      - Replace fs-export-path with the export path you specified when associating the file system with the mount target.
      - Replace directory-path with the path from the root directory to subdirectory you want to mount.

      
      ```
      mount 10.x.x.x:/fs-export-path/directory-path X:
      ```

   b. If you're Using Windows File Explorer on page 1967, enter the following in the Folder field of the drive letter you want to map the file system to (step 11):
      - Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
      - Replace fs-export-path with the export path you specified when associating the file system with the mount target.
      - Replace directory-path with the path from the root directory to subdirectory you want to mount.

      ```
      \10.x.x.x\fs-export-path\directory-path
      ```

Managing File Systems

In the File Storage service, file systems are associated with a single compartment. When you select a compartment, the Console displays all file systems in the compartment. You can also see exports and snapshots associated with each file system. If there are no file systems in the compartment, see Creating File Systems on page 1948 for instructions about creating one.

The compartment has policies that indicate what actions a user can take to manage file system. UNIX permissions control what actions a user can take on the files stored in the file system. See About Security on page 1925 for more information.

Actions you can take to manage a file system include:

- Viewing file system details
- Editing file system settings
- Viewing associated file system resources
- Creating an export for the file system
- Deleting a file system

You can perform most administrative tasks for your file systems using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

To access a file system, it must have at least one export in one mount target. Next, mount the file system from an instance, and then you can create directories and read and write files. For more information about creating an export for a file system, see To create an export for a file system on page 1972 in this topic. For more information about accessing your file system, see Mounting File Systems.

Limitations and Considerations

- Each tenancy in a region can have 1 CreateFileSystem or ChangeFilesystemCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.
Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to manage file systems.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Moving File Systems to a Different Compartment

You can move file systems from one compartment to another. When you move a file system to a new compartment, its associated snapshots move with it. After you move the file system to the new compartment, inherent policies apply immediately and affect access to the file system and snapshots through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments on page 2431.

Details About Your File System

The file system details page provides the following information about your file system:

FILE SYSTEM OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your file system's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 197.

Availability Domain

When you create a file system, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your file system's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains on page 180.

CREATED

The date and time that the file system was created.

COMPARTMENT

When you create a file system, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are only accessible to those groups that have been given permission by an administrator in your organization. You need your file system's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments on page 2431.

UTILIZATION

Metered size of the file system that gets updated hourly. For more information, see File System Usage and Metering on page 2007.
RESOURCES

Resources such as exports and snapshots that are associated with the file system are listed here. Click the resource type link to see a list of each individual resource. Each export in the list shows the file system's export path and mount target. You need the export path to mount a file system.

Using the Console
To view file system details

The File Storage service displays a list of file systems in each compartment.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click View File System Details.

To change the file system name

You can change the display name of the file system.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click View File System Details.
4. Click Rename.
5. Enter the new file system name. Avoid entering confidential information. Then click Rename.

To create an export for a file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the left-hand navigation, in the List Scope section, under Compartment, select a compartment.
3. Click the name of the file system you want to create an export for, and click Create Export.

Note:

File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking Edit Details.
5. If you want to accept the defaults for the mount target, click Create. The file system is created with the information displayed. If you want to choose another mount target or change the default information, click the Edit Details link.
6. In the Mount Target Information section, specify details for the mount target that is associated with the file system:

   • Select an Existing Mount Target: Choose this option if you want to associate the file system with a mount target you already created. Choose the Mount Target from the list. Click the click here link in the dialog box if you want to enable compartment selection for the mount target.

Tip:

If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

   • Choose a different compartment.
• Create a new mount target.

• **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the [click here](#) link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

  **Important:**

  The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances that access them. For more information, see [Regions and Availability Domains](#) on page 1923.

• **Create in Compartment:** Specify the compartment you want to create the mount target in.

• **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

  **Note:**

  The mount target name is different than the DNS hostname, which is specified in step 7.

• **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.

• **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.

• **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

  **Important:**

  Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see [Configuring VCN Security Rules for File Storage](#) on page 1927.

• **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.

• **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see [VCNs and Subnets](#) on page 2821.

  **Caution:**

  Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

• **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.

   - **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
   - **Hostname:** You can specify a hostname you want to assign to the mount target.

   **Note:**
   The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

   For example, myhostname.subnet123.dnslabel.oraclevcn.com.

   Once created, the hostname may be changed in the mount target's Details page. See **Managing Mount Targets** on page 1980 for more information.

8. Click **Create**.

Next, mount the file system from an instance so that you can read and write directories and files in your file system. See **Mounting File Systems** on page 1954 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

   **Important:**
   Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. In **Exports**, click on the mount target name.
5. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in GiI)** icon.
6. Enter the maximum free space in gibibytes or the maximum inodes in gibinodes you want the File Storage service to report.
7. Click the **Save** icon.

   **Important:**
   There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the df command. For more information, see **File System Usage and Metering** on page 2007.

**To manage tags for a file system**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.
For more information, see Resource Tags on page 211.

**To move a file system to a different compartment**

1. Open the Console,
2. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
3. In the List Scope section, select a compartment.
4. Find the file system in the list, click the the Actions icon (three dots), and then click Change Compartment.
5. Choose the destination compartment from the list.
6. Click Change Compartment.

The file system is moved immediately. Moving a file system doesn't affect mounted instances.

**To move a file system to a different subnet**

There might be situations where you need to move a file system to a different subnet. For example, since you can't change subnet size, you might need to move the file system to a larger or smaller subnet as your needs change.

1. Create the new subnet. See VCNs and Subnets on page 2821 for instructions.
2. Create a new mount target in the new subnet. See To create a mount target on page 1983 for instructions.
3. Create new export with the same export path in the new mount target to the file system. See To create an export for a file system on page 1972 for instructions.
   - Choose Select Existing Mount Target
   - Be sure that the export path for the new export is exactly the same as the export path for the original export.
     The original and new mount target can exist at the same time without issue.
4. Switch over the instance mount point to the new mount target. This can be done at any time convenient to your maintenance schedule:
   a. Stop any workload application processes running on the instance mount point.
   b. Unmount the file system. See To unmount a file system on page 1964 for instructions.
   c. Mount the file system using the new mount target, but the same mount point that was previously used.
      For example: If the file system was mounted with the original mount target like this:
      ```
sudo mount 10.0.0.10:/my-export-path /mnt/MyMountPoint
      ```
      Then the new mount command would look like this:
      ```
sudo mount 10.1.1.10:/my-export-path /mnt/MyMountPoint
      ```
   d. Update any system configuration files that use the old export path. For example, /etc/fstab.
   e. Start workload applications and verify that they can access the file system as expected.
   f. After testing and verification is complete, you can delete the original mount target and subnet.

**To assign a key to a file system**

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used for.</td>
</tr>
</tbody>
</table>

---

Oracle Cloud Infrastructure User Guide
File Storage

Prerequisites:

- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 3952.
- Correctly set permissions that allow the File Storage service to use keys. For example:

  ```bash
  Allow service FssOciProd to use keys in compartment <compartment_name>
  ```

For more information, see Common Policies on page 2142.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. Under List Scope, in the Compartment list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. In Encryption Type, select Encrypt using customer-managed keys.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click Save Changes.

To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption. For more information, see Overview of Vault on page 3952.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. Under List Scope, in the Compartment list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. In Encryption Type, select Encrypt using Oracle-managed keys.
6. When you are finished, click Save Changes.

To delete a file system

You can permanently delete a file system.

Caution:

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment.
3. Find the file system you want to delete.
4. Click the Actions icon (three dots), and then click View File System Details.
5. Delete all of the file system's exports:
   - In Exports, select the check box for all exports listed, and then click Delete.
6. When all of the exports are deleted, click Delete to delete the file system.

The file system is deleted immediately, along with all of its snapshots.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 4192.
To list file systems

Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment.

For example:

```
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id>
```

To get a specific file system

Open a command prompt and run `oci fs file-system get` to retrieve information about a specific file system.

For example:

```
oci fs file-system get --file-system-id <file_system_OCID>
```

To update a file system

Open a command prompt and run `oci fs file-system update` to update a specific file system's information.

For example:

```
oci fs file-system update --file-system-id <file_system_OCID> --display-name "<New File System Name>"
```

Avoid entering confidential information.

To create an export for a file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
```

```
/example and /example2
```
For more information, see Paths in File Systems on page 2006.

**To set the file system reported free space**

Some existing application installers perform a capacity check before running an installation process. Sometimes an installation fails because of too much available capacity. The File Storage service currently reports 8 exabytes of available capacity by default for each file system.

Customers can define how much free capacity is reported as available to the operating system.

Open a command prompt and type in the following command:

```bash
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

**Important:**

The maximum free space setting affects each export in the export set. Setting the maximum free space does not limit the amount of data you can store.

**To move a file system to a different compartment**

```bash
oci fs file-system change-file-system-compartment --file-system-id <file_system_OCID> --compartment-id <destination_compartment_OCID>
```

**To update the key for a file system**

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

**Note:**

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

**Caution:**

Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 4003.
Prerequisites:

- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 3952.
- Correctly set permissions that allow the File Storage service to use keys. For example:

  ```
  Allow service FssOclProd to use keys in compartment <compartment_name>
  ```

  For more information, see Common Policies on page 2142.

Open a command prompt and run `oci fs file-system update` to update the file system with a new key.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id <target_key_id>
```

For example:

```
oci fs file-system update --file-system-id ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id ocid1.key.oc1.phx.<unique_id>
```

To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption.

Open a command prompt and run `oci fs file-system update`. Leave the `--kms-key-id` value unspecified.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id ""
```

For example:

```
oci fs file-system update --file-system-id ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id ""
```

To delete a file system

You can delete a file system if no non-deleted export resources reference it. Deleting a file system also deletes all its snapshots.

Open a command prompt and run `oci fs file-system delete` to delete a file system.

For example:

```
oci fs file-system delete --file-system-id <file_system_OCID>
```

Caution:

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage file systems:
Managing Mount Targets

This topic describes the basics of managing mount targets.

Overview

Actions you can take to manage a mount target include:

- Viewing mount target details
- Obtaining mount command samples
- Creating a new export and file system
- Editing exports and export options
- Change the reported size of exported file systems
- Deleting a mount target

You can perform most administrative tasks for your mount targets using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

Mount Target

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems. The mount target provides the IP address or DNS name that is used together with a unique export path to mount the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter:

- You can create as many exports in a mount target for different file systems as you wish.
- You can create as many exports in a mount target for a single file system as you wish.
- You can delete and re-create exports in a mount target as often as you need to.
- You can add export options to an export to control access to the file system.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

For more information, see Working with NFS Export Options on page 1934.
Limitations and Considerations

- Each availability domain is limited to two mount targets by default.
  See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.
- Each mount target can accept up to 100,000 NFS client connections. If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 1942 for more information.
- Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.
- Each mount target requires three internal IP addresses in the subnet to function:
  - Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
  - The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
  - The File Storage service doesn't "reserve" the third IP address required for high availability failover.
  - Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
  - Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to manage mount targets. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 2167 for more information.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Moving Mount Targets to a Different Compartment

You can move mount targets from one compartment to another. When you move a mount target to a new compartment, its associated export set and exports move with it. After you move the mount target to the new compartment, inherent policies apply immediately and affect access to the mount target, export set, and exports through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments on page 2431.

Details About Your Mount Target

The mount target details page provides the following information about your mount target:
MOUNT TARGET OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your mount target's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support.

CREATED

The date and time that the mount target was created.

Availability Domain

When you create a mount target, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your mount target's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains on page 180.

COMPARTMENT

When you create a mount target, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are accessible only to those groups that have been given permission by an administrator in your organization. You need your mount target's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments on page 2431.

REPORTED SIZE (GIB)

The maximum capacity in gibibytes reported by the file systems exported through this mount target. The File Storage service currently reports 8589934592 gibibytes (GiB) of available capacity by default. If you are installing an application that requires a specific reported size, you can change the reported size. Typically, setting the size to 1024 GiB is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 1985 for more information.

REPORTED INODES (GII)

The maximum capacity in gibiinodes reported by the file systems exported through this mount target. The File Storage service currently reports gibiinodes (GiI) of available inodes by default. If you are installing an application that requires specific reported inodes, you can change the reported inodes. Typically, setting the inodes to 1024 GiI is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 1985 for more information.

NETWORK SECURITY GROUPS

The network security groups that the mount target belongs to. Each mount target can belong to up to five (5) NSGs. See To add a mount target to a network security group on page 1986 for more information.

VIRTUAL CLOUD NETWORK

The VCN that contains the subnet where the mount target VNIC resides.

SUBNET

The subnet within the VCN where the mount target VNIC resides. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 2821.

IP ADDRESS

The IP address that was assigned to the mount target when it was created. You need your mount target's IP address to mount associated file systems.

HOSTNAME

The hostname that was assigned to the mount target, if any. For more information about hostnames, see DNS in Your Virtual Cloud Network on page 2910.
**FULLY QUALIFIED DOMAIN NAME**

The hostname together with the subnet domain name. For more information, see DNS in Your Virtual Cloud Network on page 2910. If you specify a hostname, you can use the FQDN to mount the file system.

**EXPORT SET OCID**

The OCID of the mount target's export set resource. Each mount target has one export set, which contains all of the exports for the mount target. You need your mount target's export set OCID when you perform export-related tasks in the Command Line Interface (CLI) or the API.

**EXPORTS**

All of the mount target's exports are listed here. The export path and name of each file system is also listed. You need the export path to mount a file system.

**Using the Console**

**To create a mount target**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>While it is possible to access mount targets from any AD in a region, for optimal performance, your mount targets should be in the same availability domain as the Compute instances that access them. For more information, see Regions and Availability Domains on page 1923.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
2. In the List Scope section, select a compartment.
   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Click Create Mount Target.
4. Enter the required mount target information. Click the click here link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources:
   - **New Mount Target Name**: Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.
     
     | Note: |
     |---|
     | The mount target name is different than the DNS hostname, which is specified in step 5. |
   - **Virtual Cloud Network Compartment**: The compartment containing the cloud network (VCN) in which to create the mount target.
   - **Virtual Cloud Network**: Select the cloud network (VCN) where you want to create the new mount target.
   - **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more</td>
</tr>
</tbody>
</table>
information, see Configuring VCN Security Rules for File Storage on page 1927.

- **Subnet Compartment**: Specify the compartment containing a subnet within the VCN to attach the mount target to.

- **Subnet**: Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 2821.

  **Caution:**
  
  Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

5. Optionally, click Show Advanced Options to configure the mount target's advanced options.

   - **IP Address**: You can specify an unused IP address in the subnet you selected for the mount target.
   
   - **Hostname**: You can specify a hostname you want to assign to the mount target.

       **Note:**
       
       The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

       For example, `myhostname.subnet123.dnslabel.oraclevcn.com`.

       Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 1980 for more information.

6. Click Create.

   **To view details of a mount target**

   1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
   2. In the List Scope section, select a compartment.

       The Console displays a list of mount targets that have already been created in the compartment, if any.

   3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount Target Details.

   **To change the mount target name**

   You can change the display name of the mount target.

       **Note:**
       
       Changing the display name doesn't affect mounting file systems exported through the mount target.

   1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
   2. In the List Scope section, select a compartment.
   3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click View Mount Target Details.
   4. Click Rename.
   5. Enter the new mount target name. Avoid entering confidential information. Then click Rename.
**To create an export and a new file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in at least one mount target in order for instances to mount the file system. The following steps create an export and a new file system. If you want to create an export for an existing file system, see **To create an export for a file system** on page 1972.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the mount target you want to create an export for, and click **Create Export**.

   **Note:**
   File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. Click **Create**.

Next, mount the file system from an instance so that you can read and write directories and files in your file system. See **Mounting File Systems** on page 1954 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

   **Important:**
   Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount target Details**.
4. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in GiI)** icon.
5. Enter the maximum size in gibibytes or the maximum inodes in gibiinodes you want the File Storage service to report.
6. Click the **Save** icon.

   **Important:**
   There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command. For more information, see **File System Usage and Metering** on page 2007.

**To delete an export**

**Note:**
Deleting an export does not impact the data stored in the associated file system. Deleting an export disconnects any instance that mounts the file system with the deleted export path. Mount targets that have no exports still count toward your service limit.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount target Details.
4. In Exports, find the export you want to delete.
5. Click the Actions icon (three dots), and then click Delete.

To manage tags for a mount target
1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount Target Details.
4. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 211.

To move a mount target to a different compartment
1. Open the navigation menu, Under Core Infrastructure, click File Storage and then click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target in the list, click the the Actions icon (three dots), and then click Change Compartment.
4. Choose the destination compartment from the list.
5. Click Change Compartment.

To add a mount target to a network security group
You can add the mount target to one or more Network Security Groups (NSGs). File storage requires specific rules to be configured for NSGs that are associated with mount targets. For more information, see Configuring VCN Security Rules for File Storage on page 1927.
1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount Target Details.
4. In the Mount Target Information tab, click the Edit link next to Network Security Groups.
5. Select a Compartment and NSG from the list.
6. Click Save.

To delete a mount target
1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you want to delete.
4. Click the Actions icon (three dots), and then click Delete.

Caution:
Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

Deleting a mount target has no effect on file system data or file system snapshots.

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI) on page 4192.
To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

**Caution:**

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

You can create a mount target that is added to a network security group (NSG).

For example:

```
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>" --nsg-ids ['"<nsg_OCID_1>", "<nsg_OCID_2>']
```

To update a mount target

Open a command prompt and run `oci fs mount-target update` to update a specific mount target's information or to add it to a network security group (NSG).

For example:

```
oci fs mount-target update --mount-target-id <mount_target_OCID> --display-name "<New Mount Target Name>" --nsg-ids ['"<nsg1_OCID>", "<nsg2_OCID>']
```

Avoid entering confidential information.

To delete a mount target

Open a command prompt and run `oci fs mount-target delete` to delete a mount target. Deleting a mount target also deletes the mount target's VNICs.

For example:

```
oci fs mount-target delete --mount-target-id <mount_target_OCID>
```

**Caution:**

Deleting a mount target can cause any clients that have mounted an associated file system to hang. Be sure to have all clients unmount the file systems before deleting the mount target.

To list mount targets

You cannot use the Console to list mount targets. Use the command line interface or the API from a host machine running a UNIX-style operating system.
Open a command prompt and run `oci fs mount-target list` to list all mount targets in a specified availability domain and compartment.

For example:

```
oci fs mount-target list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

**To get a specific mount target**

Open a command prompt and run `oci fs mount-target get` to retrieve information about a specific mount target.

For example:

```
oci fs mount-target get --mount-target-id <mount_target_OCID>
```

**To create an export**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/../example1
```
Caution:
If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2006.

To list exports
Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.
For example:

```
oci fs export list --compartment-id <target_compartment_id>
```

To get a specific export
Open a command prompt and run `oci fs export get` to retrieve information about a specific export.
For example:

```
oci fs export get --export-id <export_OCID>
```

To delete an export
Open a command prompt and run `oci fs export delete` to delete an export.
For example:

```
oci fs export delete --export-id <export_OCID>
```

Caution:
When you delete an export, any file system referenced by the export is no longer accessible through the associated mount target.

To list export sets
Open a command prompt and run `oci fs export-set list` to list all export sets in a specified availability domain and compartment.
For example:

```
oci fs export-set list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

To get a specific export set
Open a command prompt and run `oci fs export-set get` to retrieve information about a specific export set.
For example:

```
oci fs export-set get --export-set-id <export_set_OCID>
```

To update an export set
Open a command prompt and run `oci fs export-set update` to update a specific export set's information.
For example:

```bash
oci fs export-set update --export-set-id <export_set_OCID> --display-name "<New Export Set Name>"
```

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiliodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

**Important:**

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

**Important:**

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command. For more information, see [File System Usage and Metering](#) on page 2007.

Open a command prompt and type in the following command:

```bash
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

**To move a mount target to a different compartment**

```bash
oci fs mount-target change-mount-target-compartment --mount-target-id <mount_target_OCID> --compartment-id <destination_compartment_OCID>
```

**Using the API**

- CreateMountTarget
- UpdateMountTarget
- DeleteMountTarget
- GetMountTarget
- ListMountTargets
- ChangeMountTargetCompartment
- CreateExport
- DeleteExport
- GetExport
- ListExports
- UpdateExportSet
- GetExportSet
- ListExportSets

**Managing Snapshots**

The File Storage service supports snapshots for data protection of your file system. Snapshots are a consistent, point-in-time view of your file systems. Snapshots are copy-on-write, and scoped to the entire file system. The File Storage service encrypts all file system and snapshot data at rest. You can take as many snapshots as you need.
Data usage is metered against differentiated snapshot data. If nothing has changed within the file system since the last snapshot was taken, the new snapshot does not consume more storage. For more information, see File System Usage and Metering on page 2007.

Snapshots are accessible under the root directory of the file system at .snapshot/name. When you use an NFSv3 client to perform operations such as ls, du, or find on the snapshot directory, the service automatically exports the directory. The client uses nfs_d_automount() to detect and mount the directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

For data protection, you can use a tool that supports NFSv3 to copy your data to a different availability domain, region, file system, object storage, or remote location.

For best performance, we recommend that you use the parallel tar (partar) and parallel copy (parcp) tools provided in the File Storage Parallel File Toolkit for this purpose. These tools work best with parallel workloads and requests. The Parallel File Toolkit is available for Oracle Linux, Red Hat Enterprise Linux, and CentOS. You can use rsync or regular tar for other operating system types. See Installing the Parallel File Tools on page 1994 for more information.

Tip: Watch a video about protecting data with snapshots in File Storage.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2148 allows users to create and delete snapshots.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Details About Your Snapshot

The Details page provides the following information about your snapshot:

SNAPSHOT OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your snapshot's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 197.

CREATED

The date and time that the snapshot was created.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Using the Console

To create a snapshot

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you want to take a snapshot of. Click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Snapshots.
5. Click **Create Snapshot**.
6. Fill out the required information:
   - **Name**: Enter a name for the snapshot. It must be unique among all other snapshots for this file system. The name can't be changed. Avoid entering confidential information.
7. Click **Create Snapshot**. The snapshot is accessible under the root directory of the file system at `.snapshot/name`.

**To view details of a snapshot**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. In the **File Systems** list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click **View File System Details**.
4. In **Resources**, click **Snapshots**.
5. In the **Snapshots** list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click **View Snapshot Details**.

**To create a snapshot from a Unix-style instance**

You can create a snapshot from an instance that you've mounted the file system to. Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

1. Connect to your instance and open a command window.
2. Navigate to your file system's hidden `.snapshot` directory. Type the following, replacing `yourmountpoint` with the name of the directory where you mounted the file system.

   ```shell
cd /mnt/yourmountpoint/.snapshot
   mkdir snapshot-Jan1
   ls
   ```

**To restore a snapshot**

Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

You can restore a file within the snapshot, or an entire snapshot using the `cp` command. Use the `-r` option when restoring a snapshot that contains subdirectories.

For example:

```shell
cp -r .snapshot/snapshot_name/* destination_directory_name
```

Optionally, you can use `rsync`, `tar`, or another tool that supports NFSv3 to copy your data to another remote location. For optimal performance, use the **Parallel File Tools**.

For example:

```shell
parcp .snapshot/snapshot_name/* destination_directory_name
```

**To manage tags for a snapshot**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. In the **File Systems** list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click **View File System Details**.

4. In **Resources**, click **Snapshots**.

5. In the **Snapshots** list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click **View Snapshot Details**.

6. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see **Resource Tags** on page 211.

**To delete a snapshot**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system with the snapshot you want to delete.
4. Click the Actions icon (three dots), and then click **View File System Details**.
5. In **Resources**, click **Snapshots**.
6. Find the snapshot you want to delete.
7. Click **Delete**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192.

**To create a snapshot**

You can create a snapshot of a file system. A snapshot is a point-in-time view of the file system. The snapshot is accessible at `.snapshot/name`.

Open a command prompt and run `oci fs snapshot create` to create a snapshot of a file system.

For example:

```
oci fs snapshot create --file-system-id <file_system_OCID> --name "<January1>"
```

Avoid entering confidential information.

**To list snapshots**

Open a command prompt and run `oci fs snapshot list` to list all snapshots associated with a specific file system.

For example:

```
oci fs snapshot list --file-system-id <file_system_OCID>
```

**To get a specific snapshot**

Open a command prompt and run `oci fs snapshot get` to retrieve information about a specific snapshot.

For example:

```
oci fs snapshot get --snapshot-id <snapshot_OCID>
```

**To delete a snapshot**

Open a command prompt and run `oci fs snapshot delete` to delete a snapshot.

For example:

```
oci fs snapshot delete --snapshot-id <snapshot_OCID>
```
Using the API

- CreateSnapshot
- ListSnapshots
- GetSnapshot
- DeleteSnapshot

If you have issues managing snapshots, see Troubleshooting Snapshot Management on page 2022.

Using File Storage Parallel Tools

The Parallel File Tools suite provides parallel versions of `tar`, `rm`, and `cp`. These tools can run requests on large file systems in parallel, maximizing performance for data protection operations.

The toolkit includes:

- `partar`: Use this command to create and extract tarballs in parallel.
- `parrm`: You can use this command to recursively remove a directory in parallel.
- `parcp`: Use this command to recursively copy a directory in parallel.

Installing the Parallel File Tools

The tool suite is distributed as an RPM for Oracle Linux, Red Hat Enterprise Linux, and CentOS.

To install Parallel File Tools on Linux

To install Parallel File Tools on an Oracle Linux instance:

1. Open a terminal window on the destination instance.
2. Type the following command:

```
sudo yum install -y fss-parallel-tools
```

To install Parallel File Tools on CentOS and Red Hat 6.x

To install Parallel File Tools on CentOS and Red Hat 6.x:

1. Open a terminal window on the destination instance.
2. Type the following command:

```
sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol6 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
sudo yum --enablerepo=ol6_developer install fss-parallel-tools
```

To install Parallel File Tools on CentOS and Red Hat 7.x

To install Parallel File Tools on CentOS and Red Hat 7.x:

1. Open a terminal window on the destination instance.
2. Type the following command:

```
sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol7 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
sudo yum --enablerepo=ol7_developer install fss-parallel-tools
```

Oracle Cloud Infrastructure User Guide
Using the Tools - Simple Examples

Here are some simple examples of how the different tools are commonly used in Oracle Cloud Infrastructure File Storage.

To copy all files and folders from one directory to another

In this example, parcp is used to copy the contents of one folder to another. The -P option is used to set the number of parallel threads you want to use.

$parcp -P 16 /source/folder /destination/folder

To create a .TAR archive of a directory

The following command will create a .tar archive of the contents of the specified directory, and store it as a tarball in the directory. In the example below, the name of the directory that is being used to create the tarball is example.

$partar pcf example.tar example -P 16

You can also create a tarball and send it to a different directory. In the example below, the directory being used to create the tarball is example. The tarball is being created in the /test directory.

$partar pcf example.tar example -P 16 -C /test

Using the Tools - Advanced Examples

Here are some examples of how the different tools are used in more advanced scenarios.

To copy selected files or folders into a .TAR archive and exclude others

You can specify which files and folders are included when you create a .tar archive using partar. Let's say you have a directory that looks like this:

```
[opc@example sourcedir]$ ls -l
total 180
-rw-r----.  1 opc opc          0 Apr 15 02:55 example2020-04-15_02-55-33_217107549.error
-rw-r----.  1 opc opc         10 Apr 15 03:18 example2020-04-15_02-55-33_217107549.log
-rw-rw-r--.  1 opc opc         12 Apr 15 03:18 example2020-04-15_03-18-13_267771997.error
-rw-rw-r--.  1 opc opc         10 Apr 15 03:18 example2020-04-15_03-18-13_267771997.log
-rwxr-xr-x.  1 opc opc         37 Nov 30  2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30  2017 File3.txt
-rwxr-xr-x.  1 opc opc         57 Dec  1  2017 File4.txt
```

The following command creates a .tar archive that:

- Excludes all .log and .error files.
- Names the .tar archive mytar
- Sends the .tar ball from /sourcedir to /mnt/destinationdir
• Extracts the .tar archive

```
[opc@example sourcedir]$ partar cf - mytar '*.log*' --exclude '*.err*' |
                partar xf - -C /mnt/destinationdir
```

Performing `ls -l` on `/mnt/destinationdir/mytar` shows that only the desired files have been copied.

```
[opc@example mytar]$ ls -l
total 148
-rwxr-xr-x.  1 opc opc         37 Nov 30 2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30 2017 File3.txt
-rwxr-xr-x.  1 opc opc         57 Dec  1  2017 File4.txt
```

**To copy selected files or folders from one directory to another**

You can specify which files and folders are included when you use `parcp` to copy from one directory to another. Let's say you have a directory that looks like this:

```
[opc@example sourcedir]$ ls -l
total 180
-rw-r-----.  1 opc opc          0 Apr 15 02:55 example2020-04-15_02-55-33_217107549.error
-rw-r-----.  1 opc opc         10 Apr 15 03:18 example2020-04-15_02-55-33_217107549.log
-rw-r-r--.  1 opc opc         12 Apr 15 03:18 example2020-04-15_03-18-13_267771997.error
-rw-r-r--.  1 opc opc         10 Apr 15 03:18 example2020-04-15_03-18-13_267771997.log
-rwxr-xr-x.  1 opc opc         37 Nov 30 2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30 2017 File3.txt
-rwxr-xr-x.  1 opc opc         57 Dec  1  2017 File4.txt
```

First, create a `.txt` file containing a list of files you want to exclude. In this example, it's `/home/opc/list.txt`.

The following command copies the contents from `sourcedir` to `/mnt/destinationdir` and:

- Excludes `File4.txt` and the `.log` and `.error` files, as listed in `/home/opc/list.txt`.

```
[opc@example ~]$ cat /home/opc/list.txt
File4.txt
*.log*
*.err*

[opc@example ~]$ date; time sudo parcp --exclude-from=/home/opc/list.txt -P 16 --restore /sourcedir /mnt/destinationdir;
date Mon Jun  1 15:58:30 GMT 2020
real 9m55.820s
user 0m3.602s
sys 1m5.441s
Mon Jun  1 16:08:25 GMT 2020
```

Performing `ls -l` on `/mnt/destinationdir` shows that only the desired files have been copied.

```
[opc@example destinationdir]$ ls -l
total 91
-rwxr-xr-x.  1 opc opc         37 Nov 30 2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
```

Oracle Cloud Infrastructure User Guide 1996
To use PARCP as an effective alternative for RSYNC in parallel

The `--restore` option in parcp is similar to using the `-a` `-r` `-x` and `-H` options in rsync. (See [rsync(1)-Linux Man Page.](#) The `-P` option is used to set the number of parallel threads you want to use.

The `restore` option includes the following behavior:

- Recurse into directories
- Stop at file system boundaries
- Preserve hard links, symlinks, permissions, modification times, group, owners, and special files such as `named` sockets and `fifo` files

```
$parcp -P 16 --restore /source/folder/ /destination/folder/
```

You can use parcp with the `--restore` and `--delete` options to sync files between a source and target folder. This is a good substitute for using rsync in parallel. As files are added or removed from the source directory, you can run this command at regular intervals to add or remove the same files from the destination directory. You can automate syncing by using this command option in a cron job.

```
sudo parcp -P 32 --restore --delete /source/folder/ /destination/folder/
```

**File System Metrics**

You can monitor the health, capacity, and performance of your file systems and mount targets by using `metrics`, `alarms`, and `notifications`.

This topic describes the metrics emitted by the metric namespace `oci_filestorage` (the File Storage service).

**Overview of Metrics for oci_filestorage**

File Storage service metrics help you measure operations and throughput related to file systems and mount targets. The available metrics help you determine quickly if your file system is accessible, how much data is flowing through its associated mount target, and if operations are producing unexpected errors. You can get visibility into your workload IOPs and latency, and set up alarms to receive notifications if tolerance thresholds are exceeded.

File Storage metrics include these resources:

- **File system**: A high-performance shared storage entity made available to a network by an associated mount target.
- **Mount target**: An NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems.

Metrics provided for file systems can be filtered or grouped by their associated mount target.

**Raw Data Point Frequency**

For every 1-minute interval, the File Storage service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, 1-hour (60-minute), and 1-day intervals. Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the `1h` or `1d` interval values are supported. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

- The mean for each 5-minute interval is calculated over 5 raw data points.
- The mean for each 60-minute interval is calculated over 60 raw data points.
**Required IAM Policy**

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_filestorage**

The metrics listed in the following table are automatically available for any file system or mount target. You do not need to enable monitoring on the resource to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes one or more of the following dimensions:

| RESOURCEID | The OCID of the file system or mount target. |
| MOUNTTARGETID | The OCID of the mount target exporting an associated file system. |

**THROUGHPUT**

The type of request throughput:

- ReadThroughput
- WriteThroughput

**SIZE**

The request size range:

- 0–8 KiB
- 8–64 KiB
- 64 KiB – 1 MiB

**HEALTHITEM**

The type of health rate item:

- SuccessRate
- ErrorRate

### Tips for Working with File Storage Metrics

You can use the tables below to help interpret the data you see in File Storage metric charts. You can familiarize yourself with the typical metrics emitted by the File Storage service using the chart defaults.

### File System Charts

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| Read Throughput/Write Throughput | The read or write throughput of your file system in bytes per second. Read/write throughput is averaged across all mount targets that export the file system. Only the default mean statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• y-axis - bytes per second | • Ensure that your workloads have sufficient read/write bandwidth for maximum performance.  
• Identify which file systems have the highest and lowest throughput.  
• Receive notifications when read or write throughput is above or below tolerance, so you can take action. |
<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Read Requests/Write Requests** | Read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB - 1 MiB  
Only the default **mean** statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size  
• y-axis - bytes per second | • See which file systems might have lower performance than expected.  
• Measure impact of operation size on file system and workload performance.  
• Identify and monitor file systems whose workloads are consistently receiving larger read or write requests and compare performance over time.  
• Receive notifications when operation bytes per second for a larger group size is too high. |
| **Read Latency/Write Latency** | Average latency of read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB - 1 MiB  
These charts don't report zero latency, or periods when there are no read/write operations happening. Information is presented in the charts as individual data points. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which file systems might have lower performance than expected due to operation latency.  
• Measure impact of operation latency on file system and workload performance.  
• Troubleshoot possible network or application issues that might increase file system latency.  
• Receive notifications when operation latency exceeds tolerance, so you can take action. |
<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Metadata Latency** | Average latency of read or write metadata operation requests processed by your file systems in bytes per second. CREATE, GETATTR, SETATTR, ACCESS, LOOKUP, READLINK, and REMOVE operations are shown. Each operation is placed in one of these three size groups: | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which metadata operations requested by your workload have the highest and lowest latency.  
• Measure impact of metadata operation latency on file system and workload performance.  
• Receive notifications when a metadata operation exceeds tolerance.  
• Troubleshoot your application workloads. |
| **Metadata IOPs** | IOPs per second of read or write metadata operation requests processed by your file systems. CREATE, GETATTR, SETATTR, ACCESS, LOOKUP, READLINK, and REMOVE operations are shown. | • Statistic - rate  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: operation  
• y-axis - bytes per second | • See which metadata operations requested by your workload have the highest and lowest IOPs.  
• Identify specific operations that might consistently have higher or lower IOPs.  
• Receive notifications when IOPs for a metadata operation are below tolerance.  
• Troubleshoot your application workloads. |
**File Storage**

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Usage**     | The total space utilization for each file system per hour. The data in this chart is presented differently than the utilization value shown in the Details tab of the file system: | - Statistic - mean  
- Interval - 1 hour  
- Time range - 1 day | - See what the total space utilization is for all of your file systems.  
- Identify which of your file systems are consuming the most and least space.  
- Identify which of your file systems are incurring the most and least cost.  
- Use in conjunction with the information in File System Usage and Metering on page 2007 and receive notifications when usage is not within expectations. |
|               | - File system utilization is displayed in GiB. This chart displays GB.  
- File system utilization is captured once every hour. This chart captures one data point every minute.  
- There may be temporary discrepancies between the file system utilization value and the Usage chart. For example, if the usage for a file system briefly spikes during the file system's hourly update, the utilization value may temporarily appear higher than expected when compared to the Usage chart. |                          |                       |

**Mount Target Charts**

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Read Throughput/Write Throughput** | The read or write throughput of your mount target in bytes per second. Read/write throughput is averaged across all file systems exported by the mount target. Only the default mean statistic is meaningful. | - Statistic - mean  
- Interval - 1 minute  
- Time range - 3 hours  
- y-axis - bytes per second | - Ensure that your workloads have sufficient read/write bandwidth for maximum performance.  
- Identify which mount targets have the highest and lowest throughput.  
- Receive notifications when read or write throughput is below tolerance, so you can take action. |

---

Oracle Cloud Infrastructure User Guide 2004
This chart shows this information using these defaults that you can use to:

| Connections | The number of active connections for each mount target. Typically, one connection represents one NFS client. | • Statistic - sum  
• Interval - 1 minute  
• Time range - 3 hours | • See how many active connections each mount target has.  
• Measure impact of high connection count on file system and workload performance.  
• Decide if additional mount targets are required for your workload. |
| Health | The percentage of requests processed successfully by the mount target. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours | • See which mount targets have the highest and lowest percentage of successfully processed requests.  
• Identify mount targets that are not performing well and troubleshoot possible causes.  
• Receive notifications when mount target health drops below tolerance, so you can take action. |

Using the Console

To view default metric charts for a single file system

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click File Systems.
2. Click the file system to view its details.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for a single mount target

1. Open the navigation menu. Under Core Infrastructure, click File Storage and then click Mount Targets.
2. Click the mount target to view its details.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for multiple file systems and mount targets

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the file storage resource you're interested in.
3. For **Metric Namespace**, select **oci_filestorage**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Paths in File Systems**

The File Storage service uses three kinds of paths:

1. **Export Paths** are part of the information contained in an export that makes a file system available through a mount target. The export path uniquely identifies the file system within the mount target, letting you associate up to 100 file systems behind a single mount target. The export path is used by an instance to mount (logically attach to) the file system. This path is unrelated to any path within the file system or the client instance. It exists solely as a way to distinguish one file system from another within a single mount target.

In this mount command example, `10.0.0.6` is the mount target IP address. `/FileSystem1` is the unique export path that was specified when the file system was associated with a mount target during creation.

```
sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

**Acceptable:**

```
/example and /path
/example and /example2
```

**Not Acceptable:**

```
/example and /example/path
/ and /example
/example/
```
Caution:
If one file system associated to a mount target has `/` specified as an export path, you can't associate another file system with that mount target.

Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

See Managing Mount Targets on page 1980 for more information about mount targets and exports.

2. **Mount Point Paths** are paths within a client instance to a locally accessible directory to which the remote file system is mounted.

   In this mount command example, `/mnt/mountpointA` is the path to the directory on the client instance on which the external file system is mounted.

   ```
   sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
   ```

   See Mounting File Systems on page 1954 for more information.

3. **File System Paths** are paths to directories within the file system, and contain the contents of the file system. When the file system is mounted, you can create any directory structure within it you like. Snapshots of the file system can be accessed using the file system path, under the file system's root directory at `.snapshot/name`.

   The following example shows the path to a snapshot called 'January 1' when navigating from the instance:

   ```
   /mountpointA/.snapshot/January1
   ```

### File System Usage and Metering

This topic describes how usage and metering are calculated for your file systems, to help you understand and manage your service costs. This topic also describes different ways to see your file system and snapshot utilization and the differences in reporting that can occur depending on which method you use.

#### Overview

File Storage service provisioning is fully managed and automatic as your utilization scales. For more information, see Space Allocation on page 2007.

Here are the methods you can use to view your file system and snapshot usage:

- The File Storage service reports metered file system utilization and updates hourly. The metered file system utilization comes from the `meteredBytes` value in the API, and represents the authoritative utilization value that is used to count your service cost. You can access the reported utilization for each of your file systems using the Console, the Command Line Interface (CLI), or the API. For more information, see the following section File System Metered Utilization on page 2008.

- The File Storage service supports Network File System (NFS) protocol, so you can use the `df` or `du` command from your instance command line tool to see usage for mounted file systems. However, the usage reported by `du` can differ from both the `meteredBytes` value and the `df` value. For more information, see Using DF and DU Commands on page 2008.

#### Space Allocation

The File Storage service allocates space in blocks of variable size in a way that minimizes total customer cost and optimizes performance. Other storage systems might allocate blocks differently than Oracle Cloud Infrastructure File Storage. If you copy files from another storage device to your Oracle Cloud Infrastructure file system, you might see minor differences when you compare the physical file size before and after copying.
**Metering and Service Cost**

This section describes aspects of file system usage and how they affect your overall service costs.

**File System Metered Utilization**

The File Storage service reports metered utilization size for each file system. The metered utilization size is updated on an hourly cycle. You can see the metered **Utilization** size in the Console on the **Details** page of the file system. This value comes from the File Storage service API `meteredBytes` property which is the total number of bytes consumed by the file system.

The `meteredBytes` value is updated asynchronously with respect to updates to the file system. Your usage charges are calculated based on the `meteredBytes` value.

You can also use the CLI or API to obtain this information. See Managing File Systems on page 1970 for instructions about how to view your file system utilization.

<table>
<thead>
<tr>
<th><strong>Important:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>When you add or remove files from your file system, it can take the File Storage service up to one hour to report the change in metered size.</td>
</tr>
</tbody>
</table>

**Snapshot Metered Utilization**

A snapshot is a point-in-time view of your file system. Snapshots initially consume no additional usage in the file system, because they reference the original data instead of duplicating it, limiting usage cost. A snapshot doesn't change which blocks it references after it's taken.

Snapshot data usage is metered against differentiated data only. If nothing has changed within the file system since the last snapshot was taken, a new snapshot does not consume more storage. The metered size of snapshots is included in the reported `meteredBytes` value of the file system it belongs to.

For example:

1. Let's say you create a file system called "MyFileSystem" and add "File1". The new file system now contains 1 GB including metadata. After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service is 1 GB.
2. Next, you create a snapshot of "MyFileSystem" named "Snapshot1". After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service remains at 1 GB, because there's no differentiated data yet.
3. You then overwrite the first 0.5 GB of "File1". Now, "MyFileSystem" has a file that is different than the version previously captured in "Snapshot1". The `meteredBytes` value is 1.5 GB, because the differentiated data between the live file system and the snapshot is 0.5 GB.
   
   $ 1 \text{ GB (snapshot)} + 0.5 \text{ GB (differentiated data)} = 1.5 \text{ GB}$
4. If you then delete "File1". "MyFileSystem" now has a `meteredBytes` value of 1 GB, which represents just the usage for "Snapshot1".
5. Finally, delete "Snapshot1". Deleting the snapshot removes its references to the file data. **Provided no other snapshots reference the file data**, the space is relinquished and utilization returns to zero.

**Metadata Metered Utilization**

Files in the file system require space to be allocated for metadata. 512 bytes are required for each directory entry, and 8192 bytes are required for each symlink. Multiple hardlinks to a file create multiple directory entries for the file, and increases the metadata utilization. This utilization is included in the `meteredBytes` value of the file system it belongs to.

**Using DF and DU Commands**

You can use `df` or `du` commands from your instance command-line application to view usage information about your file system. To use these commands to view file system usage, the file system must first be mounted to the instance. See Managing File Systems on page 1954 for instructions on mounting your file system.
How the Commands Work

- `df` provides the amount of storage metered for your file system. Results are returned quickly, but can be up to 1 hour out of date.
- `du` provides the storage used by a directory hierarchy. The `du` command walks the directory tree, and if your hierarchy is large, it can take a long time to run and return results.

How Results can Differ

DF and DU report snapshot utilization differently

A snapshot is a point-in-time view of a file system. Snapshots reference unchanged file system data instead of duplicating it. The file system blocks that the snapshot references don't count towards the snapshot utilization. Only differentiated data increases the snapshot utilization.

- The `df` command retrieves information provided by the File Storage service using the NFS FSSTAT call. The NFS FSSTAT call accounts correctly for the way that snapshots reference file system data. Only utilization caused by differentiated data is reported.
- The `du` command descends the file system tree and uses each file's size attribute to total up the space used. When you create a snapshot, it copies the original size attribute for each file. So, if you run the `du` command, the snapshot reports the file system's size at the time the snapshot was taken, not necessarily the snapshot's actual current utilization.

For example,

1. Let's say you create file system called "MyFileSystem". You then add a 1 GB file called "FileA" to the file system. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For..</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

2. You then create "Snapshot1". The snapshot is placed in the /.snapshot folder of MyFileSystem. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For..</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

- `df` reports 0 GB for Snapshot1 because the data hasn't changed yet, so there is no space allocated for differentiated data.
- `du` reports 1 GB for Snapshot1 because it reports the copied file size attribute of FileA, which is 1 GB.

**Important:**

Charges are calculated using the `meteredBytes` value. The utilization size reported by `du` can be much larger than `meteredBytes` value. `df` reports the same value as `meteredBytes`, so you can use it to accurately view the file system size.

DF and DU count hard links differently

- `df` counts each file only once.
- `du` may count files with hard links more than once.
DF and DU count symlinks and metadata differently

- `df` reports the utilization of bytes required by File Storage for metadata and symlinks, even on empty files.
- `du` reports empty files as using zero bytes. It doesn't accurately report the bytes being used by File Storage for metadata and symlinks.

Troubleshooting Your File System

These topics cover some common issues you may run into and how to address them.

File System Setup

- Mount Command Fails
- Mount Target Creation Fails on page 2012
- Mount Target is in a Failed State on page 2021
- Write to File System Fails on page 2013
- File Storage CREATE API Operations Fail on page 2011
- Creating a File System With an Assigned Key Fails on page 2011

File System Management

- Showmount Command Fails on page 2018
- Symbolic Links (Symlinks) Produce Errors on page 2018
- Removing File Locks from a Host that is No Longer Available on page 2017
- Cannot Delete VCN - Mount Target VNIC Still Attached
- Metadata Operations Are Very Slow or Fail on page 2016
- 409 Error Occurs When Creating or Moving a File System or Mount Target on page 2019
- Cannot Mount a File System after Instance Reboot on page 2014
- Cannot Unmount a File System: Device is Busy on page 2015
- DF Operation Reports File System as 100% Used (0% Free) on page 2015
- Removing Snapshots With RM -RF Fails on page 2022
- Mounted File System No Longer Accessible on page 2017
- RSYNC is Slow When Copying Files on page 2018
- Deleted Snapshots Still Appear in DF Output on page 2022

Mount Target Management

- Cannot Delete VCN- Mount Target VNIC Still Attached on page 2019
- Mount Target is in a Failed State on page 2021

Snapshot Management

- Deleted Snapshots Still Appear in DF Output on page 2022
- Removing Snapshots With RM -RF Fails on page 2022

Application Installation

- Application Installation Fails Due to Too Much or Too Little Available Capacity on page 2024
- Application Performance is Not as Expected on page 2024
- Apache Webserver Fails on page 2023
- Oracle E-Business Suite Concurrent Processing is Slow on page 2025

• **Mounted Drive is Not Visible in File Explorer** on page 2030
• **Mounting from File Explorer Fails With "An Unexpected Error Occurred."** on page 2031
• **Access to File System using UNC Path is Slow or Fails** on page 2026

**Troubleshooting File System Setup**

Here are some issues you may run into when you set up your file system.

• **Creating a File System With an Assigned Key Fails** on page 2011
• **File Storage CREATE API Operations Fail** on page 2011
• **Mount Command Fails**
• **Mount Target Creation Fails** on page 2012
• **Write to File System Fails** on page 2013

**Creating a File System With an Assigned Key Fails**

How to resolve problems creating a file system with an assigned Oracle Cloud Infrastructure Vault key.

**Symptom:** Creating a file system with an assigned Oracle Cloud Infrastructure Vault key fails with the following exception:

```plaintext
com.oracle.bmc.model.BmcException: (401, NotAuthenticated, false) The required information to complete authentication was not provided or was incorrect.
```

**Cause:** The File Storage service requires authorization to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to the service in the first place. Authorization is provided to the service and users using specific IAM policies.

**Solution:**

1. Create a policy in the tenancy to let a user group delegate key usage in a compartment. For example:

   ```plaintext
   Allow group FileWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
   ```

2. Assign the user who is creating the file system to the group.

3. Create a policy in the tenancy to let the File Storage service use the key. For example:

   ```plaintext
   Allow service FssOciProd to use keys in compartment ABC where target.key.id = '<key_OCID>'
   ```

For more information, see **Assigning Keys** on page 3971.

**File Storage CREATE API Operations Fail**

**Symptom:** API resource create operations such as `createFileSystem` fail to create resources.

**Cause:** High volume can cause API calls to fail. If you haven't specified `retry` in your request, the operation isn't tried again, and the resource isn't created.

**Solution:** Retry the API operation. Use the `opc-retry-token` header in the create resource request. For example:

```plaintext
POST /20171215/fileSystems
```
See REST APIs on page 4368 for more information.

Mount Command Fails

This topic troubleshoots issues with file system mount commands.

Symptom: Mount command fails.

Cause: The information in the mount command is incorrect

Solution: Verify the information in your mount command, especially the export path information.

The export path is specified when you create an export for the file system in a mount target. It uniquely identifies the file system within the mount target, letting you associate multiple file systems to a single mount target. The export path is appended to the mount target IP address, and used to mount the file system.

```
sudo mount 10.0.0.6:/example/path /mnt/mountpointA
```

In this example, 10.0.0.6: is the mount target IP address, and /example/path is the export path. /mnt/mountpointA is the path to the directory on the client instance on which the external file system is mounted.

Tip:

You can find all the export paths for a file system in the Exports list shown in its Details page, together with associated mount target information.

- You can obtain the correct export path by copying mount commands directly from the file system export. These commands minimize the chance of a typing error. See To get mount command samples on page 1956 for more information.
- If one file system associated with a mount target uses an export path of '/', it will prevent you from associating more file systems with that mount target. No two file systems associated with the same mount target can have an export path that contains a complete path of the other.

See Paths in File Systems on page 2006 for more information.

Symptom: Mounting a file system using an FQDN in the mount command fails, but mounting with an IP address succeeds.

Cause: If the mount target has a hostname specified, the File Storage service creates an FQDN for it and includes it in the mount command sample for the file system. Be sure that the FQDN correctly resolves to the mount target's IP address. For more information about DNS resolution, see DNS in Your Virtual Cloud Network on page 2910.

Mount Target Creation Fails

Mount target creation can fail for various reasons:
• **You’ve exceeded your mount target limit.**

Each availability domain is limited to two mount targets by default. If you create both a file system and a mount target at the same time, it is possible for the file system to be successfully created but the mount target creation to fail because of this limitation.

This limitation can be avoided by reusing a previously created mount target for new file systems. You can reuse a single mount target to make as many file systems available on the network as you wish.

- To reuse a mount target when creating a new file system, select **Select an Existing Mount Target**. The workflow creates a new export for the file system in the existing mount target of your choice.
- To reuse a mount target for an existing file system, you must manually create a new export for the file system in the mount target. For more information, see **To create an export for a file system** on page 1972.

See **Service Limits** on page 215 for a list of applicable limits and instructions for requesting a limit increase.

• **There aren’t enough available IP addresses in your subnet.**

Each mount target requires three internal IP addresses in the subnet to function:

- Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
- The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
- The File Storage service doesn’t "reserve" the third IP address required for high availability failover.
- Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
- Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

**Write to File System Fails**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Linux-style instances:</td>
</tr>
<tr>
<td>• Mount the file system. Follow the procedure found in <strong>Mounting File Systems From Unix-Style Instances</strong> on page 1957.</td>
</tr>
<tr>
<td>• Set up security rules to work with File Storage. Follow the procedure found in <strong>Configuring VCN Security Rules for File Storage</strong> on page 1927</td>
</tr>
</tbody>
</table>

**Symptom 1:** Writing to a file system from a mounted instance fails.

For example, open a terminal window on the instance and use the `touch` command to write a 'helloworld' file:

```bash
touch /mnt/yourmountpoint/helloworld
```

The write operation fails with the error:

```bash
touch: cannot touch '/mnt/yourmountpoint/helloworld': Permission denied
```

**Cause:** When a file system is created, the `root` user owns the root directory. If you're connecting from an Oracle-provided Linux or CentOS instance, the default user is `opc`. The default user is `ubuntu` when you connect from an Oracle-provided Ubuntu instance. These default users are not root users, so you can't initially write a file or directory to a new file system with these users.

**Solution:** You can implement one of the following solutions:

- Connect as the `root` user. Then, create files or directories in the new file system.
- Connect as the `root` user. Then, change the ownership or permissions of the file system root directory to allow other users (such as `opc` or `ubuntu`) to write to the file system.
• Connect as the root user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

Learn more about updating file and directory ownership and permissions.

• Connect as the default user. Then, use the **sudo** command to write or to change permissions or ownership of files or directories. The **sudo** command temporarily provides a regular user with root user permissions. Here's an example of using the **sudo** command to write to the file system:

```bash
sudo touch /mnt/yourmountpoint/helloworld
```

Learn more about the **sudo** command.

For more information on accessing Oracle-provided instances, see Connecting to an Instance on page 733.

**Troubleshooting File System Management**

Here are some issues you may run into while managing your file system.

- Showmount Command Fails on page 2018
- Symbolic Links (Symlinks) Produce Errors on page 2018
- Removing File Locks from a Host that is No Longer Available on page 2017
- Cannot Delete VCN - Mount Target VNIC Still Attached
- 409 Error Occurs When Creating or Moving a File System or Mount Target on page 2019
- Metadata Operations Are Very Slow or Fail on page 2016
- Cannot Mount a File System after Instance Reboot on page 2014
- Cannot Unmount a File System: Device is Busy on page 2015
- DF Operation Reports File System as 100% Used (0% Free) on page 2015
- Removing Snapshots With RM -RF Fails on page 2022
- Mounted File System No Longer Accessible on page 2017
- RSYNC is Slow When Copying Files on page 2018
- Deleted Snapshots Still Appear in DF Output on page 2022

**Cannot Mount a File System after Instance Reboot**

**Symptom:** Cannot re-mount a file system after rebooting the instance.

**Cause:** The NFS client services aren't running on the instance.

**More Information:** The rpcbind and nfslock services don't automatically start at reboot by default.

**Solution:**

1. Add the file system to the instance /etc/fstab file, so the file system is automatically remounted after reboot.
   a. See To auto-mount a file system on page 1961 for instructions.
2. Set the rpcbind and nfslock services to start automatically on every reboot.
   a. Use the following commands to start the rpcbind and nfslock services:

```bash
$ service rpcbind start
$ service nfslock start
```

b. Verify that the rpcbind and nfslock services are running:

```bash
$ service rpcbind status
$ service nfslock status
```

c. Enable the services to start automatically at reboot:

```bash
$ chkconfig rpcbind on
$ chkconfig nfslock on
```
**Cannot Unmount a File System: Device is Busy**

**Symptom:** Unmounting (`umount`) fails with a message: `device is busy`. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
device is busy
```

**Cause 1:** You're attempting to run the `umount` command from within the mountpoint directory.

**Solution 1:** Move to a directory outside the file system mount point, and retry the `umount` command.

**Cause 2:** An abrupt disconnect from the file system's mount target occurred.

**More Information:** An NFS message similar to the example below is displayed:

```
parrm: B cannot remove 'mnt/directory/.nfs <unique_id>':
Device or resource busy
```

**Solution 2:**

1. Use the `fuser` or `lsof` operation to find the process that has locked the file and note its ID.
   
   See `lsof(8)` - Linux Man Page for information about how to use `lsof`.
   
   See `fuser(1)` - Linux Man Page for information about how to use `fuser`.

2. After you've identified the process that has locked the file, stop the process using the `kill` command. For example:

   ```
   kill <process_id>
   ```

   See `kill(1)` - Linux Man Page for more information.

3. Retry the `umount` command.

**DF Operation Reports File System as 100% Used (0% Free)**

**Symptom:** Running the `df` command on a mounted file system unexpectedly reports zero available space (100% used, 0% free), rather than a realistic value.

**Cause:** The mount target that exports the file system has its `Reported Size` value set incorrectly.

**Solution:** Reset the mount target's `Reported Size (GiB)` to the default value of 8589934592 GiB. For instructions, see To set the file system reported size on page 1985.

**Important:**

Changing the `Reported Size` in the mount target affects all file systems exported through the mount target.

**File System Resources Aren't Visible in the Console**

Learn about why a file system resource might not be visible to you.

**Symptom:** You create a resource, but can't view it after it's created.

**Cause:** You don't have permission to work in the compartment that the resource resides in. Resources in a compartment that you don't have access to aren't visible to you.

When you create a resource, you can specify the compartment you want to create it in. The resource doesn't have to be in the same compartment as related file system resources. Another user might move the resource from one compartment (that you have access to) to another (that you don't).

**Solution 1:** Create the resource in a compartment you have permission to work in.

**Solution 2:** Obtain permission to work in the compartment that the resource resides in. For information about setting up user access, see Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124.
Metadata Operations Are Very Slow or Fail

**Symptom:** Metadata operations such as `ls -l`, `du`, or `find` are very slow.

**Causes:**

1. `ls`, `find`, and `du` are sequential operations. They create NFS `readdir` and `readdirplus` requests proportional to the number of entries in the directory. The service has high response latency on `readdir` and `readdirplus` requests. The severity of this performance issue can vary because of the directory size, number of files, or how busy the file system is.

2. If a client performs an `ls -l` operation while another client is writing to the file system, an issue with `READDIRPLUS` can cause looping behavior on the client instance.

**Solutions for Cause 1:**

- Use `ls -ld` or `stat` instead of `ls -l`. These operations are much quicker on large directories than `ls -l`.

  For example:

  ```bash
  [opc@instance01 dd]$ time ls -l | wc -l
  401425
  real 0m39.786s
  user 0m4.389s
  sys 0m5.403s
  [opc@instance01 dd]$ time ls -ld
  drwxrwxr-x. 4 opc opc 401424 Apr 17 14:18 .
  real 0m0.009s
  user 0m0.001s
  sys 0m0.003s
  [opc@instance01 dd]$ time stat . | grep Size
  Size: 401424 Blocks: 785 IO Block: 32768 directory
  real 0m0.010s
  user 0m0.002s
  sys 0m0.003s
  [opc@instance01 dd]$
  ```

- Redistribute your files to sub-directories instead of storing a large volume of files in a single directory.

**Solutions for Cause 2:**

- Disable the `READDIRPLUS` NFS operation on the instance:
  
  1. Open a terminal window on the instance.
  2. Unmount the file system with the `umount` command. For example:

     ```bash
     sudo umount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
     ```

  3. Remount the file system, and include the `-o nordirplus` option to disable `READDIRPLUS`. For example:

     ```bash
     sudo mount -o nordirplus 10.x.x.x:/fs-export-path /mnt/yourmountpoint
     ```
• Apply a Linux kernel patch:

A Linux kernel patch is available that addresses this issue. The patch is available to install with Oracle Ksplice on Oracle Linux 7.x instances only. Oracle Ksplice lets you apply important security updates and other critical kernel updates without a reboot. The patch addressing this behavior was made available on April 17th, 2020.

Oracle Ksplice must be installed on the instance. After you install Ksplice, you can install available Ksplice patches.

See Installing and Running Oracle Ksplice on page 664 for instructions.

After you install the patch, you can verify the effective kernel version. Ksplice uptrack doesn't change the output of the uname command. uname continues to reflect the version of the kernel the instance was booted into. Instead, use uptrack-uname to see what effective kernel your instance is running. uptrack-uname has the same format as uname and supports the common uname flags, including \(-r\) and \(-a\).

For example:

```
$ uptrack-uname -r
4.14.35-1902.302.2.el7uek.x86_64
```

**Mounted File System No Longer Accessible**

**Symptom:** A file system that was previously mounted and available is no longer accessible.

**Cause:** The file system's mount target or export was deleted.

**More Information:** File systems are made available to the network using an associated mount target. An export controls how NFS clients access the file systems when they connect to the mount target. A file system needs at least one export in an associated mount target to be available for mounting. Deleting a mount target or an export of a file system makes the file system unavailable.

Even if the file system is exported through multiple mount targets, any instance that uses the deleted mount target or export information to mount the file system loses access. See Managing Mount Targets on page 1980.

**Solution:** Re-create the mount target and a new export for the file system.

1. Follow these instructions to re-create the mount target and export: To create an export for a file system on page 1972.
2. If the mount target still exists, choose Select an Existing Mount Target. If the mount target has been deleted, choose Create a New Mount Target.
3. If you're re-creating the mount target, you can re-use the same name, IP address, and hostname information as the old mount target. Click on Advanced Options to set the IP address and hostname.

**Removing File Locks from a Host that is No Longer Available**

The File Storage service supports the removal of file locks from any file system. To request the removal of file locks on a file system:

1. Go to My Oracle Support and sign in.
   
   If you are not signed in directly to Oracle Cloud Support, click Switch to Cloud Support at the top of the page.
2. Click Create Service Request.
3. Select the following from the displayed menus:
   
   • Service Type: Select Oracle Cloud Infrastructure from the list.
   • Service Name: Select the appropriate option for your organization.
   • Problem Type: FSS File System Lock Removal Request.
4. Enter your contact information.
5. Enter a Description, and then enter the following required fields specific to your issue. For most Oracle Cloud Infrastructure issues you need to include the OCID (Oracle Cloud Identifier) for each resource you need help with. See Locating Oracle Cloud Infrastructure IDs on page 128 for instructions on locating these.

- Tenancy OCID
- File System OCID
- Mount Target OCID
- Host IP Address

For help with any of the general fields in the service request or for information on managing your service requests, click Help at the top of the Oracle Cloud Support page.

**RSYNC is Slow When Copying Files**

**Symptom:** rsync runs very slowly against a file system.

**Cause:** rsync is a serial operation, so it is slow when copying a large file system, especially if snapshots are included in the process.

**Solution:** Use one of the following alternatives:

- GNU Parallel to run rsync in parallel. For example:

  ```
  time find /mnt/MyFileSystem -mindepth 1 -maxdepth 1 | parallel -P100 rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --exclude=.snapshot --ignore-errors --progress --log-file=$HOME/rsync/logs/test.log1 --quiet -e ssh () root@10.0.3.6:/mnt/rsync_target
  ```

  For more information, see GNU Parallel - GNU Project.

- File Storage Parallel Tools

  For more information and examples, see Using File Storage Parallel Tools on page 1994.

- The find command in combination with the xargs option. For example:

  ```
  find ${source_dir} -mindepth 1 -maxdepth 1 | xargs -P 24 -I {} rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --log-file=logfile_path -quiet -e ssh {} <destination_user>@<destination_instance>:<destination_dir>
  ```

  See find(1)- Linux Man Page and xargs(1)- Linux Man Page for more information.

**Showmount Command Fails**

The File Storage service supports the showmount -e command. You can use the showmount -e command to show a list of NFS exports available from a specific mount target IP address.

For example, `$ showmount -e 10.0.0.0`

To enable the command, you must create a security list rule in the subnet containing the mount target. The rule must be a stateful ingress rule for UDP traffic with a Destination Port Range of 111.

Click here for instructions about Configuring VCN Security Rules for File Storage on page 1927.

For more information about this command, see the Linux manual page about showmount.

**Important:**

Only showmount -e is supported. No other options are supported, and the -e option must be included.

**Symbolic Links (Symlinks) Produce Errors**

The File Storage service fully supports the use of symbolic links. However, symbolic links are interpreted by the client and symlinks that point outside of the mounted File Storage system may be interpreted differently by each client and lead to unexpected results, such as broken links or pointing to the wrong file. Symbolic link targets that
work on one client might be broken on another due to differences in file system layout or because clients mounted the
file system using different mount targets.

Snapshots can also break symbolic links that point to a target outside the file system’s root directory. This is because
when you create a snapshot of a file system, it becomes available as a subdirectory of the .snapshot directory.

To minimize these potential issues, use a relative path as the target path when creating a symbolic link to a file in the
network file system. Also, ensure that relative paths do not point to a target path outside the File Storage service root
directory except when the target is on the local machine. If you must use a symbolic link that points to a target path
outside the file system, use an absolute path starting with the client’s root directory.

For example:

- Pointing to "/user/bin/example" **works**.
- Pointing to "/yourmountpoint/..." does **not** work.
- Pointing to "/home/user/yourmountpoint/..." does **not** work.

### 409 Error Occurs When Creating or Moving a File System or Mount Target

**Symptom:** When creating or moving a file system or mount target from one compartment to another, you encounter a
409 error. For example:

```python
oci.exceptions.ServiceError: {'opc-request-id': '<<OPC REQUEST ID>>', 'code': 'Conflict', 'message': 'Another filesystem is currently being provisioned, try again later', 'status': 409}
```

**Cause:** There are constraints that limit the number of concurrent operations that a tenancy can perform on file system
and mount target resources in a region:

- Each tenancy in a region can have 1 CreateFileSystem or ChangeFilesystemCompartment
  operation in progress at a time.
- Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment
  operation in progress at a time.

**Solution:** Retry the operation, either manually or programmatically. The default retry strategy for the OCI SDK is to
not retry 409 conflicts, so create a custom retry strategy that retries on 409.

For more information, see [409 error occurs when creating or moving a file system or mount target in Known Issues](#).

For more information about retry strategies, see [SDK Behaviors - Retries](#).

Several examples of building a custom retry strategy are provided at [https://github.com/oracle/oci-python-sdk/blob/master/examples/retries.py](https://github.com/oracle/oci-python-sdk/blob/master/examples/retries.py).

### Troubleshooting Mount Target Management

Troubleshooting topics about mount target management.

- [Cannot Delete VCN- Mount Target VNIC Still Attached](#) on page 2019
- [Mount Target is in a Failed State](#) on page 2021

**Cannot Delete VCN- Mount Target VNIC Still Attached**

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for the file
systems that it exports. Each mount target has a VNIC to enable network access. Mount target VNICs that remain in a
VCN must be deleted before you can delete the VCN.

Deleting a mount target also deletes all of the exports of associated file systems that exist in its export set. Data in
the file systems is not affected, but the file systems are no longer available through the deleted mount target. You can
create new exports for the file system in a different mount target and subnet.

For more information, see [Managing Mount Targets](#) on page 1980.
To resolve this issue using the Console

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier mounttarget. For example:

   ocid1.mounttarget.oc1.phx.examplemounttargetid

2. Note the **Compartment** and **Subnet** information of the **VCN** you want to delete, and to assist navigation and choosing the correct mount target to delete.

3. Delete the mount target using the following steps:
   a. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
   b. In the **List Scope** section, select a compartment.
   c. Find the mount target you want to delete.
   d. Click the Actions icon (three dots), and then click **Delete**.

   **Caution:**
   Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

   **Tip:**
   In the Console, the mount target OCID can be seen in the mount target details page in the **Mount Target Information** tab. See Managing Mount Targets on page 1980 for more information about how to view the mount target details page. Be sure the mount target OCID seen on the details page matches the mount target OCID provided by the VCN delete process error message.

4. Delete the VCN.

To resolve this issue using the API

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier mounttarget. For example:

   ocid1.mounttarget.oc1.phx.examplemounttargetid

2. Delete the mount target using the following steps:
   a. Use **DeleteMountTarget** to delete the mount target. For example:

   ```
   DELETE /20171215/mountTargets/
   ocid1.mounttarget.oc1.phx.examplemounttargetid
   Host: filestorage.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   ```

   b. You can use **GetMountTarget** to verify that the mount target has been deleted. For example:

   ```
   GET /20171215/mountTargets/
   ocid1.mounttarget.oc1.phx.examplemounttargetid?compartmentId=<compartmentId>
   Host: filestorage.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   ```

   The API should return **Status 404 Not Found**.

To resolve this issue using the CLI

For general information about using the CLI, see Command Line Interface (CLI) on page 4192.
1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

   `ocid1.mounttarget.oc1.phx.examplemounttargetid`

2. Delete the mount target using the following steps:
   a. Use `oci fs mount-target delete` to delete the mount target. For example:

   ```
   oci fs mount-target delete --mount-target-id ocid1.mounttarget.oc1.phx.examplemounttargetid
   ```
   
   b. You can use `oci fs export get` to verify that the mount target has been deleted. For example:

   ```
   oci fs export get --export-id ocid1.mounttarget.oc1.phx.examplemounttargetid
   ```

   The CLI should return a message indicating the mount target is not found. For example:

   ```
   {
     "code": "NotAuthorizedOrNotFound",
     "message": "Authorization failed or requested resource not found.",
     "opc-request-id": "<requestID>",
     "status": 404
   }
   ```

   If you still can't delete the VCN, be sure there are no other resources remaining in the VCN that might prevent it. For more information, see Subnet or VCN Deletion on page 3334.

**Mount Target is in a Failed State**

**Symptom:** A mount target reports a Failed state. File systems are not accessible using the mount target's IP address.

**Possible Cause:** There are insufficient unallocated IP addresses in the subnet. The mount target cannot fail over successfully.

Each mount target requires three internal IP addresses in the subnet to function:

- Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
- The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
- The File Storage service doesn't "reserve" the third IP address required for high availability failover.
- Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
- Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

**Solution:**

1. Delete the failed mount target.

   To delete a mount target on page 1986
2. Export the file system through an active mount target. You can create a replacement mount target and then create
an export for the file system, or create an export for the file system in a pre-existing mount target.
   • You can use the same export paths for the associated file systems as the previous mount target. However, the
     export path must be unique for each file system within the mount target.
   • If you create a replacement mount target, you can use the same IP address as the previous mount target, if
     available. Be sure to explicitly specify the desired IP address when you create the mount target.

To create a mount target on page 1983
To create an export for a file system on page 1972

3. If necessary, mount the file systems again.

   Mounting File Systems on page 1954

   | Note: |
   | If a replacement mount target uses exactly the same IP address and export paths as previously existed in the deleted mount target, mounted instances reconnect automatically. |

4. To prevent a recurrence of this issue, ensure that sufficient unallocated IP addresses remain available in the
   subnet.

Troubleshooting Snapshot Management
Troubleshooting topics about snapshot management.

   • Deleted Snapshots Still Appear in DF Output on page 2022
   • Removing Snapshots With RM -RF Fails on page 2022

Deleted Snapshots Still Appear in DF Output
Resolve an issue where deleted snapshots still appear in DF output with "stale file handle".

   Symptom: Previously deleted snapshots still appear in df output with the message stale file handle.

   Cause: When you use an NFSv3 client to perform operations such as ls, du, or find on the snapshot directory, the
     service automatically exports the directory. The client uses nfs_d_automount() to detect and mount the
     directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

     If you then delete the snapshot, the mount becomes disconnected. The client still holds an active reference to the
     snapshot, but can no longer access the snapshot itself, so it reports stale file handle.

   Solution: Manually unmount the snapshot. This might require using the -f flag in the umount command. For example:

     sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint

   | Note: |
   | If the umount command fails with the message device busy, see Cannot Unmount a File System: Device is Busy on page 2015 for a solution to this problem. |

Removing Snapshots With RM -RF Fails

   Symptom: Using the rm -rf .snapshot/<snapshot_folder> operation to delete a snapshot from a
   mounted file system fails.

   Cause: Snapshots are read-only and can't be deleted by running rm -rf .snapshot/<snapshot_folder>
   from a client instance. Snapshots must be deleted using the console, CLI, or API.

   Solution: Use one of these methods to delete the snapshot:

   • Use the Console
Troubleshooting Applications

Here are some issues you might run into when installing applications that use your file system.

- Application Installation Fails Due to Too Much or Too Little Available Capacity
- Application Performance is Not as Expected
- Apache Webserver Fails
- Oracle E-Business Suite Concurrent Processing is Slow
- Access to File System is Denied Due to Stale File Handle
- Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service

Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business Suite.

Access to File System is Denied Due to Stale File Handle

Symptom: Access to a file system fails with a message: stale file handle. For example:

```
[root@example]# /mnt/MyFileSystem
[root@example]# ls -l
ls: cannot access dbclient: Stale file handle
```

Cause: This issue happens when an application opens or creates a file, deletes and closes it, and then attempts to access or delete the same file again.

**Solution 1:** Restart the application.

**Solution 2:** If Solution 1 doesn't solve the issue, unmount and re-mount the file system. This might require using the -f flag in the `umount` command. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
sudo mount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Note:**

If the `umount` command fails with the message `device busy`, see Cannot Unmount a File System: Device is Busy on page 2015 for a solution to this problem.

**Solution 3:** If the first two solutions don't solve the issue, reboot the instance.

Apache Webserver Fails

**Symptom 1:** When Apache webserver is installed on a File Storage file system, login to the web page fails and the Apache `error_log` contains messages like the following:

```
Permission denied: [client IP:port] AH00529: <FSS_mount_point>/public/.htaccess pcfg_openfile: unable to check htaccess file, ensure it is readable and that <FSS_mount_point>/public is executable

Permission denied: [client IP:port] AH00035: access to /index.php denied (filesystem path '<FSS_mount_point>/index.php') because search permissions are missing on a component of the path
```

**Additional Information:**

Permission checks show sufficient read and execute access on the directory and the files. Providing full access (777 permission) to the file storage mount point for testing purposes also fails.
Caution: The '777' permission is used strictly for testing purposes, and might compromise your security policy. Be sure to revert your file system mount point permissions to their previous state after testing is complete.

Cause: By default, the Apache webserver installation expects a local drive. You need to explicitly direct the installation to NFS.

Solution: Enable NFS compatibility for Apache.

Open a terminal on the instance and run:

```
$ sudo setsebool httpd_use_nfs on
```

Or:

```
$ sudo setsebool -P httpd_use_nfs 1
```

Application Installation Fails Due to Too Much or Too Little Available Capacity

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target.

Important:

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store.

If your application installation is failing because of too little available space, you can expand the reported available free space. If your application installation is failing because of too much reported available free space, you can reduce it. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important:

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.

To set the file system reported size on page 1985 in the Console

To set the file system reported size on page 1990 in the CLI

To set the reported free space in the API

You can use the `UpdateExportSet` operation to update the `MaxFsStatBytes`.

See REST APIs on page 4368 for more information.

Application Performance is Not as Expected

Several factors can impact application performance:

- **Available bandwidth**

  We recommend that you use bare metal Compute instances because instance bandwidth scales with the number of oCPU’s. Bare metal Compute instances provide the greatest bandwidth. Virtual machines (VMs) are bandwidth limited based on the number of CPUs consumed. Single oCPU VM Compute instances provide the least bandwidth.
• **Latency**

Subnets can be either AD-specific or regional. The type of subnet you choose to create your File Storage resources in can affect latency. You can create File Storage resources in either type of subnet.

Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet.

For more information, see [VCNs and Subnets](#) on page 2821.

**Tip:**

If you want to verify that your instance and mount target are in the same availability domain, you can view the availability domain for any mount target in its **Details** page, in the **Mount Target Information** tab:

A file system is always in the same subnet as its associated mount target.

You can also view the availability domain for any instance in its **Details** page, in the **Instance Information** tab:

• **Mount options**

By not providing explicit values for mount options such as `rsize` and `wsize`, the client and server can negotiate the window size for read and write operations that provide the best performance.

**Oracle E-Business Suite Concurrent Processing is Slow**

**Symptom:** On an Oracle E-business Suite system that uses a shared application tier file system, EBS concurrent processing is slow.

**Cause:** The `APPLLDM` environment variable is referenced by `AutoConfig` and used to control the placement of concurrent processing logs. The placement of these files can have performance implications.
**Solution:** Set APPLLDM to a value *other* than *single*, so that there are multiple log and output directories instead of one large directory. See *Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service* for instructions.

### Troubleshooting Windows NFS Connections

Here are some issues you may run into with Windows NFS Connections to your file system.

- **Create and Write to File System Fails using Windows NFS** on page 2027
- **Mounted Drive is Not Visible in File Explorer** on page 2030
- **Mounted Drive is Not Visible in PowerShell** on page 2030
- **Mounting from File Explorer Fails With "An Unexpected Error Occurred."** on page 2031
- **Access to File System using UNC Path is Slow or Fails** on page 2026

### Access to File System using UNC Path is Slow or Fails

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in *Mounting File Systems From Windows Instances* on page 1964.
- Set up security rules to work with File Storage. Follow the procedure found in *Configuring VCN Security Rules for File Storage* on page 1927

**Symptom 1:** Windows NFS connection to a file system using a Universal Naming Convention (UNC) path is significantly delayed or fails. The effect is intermittent.

**Symptom 2:** Mount fails using Windows NFS connection with "Network Error 53 "Network path not found".

**Cause:** By default, Windows network providers have higher priority than the client for NFS network provider. Initially, the delay as Windows tries each provider in the default order is significant. Subsequent attempts may be faster because the mount information is cached. After the cache times out, the delay increases again. The native Windows file system client called Distributed File System (DFS) is also given default priority over NFS client, increasing the delay.

**Solution:** Change the network provider order and disable the DFS client so that the client for NFS Network provider is tried first.

For reference, see:

- Support for UNC Naming and MUP
- Modify the protocol bindings and network provider order
- MUP and DFS Interactions

To change the network provider order and disable the DFS client on Windows 2012+

1. Click **Windows Search**.
2. Enter *regedit* in the **Search** field and press **Enter**.
3. Click **Yes** to allow changes to your device.
4. Click **HKEY_LOCAL_MACHINE**.
5. **Browse to:** System\CurrentControlSet\Control\NetworkProvider\Order
6. Change the Network Provider order from default to Nfsnp,RDPNP,LanmanWorkstation:
   a. Right-click **ProviderOrder**, and select **Modify**.
   b. In the **Value Data** field, enter Nfsnp,RDPNP,LanmanWorkstation. If there are any further items that exist in this field on your instance, enter them after LanmanWorkstation.
   c. Click **OK**.
7. **Browse to:** System\CurrentControlSet\Services\Mup.
8. Add a new DWORD32 registry entry for DisableDfs:
   a. Click Edit, and select New DWORD (32 bit) Value.
   b. In the Name field, enter DisableDfs.
   c. Right-click DisableDFS, and select Modify.
   d. In the Value Data field, enter 1.
   e. Click OK.
9. Restart the instance.

Create and Write to File System Fails using Windows NFS

**Important:** Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:
- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 1964.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 1927.

**Symptom:** After installing Windows NFS client, you can successfully mount the file system from Windows, but any attempt to create or update a file in the file system fails.

**Cause 1:** Registry entries that map the AnonymousGid and AnonymousUid to the root user are missing or in the wrong place.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using AnonymousGid and AnonymousUid. On brand new file systems, write permissions are only granted to the root user.

**Solution:** Verify that the correct registry entries are located in HKEY_LOCAL_MACHINE\Software\Microsoft\ClientForNFS\CurrentVersion\Default. If not, add the AnonymousGid and AnonymousUid registry entries to map them to the root user, and then remount the file system with the new user privileges.

**Tip:**
You can verify the AnonymousGid and AnonymousUid are correctly set for a mounted file system by opening a Windows Command Line (CMD) window and typing the mount command without any arguments. A list of all mounted file systems and their properties is shown. The AnonymousGid (GID) and AnonymousUid (UID) values should appear as 0.

For example:
```
C:\>mount
Local    Remote    Properties
-----------------------------------------------
X:       \10.0.1.0\FileSystem
       UID=0, GID=0
       rsize=1048576, wsize=1048576
       mount=soft, timeout=0.8
       retry=1, locking=yes
       fileaccess=755, lang=ANSI
casesensitive=no
```
To map the AnonymousGid and AnonymousUid to the root user

1. In the Windows Command Line (CMD) window, unmount the file system by typing the following. Replace 10.x.x.x with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

   umount 10.x.x.x:/fs-export-path X:

2. Open the registry editor (regedit):
   - Click Windows Search.
   - Enter regedit in the Search field and press Enter.
   - Click Yes to allow changes to your device.

3. Click HKEY_LOCAL_MACHINE. Then, browse to: Software\Microsoft\ClientForNFS \CurrentVersion\Default.

4. Add a new DWORD32 registry entry for AnonymousGid:
   - Click Edit, and select New DWORD (32 bit) Value.
   - In the Name field, enter AnonymousGid. Leave the value at 0.

5. Repeat step 3 to add a second DWORD32 registry entry named AnonymousUid with a value of 0.

6. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl+Shift and click Command Prompt.
7. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

```bash
nfsadmin client stop
nfsadmin client start
```

8. Close the Administrator: Windows Command Prompt (CMD) window. Open a **standard** Command Prompt Window:
   - Click **Start**, then click **Command Prompt**.

   **Important:**
   
   NFS file systems mounted as Administrator are not available to standard users.

9. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

```bash
mount 10.x.x.x:/fs-export-path X:
```

**Cause 2:** A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn’t necessary to run the Command Prompt as Administrator.

**Solution:** Unmount the file system and then remount the file system using a standard Command Prompt. (CMD)

**To remount a file system with a standard Command Prompt (CMD)**

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to **Start** and scroll down to **Apps**.
   - In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.

2. In the Administrator: Windows Command Line (CMD) window, **unmount** the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

   **Tip:**
   
   IP address and export path information is available in the **Details** page of the mount target associated with your file system. See **To view details of a mount target** on page 1984 for more information.

```bash
umount 10.x.x.x:/fs-export-path X:
```

3. **Close** the Administrator: Windows Command Line (CMD) window.

4. Open a **standard** Command Prompt Window:
   - Click **Start**, then click **Command Prompt**.

5. In the **standard** Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

```bash
mount 10.x.x.x:/fs-export-path X:
```
Mounted Drive is Not Visible in File Explorer

Important:
Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 1964.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 1927.

Symptom: After installing Windows NFS client, you can successfully mount the file system from Windows, but the file system drive is not visible in File Explorer.

Cause: A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

Solution: Unmount the file system and then remount the file system using a standard Command Prompt (CMD). See To remount a file system with a standard Command Prompt (CMD) on page 2029.

Mounted Drive is Not Visible in PowerShell

Important:
Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 1964.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 1927.

Symptom: After installing Windows NFS client, you can successfully mount the file system from either Windows File Explorer or the Command Prompt (CMD) using mount or net use commands. However, the file system drive is not visible in PowerShell.

Cause: A known issue exists where drives mapped from outside PowerShell aren't visible from within PowerShell.

Solution: Unmount the file system and remount the file system within PowerShell, using options to make it visible in File Explorer and in the CMD application.

To unmount a file system using the CMD prompt

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl-Shift and click Command Prompt.
2. In the Administrator: Windows Command Line (CMD) window, unmount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

   Tip:
   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 1984 for more information.

   umount 10.x.x.x:/fs-export-path X:

To map a drive in PowerShell and make it visible

You can map a drive in PowerShell and then use options to make it visible from File Explorer and the Windows Command Line (CMD).

1. Open Windows PowerShell and run as Administrator:
   a. Go to Start and click the Windows PowerShell icon.
   b. In Windows PowerShell, type the following to run as Administrator:
      ```powershell
      Start-Process powershell -Verb runAs
      ```
   c. In the User Account Control window, click Yes. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. Type the following cmdlet. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to:
   ```powershell
   New-PSDrive X -PsProvider FileSystem -Root "\10.x.x.x\fs-export-path" -Persist
   ```

Mounting from File Explorer Fails With "An Unexpected Error Occurred."

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 1964.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 1927

**Symptom:** The IP address and export path are correctly represented in the Folder field. When you click Finish, the system attempts to connect to the file system, but fails with an error: "The mapped network drive could not be created because the following error has occurred: An unexpected error occurred."

**Solution 1:** Reboot the instance, and mount the file system again using File Explorer.

**Solution 2:** Mount the file system using the Command Prompt.
Chapter 19

Functions

This chapter explains how to create, deploy, and invoke functions using Oracle Functions.

Overview of Functions

Oracle Functions is a fully managed, multi-tenant, highly scalable, on-demand, Functions-as-a-Service platform. It is built on enterprise-grade Oracle Cloud Infrastructure and powered by the Fn Project open source engine. Use Oracle Functions (sometimes abbreviated to just Functions) when you want to focus on writing code to meet business needs.

The serverless and elastic architecture of Oracle Functions means there's no infrastructure administration or software administration for you to perform. You don't provision or maintain compute instances, and operating system software patches and upgrades are applied automatically. Oracle Functions simply ensures your app is highly-available, scalable, secure, and monitored. With Oracle Functions, you can write code in Java, Python, Node, Go, and Ruby (and for advanced use cases, bring your own Dockerfile, and Graal VM). You can then deploy your code, call it directly or trigger it in response to events, and get billed only for the resources consumed during the execution.

Oracle Functions is based on Fn Project. Fn Project is an open source, container native, serverless platform that can be run anywhere - any cloud or on-premises. Fn Project is easy to use, extensible, and performant. You can download and install the open source distribution of Fn Project, develop and test a function locally, and then use the same tooling to deploy that function to Oracle Functions.

You can access Oracle Functions using the Console, a CLI, and a REST API. You can invoke the functions you deploy to Oracle Functions using the CLI or by making signed HTTP requests.

Oracle Functions is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality. See Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124.

To get set up and running quickly with Oracle Functions, see the Quick Start Guides. A number of related Developer Tutorials are also available.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

For general information about using the REST API, see REST APIs on page 4368.
Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

The following Oracle Functions resources emit events:

- applications
- functions

You can also have events in other services invoke functions in Oracle Functions. See Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services on page 2095.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Oracle Functions Capabilities and Limits

The number of functions and applications you can create in a region is controlled by Oracle Functions service limits (see Functions Limits on page 225). The default service limits vary according to your payment method. If you need more capacity, you can submit a request to increase the default service limits (see Requesting a Service Limit Increase on page 217).

The maximum amount of data you can send to a function (the function's request payload) is 6MB. The maximum amount of data a function can return in response to a request (the function's response payload) is 6MB. These limits are fixed and cannot be changed.

Some other Oracle Functions capabilities and limits are also fixed. However, there are also a number that you can change. See Changing Oracle Functions Default Behavior on page 2095.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more information about policies for Oracle Functions, see:

- Create Policies to Control Access to Network and Function-Related Resources on page 2041
- Details for Functions on page 2276
Oracle Functions Concepts

This topic describes key concepts you need to understand when using Oracle Functions.

Functions Developers

Oracle Cloud Infrastructure users who use Oracle Functions to create and deploy functions are referred to as 'functions developers'. To use Oracle Functions, functions developers must have Oracle Cloud Infrastructure user accounts. Their user accounts must belong to groups to which appropriate policies grant access to function-related resources.

See Create Groups and Users to use with Oracle Functions, if they don't exist already on page 2039.

Applications

In Oracle Functions, an application is:

• a logical grouping of functions
• a way to allocate and configure resources for all functions in the application
• a common context to store configuration variables that are available to all functions in the application
• a way to ensure function runtime isolation

When you define an application in Oracle Functions, you specify the subnets in which to run the functions in the application. You also specify whether to enable logging for the functions in the application.

When functions from different applications are invoked simultaneously, Oracle Functions ensures these function executions are isolated from each other.

Best practice is to group multiple functions in a single application for better efficiency and performance.

Oracle Functions shows applications and their functions in the Console.

See Creating Applications on page 2061.

Functions

In Oracle Functions, functions are:

• small but powerful blocks of code that generally do one simple thing
• grouped into applications
• stored as Docker images in a specified Docker registry
• invoked in response to a CLI command or signed HTTP request

When you deploy a function to Oracle Functions using the Fn Project CLI, the function is built as a Docker image and pushed to a specified Docker registry.

A definition of the function is stored as metadata in the Oracle Functions server. The definition describes how the function is to be executed and includes:

• the Docker image to pull when the function is invoked
• the maximum length of time the function is allowed to execute for
• the maximum amount of memory the function is allowed to consume

Oracle Functions shows functions, and the applications into which they are grouped, in the Console.

See Creating, Deploying, and Invoking a Helloworld Function on page 2059.

Invocations

In Oracle Functions, a function's code is run (or executed) when the function is called (or invoked). You can invoke a function that you've deployed to Oracle Functions from:

• The Fn Project CLI.
Functions

- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions pulls the function's Docker image from the specified Docker registry, runs it as a Docker container, and executes the function. If there are subsequent requests to the same function, Oracle Functions directs those requests to the same container. After a period being idle, the Docker container is removed.

Oracle Functions shows information about function invocations in metric charts.

See Invoking Functions on page 2071.

Triggers

A trigger is the result of an action elsewhere in the system, that sends a request to invoke a function in Oracle Functions. For example, an event in the Events service might cause a trigger to send a request to Oracle Functions to invoke a function. Alternatively, a trigger might send regular requests to invoke a function on a defined, time-based schedule.

A function might not be associated with any triggers, or it can be associated with one or multiple triggers.

How Oracle Functions Works

This topic describes how Oracle Functions works when you deploy a function, and when you invoke a function.

What Happens When You Deploy a Function to Oracle Functions?

When you have written the code for a function and it's ready to deploy, you can use a single Fn Project CLI command to perform all the deploy operations in sequence:

- building a Docker image from the function
- providing a definition of the function in a func.yaml file that includes:
  - the maximum length of time the function is allowed to execute for
  - the maximum amount of memory the function is allowed to consume
- pushing the image to the specified Docker registry
- uploading function metadata (including the memory and time restrictions, and a link to the image in the Docker registry) to the Fn Server
- adding the function to the list of functions shown in the Console

The above process of deploying a function to Oracle Functions is shown in the diagram.
What Happens When You Invoke a Function?

You can invoke a function that you've deployed to Oracle Functions from:

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions first verifies the request with the IAM service. Assuming the request passes authentication and authorization checks, Oracle Functions then passes the request to the Fn Server, which uses the function definition to:

- identify the Docker image of the function to pull from the Docker registry
- execute the function by running the function’s image as a container on an instance in a subnet associated with the application to which the function belongs

When the function is executing inside the container, the function can read from and write to other resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services. You can specify the maximum length of time the function is allowed to execute by setting a timeout in the func.yaml file or in the Console.

Oracle Functions stores the function's logs in Oracle Cloud Infrastructure or in an external logging destination.

When the function has finished executing and after a period being idle, the Docker container is removed. If Oracle Functions receives another call to the same function before the container is removed, the second request is routed to the same running container. If Oracle Functions receives a call to a function that is currently executing inside a running container, Oracle Functions scales horizontally to serve both incoming requests and a second Docker container is started.

Oracle Functions shows information about function invocations in metric charts.

The above process of invoking a function is shown in the diagram.
Functions

Oracle Functions Resiliency, Availability, Concurrency, and Scalability

Resiliency and Availability

Resiliency and availability refers to the ability of a system to continue operating, despite the failure or sub-optimal performance of some of its components.

In the case of Oracle Functions:

- The control plane is a set of components that manages function definitions.
- The data plane is a set of components that executes functions in response to invocation requests.

For resiliency and high availability, both the control plane and data plane components are distributed across different availability domains and fault domains in a region. If one of the domains ceases to be available, the components in the remaining domains take over to ensure that function definition management and execution are not disrupted.

When functions are invoked, they run in the subnets specified for the application to which the functions belong. For resiliency and high availability, best practice is to specify a regional subnet for an application (or alternatively, multiple AD-specific subnets in different availability domains). If an availability domain specified for an application ceases to be available, Oracle Functions runs functions in an alternative availability domain.

Concurrency and Scalability

Concurrency refers to the ability of a system to run multiple operations in parallel using shared resources. Scalability refers to the ability of the system to scale capacity (both up and down) to meet demand.

In the case of Functions, when a function is invoked for the first time, the function's image is run as a container on an instance in a subnet associated with the application to which the function belongs. When the function is executing inside the container, the function can read from and write to other shared resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services.

If Oracle Functions receives multiple calls to a function that is currently executing inside a running container, Oracle Functions automatically and seamlessly scales horizontally to serve all the incoming requests. Oracle Functions starts multiple Docker containers, up to the limit specified for your tenancy. The default limit is 60 GB of RAM reserved for function execution per availability domain, although you can request an increase to this limit. Provided the
When a tenancy is configured, you will have access, via a suitable policy and user account, to a compartment that has a VCN with at least one public subnet (and an internet gateway) or at least one private subnet (and a service gateway). For more information about these network components, see Networking on page 2746.

You will also have access to a Docker registry in which to store images. This documentation assumes you will be using Oracle Cloud Infrastructure Registry as your Docker registry and provides instructions accordingly. For more information, see Overview of Registry on page 3506.

• You must have configured your client environment for functions development. There are a number of different client environment configuration tasks to complete. For more information, see Configuring Your Client Environment for Function Development on page 2045.

To get set up and running quickly with Oracle Functions, see the Quick Start Guides.

### Availability by Region

Oracle Functions is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 180. Refer to that topic to see region identifiers, region keys, and availability domain names.

### Configuring Your Tenancy for Function Development

Before you can start using Oracle Functions to create and deploy functions, you have to set up your tenancy for function development.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. Oracle Functions users are typically not members of the Administrators group, and do not have to be. However, a member of the Administrators group does need to perform a number of administrative tasks to enable users to use Oracle Functions.

To set up your tenancy for function development, you have to complete the following tasks in the order shown in this checklist (the instructions in the topics below assume that you are a tenancy administrator):

<table>
<thead>
<tr>
<th>Task #</th>
<th>Tenancy Configuration Task</th>
<th>Done?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><strong>Create Groups and Users to use with Oracle Functions, if they don't exist already</strong> on page 2039</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><strong>Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already</strong> on page 2039</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><strong>Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already</strong> on page 2040</td>
<td></td>
</tr>
</tbody>
</table>
Click each of the links in turn, and follow the instructions.

When you have set up your tenancy for function development, the next step is to set up your client development environment (see Configuring Your Client Environment for Function Development on page 2045).

Create Groups and Users to use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create Oracle Cloud Infrastructure user accounts, along with a group to which the user accounts belong. Later on, you'll define policies to give the group (and the user accounts that belong to it) access to function-related resources. If a suitable group and user accounts already exist, there's no need to create new ones.

To create groups and users to use with Oracle Functions:

1. Log in to the Console as a tenancy administrator.
2. If a suitable group for Oracle Functions users doesn't exist already, create such a group as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list of the groups in your tenancy is displayed.
   b. Click Create Group and create a new group (see To create a group on page 2420). Give the group a meaningful name (for example, acme-functions-developers) and description. Avoid entering confidential information.
3. If suitable user accounts for Oracle Functions users don't exist already, create users as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
   b. Click Create User and create one or more new users (see To create a user on page 2417).
4. If they haven't been added already, add users to the group to use Oracle Functions as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
   b. Select one or more users and add them to the group authorized to use Oracle Functions (see To add a user to a group on page 2417).

Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create:

- a compartment to own network resources (a VCN, a public or private subnet, and other resources such as an internet gateway or service gateway, a route table, security lists)
• a compartment to own function-related resources (functions, applications)

Note that the same compartment can own both network resources and function-related resources. Alternatively, you can create two separate compartments for network resources and function-related resources.

If suitable compartments already exist, there’s no need to create new ones.

To create a compartment to own network resources and/or function-related resources in the tenancy:

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A list of the compartments in your tenancy is displayed.
3. Click Create Compartment and create a new compartment (see To create a compartment on page 2442). Give the compartment a meaningful name (for example, acme-network, acme-functions-compartment) and description. Avoid entering confidential information.

Create the VCN and Subnets to Use with Oracle Functions, if they don’t exist already

Before users can start using Oracle Functions to create and deploy functions, a VCN containing the subnets in which to create functions and applications must already exist. The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong.

Each subnet in the VCN must have a CIDR block that provides at least a certain minimum number of free IP addresses, as follows:

• AD-specific subnets must have a minimum of 12 free IP addresses
• regional subnets must have a minimum of 32 free IP addresses

Note that Oracle strongly recommends each subnet has a CIDR block that provides more than the minimum number of free IP addresses.

To support the largest possible number of concurrent connections, Oracle also strongly recommends that the security lists used by subnets in the VCN only have stateless rules.

If a suitable VCN already exists, there's no need to create a new one.

If you do decide to create a new VCN, you have several options, including the following:

• You can create the new VCN and have related resources created automatically at the same time, using one of the VCN wizards. For example, this topic describes how to use the VCN with Internet Connectivity wizard to create a VCN. As well as creating the VCN, the VCN with Internet Connectivity wizard creates a public regional subnet and a private regional subnet, along with an internet gateway, a NAT gateway, and a service gateway. The VCN with Internet Connectivity wizard also creates route tables and security lists. For more information about the VCN wizards, see Virtual Networking Quickstart on page 2820.
• You can create just the VCN initially, and then create the related resources yourself later (see VCNs and Subnets on page 2821). In this case, you can choose which of the following to create:
  
  • Public subnets and an internet gateway (see Internet Gateway on page 3243). In this case, a route table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to All <region> services In Oracle Services Network, and its IP Protocol property set to All).
  
  • Private subnets and a service gateway (see Access to Oracle Services: Service Gateway on page 3256). In this case, the service gateway must be set up to allow access to All <region> Services In Oracle Services Network. A route table must include a route rule that targets the service gateway, with its Destination Service property set to All <region> Services In Oracle Services Network. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to
All <region> services In Oracle Services Network, and its IP Protocol property set to All).

For example, if you don't want to expose traffic over the public internet, create private subnets and a service gateway (see Oracle Functions Support for Private Network Access on page 2094).

Note that to use an external logging destination like Papertrail, you have to create a VCN with public subnets (see Storing and Viewing Function Logs on page 2078).

To create a VCN to use with Oracle Functions, using the VCN with Internet Connectivity wizard to create related resources automatically:

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
3. Choose the compartment that will own the network resources (on the left side of the page). For example, acme-network.

The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong. The page updates to display only the resources in that compartment.

4. Click Start VCN Wizard to create a new VCN.
5. In the Start VCN Wizard dialog box, select VCN with Internet Connectivity and click Start VCN Wizard.

Note that the following instructions assume that you select the VCN with Internet Connectivity wizard to create the VCN and related resources automatically. However, if a different VCN wizard is a better fit for your requirements, select that wizard instead and configure it appropriately (see Virtual Networking Quickstart on page 2820).

6. On the Configuration page, enter:
   - **Name**: A meaningful name for the cloud network, such as acme-functions-vcn. The name doesn't have to be unique, but it cannot be changed later in the Console. Avoid entering confidential information.
   - **Compartment**: The compartment that will own the network resources (by default, the compartment you selected earlier is shown). For example, acme-network.
   - **VCN CIDR Block, Public Subnet CIDR Block, and Private Subnet CIDR Block**: CIDR blocks for the VCN, and the public and private regional subnets. The CIDR blocks you specify for the regional subnets must not overlap, and must have a minimum of 32 free IP addresses.
   - **Use DNS Hostnames in this VCN**: Select this option.
7. Click Next and on the Review and Create page, verify the details of the VCN and related resources that will be created.
8. Click Create to create the VCN, along with the related resources.
9. Click View Virtual Cloud Network to see details of the VCN and the related resources that have been created.

**Create Policies to Control Access to Network and Function-Related Resources**

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create a number of Oracle Cloud Infrastructure policies to grant access to function-related and network resources. You have to:

- Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories on page 2043
- Create a Policy to Give Oracle Functions Users Access to Function-Related Resources on page 2043
- Create a Policy to Give Oracle Functions Users Access to Logging Resources on page 2044
- Create a Policy to Give Oracle Functions Users Access to Network Resources on page 2045

See Details for Functions on page 2276 for more information about policies.

**Tip:**

As an alternative to creating separate policies to grant access to network and function-related resources, you can create a single policy containing all the necessary policy statements. A quick way to create such a policy is to use
the Policy Builder and select the policy template Let users create, deploy,
and manage functions and applications using Cloud Shell on page 2158.
This policy template contains all the policy statements required to use Oracle
Functions. See Writing Policy Statements with the Policy Builder on page
2451.

### Summary of Policies to Create for Oracle Functions

<table>
<thead>
<tr>
<th>Policy to give:</th>
<th>Where to create the policy:</th>
<th>Statement:</th>
<th>More information and examples:</th>
</tr>
</thead>
</table>
| Users access to repositories in Oracle Cloud Infrastructure Registry | Root compartment | Allow group <group-name> to manage repos in tenancy  
Allow group <group-name> to read objectstorage-namespaces in tenancy | Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories on page 2043 |
| Users access to function-related resources | Compartment that owns function-related resources | Allow group <group-name> to manage functions-family in compartment <compartment-name>  
Allow group <group-name> to read metrics in compartment <compartment-name> | Create a Policy to Give Oracle Functions Users Access to Function-Related Resources on page 2043 |
| Users access to logging resources | Root compartment | Allow group <group-name> to read logging-family in tenancy  
Allow group <group-name> to manage logging-family in compartment <compartment-name> | Create a Policy to Give Oracle Functions Users Access to Logging Resources on page 2044 |
| Users access to network resources | Compartment that owns network resources | Allow group <group-name> to use virtual-network-family in compartment <compartment-name> | Create a Policy to Give Oracle Functions Users Access to Network Resources on page 2045 |
Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories

When Oracle Functions users work with functions, they have to access repositories in Oracle Cloud Infrastructure Registry. Users can only access repositories that the groups to which they belong have been granted access. To enable users to access a repository, you must create an identity policy to grant the groups access to that repository.

To create a policy to give Oracle Functions users access to repositories in Oracle Cloud Infrastructure Registry:

1. Log in to the Console as a tenancy administrator and create a new policy in the root compartment:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-functions-developers-ocir-access).

2. Specify a policy statement to enable the group to obtain the auto-generated Object Storage namespace string of the tenancy (required to log in to Oracle Cloud Infrastructure Registry):

   ```
   Allow group <group-name> to read objectstorage-namespaces in tenancy
   ```

   where `<group-name>` is the name of the group to which users using Oracle Functions belong.

   For example:

   ```
   Allow group acme-functions-developers to read objectstorage-namespaces in tenancy
   ```

   The above policy statement also provides access to function logs stored in a storage bucket in Oracle Cloud Infrastructure Object Storage (see Storing and Viewing Function Logs on page 2078).

3. Specify a policy statement to give the group access to repositories in Oracle Cloud Infrastructure Registry:

   ```
   Allow group <group-name> to manage repos in tenancy
   ```

   where `<group-name>` is the name of the group to which users using Oracle Functions belong.

   For example:

   ```
   Allow group acme-functions-developers to manage repos in tenancy
   ```

   The above policy statement gives the group permission to manage all repositories in the tenancy. If you consider this to be too permissive, then you can restrict the repositories to which the group has access by including a where clause in the manage repos statement. Note that if you do include a where clause, you must also include a second statement in the policy to enable the group to inspect all repositories in the tenancy (when using the Console).

   For example, the following policy statements restrict the group to accessing only repositories with names that start 'acme-web-app', but also enables the group to inspect all repositories in the tenancy:

   ```
   Allow group acme-functions-developers to inspect repos in tenancy
   Allow group acme-functions-developers to manage repos in tenancy where all {target.repo.name=/acme-web-app*/ }
   ```

4. Click Create.

Create a Policy to Give Oracle Functions Users Access to Function-Related Resources

When Oracle Functions users create functions and applications, they have to specify a compartment for those function-related resources (including for metrics emitted by Oracle Functions). Users can only specify a compartment that the groups to which they belong have been granted access. To enable users to specify a compartment, you must create an identity policy to grant the groups access to that compartment.
To create a policy to give Oracle Functions users access to function-related resources in the compartment that will own those resources:

1. Log in to the Console as a tenancy administrator and create a new policy in the compartment that will own Oracle Functions resources:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-functions-developers-manage-access).

2. Specify a policy statement to give the group access to all function-related resources in the compartment:

   Allow group <group-name> to manage functions-family in compartment <compartment-name>

   For example:

   Allow group acme-functions-developers to manage functions-family in compartment acme-functions-compartment

3. Specify a second policy statement to give the group access to metrics emitted by Oracle Functions:

   Allow group <group-name> to read metrics in compartment <compartment-name>

   For example:

   Allow group acme-functions-developers to read metrics in compartment acme-functions-compartment

4. Click Create.

Create a Policy to Give Oracle Functions Users Access to Logging Resources

When Oracle Functions users define an application, they can enable logging to store and view function logs in the Oracle Cloud Infrastructure Logging service. Users can only view logs that the groups to which they belong have been granted access. To enable users to store and view function logs in the Oracle Cloud Infrastructure Logging service, you must create an identity policy to grant the groups access to logging resources.

To create a policy to enable Oracle Functions users to store and view function logs in the Oracle Cloud Infrastructure Logging service:

1. Log in to the Console as a tenancy administrator and create a new policy in the tenancy:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-functions-developers-logging-access).

2. Specify a policy statement to give the group read access to all logging resources in the tenancy:

   Allow group <group-name> to read logging-family in tenancy

   For example:

   Allow group acme-functions-developers to read logging-family in tenancy
3. Specify a policy statement to give the group full access to logging resources in the compartment that will own logging resources:

```
Allow group <group-name> to manage logging-family in compartment <compartment-name>
```

For example:

```
Allow group acme-functions-developers to manage logging-family in compartment acme-functions-compartment
```

4. Click Create.

**Create a Policy to Give Oracle Functions Users Access to Network Resources**

When Oracle Functions users create a function or application, they have to specify a VCN and a subnet in which to create them. Users can only specify VCNs and subnets in compartments that the groups to which they belong have been granted access. To enable users to specify a VCN and subnet, you must create an identity policy to grant the groups access to the compartment.

To create a policy to give Oracle Functions users access to network resources:

1. Log in to the Console as a tenancy administrator and create a new policy in the compartment that will own network resources:
   
a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   
b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-functions-developers-manage-network-access).

2. Specify a policy statement to give the group access to the network resources in the compartment:

```
Allow group <group-name> to use virtual-network-family in compartment <compartment-name>
```

For example:

```
Allow group acme-functions-developers to use virtual-network-family in compartment acme-network
```

3. Click Create.

**Configuring Your Client Environment for Function Development**

Before you can start using Oracle Functions to create and deploy functions, you have to set up your client environment for function development. Note that prior to setting up your client environment, you must already have set up your tenancy (see Configuring Your Tenancy for Function Development on page 2038).

**Different Options for Function Development Environments**

When setting up your Oracle Functions development environment, you have different options:

- **Option 1: Setting up Cloud Shell. (Recommended)** For users trying out Oracle Functions for the first time, this is the recommended way to get started quickly. By copying and pasting a few commands from the Console into the Cloud Shell window, you can set up an Oracle Functions development environment in just a few minutes.

  This option enables you to experiment creating, deploying, and invoking new functions. You can also explore Oracle Functions using the samples on Git Hub (see Oracle Functions Samples). If you want to set up Cloud Shell as your Oracle Functions development environment, see the instructions in the Oracle Functions on Cloud Shell Quick Start Guide.
Functions

- **Option 2: Setting up a local machine.** For most users (especially Mac and Linux users), this will be the way to work with Oracle Functions. If you set up a local machine, you'll have to specify `--provider oracle` when you create a new Fn Project CLI context.

  This option enables Oracle Functions to perform authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

  This documentation assumes you want to set up a local machine as your client environment, and provides instructions accordingly (see Setting up a Local Machine as a Development Environment on page 2046). Instructions for setting up a local machine are also included in the Oracle Functions in a Local Dev Environment Quick Start Guide.

- **Option 3: Setting up an Oracle Cloud Infrastructure compute instance.** For some users, this will be more convenient than setting up a local machine. If you set up an Oracle Cloud Infrastructure compute instance, you'll have to specify `--provider oracle-ip` when you create a new Fn Project CLI context.

  This option enables Oracle Functions to perform authentication and authorization using instance OCIDs, dynamic groups, and policies granting permissions to those dynamic groups. This approach removes the requirement for users to manage private keys. Note that to set up an Oracle Functions development environment on an Oracle Cloud Infrastructure compute instance, you must:
  
  - have permission to create dynamic groups
  - create a new dynamic group that includes the compute instance's OCID
  - create a policy to give the new dynamic group access to function resources, network resources, and Oracle Cloud Infrastructure Registry
  - specify `--provider oracle-ip` when you create a new Fn Project CLI context

  If you want to set up an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, see the instructions in the Oracle Functions on an OCI Compute Instance Quick Start Guide.

### Setting up a Local Machine as a Development Environment

To set up a local machine as your client environment for function development, you have to complete the following tasks in the order shown in this checklist:

<table>
<thead>
<tr>
<th>Task #</th>
<th>Development Environment Configuration Task</th>
<th>Done?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2047</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>3. Create and Configure a Copy of oci-curl on page 2050</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>4. Install Docker for Use with Oracle Functions on page 2052</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>5. Install the Fn Project CLI on page 2053</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2055</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2056</td>
<td></td>
</tr>
</tbody>
</table>
Click each of the links in the checklist in turn, and follow the instructions.

When you have completed all of the development environment configuration tasks, confirm your configuration is correct (see Verifying Your Configuration for Function Development on page 2058).

1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions

Before using Oracle Functions, you have to set up an Oracle Cloud Infrastructure API signing key.

The instructions in this topic assume:

- you are using Linux
- you are following Oracle's recommendation to provide a passphrase to encrypt the private key

For more information and other options, see Required Keys and OCIDs on page 4179.

The instructions below describe how to create a new ~/.oci directory, how to generate a new private key file and public key file in that ~/.oci directory, how to upload the public key to Oracle Cloud Infrastructure to create a new API signing key, and how to obtain a fingerprint for the public API key. Be aware that instructions and examples elsewhere in this documentation assume the ~/.oci directory exists and contains the private and public key files.

If your user account already has an API signing key, create the ~/.oci directory if it doesn't exist, and then go straight to 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049.

If your user account doesn't already have an API signing key, follow the steps below, but note the following:

- If the ~/.oci directory doesn't exist, create it.
- If the ~/.oci directory already exists, go straight to the step below that instructs you to generate a private key file.
- If the ~/.oci directory already exists and already contains a private key file and public key file, and you know the passphrase that was used to encrypt the existing private key file, there's no need to create new private and public key files. Instead, go straight to the step below that instructs you to create a new API signing key and upload the public key value to Oracle Cloud Infrastructure to obtain a fingerprint.
- If you already have a private key file and public key file but they are not in the ~/.oci directory, and you know the passphrase that was used to encrypt the existing private key file, there's no need to create new private and public key files. Having created the ~/.oci directory if it doesn't exist, go straight to the step below that instructs you to create a new API signing key and upload the public key value to Oracle Cloud Infrastructure to obtain a fingerprint.

To set up an API signing key:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that the ~/.oci directory does not already exist. For example, by entering:

   ```bash
   ls ~/.oci
   ```

3. Assuming the ~/.oci directory does not already exist, create it. For example, by entering:

   ```bash
   mkdir ~/.oci
   ```
4. Generate a private key encrypted with a passphrase that you provide by entering:

```bash
openssl genrsa -out ~/.oci/<private-key-file-name>.pem -aes128 2048
```

where `<private-key-file-name>` is a name of your choice for the private key file (for example, `john_api_key_private.pem`).

For example:

```bash
openssl genrsa -out ~/.oci/john_api_key_private.pem -aes128 2048
```

The output from the above command shows the status of the private key generation operation, and prompts you for a passphrase:

```bash
Generating RSA private key, 2048 bit long modulus
....+++ .................................................................+++ 
```

```bash
e is 65537 (0x10001) 
```

```bash
Enter pass phrase for /Users/johndoe/.oci/john_api_key_private.pem: 
```

5. When prompted, enter a passphrase to encrypt the private key file. Be sure to make a note of the passphrase you enter, as you will need it later.

6. When prompted, re-enter the passphrase to confirm it.

7. Confirm that the private key file has been created in the directory you specified. For example, by entering:

```bash
ls -l ~/.oci/john_api_key_private.pem
```

The output from the above command confirms the creation of the private key file.

```bash
-rw-r--r-- 1 johndoe staff 1766 Jul 14 00:24 /Users/johndoe/.oci/john_api_key_private.pem
```

8. Change permissions on the file to ensure that only you can read it. For example, by entering:

```bash
chmod go-rwx ~/.oci/john_api_key_private.pem
```

9. Generate a public key (in the same location as the private key file) by entering:

```bash
openssl rsa -pubout -in ~/.oci/<private-key-file-name>.pem -out ~/.oci/<public-key-file-name>.pem
```

where:

- `<private-key-file-name>` is what you specified earlier as the name of the private key file (for example, `john_api_key_private.pem`)
- `<public-key-file-name>` is a name of your choice for the public key file (for example, `john_api_key_public.pem`)

For example:

```bash
openssl rsa -pubout -in ~/.oci/john_api_key_private.pem -out ~/.oci/john_api_key_public.pem
```

The output from the above command shows the status of the public key generation operation, and prompts you for a passphrase:

```bash
Enter pass phrase for /Users/johndoe/.oci/john_api_key_private.pem: 
```

10. When prompted, enter the same passphrase you previously entered to encrypt the private key file.
11. Confirm that the public key file has been created in the directory you specified. For example, by entering:

```
ls -l ~/.oci/
```

The output from the above command confirms the creation of the public key file.

```
-rw------- 1 johndoe staff 1766 Jul 14 00:24 john_api_key_private.pem
-rw-r----- 1 johndoe staff 451 Jul 14 00:55 john_api_key_public.pem
```

12. Copy the contents of the public key file you just created. For example, by entering:

```
cat ~/.oci/john_api_key_public.pem | pbcopy
```

13. Having created the API key pair, upload the public key value to Oracle Cloud Infrastructure:

   a. Log in to the Console as the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions.
   
   b. In the top-right corner of the Console, open the Profile menu (👤) and then click User Settings to view the details.
   
   c. On the API Keys page, click Add Public Key.
   
   d. Paste the public key's value into the window and click Add.
   
   e. (Optional) Note the fingerprint value. You'll use the fingerprint in a subsequent configuration task, so you might want to copy it to a convenient and secure location.

When you have completed the steps in this topic, go on to 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049.

2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File

Before using Oracle Functions, you must have an Oracle Cloud Infrastructure CLI configuration file that contains the credentials of the user account that you will be using to create and deploy functions. These user account credentials are referred to as a 'profile'.

By default, the Oracle Cloud Infrastructure CLI configuration file is located at `~/.oci/config`. You might already have a configuration file as a result of installing the Oracle Cloud Infrastructure CLI. However, you don't need to have installed the Oracle Cloud Infrastructure CLI in order to use Oracle Functions.

The Oracle Cloud Infrastructure CLI configuration file can contain several profiles. If you already have a configuration file containing one or more profiles, you have to add a new profile to the existing file for the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions.

The instructions in this topic assume:

- you are using Linux
- you have already completed the steps in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2047

To create a profile in the Oracle Cloud Infrastructure CLI configuration file for the user account that you will be using to create and deploy functions:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm the contents of the `~/.oci` directory. For example, by entering:

```
ls -l ~/.oci/
```

The output from the above command shows the contents of the `~/.oci` directory:

```
-rw------- 1 johndoe staff 1766 Jul 14 00:24 john_api_key_private.pem
```
3. Do one of the following, depending on whether the ~/.oci directory already contains a file called config:
   • If the ~/.oci directory already contains a file called config, open the file in a text editor.
   • If the ~/.oci directory doesn't yet contain a file called config, create the file and open it in a text editor. For example, by entering:

     vim ~/.oci/config

4. Add a new profile to the ~/.oci/config file as follows:

   [<profile-name>]
   user=<user-ocid>
   fingerprint=<public-key-fingerprint>
   key_file=<full-path-to-private-key-pem-file>
   tenancy=<tenancy-ocid>
   region=<region-identifier>
   pass_phrase=<passphrase>

where:

   • <profile-name> is a name of your choosing for the profile.
   • <user-ocid> is the OCID of the Oracle Cloud Infrastructure user account you will be using to create and deploy functions. See Where to Get the Tenancy's OCID and User's OCID on page 4184.
   • <public-key-fingerprint> is the fingerprint of the public API key value that you uploaded in the Console in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2047.
   • <full-path-to-private-key-pem-file> is the full path to the private key file that you created in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2047.
   • <tenancy-ocid> is the OCID of the tenancy in which you will be creating and deploying functions. See Where to Get the Tenancy's OCID and User's OCID on page 4184.
   • <region-identifier> is the identifier of the Oracle Cloud Infrastructure region in which you will be creating and deploying functions. For example, us-phoenix-1. See Availability by Region on page 2038.
   • <passphrase> is the passphrase you entered in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2047).

For example:

   [john-oci-profile]
   user=ocid1.user.oc1..aaaaaaaas...7ap
   key_file=~/.oci/john_api_key_private.pem
   tenancy=ocid1.tenancy.oc1..aaaaaaap...keq
   region=us-phoenix-1
   pass_phrase=<your-passphrase>

When you have completed the steps in this topic, go on to 3. Create and Configure a Copy of oci-curl on page 2050.

**3. Create and Configure a Copy of oci-curl**

You can use a bash script provided by Oracle (commonly referred to as oci-curl) to invoke a function. The oci-curl script creates a signed request, based on credentials you provide in the body of the script. For more information about oci-curl, see Request Signatures - Bash.

To use oci-curl to invoke a function, you must provide the credentials of an Oracle Cloud Infrastructure user that has been granted access to resources in the same tenancy and belonging to the same compartment as the function (see Create Policies to Control Access to Network and Function-Related Resources on page 2041).
Typically you'll want to invoke a function as the functions developer that's configured for your development environment. The instructions below assume that is the case.

The instructions in this topic assume you have already completed the steps in 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049.

To create and configure a copy of oci-curl:

1. Log in to your development environment as a functions developer.
2. Create a copy of the oci-curl script file in your development environment and add your credentials to the file as follows:
   a. In a browser navigate to https://docs.cloud.oracle.com/iaas/Content/Resources/Assets/signing_sample_bash.txt to see the oci-curl code as raw text.
   b. Select all the text and copy it.
   c. In a text editor, open a new file in a convenient location. For example, in a terminal window, you might create a new subdirectory in your home directory and open a new file in that directory by entering:

```
$ cd ~
$ mkdir oci-curl
$ vim ~/oci-curl/oci-curl.sh
```

The name and location of the new file is up to you, but the following instructions assume `~/oci-curl/oci-curl.sh`.

   d. Paste the oci-curl script code that you copied earlier into the new file.
   e. Save the file but leave it open so you can add your credentials.
3. Replace the sample credentials in the oci-curl.sh file with those of the user account that you want to invoke functions, as follows:
   a. Locate the following lines in the oci-curl.sh file that contain sample credential values:

```
# TODO: update these values to your own
local tenancyId="ocid1.tenancy.oc1..aaaaaaaab______dsq";
local authUserId="ocid1.user.oc1..aaaaaaaas______o3r";
local privateKeyPath="/Users/someuser/.oci/oci_api_key.pem";
```

   Tip:

Typically you'll want to invoke a function as the functions developer that's configured for your development environment. If that's the case,
open the ~/.oci/config file so you can easily copy values from there to replace the sample values in the oci-curl.sh file.

b. Change the value of the tenancyId parameter in the oci-curl.sh file by replacing the sample value in quotes with the OCID of the tenancy in which the function has been deployed. For example:

```
local tenancyId="ocid1.tenancy.oc1..aaaaaaaap______keq";
```

c. Change the value of the authUserID parameter in the oci-curl.sh file by replacing the sample value in quotes with the OCID of the user account that you want to run the function. The user account must have access to resources in the same tenancy and belonging to the same compartment as the function. For example:

```
local authUserId="ocid1.user.oc1..aaaaaas______7ap";
```

d. Change the value of the keyFingerprint parameter in the oci-curl.sh file by replacing the sample value in quotes with the fingerprint of the user's public key uploaded to Oracle Cloud Infrastructure. For example:

```
```

e. Change the value of the privateKeyPath parameter in the oci-curl.sh file by replacing the sample value in quotes with the full path to the private key file that is paired with the public key for which you provided the fingerprint. For example:

```
local privateKeyPath="/Users/johndoe/.oci/john_api_key_private.pem";
```

4. Save and close the oci-curl.sh file.

**Note:**

When you've deployed functions to Oracle Functions and you want to use oci-curl to invoke them, you will first have to run the `source` command to set up the current shell environment for oci-curl. See Invoking Functions on page 2071.

When you have completed the steps in this topic, go on to 4. Install Docker for Use with Oracle Functions on page 2052.

4. **Install Docker for Use with Oracle Functions**

Before using Oracle Functions, a version of Docker supported by Fn Project must be installed in your development environment. If Docker is not already installed, or the installed version of Docker is not supported, you'll have to install or upgrade Docker.

The instructions in this topic assume you have already completed the steps in 3. Create and Configure a Copy of oci-curl on page 2050.

To confirm that a supported version of Docker is installed in your development environment:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that Docker is installed by entering:

```
docker version
```

3. Do one of the following, depending on the message you see:

- If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding to the next step. See the Docker documentation for information about installing Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.
- If you see a message indicating the version of Docker that's installed, go to the next step.
4. Assuming Docker is installed, go to the Fn Project home page on GitHub to confirm that the installed version of Docker is at least the minimum version specified in the Pre-requisites section. If the installed version of Docker is not supported by Fn Project, you have to upgrade the version of Docker before proceeding. See the Docker documentation for information about upgrading Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.

When you have completed the steps in this topic, go on to 5. Install the Fn Project CLI on page 2053.

5. Install the Fn Project CLI

Before using Oracle Functions, the Fn Project CLI must be installed in your development environment. You can install the Fn Project CLI in a number of different ways according to your environment. The instructions in this topic assume you have already completed the steps in 4. Install Docker for Use with Oracle Functions on page 2052.

To install the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. Open the README.md file in the fnproject/cli repository on GitHub and follow the appropriate instructions for installing the Fn Project CLI in your development environment. As a convenient overview, the instructions are summarized below:
   • In a MacOS environment using Homebrew, install the Fn Project CLI by entering:
     `brew install fn`
   • In a Linux or MacOS environment, install the Fn Project CLI by entering:
     `curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh`
     If prompted for a password, enter the superuser's password.
   • In a Linux, MacOS, or Windows environment, install the Fn Project CLI by downloading the binary from the Releases page and running it.
3. In a terminal window, confirm that the CLI has been installed by entering:
   `fn version`

Assuming the Fn Project CLI has been installed correctly, you'll see a message indicating the version of the CLI that has been installed.

When you have completed the steps in this topic, go on to 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053.

6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure

Before using Oracle Functions, you have to configure the Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy. When the Fn Project CLI is initially installed, it's configured for a local development 'context'. To configure Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy instead, you have to create a new context. The context specifies Oracle Functions endpoints, the OCID of the compartment to which deployed functions will belong, and the address of the Docker registry to and from which to push and pull images.

You can define multiple contexts, each stored in a different context file in .yaml format. By default, the individual context files are stored in the `~/.fn/contexts` directory. The `~/.fn/config.yaml` file specifies which context file Fn Project uses.

To create a new context, you can create a new context file manually and edit the `~/.fn/config.yaml` file by hand to point to that file. Alternatively, you can use the Fn Project CLI to interactively create the new context file and instruct the Fn Project CLI to start using that file, as described below.
The instructions in this topic assume you have already completed the steps in 5. Install the Fn Project CLI on page 2053.

To create a new context file using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create the new Fn Project CLI context for Oracle Cloud Infrastructure by entering:

   `fn create context <my-context> --provider oracle`

   where `<my-context>` is a name of your choosing. For example:

   `fn create context johns-oci-context --provider oracle`

3. Specify that the Fn Project CLI is to use the new context by entering:

   `fn use context <my-context>`

   where `<my-context>` is the name you specified in the previous step. For example:

   `fn use context johns-oci-context`

4. Configure the new context with the OCID of the compartment that you want to own the deployed functions (you might have created a new compartment specifically for this purpose, see Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already on page 2039) by entering:

   `fn update context oracle.compartment-id <compartment-ocid>`

   For example:

   `fn update context oracle.compartment-id ocid1.compartment.oc1..aaaaaaaarvdfa72n...`

5. Configure the new context with the api-url endpoint to use when calling the API by entering:

   `fn update context api-url <api-endpoint>`

   where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format https://functions.<region-identifier>.oci.oraclecloud.com. The `<region-identifier>` in `<api-endpoint>` is the identifier of the Oracle Cloud Infrastructure region in which you'll be creating and deploying functions. For example, us-phoenix-1.

   For example:

   `fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com`
6. Configure the new context with the address of the Docker registry that you want to use with Oracle Functions by entering:

```
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

where:

- `<region-key>` is the key of the Oracle Cloud Infrastructure Registry region. For example, `phx` for Phoenix. See Availability by Region on page 3508.
  
  Oracle recommends that the Docker registry you specify is in the same region as the subnet on which you intend functions to run.

- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the Tenancy Information page). For example, the namespace of the `acme-dev` tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

- `<repo-name>` is a repository name to pre-pend to the names of functions that you deploy.

  For example:

```
fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo
```

7. (Optional) Verify the Fn Project CLI context you've created by viewing the context file. For example, by entering:

```
more ~/.fn/contexts/johns-oci-context.yaml
```

The context file contains:

```
api-url: https://functions.us-phoenix-1.oci.oraclecloud.com
provider: oracle
registry: phx.ocir.io/ansh81vru1zp/acme-repo
```

When you have completed the steps in this topic, go on to 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2055.

**7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter**

Before using Oracle Functions, you have to configure the Fn Project CLI to use the new profile you added to the Oracle Cloud Infrastructure CLI configuration file `~/.oci/config` (see 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049). The profile you added contains the credentials of the user account you'll be using to create and deploy functions.

Note that unless you specify otherwise, the Fn Project CLI will attempt to use a profile in the `~/.oci/config` file named `default`.

The instructions in this topic assume you have already completed the steps in 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053.

To configure the Fn Project CLI to use the profile you've created for use with Oracle Functions:

1. Log in to your development environment as a functions developer.

2. In a terminal window, configure the Fn Project CLI context with the name of the profile you've created for use with Oracle Functions by entering:

```
fn update context oracle.profile <profile-name>
```

For example:

```
fn update context oracle.profile john-oci-profile
```
When you have completed the steps in this topic, go on to 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2056.

8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry

Before using Oracle Functions, the user account you'll be using to create and deploy functions must have an Oracle Cloud Infrastructure auth token. You use the auth token as the password when logging Docker in to Oracle Cloud Infrastructure Registry

The instructions in this topic assume you have already completed the steps in 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2055.

If the user account already has an auth token, go straight on to 9. Start Docker on page 2056. Otherwise, if the user account does not have an auth token, generate an auth token now.

To generate an auth token for the user account you'll be using to create and deploy functions:

1. Log in to the Console as a functions developer.
2. In the top-right corner of the Console, open the Profile menu ( ) and then click User Settings to view the details.
3. On the Auth Tokens page, click Generate Token.
4. In the Generate Token dialog:
   a. Enter a meaningful description for the auth token. For example, John's auth token for use with Oracle Functions. Avoid entering confidential information.
   b. Click Generate Token. The new auth token is displayed. For example, 6<!)N___________6MqX.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

When you have completed the steps in this topic, go on to 9. Start Docker on page 2056.

9. Start Docker

Before using Oracle Functions, Docker must be running in your development environment. If it is not running, you must start Docker before proceeding.

The instructions in this topic assume you have already completed the steps in 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2056.

To verify that Docker is running:

1. Log in to your development environment as a functions developer.
2. In a terminal window, launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:
   
   docker run hello-world

3. Do one of the following, depending on the message you see:
   - If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation for information about starting Docker on your platform.
   - If you see an error message indicating that the network timed out while trying to connect and advising you to check your internet connection or whether you are behind a proxy, your development environment might be behind a corporate proxy server or firewall. In which case, you will probably need to set the http_proxy, https_proxy, and no_proxy environment variables. Ask your network administrator for advice.
   - If you see a message like the one shown below, Docker is already running and you can proceed:

```
Hello from Docker.
This message shows that your installation appears to be working correctly.
```
When you have completed the steps in this topic, go on to 10. Log in to Oracle Cloud Infrastructure Registry on page 2057.

### 10. Log in to Oracle Cloud Infrastructure Registry

Before using Oracle Functions, you have to log Docker in to the Docker registry in which you are going to store your functions as Docker images. This is the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

You can store functions in public and private repositories in Oracle Cloud Infrastructure Registry, an Oracle-managed registry built on top of Oracle Cloud Infrastructure.

When you log Docker into a Docker registry, you have to provide the appropriate authentication details. For example, in the case of Oracle Cloud Infrastructure Registry, you have to provide the tenancy Object Storage namespace, the user name, and the user's auth token.

The instructions in this topic assume you have already completed the steps in 9. Start Docker on page 2056.

To log Docker into Oracle Cloud Infrastructure Registry:

1. **Log in to your development environment as a functions developer.**
2. **In a terminal window, log in to Oracle Cloud Infrastructure Registry by entering:**
   ```
docker login <region-key>.ocir.io
   ```
   where `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053). For example, `phx` for Phoenix. See Availability by Region on page 3508.
   
   For example:
   ```
docker login phx.ocir.io
   ```
3. **When prompted for **Username**, enter the name of the user you will be using with Oracle Functions to create and deploy functions, in the format:**
   ```
   <tenancy-namespace>/<username>
   ```
   where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the **Tenancy Information** page). For example, `ansh81vrulzp/jdoe@acme.com`.
   
   Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).
   
   If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.
   
   You must have already generated an Oracle Cloud Infrastructure auth token for the user you specify (see 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2056).
4. **When prompted for **Password**, enter the user's Oracle Cloud Infrastructure auth token.** Having entered the password, Docker might warn you that the password is stored unencrypted in the Docker configuration file. The warning includes a link to the Docker documentation where you can find out how to configure a credential helper. Oracle recommends you review the information in the Docker documentation and consider using an external credentials store for increased security.

When you have completed the steps in this topic, you have completed the configuration tasks for your client environment. Go on to Verifying Your Configuration for Function Development on page 2058 to confirm that the Fn Project CLI can communicate with the API endpoint.
Verifying Your Configuration for Function Development

Before using Oracle Functions, it's a good idea to confirm that you have successfully completed:

- the tasks for Configuring Your Tenancy for Function Development on page 2038
- the tasks for Configuring Your Client Environment for Function Development on page 2045

If you have successfully completed the configuration tasks, the Fn Project CLI will be able to communicate with the API endpoint.

To confirm that the Fn Project CLI can communicate with the API endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, try and view a list of applications that have been defined in Oracle Functions by entering:

   ```
   fn list apps
   ```

3. If you see either of the following, you can proceed to create and deploy functions because your system is configured correctly:
   - A message indicating that no applications have been found, which is expected if this is the first time the tenancy has been configured for Oracle Functions.
   - A list of applications that have already been created, which is expected if other users are already using the tenancy for functions development.

4. If you see an error message, it's likely that the Fn Project CLI cannot communicate with the API endpoint due to some incorrect configuration. Do the following:
   - Review the configuration tasks to confirm you completed them as instructed (see Configuring Your Tenancy for Function Development on page 2038 and Configuring Your Client Environment for Function Development on page 2045).
   - Review the solutions for common problems (see Troubleshooting Oracle Functions on page 2097).

Using the Fn Project CLI with Oracle Functions

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions.

To enable you to use the Fn Project CLI with Oracle Functions, you perform a number of preparatory tasks. See Configuring Your Client Environment for Function Development on page 2045.

Most Fn Project CLI commands have a similar syntax:

```
fn [global options] <command> [command options] [subcommands] [arguments]
```

For example, to:

- list all the available applications, use the command:

  ```
  fn list apps
  ```

- create an application, use a command like:

  ```
  fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
  ```

- invoke a function, use a command like:

  ```
  fn invoke helloworld-app helloworld-func
  ```

- change the profile that the Fn Project CLI uses for its context, use a command like:

  ```
  fn update context oracle.profile john-oci-profile
  ```
To see a complete list of Fn Project CLI commands, you can:

- Log in to your development environment as a functions developer and enter `fn --help` or `fn -h` in a terminal window.
- In a web browser, go to the Fn Project CLI documentation.

To see detailed information about individual Fn Project CLI commands, you can:

- Log in to your development environment as a functions developer and enter `fn <command> [subcommand] --help` or `fn <command> [subcommand] -h` in a terminal window. For example:

```
fn create --help
```

```
fn update app -h
```

- In a web browser, go to the Fn Project CLI documentation and select the command from the list.

From time to time, new versions of the Fn Project CLI are released. To:

- See which version of the Fn Project CLI is currently installed and whether it is the most recent version, log in to your development environment as a functions developer and enter `fn version` in a terminal window. The Fn Project CLI version number is displayed. If a more recent version of the Fn Project CLI is available, the number of the latest available version is also displayed.
- Upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in 5. Install the Fn Project CLI on page 2053.

### Creating, Deploying, and Invoking a HelloWorld Function

You can start off using Oracle Functions by using Fn Project CLI commands to:

- create a simple helloworld function written in java
- push the image to the Docker registry that's configured for Oracle Functions
- deploy the function to an application in Oracle Functions
- invoke the function

**Tip:**

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2097).

To get started with Oracle Functions:

1. **Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions on page 2038.** Specifically, that you have:
   - set up your tenancy (see Configuring Your Tenancy for Function Development on page 2038)
   - set up your development environment (see Configuring Your Client Environment for Function Development on page 2045)
2. Log in to the Console as a functions developer.
3. Use the Console to create a new application in Oracle Functions:
   
a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.

b. Select the region you intend to use for Oracle Functions. Oracle recommends that you use the same region as the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

c. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

   The **Applications** page shows the applications already defined in the compartment.

d. Click **Create Application** and specify:
   
   • The name for the new application as helloworld-app.
   • The VCN and subnet (or subnets, up to a maximum of three) in which to run the function. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that subnets are in the same region as the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

   e. Click **Create**.

4. Log in to your development environment as a functions developer.

5. In a terminal window, create a helloworld java function by entering:

   ```
   fn init --runtime java helloworld-func
   ```

   A directory called helloworld-func is created, containing:
   
   • A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
   • A /src directory containing source files and directories for the helloworld function (including /src/main/java/com/example/fn/HelloFunction.java).
   • A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

6. Change directory to the newly created helloworld-func directory.

7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called helloworld-func, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app:

   ```
   fn -v deploy --app helloworld-app
   ```

   The -v option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 2058).
8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the helloworld-func image has been pushed to Oracle Cloud Infrastructure Registry successfully:
   a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Registry**.
   b. Choose the registry’s region.
      You see all the repositories in the registry to which you have access. The image you pushed is in a new repository with a name constructed from:
      - the repository name in the address of the Docker registry in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053)
      - the name of the helloworld-func image
      For example, the new repository might be called `acme-repo/helloworld-func`.
   c. Click the name of the new repository. You see details of the helloworld-func image that's been pushed to Oracle Cloud Infrastructure Registry.

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:
   a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
   b. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
      The **Applications** page shows that an application called helloworld-app has been created.
   c. Click the helloworld-app application to see the functions within it.
      The **Functions** page shows that the helloworld-func function has been deployed to Oracle Functions.

10. In a terminal window, invoke the helloworld-func function by entering:
    ```
    fn invoke helloworld-app helloworld-func
    ```
    The 'Hello World !' message is displayed.

Congratulations! You've successfully created and deployed your first function to Oracle Functions!

**Creating Applications**

You can create applications in Oracle Functions in readiness for deploying functions. An application need not contain any functions.

You can create applications using the Console, the Fn Project CLI, and the API.

For more information about applications, see **Applications** on page 2034.

**Using the Console**

To create a new application in Oracle Functions using the Console:

1. Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in **Preparing for Oracle Functions** on page 2038. Specifically, that you have:
   - set up your tenancy (see **Configuring Your Tenancy for Function Development** on page 2038)
   - set up your development environment (see **Configuring Your Client Environment for Function Development** on page 2045)
2. Log in to the Console as a functions developer.
3. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
4. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
5. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

The Applications page shows the applications already defined in the compartment.

6. Click Create Application and specify:
   - A name for the new application (for example, acmeapp). Avoid entering confidential information.
   - The VCN and subnet (or subnets, up to a maximum of three) in which to run functions. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that the subnets are in the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

7. Click Create.

The new application appears in the list of applications.

Using Fn Project CLI Commands

To create a new application in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new application by entering:

   ```
   fn create app <app-name> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:
   - `<app-name>` is the name of the new application. Avoid entering confidential information.
   - `<subnet-ocid>` is the OCID of the subnet (or subnets, up to a maximum of three) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, specify multiple subnets (enclose each OCID in double quotes separated by commas, in the format '"<subnet-ocid>"'). Oracle recommends that the subnets are in the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

   For example:

   ```
   fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaacnh..."]'
   ```

   An application is created in Oracle Functions, in the tenancy and region implied by the subnet OCID and belonging to the compartment specified in the Fn Project CLI context file.

3. Verify that the new application has been created by entering:

   ```
   fn list apps
   ```

   For example:

   ```
   $ fn list apps
   acmeapp
   ```
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage applications:

- CreateApplication
- DeleteApplication
- GetApplication
- UpdateApplication

Creating and Deploying Functions

You use Fn Project CLI commands to create and deploy functions to Oracle Functions.

Tip:

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2097).

Using Fn Project CLI Commands

To create and deploy a function to Oracle Functions using Fn Project CLI commands:

1. Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions on page 2038. Specifically, that you have:
   - set up your tenancy (see Configuring Your Tenancy for Function Development on page 2038)
   - set up your development environment (see Configuring Your Client Environment for Function Development on page 2045)
2. If the application to which you want to add the function doesn't yet exist in Oracle Functions, create it now using the Fn Project CLI or the Console. For example, you might create a new application called acmeapp. See Creating Applications on page 2061.
3. Log in to your development environment as a functions developer.
4. In a terminal window, change directory to the directory containing the function code.
5. Initialize the function by entering:

```bash
fn init --runtime <runtime-language> <function-name>
```

where:

- `<runtime-language>` is one of the supported runtime languages (currently go, java, node, python, and ruby are supported)
- `<function-name>` is the name to use as the function name. If you don't specify a function name, the name of the current directory (in lower case) is used. Avoid entering confidential information.

For example:

```bash
fn init --runtime java acme-func
```

A directory is created with the function name you specified, containing:

- A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
- A `src` directory containing source files and directories.
- A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

Note that depending on the runtime language you specify, the `fn init` command might create an `/example` directory containing code for a helloworld application. As a matter of good practice, you'll probably want to delete the `/example` directory.

6. Change directory to the newly created directory.

7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image, push the image to the specified Docker registry, and deploy the function to Oracle Functions:

```bash
fn -v deploy --app <app-name>
```

where `<app-name>` is the name of the application in Oracle Functions to which you want to add the function.

For example:

```bash
fn -v deploy --app acmeapp
```

The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 2058).

Note that you can build, push, and deploy the function using separate Fn Project commands, instead of the single `fn deploy` command.

8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the image has been pushed to Oracle Cloud Infrastructure Registry successfully:

a. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Container Registry.

b. Choose the registry's region.

You see all the repositories in the registry to which you have access. The image you pushed is in a new private repository with a name constructed from:

- the repository name in the address of the Docker registry in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053)
- the name of the image you pushed

For example, the new repository might be called `acme-repo/acme-func`.

c. Click the name of the new repository. You see details of the image that's been pushed to Oracle Cloud Infrastructure Registry.
9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.

   b. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

      The **Applications** page shows the applications in the compartment, including the one you specified in the `fn deploy` command.

   c. Click the name of the application you specified in the `fn deploy` command to see the functions within it.

      The **Functions** page shows that the function has been deployed to Oracle Functions.

### Using Custom Dockerfiles

When you build or deploy a function with Oracle Functions, a Docker image is created and pushed to a Docker registry. As with any Docker image, the instructions to build the image are contained in a Dockerfile.

If the function is written in one of the languages supported by an Fn Project FDK (Functions Development Kit), Oracle Functions uses the `runtime:`, `build_image:`, and `run_image:` settings in a `func.yaml` file to determine the language (and therefore the build-time and run-time dependencies) to include in the Docker image. If you use the `fn init` command to initialize the function, a `func.yaml` file is created for you. For example, a `func.yaml` might look like:

```yaml
schema_version: 20180708
name: hello-java
version: 0.0.1
runtime: java
build_image: fnproject/fn-java-fdk-build:jdk11-1.0.116
run_image: fnproject/fn-java-fdk:jre11-1.0.116
cmd: com.example.fn.HelloFunction::handleRequest
```

When you build or deploy the function, Oracle Functions uses the settings in the `func.yaml` file to create a temporary Dockerfile containing the instructions from which to build the Docker image. For example, a temporary Dockerfile is shown below.

```bash
FROM fnproject/fn-java-fdk-build:jdk11-1.0.116 as build-stage
WORKDIR /function
ENV MAVEN_OPTS -Dhttp.proxyHost= -Dhttp.proxyPort= -Dhttps.proxyHost= -Dhttps.proxyPort= -Dhttp.nonProxyHosts= -Dmaven.repo.local=/usr/share/maven/ref/repository
ADD pom.xml /function/pom.xml
ADD src /function/src
RUN ["mvn", "package"]
FROM fnproject/fn-java-fdk:jre11-1.0.116
WORKDIR /function
COPY --from=build-stage /function/target/*.jar /function/app/
CMD ["com.example.fn.HelloFunction::handleRequest"]
```

Having created the Docker image, Oracle Functions deletes the temporary Dockerfile.

If you want more control over the Docker image that is created, you can modify the Dockerfile that Oracle Functions creates. Alternatively, you can create your own Dockerfile entirely from scratch. In both cases, the Dockerfile is referred to as a 'custom Dockerfile'. This workflow is sometimes referred to as Bring-Your-Own-Dockerfile, or BYOD.

When you build or deploy the function, Oracle Functions uses the instructions in the custom Dockerfile to build the Docker image.
To have Oracle Functions use a custom Dockerfile when building a Docker image:

1. Make a copy of the Dockerfile you want to use as a custom Dockerfile.
2. Save the new file to the directory containing the func.yaml file.
3. Give the new file the name Dockerfile.

Note that you must name the file Dockerfile.
4. Open the file named Dockerfile in an editor of your choice.

For example, the Dockerfile file might contain the following lines to install the Oracle Instant Client from an oraclelinux:7-slim base image:

```
FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && \
    yum-config-manager --disable ol7_developer_EPEL && \
    yum -y install oracle-instantclient19.3-basiclite nodejs && \
    rm -rf /var/cache/yum
WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js
```

5. Include the following lines in the file named Dockerfile (as described in Permissions Granted to Containers Running Functions on page 2094):

```
groupadd --gid 1000 fn && \
adduser --uid 1000 --gid fn fn
```

For example:

```
FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && \
    yum-config-manager --disable ol7_developer_EPEL && \
    yum -y install oracle-instantclient19.3-basiclite nodejs && \
    rm -rf /var/cache/yum && \
groupadd --gid 1000 fn && \
adduser --uid 1000 --gid fn fn
WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js
```

6. Save the file named Dockerfile. You can now use the Dockerfile file as a custom Dockerfile.
7. In the func.yaml file, change the value of the runtime: parameter to runtime: docker.

For example, if the func.yaml file contains runtime: java, change it to runtime: docker.
8. Use the fn build or fn deploy commands to build or deploy the function.

Oracle Functions uses the instructions in the custom Dockerfile (the file named Dockerfile) to build the Docker image for the function, and push it to the Docker registry.

**Creating Functions from Existing Docker Images**

You can create a new function definition in the Oracle Functions server in different ways:

- Using the Console or the Fn Project CLI command fn create function to create a new function based on an existing Docker image that has already been pushed to the Docker registry (as described in this topic).
• Using the single Fn Project CLI command `fn deploy` to build a new Docker image, push the image to the Docker registry, and create a new function based on the image in one step (as described in Creating and Deploying Functions on page 2063).
• Using the API (see CreateFunction).

When using the Console or the `fn create function` command to create a new function based on an existing Docker image, you specify function metadata to store in the Oracle Functions server. For example, the maximum length of time the function is allowed to execute for.

The existing image on which you base a new function must be suitable for use with Oracle Functions. Typically, to build and push a suitable image, you or somebody else will use Fn Project CLI commands and/or Docker CLI commands. For example, having written your function code and a `func.yaml` file containing function metadata (perhaps based on the template `helloworld` function and `func.yaml` created using `fn init`), you can:

• Use `fn build` to build a new Docker image from the function.
• Use `docker push` to push the image to the Docker registry.

With the image in the Docker registry, you can then use the Console to create a function based on the image, as described in this topic.

**Using the Console**

To use the Console to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

   The **Applications** page shows the applications defined in the compartment.
5. Click the name of the application in which you want to create the new function.
6. Click **Create Function** and specify:
   • **Name**: A name for the new function. Avoid entering confidential information.
   • **Image**: The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version.
   • **Memory**: The maximum amount of memory the function can use during execution.
   • **Timeout**: The maximum amount of time the function will be allowed to run for.
   • **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click **Create** to create the new function in the Oracle Functions server.

The new function is shown in the Console, in the list of functions in the application you selected.

**Using Fn Project CLI Commands**

To use the Fn Project CLI to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new function by entering:

```
fn create function <app-name> <function-name> <image-name>
```

where:
- `<app-name>` is the name of an existing application in which to create the new function.
- `<function-name>` is the name of the new function you want to create. Avoid entering confidential information.
- `<image-name>` is the name of the existing image in the Docker registry on which to base the new function.

For example:

```
fn create function acmeapp acme-func phx.ocir.io/ansh81vrlzp/acme-repo/acme-func:0.0.3
```

A new function is created in Oracle Functions, based on the existing image and with the name you specified.

3. Verify that the new function has been created by entering:

```
fn list functions <app-name>
```

For example:

```
$ fn list functions acme-app
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>IMAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>acme-func</td>
<td>phx.ocir.io/ansh81vrlzp/acme-repo/acme-func:0.0.3</td>
</tr>
</tbody>
</table>

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage functions:
- `CreateFunction`
- `DeleteFunction`
- `GetFunction`
- `UpdateFunction`

**Sample Functions, Solution Playbooks, Reference Architectures, and Developer Tutorials**

**Sample Functions**

When you set up your development environment for Oracle Functions, simple helloworld functions are included by default. These sample functions enable you to get up and running quickly with Oracle Functions.

In addition, a number of how-to's, patterns, use cases, and other samples are available in the Oracle Functions samples repository on GitHub. These include:
- examples of how to interact with other Oracle Cloud Infrastructure services
- examples of how to optimally connect to databases
- examples of how to use Cloud Events to trigger functions
- use cases for IT Governance, Data Processing, SaaS Application Extensions, and more
Solution Playbooks

Solution playbooks are targeted, cross-product explanations and architectures showing how to handle or implement a specific scenario on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Extend SaaS Applications with a Cloud Native Approach

The Extend SaaS Applications with a Cloud Native Approach solution playbook shows how to design a SaaS extension for Oracle Fusion Applications Cloud Service using a Cloud Native approach.

In this high-level design, Oracle Functions serves as the back-end implementation of a REST API, secured by Oracle Identity Cloud Service. Authentication is handled by Oracle Cloud Infrastructure API Gateway.

Reference Architectures

Reference architectures are architectures, configurations, and best practices for deploying on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Automate Loading Data to a Data Warehouse Using a Serverless Application

The Automate Loading Data to a Data Warehouse Using a Serverless Application reference architecture shows how to use a serverless function to automate the process of extracting data from files generated by various databases or applications and loading the data into a data warehouse for analysis.

In this architecture, the Events service is triggered when zipped CSV files are uploaded to a specific bucket in Oracle Cloud Infrastructure Object Storage. The emitted event invokes a function in Oracle Functions, which extracts the data from the uploaded files and loads the data into an Oracle Autonomous Data Warehouse instance. After the data is loaded to the data warehouse, the processed CSV files are moved to a different bucket in Object Storage.

Developer Tutorials

Developer Tutorials show you how to complete development-related tasks with step-by-step instructions. Developer Tutorials for Oracle Functions are available in the Oracle Cloud Infrastructure documentation.

Viewing Functions and Applications

Having deployed functions to Oracle Functions, you'll typically want to view the functions you've deployed, along with other functions in the same application and different applications. For example, you might want to see:

- all the applications in a compartment
- details of the image for a given function

You can view applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

To view details of applications and functions deployed to Oracle Functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Functions.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
4. Select the compartment containing the applications and functions that you want to see information about.

The Applications page shows all the applications in the compartment you selected.
5. Click the name of an application to see the functions within it.

The **Functions** page shows details for all the functions within the application you selected, including:

- the Docker image created for each function
- when the function was last updated

6. Click the name of a function on the **Functions** page to see additional information about that function, including the values of timeout and memory configuration parameters.

**Using Fn Project CLI Commands**

To view details of applications and functions deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.

2. If you want to see details about applications, in a terminal window:

   - Enter the following command to see a simple list of applications:
   ```
   fn list apps
   ```
   For example:
   ```
   $ fn list apps
   acme-app
   ```
   - Enter the following command to see more detail about a particular application:
   ```
   fn inspect app <app-name>
   ```
   For example:
   ```
   $ fn inspect app acme-app
   {
   "annotations": {
      "oracle.com/oci/appCode": "fht7ns4mn2q",
      "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq",
      "oracle.com/oci/subnetIds": [
         "ocid1.subnet.oc1.phx.aaaaaaaaao...
      ],
      "oracle.com/oci/tenantId": "oci1.tenancy.oc1..aaaaaaap...keq",
      "created_at": "2018-07-13T17:54:34.000Z",
      "id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
      "name": "acme-app",
      "updated_at": "2018-07-13T17:54:34.000Z"
   }
   ```

3. If you want to see details about functions, in a terminal window:

   - Enter the following command to see a simple list of functions in a particular application:
   ```
   fn list functions <app-name>
   ```
   For example:
   ```
   $ fn list functions acme-app
   NAME            IMAGE
   acme-func       phx.ocir.io/ansh81vrulzp/acme-repo/acme-func:0.0.3
   ```
Functions

- Enter the following command to see more detail about a particular function:

  $ fn inspect function <app-name> <function-name>

For example:

  $ fn inspect function acme-app acme-func

  {
    "annotations": {
      "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke",
      "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq"
    },
    "app_id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
    "created_at": "2018-07-26T12:50:53.000Z",
    "format": "default",
    "id": "ocid1.fnfunc.oc1.phx.aaaa___uxoa",
    "image": "phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3",
    "memory": 128,
    "name": "acme-func",
    "timeout": 30,
    "updated_at": "2018-07-26T13:59:18.000Z"
  }

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to see details about applications and functions:

- ListApplications
- ListFunctions

Invoking Functions

You can invoke a function that you've deployed to Oracle Functions in different ways:

- Using the Fn Project CLI.
- Using the Oracle Cloud Infrastructure CLI.
- Using the Oracle Cloud Infrastructure SDKs.
- Making a signed HTTP request to the function's invoke endpoint. Every function has an invoke endpoint.

Each of the above invokes the function via requests to the API. Any request to the API must be authenticated by including a signature and the OCID of the compartment to which the function belongs in the request header. Such a request is referred to as a 'signed' request. The signature includes Oracle Cloud Infrastructure credentials in an encrypted form.

If you use the Fn Project CLI or the Oracle Cloud Infrastructure CLI to invoke a function, authentication is handled for you. See Using the Fn Project CLI to Invoke Functions on page 2072 and Using the Oracle Cloud Infrastructure CLI to Invoke Functions on page 2072.

If you use an Oracle Cloud Infrastructure SDK to invoke a function, you can use the SDK to handle authentication. See Using SDKs to Invoke Functions on page 2073.
If you make a signed HTTP request to a function's invoke endpoint, you'll have to handle authentication yourself by including a signature and the OCID of the compartment to which the function belongs in the request header. You can do this in different ways:

- Using the Oracle Cloud Infrastructure CLI `raw-request` command. See Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command) on page 2074.
- Using a bash script provided by Oracle (commonly referred to as oci-curl). See Sending a Signed Request to a Function's Invoke Endpoint (using oci-curl) on page 2075.
- Writing code to programmatically sign requests. For information about the required credentials and how to sign the requests, see Request Signatures on page 4383.

Tip:
If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2097).

Using the Fn Project CLI to Invoke Functions

To invoke a function deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   fn invoke <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function you want to invoke
   - `<function-name>` is the name of the function you want to invoke

   For example:

   ```
   fn invoke helloworld-app helloworld-func
   ```

   Output:

   ```
   Hello World !
   ```

   Tip:
   If you want to pass arguments and values to a function, prefix the `fn` `invoke` command with `echo -n "<argument>=<value>" |`

   If the function is expecting the argument and value as JSON, use a valid JSON format. For example:

   ```
   echo -n '{"name":"John"}' | fn invoke helloworld-app helloworld-func
   ```

   Output:

   ```
   Hello John !
   ```

Using the Oracle Cloud Infrastructure CLI to Invoke Functions

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the Oracle Cloud Infrastructure CLI will facilitate Oracle Cloud Infrastructure authentication. For information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 4192.
These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function using the Oracle Cloud Infrastructure CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   oci fn function invoke <function-ocid> --file "<output-filepath>" --body "<request-parameters>"
   ```

   where:

   - `<function-ocid>` is the OCID of the function you want to invoke. To find out a function's OCID, use the `fn inspect` command to see the value of the function's `id` property (see Viewing Functions and Applications on page 2069).
   - `<output-filepath>` is the path and name of a file to write the response to. To write the response to stdout, specify `--file "-"`
   - `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. For example, `--body '{"name":"John"}'`. Note that you must include `--body ""` in the request, even if there are no request parameters to pass.

   For example:

   - ```
   oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body ""
   ```

   Output:

   ```
   Hello World !
   ```

   - ```
   oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body '{"name":"John"}'
   ```

   Output:

   ```
   Hello John !
   ```

### Using SDKs to Invoke Functions

If you're writing a program to invoke a function in a language for which an Oracle Cloud Infrastructure SDK exists, Oracle recommends you use that SDK to send API requests to invoke the function. Among other things, the SDK will facilitate Oracle Cloud Infrastructure authentication.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the `InvokeFunction` API operation to invoke functions.

### Obtaining a Function's Invoke Endpoint

When invoking a function using oci-curl or the Oracle Cloud Infrastructure CLI `raw-request` command, you have to specify the function's invoke endpoint.

To obtain a function's invoke endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

```bash
fn inspect function <app-name> <function-name>
```

where:
- `<app-name>` is the name of the application containing the function for which you want to obtain the invoke endpoint
- `<function-name>` is the name of the function for which you want to obtain the invoke endpoint

For example:

```bash
fn inspect function helloworld-app helloworld-func
```

Output:

```json
{
   "annotations": {
      "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke",
      ...
   }
}
```

The function's invoke endpoint is the value of "fnproject.io/fn/invokeEndpoint". For example, "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke" (abbreviated for readability).

**Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command)**

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the CLI will facilitate Oracle Cloud Infrastructure authentication. For more information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 4192.

These instructions assume:
- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using the Oracle Cloud Infrastructure CLI raw-request command:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint on page 2073).

   For example, "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke" (abbreviated for readability).
3. Use the Oracle Cloud Infrastructure CLI raw-request command to invoke the function by sending a signed POST request to the function's invoke endpoint by entering:

```
oci raw-request --http-method POST --target-uri <invoke-endpoint> --request-body "<request-parameters>"
```

where:

- `<invoke-endpoint>` is the endpoint you obtained in the earlier step.
- `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. Note that you must include `--request-body ""` in the request, even if there are no request parameters to pass.

For example:

```
```

Output:

```
Hello World!
```

```
```

Output:

```
Hello John!
```

4. Assuming a passphrase was provided to encrypt the API signing key (as recommended by Oracle), enter the passphrase when prompted.

**Sending a Signed Request to a Function's Invoke Endpoint (using oci-curl)**

When you followed the instructions to prepare your client environment for Oracle Functions, you installed and configured oci-curl in readiness for using it to invoke functions. Among other things, oci-curl will facilitate Oracle Cloud Infrastructure authentication.

These instructions assume:

- you have already configured oci-curl appropriately (see 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2055)
- you want to invoke a function as the functions developer that’s configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using oci-curl:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint on page 2073).

For example, "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke" (abbreviated for readability).
3. In a terminal window, use the `source` command to set up the current shell environment for oci-curl by entering:

```
source <path-to-script>/oci-curl.sh
```

where `<path-to-script>` is the path to the location of the oci-curl.sh script (see 3. Create and Configure a Copy of oci-curl on page 2050). For example:

```
source ~/oci-curl/oci-curl.sh
```

4. In the same terminal window in which you entered the `source` command, use oci-curl to invoke the function by sending a signed POST request to the function's invoke endpoint by entering:

```
oci-curl "<invoke-endpoint-host>" post <filename> "<invoke-endpoint-path>"
```

where:

- `<invoke-endpoint-host>` is the first half of the endpoint you obtained in the earlier step, excluding `https://` and up to (and including) `.oraclecloud.com`. For example, `fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com`
- `<filename>` is the name of a file containing data to pass to the function (you must specify a file, even if it's empty). For example, `payload.json`
- `<invoke-endpoint-path>` is the second half of the endpoint you obtained in the earlier step, from (but not including) `.oraclecloud.com` onwards. For example, `/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke`

For example, combining the previous examples, you might enter:

```
oci-curl "fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com" post payload.json "/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke"
```

5. Assuming a passphrase was provided to encrypt the API signing key (as recommended by Oracle), enter the passphrase when prompted.

## Controlling Access to Invoke and Manage Functions

When configuring a tenancy for function development, the steps in Create a Policy to Give Oracle Functions Users Access to Function-Related Resources on page 2043 instruct you to specify the following identity policy:

```
Allow group <group-name> to manage functions-family in compartment <compartment-name>
```

This identity policy enables authenticated users in the specified group to manage (that is, create, update, and delete) functions and applications in the named compartment, and also enables those users to invoke functions in the compartment. This policy typically meets the requirements of functions developers developing and testing multiple functions in your organization.

However, this identity policy might be too permissive to meet your security requirements to control the invocation and management of functions in production environments. For example, in a production environment you might want to prevent users from invoking functions completely, or restrict users to invoking just functions in a specific application, or to invoking just a particular function.

To control the functions that users in a group can invoke and manage, set up identity policies:

1. To control the functions that a user can invoke and manage, confirm that they are not in a group that has been given the manage functions-family permission.
2. If you want to enable users in a group to create, update, and delete applications and functions in a compartment, but to be unable to invoke functions, enter the following policy statements:

```plaintext
Allow group <group-name> to manage fn-app in compartment <compartment-name>

Allow group <group-name> to manage fn-function in compartment <compartment-name>
```

3. If you want to allow invocations of particular functions only, or invocations of functions in particular applications only, include the appropriate function and application OCIDs in suitable policy statements. For example:

- To enable users to invoke all the functions in a specific application, enter a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id = '<application-OCID>'
  ```

- To enable users to invoke one specific function, enter a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id = '<function-OCID>'
  ```

- To enable users to invoke all the functions in all applications except for functions in one specific application, enter a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id != '<application-OCID>'
  ```

- To enable users to invoke all the functions in a compartment except for one specific function, enter a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id != '<function-OCID>'
  ```

- To enable users to invoke two specific functions, enter a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.function.id='<function-OCID>'}
  ```

- To enable users to invoke one specific function along with all the functions in a specific application, a policy statement in the following format:

  ```plaintext
  Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.app.id='<application-OCID>'}
  ```
4. If you want to allow function invocation and management requests only from particular IP addresses:
   a. Create a network source to specify the allowed IP addresses, if a suitable network source doesn't exist already (see Managing Network Sources on page 2427).
   b. Add a policy statement to enable only those IP addresses in the network source to invoke or manage functions. For example:
      - To only allow function invocation requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
        
        ```
        Allow group <group-name> to use fn-invocation in compartment <compartment-name> where request.networkSource.name='corpnet'
        ```
      - To only allow function management requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
        
        ```
        Allow group <group-name> to manage functions-family in compartment <compartment-name> where request.networkSource.name='corpnet'
        ```

Storing and Viewing Function Logs

When a function is invoked, you'll typically want to access the function's logs for troubleshooting. The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs. See Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging on page 2078. For more information about the contents of function logs, see Details for Functions on page 2603.

Alternatively, there might be occasions when you want to send function logs to an external logging destination like Papertrail. To send logs to an external logging destination instead of the Oracle Cloud Infrastructure Logging service, you use the Fn Project CLI to specify a syslog URL. See Using Fn Project CLI Commands to Specify a syslog URL on page 2079.

Note that to store and view logs for a function, the function must include print statements. For example:

- For node.js: `console.log('Entering Hello Node.js function');`
- For java: `System.err.println("Entering Java Hello World Function");`
- For go: `fmt.Println("Entering Hello Go function")`

Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging

To enable and view function logs in the Oracle Cloud Infrastructure Logging service:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Functions.
3. Select the region and compartment containing the application with functions for which you want to create, enable, and view logs.
   The Applications page shows all the applications in the compartment you selected.
4. Select the application with functions for which you want to enable, view, and log.
5. To create and enable a new function log in the Oracle Cloud Infrastructure Logging service:
   a. Under Resources, click Logs, click the Actions icon (three dots), and then click Enable Log and specify:
      • **Compartment:** The compartment in which to create the new log. By default, the current compartment.
      • **Log Group:** The log group in which to create the new log. Select an existing log group, or select:
         • **Auto-create a default log group** to create a default log group with a default name (DEFAULT_GROUP), if one doesn't exist already.
         • **Create a new log group** to create a new log group with a name and description that you provide.
      • **Log Name:** The name of the new log. By default, `<application-name>_invoke`.
      • **Log Retention:** The length of time to retain log data.
   b. Click Enable Log to create the new log (and the new log group, if you specified one).

   For more information, see Enabling Logging for a Resource on page 2591.

6. To enable an existing function log, under Resources, click Logs, click the Actions icon (three dots), and then click Enable Log.

7. To view the data in an existing function log, under Resources, click Logs, and then click the name of the log you want to view in the Log Name column.

   The log opens in the log group's Log Details page, enabling you to sort and filter log data by time.

**Using Fn Project CLI Commands to Specify a syslog URL**

The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs.

Alternatively, you can send function logs to an external logging destination like Papertrail instead by using the Fn Project CLI to specify a syslog URL. Note that to use an external logging destination, you must have set up a VCN with public subnets and an internet gateway (see Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already on page 2040).

To send function logs to an external logging destination by setting the syslog URL:

1. Log in to your development environment as a functions developer.
2. To create a new application and specify that all functions in the application send their logs to an external logging destination, enter:

   ```
   fn create app <app-name> --syslog-url <logging-service-url> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:
   • `<app-name>` is the name of the new application. Avoid entering confidential information.
   • `<logging-service-url>` is the syslog URL to which to send logs.
   • `<subnet-ocid>` is the OCID of the public subnet (or subnets, up to a maximum of six) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets (enclose each OCID in double quotes separated by commas, in the format '"<subnet-ocid>" ,"<subnet-ocid>"'). Oracle recommends that the public subnets
Functions

are in the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

For example:

```shell
fn create app acmeapp --syslog-url tcp://my.papertrail.com:4242 --
annotation oracle.com/oci/
subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
```

Note that if you subsequently set up Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.

3. To update an existing application and specify that all functions in the application send their logs to an external logging destination, enter:

```shell
fn update app <app-name> --syslog-url <logging-service-url>
```

where:
- `<app-name>` is the name of the application to update
- `<logging-service-url>` is the syslog URL to which to send logs

For example:

```shell
fn update app acmeapp --syslog-url tcp://my.papertrail.com:4242
```

4. To update an existing application and remove the external logging destination specified for the syslog URL, enter:

```shell
fn update app <app-name> --syslog-url ''
```

where:
- `<app-name>` is the name of the application to update

For example:

```shell
fn update app acmeapp --syslog-url ''
```

### Previously Supported Logging Options

In earlier Oracle Functions releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could specify where Oracle Functions stores a function's logs by setting up a 'logging policy' for the application containing the function. Previously, you could use the Console to set up a logging policy to:

- Store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage by selecting the OCI **Logging** option.
  
  To view function logs in a storage bucket, the group to which you belong must have been granted access with the following identity policy statements:

  ```
  • Allow group <group-name> to manage object-family in compartment <compartment-name>
  • Allow group <group-name> to read objectstorage-namespaces in compartment <compartment-name>
  ```

  (Usually created when configuring your tenancy for function development. See Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories on page 2043.)

- Store logs by sending them to an external logging destination like Papertrail by selecting the **Syslog URL** option.

For an existing application where you have previously already set up a logging policy, the above functionality is still supported and the existing logging policy is applied. However, note the following:

- You cannot use the Console to set up a new logging policy or edit an existing logging policy.
• If the existing logging policy specified storing function logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage:
  • The ability to store logs in Object Storage will be deprecated in a future release.
  • Oracle recommends you switch to storing logs using Oracle Cloud Infrastructure Logging.
  • If you do switch to using Oracle Cloud Infrastructure Logging to store logs, you cannot revert to storing the logs in Object Storage.
  • Logs stored in Object Storage will continue to exist (with each log name including the OCID of the associated function, as before).
• If the existing logging policy specified a syslog URL:
  • If you switch to using Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.
  • If you want to change the syslog URL in the existing logging policy, you have to use the Fn Project CLI to change it.

Updating Functions

Having previously created a function definition in the Oracle Functions server, you can change some, but not all, of the function's properties. For example, you can change the maximum length of time a function is allowed to execute for, but you cannot change the function's name.

You can change the Docker image on which a function is based. If you do want to change the image, the replacement image must be suitable for use with Oracle Functions, and must have already been pushed to the Docker registry. With the replacement image in the Docker registry, you can then update a function's definition so that it is based on the replacement image, as described in this topic. If the replacement image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2083.

You can update functions using the Console, the Fn Project CLI, and the API.

Using the Console to update an existing function

To use the Console to update an existing function in the Oracle Functions server:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Functions.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

The Applications page shows the applications defined in the compartment.
5. Click the name of the application containing the existing function that you want to update.
6. Click the name of the function that you want to update.
7. Click Edit and update some or all of the following properties:
  • Image: The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2083.
  • Memory: The maximum amount of memory the function can use during execution.
  • Timeout: The maximum amount of time the function will be allowed to run for.
8. Click Save to update the function in the Oracle Functions server.

The function's updated properties are shown in the Console.
Using Fn Project CLI Commands

To use the Fn Project CLI to update an existing function in the Oracle Functions server:

1. Log in to your development environment as a functions developer.
2. In a terminal window, update properties of an existing function by entering:

   ```
   fn update function <app-name> <function-name> --image <image-name> --
   <property> <value>
   ```

   where:
   - `<app-name>` is the name of an existing application containing the existing function.
   - `<function-name>` is the name of the existing function you want to update.
   - `--image <image-name>` (optionally) is the name of an existing image in the Docker registry that you now want to base the function on, instead of the previously specified image. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2083.
   - `--<property> <value>` (optionally) is the property you want to update, and the new value you want it to have. Enter `fn update function --help` to see a list of properties and valid values.

   For example:

   ```
   fn update function acmeapp acme-func --image phx.ocir.io/ansh81vrlzpsi
   acme-repo/acme-func:0.0.4 --timeout 60
   ```

   ```
   fn update function acmeapp acme-func --memory 256
   ```

   The properties of the existing function are updated with the values you specified.

3. Verify that the function has been updated by entering:

   ```
   fn inspect function <app-name> <function-name>
   ```

   For example:

   ```
   fn inspect function acme-app acme-func
   ```

   Output:

   ```
   {
     "annotations": {
       "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-
phoenix-1.functions.oci.oraclecloud.com/20181201/functions/
ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke",
       "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq"
     },
     "app_id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
     "created_at": "2018-07-26T12:50:53.000Z",
     "format": "default",
     "id": "ocid1.fnfunc.oc1.phx.aaaa____uxoa",
     "image": "phx.ocir.io/ansh81vrlzpsi/acme-repo/acme-func:0.0.4",
     "memory": 256,
     "name": "acme-func",
     "timeout": 60,
     "updated_at": "2018-07-26T13:59:18.000Z"
   }
```
Functions

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the UpdateFunction API operation to update functions.

Notes About Image Digests

Images in a Docker registry are identified by repository, name, and a tag. In addition, Docker gives each version of an image a unique alphanumeric digest. When pushing an updated Docker image, it's recommended best practice to give the updated image a new tag to identify it, rather than reusing an existing tag. However, even if you push an updated image and give it the same name and tag as an earlier version, the newly pushed version will have a different digest to the earlier version.

When you create a function with Oracle Functions, you specify the name and tag of a particular version of an image on which to base the function. To avoid later inconsistencies, Oracle Functions also records the unique digest of that particular version of the image.

By default, if you push an updated version of an image to the Docker registry with the same name and tag as the original version of the image on which a function is based, Oracle Functions continues to use the original digest to pull the original version of the image. This might be the behavior you require. However, if you want Oracle Functions to pull the later version of the image, you can explicitly change the digest that Oracle Functions uses to identify which version of the image to pull in one of the following ways:

- Use the `fn update function` command and specify the original name and tag of the version of the image on which you want the function to be based. For example:

```
fn update function acmeapp acme-func --image phx.ocir.io/ansh81vrulzp/acme-repo/acme-func:0.0.4 --annotation oracle.com/oci/imageDigest="""'
```

Oracle Functions will update the digest recorded for the image on which the function is based to be the digest of the image in the Docker registry that has the name and tag you specify.

- Use the `fn update function` command and specify the digest of the version of the image on which you want the function to be based. For example:

```
fn update function acmeapp acme-func --annotation oracle.com/oci/imageDigest='sha256:8af7cb8d7______c498c0'
```

Oracle Functions will update the digest recorded for the image on which the function is based to be the digest you specify.

- Use the Console and click Edit Function on the Function Information tab, re-select the original name and tag of the version of the image on which the function is currently based, and click Save Changes. Oracle Functions will update the digest recorded for the image on which the function is based.

- Use the Oracle Cloud Infrastructure API or an Oracle Cloud Infrastructure SDK (for more information, see REST APIs on page 4368 and Software Development Kits and Command Line Interface on page 4225).

Deleting Applications and Functions

You can delete applications and functions in Oracle Functions that you or other functions developers have created, provided you have been granted the necessary permission (FN_APP_DELETE or FN_FUNCTION_DELETE as appropriate).

Note the following:

- Deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 3520).

- Deleting applications and functions is permanent. You cannot undelete an application or function that you've deleted.
Functions

• Deleting a function does not necessarily enable you to immediately delete the subnet and VCN in which the function runs. Expect to wait up to five minutes after the function was last invoked before you can delete the associated network resources.

You can delete applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

When using the Console to delete applications and functions, note that:

• when you delete an application, all of its functions are also deleted
• you're always prompted to confirm deletion because you cannot undelete an application or function later

To delete applications and functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Functions.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
   The Applications page shows the applications defined in the compartment.
5. To delete an application, and all of its functions:
   a. Click the name of the application you want to delete.
   b. On the Application Detail page, click Delete and confirm you want to delete the application as follows:
      • If the application does not have functions within it, click Delete to confirm that you want to delete the application.
      • If the application does have functions within it, you are shown a list of the functions in the application. To delete the application, enter DELETE <APPLICATION-NAME> in the text box, and click Delete.
   Note that deleting an application and all of its functions does not delete the Docker images on which the functions are based. To delete the images, you have to delete them explicitly (see Deleting and Undeleting an Image on page 3520).
6. To delete a function:
   a. Click the name of the application containing the function you want to delete.
   b. On the Application Detail page, click the name of the function you want to delete.
   c. On the Function Detail page, click Delete and confirm you want to delete the function.
   Note that deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 3520).

Using Fn Project CLI Commands

When using the Fn Project CLI to delete applications and functions, note that you cannot delete an application if it contains functions (you must delete the functions first).

To delete applications and functions in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. To delete an application:
   a. In a terminal window, enter:

   ```bash
   fn delete app <app-name>
   ```

   where `<app-name>` is the name of the application to delete.

   For example:

   ```bash
   fn delete app acmeapp
   ```

   b. Verify that the application has been deleted by entering:

   ```bash
   fn list apps
   ```

3. To delete a function:
   a. In a terminal window, enter:

   ```bash
   fn delete function <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function you want to delete.
   - `<function-name>` is the name of the function you want to delete.

   For example:

   ```bash
   fn delete function acmeapp acme-func
   ```

   b. Verify that the function has been deleted by entering:

   ```bash
   fn list functions <app-name>
   ```

   For example:

   ```bash
   fn list functions acmeapp
   ```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to delete applications and functions:

- DeleteApplication
- DeleteFunction

Passing Custom Configuration Parameters to Functions

The code in functions you deploy to Oracle Functions will typically require values for different parameters. Some pre-defined parameters are available to your functions as environment variables. But you’ll often want your functions to use parameters that you’ve defined yourself. For example, you might create a function that reads from and writes to a database. The function will require a database connect string, comprising a username, password, and hostname. You’ll probably want to define username, password, and hostname as parameters that are passed to the function when it’s invoked.

To pass user-defined parameters to a function deployed in Oracle Functions, you create key-value pairs known as custom configuration parameters. You can create custom configuration parameters that are:

- application-wide, meaning they are passed to every function in an application
function-specific, meaning they are passed to the particular function for which they are defined (function-specific parameters override application-wide parameters with the same name)

To create custom configuration parameters, you can use:

- the `config:` section of a function's `func.yaml` file, to define function-specific custom configuration parameters
- the Console and the Fn Project CLI, to define both application-wide and function-specific custom configuration parameters

Oracle Functions combines all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

**Using the Console**

To specify custom configuration parameters to pass to functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

   The **Applications** page shows the applications defined in the compartment.
5. Click the name of the application containing functions to which you want to pass custom configuration parameters:
   - To pass one or more custom configuration parameters to every function in the application, click **Configuration** to see the **Configuration** section for the application.
   - To pass one or more custom configuration parameters to a particular function, click the function's name to see the **Configuration** section for the function.
6. In the **Configuration** section, specify details for the first custom configuration parameter:
   - **Key**: The name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number. For example, `username`
   - **Value**: A value for the custom configuration parameter. The value must only contain printable unicode characters. For example, `jdoe`
7. Click the plus button to save the new custom configuration parameter.

   Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb. You cannot save the new custom configuration parameter if the size of the serially-encoded configuration object would be greater than 4Kb.
8. (Optional) Enter additional custom configuration parameters as required.

**Using Fn Project CLI Commands**

To specify custom configuration parameters to pass to functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer and open a terminal window.
2. To specify one or more custom configuration parameters to pass to every function in an existing application, enter:

```
fn config app <app-name> <key> <value>
```

where:

- `<app-name>` is the name of the application containing the functions to which you want to pass the custom configuration parameter.
- `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
- `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```
fn config app acmeapp username jdoe
```

Note the following:

- You can also define application-wide custom configuration parameters when you create a new application using the `fn create app` command.
- Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

3. To specify one or more custom configuration parameters to pass to a particular function, enter:

```
fn config function <app-name> <function-name> <key> <value>
```

where:

- `<app-name>` is the name of the application containing the function to which you want to pass the custom configuration parameter.
- `<function-name>` is the name of the function to which to pass the custom configuration parameter.
- `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
- `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```
fn config function acmeapp acme-func username jdoe
```

Note the following:

- You can also define function-specific custom configuration parameters when you create a new function using the `fn create function` command.
- Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

### Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these API operations to define custom configuration parameters:

- `CreateFunction`
- `UpdateFunction`
- `CreateApplication`
Functions

- UpdateApplication

Accessing File Systems from Running Functions

A function you've deployed to Oracle Functions can access the file system of the container in which it's running as follows:

- the function can read files from all directories
- the function can write files to the /tmp directory

For example, you might want a function to download an Excel file and then read its contents. To meet this requirement, you might create a function that writes the file to the /tmp directory in the container's filesystem, and then subsequently reads the file.

When writing files to the /tmp directory, the /tmp directory is generally always writable. However, the maximum allowable size of the /tmp directory depends on the maximum memory threshold specified for the function:

<table>
<thead>
<tr>
<th>Maximum memory threshold for the function (MB)</th>
<th>Maximum allowed size of /tmp (MB)</th>
<th>Maximum allowed number of files (inodes) in /tmp</th>
</tr>
</thead>
<tbody>
<tr>
<td>128MB</td>
<td>32MB</td>
<td>1024</td>
</tr>
<tr>
<td>256MB</td>
<td>64MB</td>
<td>2048</td>
</tr>
<tr>
<td>512MB</td>
<td>128MB</td>
<td>4096</td>
</tr>
<tr>
<td>1024MB</td>
<td>256MB</td>
<td>8192</td>
</tr>
</tbody>
</table>

Note that the /tmp directory might be shared by multiple invocations of the function. A file written by an earlier invocation of a function could still exist when the function is invoked a second time. It is your responsibility to delete any files to avoid unexpected behavior.

Integrating Oracle Functions with Other Oracle Products

You can integrate functions you've deployed to Oracle Functions with other Oracle products, as described in the following topics:

- Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2088
- Connecting to Oracle Autonomous Database Instances from Running Functions on page 2093

Accessing Other Oracle Cloud Infrastructure Resources from Running Functions

When a function you've deployed to Oracle Functions is running, it can access other Oracle Cloud Infrastructure resources. For example:

- You might want a function to get a list of VCNs from the Networking service.
- You might want a function to read data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.

To enable a function to access another Oracle Cloud Infrastructure resource, you have to include the function in a dynamic group, and then create a policy to grant the dynamic group access to that resource. For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups on page 2422.

Having set up the policy and the dynamic group, you can then include a call to a 'resource principal provider' in your function code. The resource principal provider uses a resource provider session token (RPST) that enables the function to authenticate itself with other Oracle Cloud Infrastructure services. The token is only valid for the resources to which the dynamic group has been granted access.

Note also that the token is cached for 15 minutes. So if you change the policy or the dynamic group, you will have to wait for 15 minutes to see the effect of your changes.
Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

Using the Console
To enable a running function to access other Oracle Cloud Infrastructure resources:

1. Log in to the Console and create a new dynamic group:

   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.

   b. Follow the instructions in To create a dynamic group on page 2423, and give the dynamic group a name (for example, acme-func-dyn-grp).

   c. When specifying a rule for the dynamic group, consider the following examples:

      • If you want all functions in a compartment to be able to access a resource, enter a rule similar to the following that adds all functions in the compartment with the specified compartment OCID to the dynamic group:

        ```
        ALL {resource.type = 'fnfunc', resource.compartment.id = 'ocid1.compartment.oc1..aaaaaaaa23______smwa'}
        ```

      • If you want a specific function to be able to access a resource, enter a rule similar to the following that adds the function with the specified OCID to the dynamic group:

        ```
        resource.id = 'ocid1.fnfunc.oc1.iad.aaaaaaaaacq______dnya'
        ```

      • If you want all functions with a specific defined tag to be able to access a resource, enter a rule similar to the following that adds all functions with the defined tag to the dynamic group:

        ```
        ALL {resource.type = 'fnfunc', tag.department.operations.value = '45'}
        ```

      Note that free-form tags are not supported. For more information about tagging, see Resource Tags on page 211.

   d. Click Create Dynamic Group.

   Having created a dynamic group that includes the function, you can now create a policy to give the dynamic group access to the required Oracle Cloud Infrastructure resource.
Functions

2. Create a new policy:
a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acmefunc-dyn-grp-policy).
c. When specifying a policy statement, consider the following examples:
•

If you want functions in the acme-func-dyn-grp to be able to get a list of all the VCNs in the tenancy,
enter a rule similar to the following:
allow dynamic-group acme-func-dyn-grp to inspect vcns in tenancy

•

If you want functions in the acme-func-dyn-grp to be able to read and write to a particular Object
Storage bucket, enter a rule similar to the following:
allow dynamic-group acme-func-dyn-grp to manage objects
in compartment acme-storage-compartment where all
{target.bucket.name='acme-functions-bucket'}

•

If you want functions in the acme-func-dyn-grp to be able to read and write to all resources in a
compartment, enter a rule similar to the following:
allow dynamic-group acme-func-dyn-grp to manage all-resources in
compartment acme-storage-compartment

d. Click Create to create the new policy.
3. Include a resource principal provider in the function code to enable the function to authenticate with other Oracle
Cloud Infrastructure services. See:
•
•

Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the
Networking Service on page 2090
Example: Adding a Custom Resource Principal Provider to a Function on page 2091

Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of
VCNs from the Networking Service
Having added a function to a dynamic group, and created a policy that allows the dynamic group to list the VCNs
in the tenancy, you could include code similar to the following example to get a list of VCNs from the Networking
service. This example uses the Oracle resource principal provider to extract credentials from the RPST token.
import io
import json
from fdk import response
import oci
def handler(ctx, data: io.BytesIO=None):
signer = oci.auth.signers.get_resource_principals_signer()
resp = do(signer)
return response.Response(ctx,
response_data=json.dumps(resp),
headers={"Content-Type": "application/json"} )
def do(signer):
# List VCNs -------------------------------------------------------client = oci.core.VirtualNetworkClient({}, signer=signer)
try:
vcns = client.list_vcns(signer.compartment_id)
vcns = [[v.id, v.display_name] for v in vcns.data]
except Exception as e:
vcns = str(e)
return {"vcns": vcns, }

Oracle Cloud Infrastructure User Guide

2090


Example: Adding a Custom Resource Principal Provider to a Function

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

The container in which a function executes includes a directory tree that holds Oracle Cloud Infrastructure compatible credentials, specifically:

- A resource principal session token (RPST) in a file named `rpst`. The RPST token is formatted as a JWT token, and includes claims that identify the function's host tenancy and compartment.
- A private key for use in making requests to Oracle Cloud Infrastructure services on behalf of the function, in a file named `private.pem`.

The following environment variables are set inside the container in which the function executes:

- `OCIRESOURCEPRINCIPALVERSION`, containing the value `2.2`.
- `OCIRESOURCEPRINCIPALRPST`, containing the absolute path to the `rpst` file (including the filename).
- `OCIRESOURCEPRINCIPALPRIVATEPEM`, containing the absolute path to the `private.pem` file (including the filename).
- `OCIRESOURCEPRINCIPALREGION`, containing the region identifier in which the function is deployed (for example, `us-phoenix-1`).

To enable a function to access another Oracle Cloud Infrastructure service, add code to the function so that it can authenticate itself with the other resource:

1. Add code that loads the RPST token from the path in the `OCIRESOURCEPRINCIPALRPST` environment variable.
2. Add code that loads the private key from the path in the `OCIRESOURCEPRINCIPALPRIVATEPEM` environment variable.
3. Add code that uses the RPST token and the private key to create an Oracle Cloud Infrastructure request signature (see Request Signatures on page 4383).
4. Add code that constructs the request to the other Oracle Cloud Infrastructure resource.

If necessary, you can identify:

- The endpoints of other Oracle Cloud Infrastructure services in the same (local) region as the function, using the region identifier in the `OCIRESOURCEPRINCIPALREGION` environment variable.
- The function's host tenancy and compartment, using the `res_tenant` and `res_compartment` claims in the RPST token.

For example, the sample Python function below includes a custom resource principal provider that extracts credentials from the RPST token. It then submits a GET request to the IAM API's getTenancy operation to return the OCID of the function's tenancy.

```python
#!/usr/bin/env python3
import base64
import email.utils
import hashlib
import httpsig_cffi.sign
import json
import logging
import os.path
import re
import requests.auth
import urllib.parse

LOG = logging.getLogger(__name__)
```
The following class is derived from the Python section in https://docs.cloud.oracle.com/iaas/Content/API/Concepts/signingrequests.htm:

class SignedRequestAuth(requests.auth.AuthBase):
    """A requests auth instance that can be reused across requests""
    generic_headers = [
        "date",
        "(request-target)",
        "host"
    ]
    body_headers = [
        "content-length",
        "content-type",
        "x-content-sha256",
    ]
    required_headers = {
        "get": generic_headers,
        "head": generic_headers,
        "delete": generic_headers,
        "put": generic_headers + body_headers,
        "post": generic_headers + body_headers,
    }

    def __init__(self, key_id, private_key):
        # Build a httpsig_cffi.requests_auth.HTTPSignatureAuth for each
        # HTTP method's required headers
        self.signers = {}
        for method, headers in self.required_headers.items():
            signer = httpsig_cffi.sign.HeaderSigner(
                key_id=key_id, secret=private_key,
                algorithm="rsa-sha256", headers=headers[:]
            )
            use_host = "host" in headers
            self.signers[method] = (signer, use_host)

    def inject_missing_headers(self, request, sign_body):
        # Inject date, content-type, and host if missing
        request.headers.setdefault("date", email.utils.formatdate(usegmt=True))
        request.headers.setdefault("content-type", "application/json")
        request.headers.setdefault("host", urllib.parse.urlparse(request.url).netloc)

        # Requests with a body need to send content-type,
        # content-length, and x-content-sha256
        if sign_body:
            body = request.body or ""
            if "x-content-sha256" not in request.headers:
                m = hashlib.sha256(body.encode("utf-8"))
                base64digest = base64.b64encode(m.digest())
                base64string = base64digest.decode("utf-8")
                request.headers["x-content-sha256"] = base64string
                request.headers.setdefault("content-length", len(body))

    def __call__(self, request):
        verb = request.method.lower()
        # nothing to sign for options
        if verb == "options":
            return request
        signer, use_host = self.signers.get(verb, (None, None))
        if signer is None:
            raise ValueError("Don't know how to sign request verb ".format(verb))
# Inject body headers for put/post requests, date for all requests

```python
sign_body = verb in \["put", "post"]
self.inject_missing_headers(request, sign_body=sign_body)
```

```python
if use_host:
    host = urllib.parse.urlparse(request.url).netloc
else:
    host = None

signed_headers = signer.sign(
    request.headers, host=host,
    method=request.method, path=request.path_url)
request.headers.update(signed_headers)
return request
```

```python
def rp_auther():
    if os.environ['OCI_RESOURCE_PRINCIPAL_VERSION'] != "2.2":
        raise EnvironmentError('{} must be set to the value "2.2"'.format('OCI_RESOURCE_PRINCIPAL_VERSION'))
    rpst = os.environ['OCI_RESOURCE_PRINCIPAL_RPST']
    if os.path.isabs(rpst):
        with open(rpst) as f:
            rpst = f.read()
    private_key = os.environ['OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM']
    if os.path.isabs(private_key):
        with open(private_key) as f:
            private_key = f.read()
    return get_claims(rpst), SignedRequestAuth('ST${}'.format(rpst),
        private_key)

def get_claims(rpst):
    """Parse an RPST as a JWT; return a dictionary of claims
    
The claims that are important are: sub, res_compartment, and res_tenant. These carry the resource OCID together with its location.
    """
    s = rpst.split('.')[1]
    s += "=" * ((4 - len(s) % 4) % 4)  # Pad to a multiple of 4 characters
    return json.loads(base64.b64decode(s).decode('utf-8'))

# Use RP credentials to make a request
region = os.environ['OCI_RESOURCE_PRINCIPAL_REGION']
claims, rp_auth = rp_auther()
response = requests.get("https://identity.{}.oraclecloud.com/20160918/
    tenancies/\{".format(region, claims['res_tenant']), auth=rp_auth)
print(response.json())
```

## Connecting to Oracle Autonomous Database Instances from Running Functions

You can deploy a function to Oracle Functions that connects to Oracle Autonomous Database instances.

Note that an Oracle Autonomous Database instance can be protected by an access control list (ACL). If the ACL is enabled, only those IP addresses and VCNs explicitly added to the ACL are allowed to connect to the database.

If you want a function running in a private subnet to connect to an Oracle Autonomous Database instance that has ACL enabled, edit the database's access control list and add the VCN.
If you want a function running in a public subnet to connect to an Oracle Autonomous Database instance that has ACL enabled:

1. Remove the default route rule that routes all outgoing internet traffic through the VCN's internet gateway.
2. Add a NAT gateway to the VCN.
3. Configure the subnet's route table with a rule that sends all outgoing internet traffic to the NAT gateway, and configure the subnet's security lists to allow internet traffic.
4. Review the NAT gateway's properties to obtain its public IP address.
5. Edit the database's access control list and add the NAT gateway's public IP address.

For more information about Oracle Autonomous Databases and ACLs, see Access Control Lists (ACLs) for Databases on Shared Exadata Infrastructure on page 1153.

Permissions Granted to Containers Running Functions

When a function you've deployed to Oracle Functions is invoked, it runs inside a container. The operations that a container can perform are determined by the user ID (UID) and group ID (GID) specified when the container is started. If a UID or GID is not specified, the container runs processes as the root user, with all the default capabilities enabled.

When starting a container to run a function, Oracle Functions always specifies a user named 'fn' with a UID of 1000, and a group name 'fn' with a GID of 1000. No privileges are granted to UID 1000 and GID 1000, so the container (and the function running inside it) does not acquire the default capabilities listed in the Docker documentation. In addition, the container is prevented from gaining privileges.

As a result, do not create and deploy functions that:

• depend on capabilities that are unavailable
• depend on privilege elevation (for example, su, sudo or setuid)

If you are using your own Dockerfile, include the following lines:

```bash
groupadd --gid 1000 fn && 
adduser --uid 1000 --gid fn fn
```

For example:

```bash
FROM oraclelinux:7-slim
RUN  yum -y install oracle-release-el7 oracle-nodejs-release-el7 & & \ 
    yum-config-manager --disable ol7_developer_EPEL & & \ 
    yum -y install oracle-instantclient19.3-basiclite nodejs & & \ 
    rm -rf /var/cache/yum & & \ 
    groupadd --gid 1000 fn & & \ 
    adduser --uid 1000 --gid fn fn
WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js
```

Note that if you do not include the `groupadd` and `adduser` lines in the above example Dockerfile, you will see the following error message:

```
(cx_Oracle.DatabaseError: ORA-12560: TNS:protocol adapter error
```

Oracle Functions Support for Private Network Access

Oracle Functions supports private communication between a function in a VCN and other Oracle Cloud Infrastructure resources and supported services in the Oracle Services Network without the traffic going over the internet. You can:
• enable a function in the VCN to access other resources and services
• enable other resources and services to invoke functions in the VCN

To provide such private access:

• create and deploy functions in private subnets
• add a service gateway to the VCN

For more information, see Access to Oracle Services: Service Gateway on page 3256.

Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services

You can invoke functions in Oracle Functions from other Oracle Cloud Infrastructure services. Typically, you’ll want an event in another service to trigger a request to invoke a function defined in Oracle Functions.

This functionality is currently available in:

• The Events service. For more information, see Functions on page 1877 in Services that Produce Events on page 1817.
• The Notifications service. For more information, see Notifications Overview on page 3350. For a scenario, see Scenario A: Automatically Resize VMs on page 3366.
• The API Gateway service. For more information, see Adding a Function in Oracle Functions as an API Gateway Back End on page 410.
• The Oracle Integration service, using the OCI Signature Version 1 security policy. For more information, see Configure Oracle Integration to Call Oracle Cloud Infrastructure Functions with the REST Adapter in Using the REST Adapter with Oracle Integration.
• The Service Connector Hub service. For more information, see Service Connector Hub Overview on page 3750. For a scenario, see Scenario: Send Log Data to an Autonomous Database on page 3767.

Changing Oracle Functions Default Behavior

You can change several aspects of Oracle Functions default behavior using configuration parameters and environment variables.

Depending on the parameter, you can override a default value by specifying an alternative value in the following ways (note the order of precedence):

• by adding an entry to the func.yaml file (which overrides default values)
• by explicitly setting an environment variable (which overrides values set in the func.yaml file)
• by including a command option when you invoke the function using the Fn Project CLI (which overrides values set in environment variables or in the func.yaml file)

The following table indicates the parameters you can set, the default value, and where the default value can be overridden.

<table>
<thead>
<tr>
<th>Parameter Description</th>
<th>Default Value</th>
<th>Units</th>
<th>func.yaml Parameter</th>
<th>Environment Variable</th>
<th>Fn CLI option</th>
<th>Notes</th>
</tr>
</thead>
</table>
| Maximum time a function will be allowed to run | 30 | Seconds | timeout | n/a | n/a | Maximum value: 300
Best practice is to specify a timeout that is close to that likely to be required, rather than significantly more. |
<table>
<thead>

<td>If this limit is exceeded during execution, the function is stopped and an error message is logged.</td>
</tr>
</tbody>
</table>

For more information about the above parameters, and other configuration parameters, see Func files in the Fn Project documentation.

**Differences between Oracle Functions and Fn Project**

In general, Oracle Functions and Fn Project are very similar. However there are some differences, as detailed below.

**Differences in Authentication When Making API Calls**

When you use the Oracle Cloud Infrastructure API with Oracle Functions, in the request header you have to provide:

- the OCID of the compartment to which the function belongs
- Oracle Cloud Infrastructure authentication details

**Differences When Invoking Functions**

To invoke a function deployed to Oracle Functions, you have to explicitly specify an Oracle Cloud Infrastructure endpoint (unless you're using the Fn Project CLI).

For example, when you use oci-curl to invoke a function, you have to send a request to the function's invoke endpoint (for example `https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke`).

You can obtain the appropriate endpoint by making a call to the API, either directly or by using the Fn Project CLI command:

```
fn inspect function <app-name> <function-name>
```

**Additional Context Configuration Parameters in Oracle Functions**

As well as supporting Fn Project context configuration parameters, Oracle Functions also has some additional parameters, as shown in the following table.
<table>
<thead>
<tr>
<th>Additional Parameter</th>
<th>Set in</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
</table>
| provider             | A context configuration .yaml file in ~/.fn/contexts | oracle          | Enables Oracle Functions rather than Fn Project functionality. When provider is set to oracle, the following parameters are valid:  
  - oracle.compartment-id  
  - oracle.profile  
  See 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053. |
| oracle.compartment-id| A context configuration .yaml file in ~/.fn/contexts | <compartment-ocid> | Specifies the OCID of the Oracle Cloud Infrastructure compartment that owns function-related resources.  
  See 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053. |
| oracle.profile       | A context configuration .yaml file in ~/.fn/contexts | <profile-name>   | Specifies which profile to use from the ~/.oci/config file. If not set, the profile named default is used.  
  See 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2055 |

**Use of Annotations**

When you're creating and viewing Oracle Functions resources using the Fn Project CLI, annotations enable you to identify and specify associated Oracle Cloud Infrastructure resources.

For example:

- When you're using the Fn Project CLI to create a new application, you use the --annotation parameter to specify the OCID of the subnet in which to run the function.
- When you're using the Fn Project CLI to view the properties of a function, the annotations element shows the OCID of the compartment that owns the function.

Note that unlike other configuration parameters and environment variables, annotation values cannot be passed as arguments to running Docker containers.

**Troubleshooting Oracle Functions**

This topic covers common issues related to Oracle Functions and how to address them.

Use the following techniques to find out more about an error or issue:
• **Use DEBUG=1 to see more details about an error:** If you encounter an unexpected error when using an Fn Project CLI command, you can find out more about the problem by starting the command with the string DEBUG=1 and running the command again. For example:

```
DEBUG=1 fn invoke helloworld-app helloworld-func
```

Note that DEBUG=1 must appear before the command, and that DEBUG must be in upper case.

• **Use --display-call-id when invoking functions to aid issue resolution:** If you encounter an issue when invoking a function, you can engage with Oracle Support. Oracle Support can investigate the issue more efficiently if you provide the call id of the function invocation. You can obtain the call id using the --display-call-id command option. For example:

```
fn invoke helloworld-app helloworld-func --display-call-id
```

Output:

```
Call ID: 01CS23SDG71BT2N9GZJ002DQM5
Hello World!
```

The issues in this topic are organized in the following broad categories:

• **Setting up and running Oracle Functions**

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>401: Not authenticated</strong></td>
<td>Running Fn Project CLI commands returns a 401 error on page 2100</td>
</tr>
<tr>
<td><strong>404: Resource is not authorized or not found</strong></td>
<td>Running Fn Project CLI commands returns a 404 error on page 2100</td>
</tr>
<tr>
<td><strong>x509: decryption password incorrect</strong></td>
<td>Running Fn Project CLI commands returns an X509: decryption password incorrect error on page 2100</td>
</tr>
<tr>
<td><strong>Error response from daemon... unknown: Unauthorized</strong></td>
<td>Performing Docker-related operations with the Fn Project CLI displays an &quot;Error response from daemon... unknown: Unauthorized” message on page 2101</td>
</tr>
<tr>
<td><strong>asn1:structure error: tags don't match</strong></td>
<td>Running an Fn Project CLI command displays an &quot;Fn: asn1:structure error: tags don't match” message on page 2101</td>
</tr>
<tr>
<td><strong>Client version: n.n.nn is not latest: n.n.nn</strong></td>
<td>Running fn version shows that a more recent version of the Fn Project CLI is available on page 2101</td>
</tr>
</tbody>
</table>

• **Creating applications and functions**

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Unable to create your app, please try again.</strong></td>
<td>Creating a new application displays an error message in the New Application dialog on page 2101</td>
</tr>
</tbody>
</table>

• **Deploying applications and functions**

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>unauthorized: incorrect username or password</strong></td>
<td>Deploying an application returns an &quot;unauthorized: incorrect username or password” message on page 2102</td>
</tr>
</tbody>
</table>
### Functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>denied: requested access to the resource is denied</td>
<td>Deploying a function returns an &quot;error running docker push, are you logged into docker?&quot; message on page 2102</td>
</tr>
<tr>
<td>Fn: error running docker push, are you logged into docker?: exit status 1</td>
<td></td>
</tr>
<tr>
<td>500: Internal server error</td>
<td>Deploying a function returns a ListTriggers message and a 500 error on page 2102</td>
</tr>
<tr>
<td>Image &lt;image-name&gt; does not exist or you do not have access to use it.</td>
<td>Deploying a function returns an &quot;Image does not exist or you do not have access to use it&quot; message on page 2103</td>
</tr>
<tr>
<td>401: Missing subnets annotation</td>
<td>Deploying a function to Oracle Functions returns &quot;Fn: Missing subnets annotation&quot; message on page 2103</td>
</tr>
</tbody>
</table>

### Invoking functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>502: Function failed</td>
<td>Invoking a function returns a Function failed message and a 502 error on page 2103</td>
</tr>
<tr>
<td>502: Syslog endpoint unavailable</td>
<td>Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error on page 2103</td>
</tr>
<tr>
<td>502: Failed to pull function image</td>
<td>Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error on page 2103</td>
</tr>
<tr>
<td>502: subnet ocid1.subnet.... is out of IPs</td>
<td>Invoking a function returns a FunctionInvokeSubnetOutOfRange message and a 502 error on page 2104</td>
</tr>
<tr>
<td>502: subnet ocid1.subnet.... does not exist or Oracle Functions is not authorized to use it</td>
<td>Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a subnet issue) on page 2105</td>
</tr>
<tr>
<td>502: dhcp options ocid1.dhcpoptions.... does not exist or Oracle Functions is not authorized to use it</td>
<td>Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a DHCP Options issue) on page 2105</td>
</tr>
<tr>
<td>504: Container failed to initialize, please ensure you are using the latest fdk and check the logs 'ModuleNotFoundError: No module named 'contextvars'</td>
<td>Invoking a function returns a FunctionInvokeContainerInitFail error message, a 504 error, and a 'ModuleNotFoundError: No module named 'contextvars' log message on page 2105</td>
</tr>
<tr>
<td>504: Container failed to initialize, please ensure you are using the latest fdk and check the logs</td>
<td>Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out' messages, and a 504 error on page 2106</td>
</tr>
<tr>
<td>504: Timed out</td>
<td>Invoking a function returns a FunctionInvokeTimeout message and a 504 error on page 2106</td>
</tr>
</tbody>
</table>
**Functions**

- **Miscellaneous**

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>error getting credentials - err: exit status 1, out: Error spawning command line <code>dbus-launch --autolaunch...</code></td>
<td>When running Oracle Functions on Ubuntu, Docker login returns an &quot;error getting credentials - err: exit status 1...&quot; message on page 2107</td>
</tr>
</tbody>
</table>

**Issues setting up and running Oracle Functions**

You might encounter these issues when setting up and running Oracle Functions.

**Running Fn Project CLI commands returns a 401 error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that the credentials specified for your current profile in the `~/.oci/config` file are authenticating you correctly:

```
$ fn list apps
Fn: [GET /apps][401] ListApps default &{Fields: Message:Not authenticated}
```

For example:

- Does `user` specify the OCID of your Oracle Cloud Infrastructure user account?
- Does `fingerprint` specify the fingerprint of the public API key value uploaded to the Console?
- Does `key_file` specify the full path to the private key file?

See 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049. Also see API Errors on page 4372.

**Running Fn Project CLI commands returns a 404 error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that you are authorized to access function-related and network resources:

```
$ fn list apps
Fn: [GET /apps][404] ListApps default &{Fields: Message:Resource is not authorized or not found}
```

For example:

- Does `oracle.compartment-id` in your current context correctly specify the OCID of the compartment that owns deployed functions?
- Have policies been set up correctly to give group access to function-related and network resources?
- If you are using a local machine as your Oracle Functions development environment, has your user account been included correctly in the group to which access to function-related and network resources has been granted?
- If you are using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, has the compute instance's OCID been included correctly in the dynamic group that has been granted access to Oracle Cloud Infrastructure Registry?
- Has a policy been set up to give Oracle Functions access to network resources?

See Different Options for Function Development Environments on page 2045. 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053, and Create Policies to Control Access to Network and Function-Related Resources on page 2041. Also see API Errors on page 4372.

**Running Fn Project CLI commands returns an X509: decryption password incorrect error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that the `pass_phrase` specified for your current profile in the `~/.oci/config` file is correct:

```
$ fn list apps
```
Functions

See [2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File](#) on page 2049.

**Performing Docker-related operations with the Fn Project CLI displays an "Error response from daemon... unknown: Unauthorized" message**

To enable the Fn Project CLI to access the Docker registry specified in the Fn Project CLI context, the local Docker client (the Docker daemon on Linux) in your development environment must be logged in to that Docker registry. If the Docker client is not logged in to the Docker registry, you see a message similar to the following:

```
Error response from daemon: Get https://phx.ocir.io/v2/: unknown: Unauthorized
```

Follow the instructions in [10. Log in to Oracle Cloud Infrastructure Registry](#) on page 2057 to log the Docker client in to the appropriate Oracle Cloud Infrastructure Registry, an Oracle-managed Docker registry available in a number of different regions.

**Running an Fn Project CLI command displays an "Fn: asn1:structure error: tags don't match" message**

When running an Fn Project CLI command, you might see a message similar to the following:

```
Fn: asn1: structure error: tags don't match (16 vs {class:1 tag:15 length:112 isCompound:true}) {optional:false explicit:false application:false private:false defaultValue:<nil> tag:<nil> stringType:0 timeType:0 set:false omitEmpty:false} pkcs1PrivateKey @2
```

This message indicates a problem with the format of the private key. Double-check the private key is PEM-encoded by opening the private key file in the ~/.oci directory and confirming that the private key starts with `BEGIN RSA PRIVATE KEY`. For more information about generating keys, see [1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions](#) on page 2047.

**Running fn version shows that a more recent version of the Fn Project CLI is available**

If you see a message similar to the following when you enter the `fn version` command, a more recent version of the Fn Project CLI is available:

```
$ fn version
Client version: 0.5.33 is not latest: 0.5.34
Server version: ?
```

To upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in [5. Install the Fn Project CLI](#) on page 2053.

**Issues creating applications and functions**

You might encounter these issues when creating applications and functions with Oracle Functions.

**Creating a new application displays an error message in the New Application dialog**

If you've already reached the limit for the number of applications in your tenancy, you might see a message similar to the following in the New Application dialog when trying to create a new application:

```
Unable to create your app, please try again.
```

Double-check how many applications already exist in your tenancy. Compare that with the number of applications you're allowed to create. See [Oracle Functions Capabilities and Limits](#) on page 2033.

If you've exceeded the number of applications allowed in your tenancy, consider:
• Deleting unwanted applications (see Deleting Applications and Functions on page 2083).
• Requesting an increase to the application limit (see Service Limits on page 215 for instructions).

Issues deploying applications and functions

You might encounter these issues when deploying applications and functions with Oracle Functions.

Deploying an application returns an "unauthorized: incorrect username or password" message

When deploying an application, you might see a message similar to the following:

```sh
$ fn -v deploy --app acme-app
Deploying go-app to app: acme-app
Bumped to version 0.0.2
Building image phx.ocir.io/ansh81vru1zp/acme-repo/go-app:0.0.2
FN_REGISTRY: phx.ocir.io/ansh81vru1zp/acme-repo
Current Context: acme-functions-compartment
Sending build context to Docker daemon 5.12kB
Step 1/10 : FROM fnproject/go:dev as build-stage
Get https://registry-1.docker.io/v2/fnproject/go/manifests/dev:
  unauthorized: incorrect username or password
```

The message indicates an unnecessary and unsuccessful attempt to log in to Docker Hub. To resolve this situation, log out from Docker using the following command:

```sh
docker logout
```

Having logged out from Docker, re-run the command to deploy the application.

Deploying a function returns an "error running docker push, are you logged into docker?" message

If you see a message similar to the following when deploying a function, double-check that your development environment doesn't have the FN_REGISTRY environment variable set to your Docker username:

```sh
The push refers to repository [docker.io. ... .
  ...
  denied: requested access to the resource is denied
Fn: error running docker push, are you logged into docker?: exit status 1
See fn <command> --help' for more information.
```

If you have used the open source Fn Project platform, you might have followed instructions in the Fn Project documentation to set the FN_REGISTRY environment variable to your Docker username to enable interaction with the official Docker registry (docker.io).

The FN_REGISTRY environment variable overrides the value of the registry option in your Fn Project CLI context.

To use the Fn Project CLI with Oracle Functions, do one of the following:

• Unset the FN_REGISTRY environment variable.
• Override the FN_REGISTRY environment variable using the --registry global option whenever you enter an Fn Project CLI command that interacts with Oracle Cloud Infrastructure Registry.

Deploying a function returns a ListTriggers message and a 500 error

When deploying a function that you've previously created using an earlier version of the Fn Project CLI, you might see a message similar to the following:

```sh
Fn: [GET /triggers][500] ListTriggers default &{Fields: Message:Internal server error}
```
This message indicates that the function's `func.yaml` file contains one or more HTTP trigger definitions. Oracle Functions does not currently support HTTP triggers. To deploy the function, remove the `triggers:` section from the `func.yaml` file.

To avoid creating new `func.yaml` files containing trigger definitions, follow the instructions in 5. Install the Fn Project CLI on page 2053 to upgrade the Fn Project CLI to the most recent version.

**Deploying a function returns an "Image does not exist or you do not have access to use it" message**

When deploying a function using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, you might see a message similar to the following:

```
Fn: Image phx.ocir.io/ansh8lvrulzp/acme-repo/helloworld-func:0.0.2 does not exist or you do not have access to use it.
```

This message indicates that the compute instance does not have access to Oracle Cloud Infrastructure Registry. Double-check that a policy statement (similar to the one below) exists in the tenancy's root compartment to allow a dynamic group that includes the compute instance's OCID to access Oracle Cloud Infrastructure Registry:

```
Allow dynamic-group <dynamic-group-name> to read repos in tenancy
```

For more information about using an Oracle Cloud Infrastructure compute instance as your development environment, see Different Options for Function Development Environments on page 2045.

**Deploying a function to Oracle Functions returns "Fn: Missing subnets annotation" message**

When you deploy a function to Oracle Functions, you might see the following message:

```
$ fn deploy --app joes-helloworld-app
Deploying helloworld-func to app: joes-helloworld-app.
.
.
Fn: Missing subnets annotation
```

If you see the `Fn: Missing subnets annotation` message, confirm that you entered the correct application name. For example:

- the application might not be in the compartment currently specified by the Fn Project CLI context
- the application might have existed previously, but has subsequently been deleted

**Issues invoking functions**

You might encounter these issues when invoking functions deployed to Oracle Functions.

**Invoking a function returns a Function failed message and a 502 error**

If there is a problem with a function's code, you will see the following error when you invoke the function:

```
Fn: Error invoking function. status: 502 message: Function failed
```

To investigate the issue with the function's code, check the logs output by the function. The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs. Note that to store and view logs for a function, the function must include print statements. For more information, see Storing and Viewing Function Logs on page 2078.

**Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error**

Oracle Functions enables you to send a function's logs to an external logging destination (like Papertrail) by setting a syslog URL for the application. See Storing and Viewing Function Logs on page 2078.
Functions

If the syslog URL is invalid or unreachable, you will see the following error when you invoke the function:
{"code":"FunctionInvokeSyslogUnavailable","message":"Syslog endpoint
unavailable"}
Fn: Error invoking function. status: 502 message: Syslog endpoint
unavailable
To confirm that the external logging destination's URL is the cause of the error:
1. Update the application to unset the syslog URL using the Fn Project CLI. For example, by entering:
fn update app helloworld-app --syslog-url ''
2. Deploy the function you want to run. See Creating and Deploying Functions on page 2063.
3. Invoke the function. See Invoking Functions on page 2071.
If the function runs successfully, the external logging destination's URL is not reachable from the subnet in which the
function is running. Double-check that:
•
•
•

The external logging destination's URL is valid.
The external logging destination's URL is publicly accessible.
The subnet in which the function is running has outbound access to the public internet.

Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error
When you invoke a function, Oracle Functions pulls the corresponding image from Oracle Cloud Infrastructure
Registry using the VCN and subnets specified for the application.
If Oracle Functions is unable to pull the image, the following message is returned when you invoke a function:
{"code":"FunctionInvokeImageNotAvailable","message":"Failed to pull function
image"}
Fn: Error invoking function. status: 502 message: Failed to pull function
image

Possible solutions:
•
•
•

Double-check that the image specified for the function still exists in the specified location in Oracle Cloud
Infrastructure Registry.
Double-check that Oracle Cloud Infrastructure is available (this message is returned if Oracle Cloud Infrastructure
is unexpectedly unavailable).
Double-check that the VCN includes an internet gateway or service gateway. For Oracle Functions to be able
to access Oracle Cloud Infrastructure Registry to pull an image, the VCN must include an internet gateway or a
service gateway, as follows:
•

•

If public subnets were specified for the application, the VCN must also include an internet gateway. A route
table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set
to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure
Registry (for example, with its Destination Type property set to Service, its Destination Service property
set to All <region> services In Oracle Services Network, and its IP Protocol property set
to All).
If private subnets were specified for the application, the VCN must also include a service gateway. The
service gateway must be set up to allow access to All <region> Services In Oracle Services
Network. A route table must include a route rule that targets the service gateway, with its Destination
Service property set to All <region> Services In Oracle Services Network. A security
list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example,

Oracle Cloud Infrastructure User Guide

2104


Functions

with its Destination Type property set to Service, its Destination Service property set to All <region>
services In Oracle Services Network, and its IP Protocol property set to All).
If an internet gateway or service gateway has not been defined for the VCN already, define one now.
Invoking a function returns a FunctionInvokeSubnetOutOfIPs message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeSubnetOutOfIPs","message":"subnet
ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs"}
Fn: Error invoking function. status: 502 message: subnet
ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs
If you see this error, double-check that each subnet in the VCN has at least the required minimum number of free IP
addresses specified in Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already on page
2040.
Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a
subnet issue)
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeSubnetNotAvailable","message":"subnet
ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not
authorized to use it"}
Fn: Error invoking function. status: 502 message: subnet
ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not
authorized to use it
If you see this error, double-check that the subnet specified for the application still exists.
Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a
DHCP Options issue)
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeSubnetNotAvailable","message":"dhcp options
ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions
is not authorized to use it"}
Fn: Error invoking function. status: 502 message: dhcp options
ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions
is not authorized to use it
If you see this error, double-check that the set of DHCP Options in the VCN specified for the application still exists.
Invoking a function returns a FunctionInvokeContainerInitFail error message, a 504 error, and a
'ModuleNotFoundError: No module named 'contextvars'' log message
When you invoke a Python 3.6 function that you've deployed to Oracle Functions, you might see the following error
message:
{"code":"FunctionInvokeContainerInitFail","message":"Container failed to
initialize, please ensure you are using the latest fdk and check the logs"}
Fn: Error invoking function. status: 504 message: Container failed to
initialize, please ensure you are using the latest fdk and check the logs
If you see this error, check the function's logs. If you see a "ModuleNotFoundError: No module named
'contextvars' message in the function's logs:

Oracle Cloud Infrastructure User Guide

2105


1. Add the following line to the function's requirements.txt file:

   fdk>=0.1.21

2. Re-deploy the function to Oracle Functions.
3.Invoke the function again.

**Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out' messages, and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function execution is subject to a maximum memory threshold. If this limit is exceeded, function execution stops and the following error message is returned:

```
{
  "code":"FunctionInvokeContainerInitFail","message":"Container failed to initialize, please ensure you are using the latest fdk and check the logs"
}
```

Fn: Error invoking function. status: 504 message: Container failed to initialize, please ensure you are using the latest fdk and check the logs

If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see [Changing Oracle Functions Default Behavior](#) on page 2095).

For example, to set a function's maximum memory threshold to 256MB, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and select **256** from the **Memory (in MBs)** drop-down list.
- Add the following line to the function's func.yaml file. This will set the maximum memory threshold to 256MB whenever the function is invoked:

```
memory: 256
```

Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you enter the `fn init --runtime python <function-name>` command to create the helloworld function, the line `memory: 256` is added to the func.yaml file automatically.

**Invoking a function returns a FunctionInvokeTimeout message and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function is only allowed to run for a certain amount of time. If this time limit is exceeded, function execution stops and the following error message is returned:

```
{
  "code":"FunctionInvokeTimeout","message":"Timed out"
}
```

Fn: Error invoking function. status: 504 message: Timed out

If you see this error, increase the maximum time a function is allowed to run for. For example, to set the maximum time to 120 seconds, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and enter **120** in the **Timeout** field.
- Add the following line to the function's func.yaml file. This will set the maximum time limit to 120 seconds whenever the function is invoked:

```
timeout: 120
```

Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.
You might also see this error message when a function running in a public subnet is unable to connect to an Oracle Autonomous Database instance that has access control lists (ACLs) enabled. If this is the case, see Connecting to Oracle Autonomous Database Instances from Running Functions on page 2093 for more information about:

- Configuring the subnet to send all outgoing internet traffic to a NAT gateway, and to allow internet traffic.
- Adding the NAT gateway's public IP address to the database's access control list.

Miscellaneous issues when using Oracle Functions

You might encounter these miscellaneous issues when using Oracle Functions.

When running Oracle Functions on Ubuntu, Docker login returns an "error getting credentials - err: exit status 1..." message

When you configure your development environment for Oracle Functions, you have to install Docker (see 4. Install Docker for Use with Oracle Functions on page 2052). If your development environment is running Ubuntu, when you follow the subsequent instructions to log in to Oracle Cloud Infrastructure Registry using Docker (see 10. Log in to Oracle Cloud Infrastructure Registry on page 2057), you might see a message similar to the following:

```
error getting credentials - err: exit status 1, out: Error spawning command line 'dbus-launch --autolaunch=d7159335070ef1c0854c75de55c8f588 --binary-syntax --close-stderr': Child process exited with code 1
```

For more information about this Docker issue, including likely causes and possible resolutions, see https://github.com/docker/docker-credential-helpers/issues/60.

Function Metrics

You can monitor the health, capacity, and performance of functions you've deployed to Oracle Functions by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci.faas` (the Oracle Functions service).

Resources: functions

Overview of the Oracle Functions Service Metrics

Oracle Functions monitors function execution, and collects and reports metrics such as:

- The number of times a function is invoked.
- The length of time a function runs for.
- The number of times a function failed.
- The number of requests to invoke a function that returned a '429 Too Many Requests' error in the response (known as 'throttled function invocations').

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

For more information about the policy statement required to access metrics emitted by Oracle Functions, see Create a Policy to Give Oracle Functions Users Access to Function-Related Resources on page 2043.

Available Metrics: oci.faas

The metrics listed in the following tables are automatically available for any functions you create. You do not need to enable monitoring on the resource to get these metrics.
Oracle Functions metrics include the following dimensions:

**APPLICATIONID**

The *OCID* of the application containing functions.

**RESOURCEID**

The *OCID* of the function.

**RESPONSETYPE**

The response when a function is invoked (one of Success, Error, or Throttled).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionExecutionDuration</td>
<td>Function Duration</td>
<td>ms</td>
<td>Total function execution duration. Expressed in milliseconds.</td>
<td>applicationId, resourceId</td>
</tr>
<tr>
<td>FunctionInvocationCount</td>
<td>Function Invocations</td>
<td>count</td>
<td>Total number of function invocations.</td>
<td>applicationId, resourceId</td>
</tr>
<tr>
<td>FunctionResponseCount</td>
<td></td>
<td>count</td>
<td>Total number of function responses.</td>
<td>applicationId, resourceId</td>
</tr>
</tbody>
</table>

**Using the Console**

**To view default metric charts for a single function**

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Functions.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that’s specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).
3. Select the compartment containing the application with functions for which you want to view metrics.
   The Applications page shows all the applications in the compartment you selected.
4. Click the name of the application containing the function for which you want to view metrics.
5. Click the name of the function for which you want to view metrics.

   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faaas on page 2107.

   For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Not seeing the function metrics data you expect?**

If you don't see the metrics data for a function that you expect, see the following possible causes and resolutions.
<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missing functions: A function I invoked is missing from the Invocations chart.</td>
<td>The chart range (time period or x-axis window) does not cover the time of invocation.</td>
<td>Adjust the chart range or time period as necessary.</td>
</tr>
<tr>
<td>Gaps in metrics data: The chart line is discontinuous. I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>No metrics data exist in the times indicated by the gaps.</td>
<td>Smooth out the display by increasing the chart interval to see if gaps are removed.</td>
</tr>
<tr>
<td>Empty charts: The Errors and Throttles charts never show data.</td>
<td>No metrics data exists for these charts in the specified chart range. No errors have occurred, and no requests have been throttled. Empty Errors and Throttles charts are expected.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Throttles data: The Throttles chart shows data. What should I do?</td>
<td>Data in the Throttles chart indicates at least one request to invoke a function returned a ‘429 Too Many Requests’ error in the response.</td>
<td>Resubmit the throttled invocation requests. Submit future invocation requests less frequently.</td>
</tr>
</tbody>
</table>

**To view default metric charts for all functions in an application**

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see **6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure** on page 2053).
3. Select the compartment containing the application for which you want to view function metrics.
   
   The **Applications** page shows all the applications in the compartment you selected.
4. Click the name of the application for which you want to view function metrics.
5. Under **Resources**, click **Metrics**.
   
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see **Available Metrics: oci_faaas** on page 2107.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view default metric charts for all the functions in all the applications in a compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2053).

3. Select the compartment containing the applications for which you want to view function metrics.

4. For Metric Namespace, select `oci_faas`.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace. For more information about the emitted metrics, see Available Metrics: `oci_faas` on page 2107.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 20

Health Checks

This chapter explains how to monitor the health of your endpoints.

Overview of the Health Checks Service

The Oracle Cloud Infrastructure Health Checks service provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. By using Health Checks, users can ensure that they are immediately aware of any availability issue affecting their customers.

Health Checks Service Components

The following list describes the key components used in creating a health check.

**MONITORS**

Monitors allow you to continuously monitor the health of public-facing endpoints. You can configure monitors to use either HTTP and ping protocols. Monitors are classified as either Basic or Premium, based on the configured test interval. A monitor is considered Premium if the test interval is set to 10 seconds, and considered Basic if the test interval is greater than 10 seconds. Behavioral differences do not exist between a Basic and Premium monitor, other than the frequency that the monitor is run.

**ON-DEMAND PROBES**

On-demand probes allow you to run a one-time probe to assess the health of a public-facing endpoint. You can configure on-demand probes to use either or both HTTP and ping protocols. This feature is only available through the REST API. A limit exists on how many on-demand probes can be run in a 24-hour period. On-demand credits are consumed as the probes are run, and replenished gradually over time.

**VANTAGE POINTS**

Vantage points are geographic locations from which monitors and probes can be run to your specified target. Oracle Cloud Infrastructure maintains dozens of vantage points around the world.

**PROTOCOLS**

The Health Checks service allows you to configure both HTTP and ping type monitors. Each type has respective protocols.

Ways to Access the Health Checks Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.
Health Checks

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Health Checks Service Capabilities and Limits

The Oracle Cloud Infrastructure Health Checks service is limited to 1000 endpoint tests per account.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Health Checks, see Details for the Health Checks Service on page 2278.

Policy examples:

- To enable all operations on Health Checks for all users in a tenant:

  Allow any-user to manage health-check-family in tenancy

- To enable all operations on Health Checks for all users in a compartment:

  Allow any-user to manage health-check-family in compartment <Compartment Name>

- To enable all operations on Health Checks for a specific user group:

  Allow group <Your Group Name> to manage health-check-family in compartment <Compartment Name>

Moving Health Checks to a Different Compartment

You can move health checks from one compartment to another. When you move a health check to a new compartment, its associated monitor and test results moves with it. After the move, health checks are accessible through the SDK, CLI, and Console. For more information, see Managing Compartments on page 2431.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.
Getting Started With the Health Checks API

The Health Checks service allows you to configure and deploy monitors and on-demand probes using the Health Checks API. Use the following guide to learn how to set up monitors and probes then retrieve their results using the REST API.

**Note:**
Monitors, metrics, and probes created with the API, SDK and CLI are associated with the region where they were configured. While using the API, you must perform monitor updates (including compartment changes), metrics retrieval, and probe results retrieval in the region where they were configured. However, you can get a list of currently configured monitors and monitor details in every region, no matter where the monitors were configured.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Endpoints

The Health Checks API can be accessed via the following endpoints:

- https://healthchecks.ap-chuncheon-1.oraclecloud.com/20180501
- https://healthchecks.ap-hyderabad-1.oraclecloud.com/20180501
- https://healthchecks.ap-melbourne-1.oraclecloud.com/20180501
- https://healthchecks.ap-mumbai-1.oraclecloud.com/20180501
- https://healthchecks.ap-osaka-1.oraclecloud.com/20180501
- https://healthchecks.ap-seoul-1.oraclecloud.com/20180501
- https://healthchecks.ap-sydney-1.oraclecloud.com/20180501
- https://healthchecks.ap-tokyo-1.oraclecloud.com/20180501
- https://healthchecks.ca-montreal-1.oraclecloud.com/20180501
- https://healthchecks.ca-toronto-1.oraclecloud.com/20180501
- https://healthchecks.eu-amsterdam-1.oraclecloud.com/20180501

Health Checks

Available Protocols For Probes and Monitors

You can configure monitors and probes to use HTTP or ping requests. You will need to ensure that the endpoint being monitored is configured to accept the specified protocol.

**HTTP** - Configure a GET or HEAD request using HTTP/1.1 to test the target for availability. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

**HTTPS** - Configure an encrypted HTTPS GET or HEAD request to test the availability of any secure hosted target. Defaults to port 443. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

**ICMP** - Configure an ICMP echo request ping. The results include the round trip time (RTT) latency.

**TCP** - Configure a TCP handshake to the specified end point. You should be sure to own this endpoint as testing this connection can be costly to the recipient. The results include the round trip time (RTT) latency.

Create A Monitor

Monitors allow you to monitor the health of endpoints over time. The following example shows how to create an HTTPS monitor that checks the health of www.example.com at an interval of every 30 seconds using a GET request.

```json
POST /20180501/httpMonitors
{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "protocol": "HTTPS",
    "port": 443,
    "targets": [
        "www.example.com"
    ],
    "timeoutInSeconds": 30,
    "method": "GET",
    "displayName": "Example HTTP monitor",
    "intervalInSeconds": 30
}
```

Targets can be either hostnames or IP addresses and the `path` field can be used to specify an optional path, such as `www.example.com/project/help.htm`. Optionally, you can specify which geographic locations you would like the monitor to launch from by using the `vantagePointNames` field. At least one vantage point must be listed when using this field. For a list of available vantage points, see Vantage Points on page 2117.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the `resultsUrl` field of the response.

```json
{
    "id": "ocid1.httpmonitor.OC2..<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "resultsUrl": "https://healthchecks.us-ashburn-1.oraclecloud.com/20180501/httpProbeResults/ocid1.httpmonitor.OC2..<unique_ID>",
    "targets": [
        "www.example.com",
        "www.oracle.com"
    ],
    "vantagePointNames": [
        "ibm-sjc",
        "aws-dub",
        "dgo-nyc"
    ],
    "protocol": "HTTPS",
    "timeoutInSeconds": 30,
    "displayName": "Example Monitor",
```
Health Checks

For more information about creating an HTTP monitor, see CreateHttpMonitor.

**Note:**
You can configure a similar style monitors using TCP or ICMP protocols. For more information, see CreatePingMonitor.

Create An On-Demand Probe

Probes are one-off health assessments of an endpoint that can be deployed at anytime. The following example shows how to create an on-demand HTTP probe that checks the health of www.example.com with a GET request.

```
POST /20180501/httpProbeResults
{
   "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
   "protocol": "HTTP",
   "targets": [
      "www.example.com"
   ],
   "timeoutInSeconds": 30,
   "method": "GET"
}
```

Targets can be either hostnames or IP addresses and the path field can be used to specify an optional path, such as www.example.com/project/help.htm. Additionally, you can specify which geographic locations you would like the probe to launch from by using the vantagePointNames field. For a list of available vantage points, see Vantage Points on page 2117.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the resultsUrl field of the response. It will take a few moments for results to display once the tests have been configured.

```
{
   "id":"ocid1.pingprobe.OC2..<unique_ID>",
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "resultsUrl":"https://healthchecks.us-ashburn-1.oraclecloud.com/20180501/pingProbeResults/ocid1.pingprobe.OC2..<unique_ID>",
   "targets":[
      "www.example.com"
   ],
   "vantagePointNames": [
      "ibm-sjc",
      "aws-dub",
      "dgo-nyc"
   ],
   "protocol":"ICMP",
   "timeoutInSeconds":30
}
```

For more information about creating a probe, see CreateOnDemandHttpProbe.

**Note:**
You can configure similar style probes using TCP or ICMP protocols. For more information, see CreateOnDemandPingProbe.
Health Checks

Retrieving Probe And Monitor Results

Probe and monitor results can be retrieved from URL in the `resultsUrl` field of a monitor or probe creation response. It will take a few moments for results to display once the tests have been configured. Results can also be retrieved at anytime using the following methods:

- **ListPingProbeResults** - For monitors or on-demand probes using TCP or ICMP protocols.
- **ListHttpProbeResults** - For monitors or on-demand probes using HTTP protocols.

Retrieving results for an on-demand probe or monitor requires the probe or monitor's configuration ID as a parameter. On-demand probe and configuration IDs are assigned upon their creation and are returned in the id field of the POST response. You can also use the **ListHttpMonitor** method to retrieve a list of currently configured monitors and probes using HTTP protocols. Use the **ListPingMonitors** method to retrieve a list of currently configured monitors and probes using TCP and ICMP protocols.

The following is an example of results retrieved using `GET /httpProbeResults/ {probeConfigurationId}`.

```
{
    "key": "651b9f3a46041cace0530204060ae27e",
    "probeConfigurationId": "ocid1.httpmonitor.OC2..<unique_ID>",
    "startTime": 1517323711505,
    "target": "www.example.com",
    "vantagePointName": "dgo-nyc",
    "protocol": "HTTPS",
    "connection": {
        "connectDuration": 114,
        "secureConnectDuration": 99,
        "address": "93.184.216.34",
        "port": 443
    },
    "dns": {
        "domainLookupDuration": 29,
        "addresses": [
            "93.184.216.34",
        ]
    },
    "statusCode": 200,
    "fetchStart": 1517323711505,
    "domainLookupStart": 1517323711505,
    "domainLookupEnd": 1517323711534,
    "connectStart": 1517323711535,
    "secureConnectionStart": 1517323711550,
    "connectEnd": 1517323711649,
    "requestStart": 1517323711649,
    "responseStart": 1517323711673,
    "responseEnd": 1517323711676,
    "duration": 171,
    "encodedBodySize": 1270,
    "isTimedOut": false,
    "isHealthy": true
}
```

Vantage Points

Vantage points are geographic locations from which monitors and probes can be launched. Oracle Cloud Infrastructure maintains vantage points on the infrastructure of cloud providers around the world, including AWS, IBM, and Azure. The list below is a sampling of the vantage points available. The list of vantage points is dynamic and changes frequently. Use the **ListHealthChecksVantagePoints** method to return a list of available vantage points.
## Managing Health Checks

The Health Checks service allows you to monitor the health of IP addresses and hostnames, as measured from geographic vantage points of your choosing, using HTTP and ping probes. After configuring a health check, you can view the monitor's results. The results include the location from which the host was monitored, the availability of the endpoint, and the date and time the test was performed.

### Using the Console

To add a health check

<table>
<thead>
<tr>

</tbody>
</table>

**Important:**

If you have selected the HTTPS protocol for this monitor and have entered an IP address as a Target to be monitored, you must specify a Host header with the domain name associated with the TLS certificate for that target. If you do not add the Host header, the TLS connection phase will not complete.
Health Checks

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Click Create Health Check.
3. In the Create Health Check dialog box, enter the following:
   - **Health Check Name**: The name used for the health check. Avoid entering confidential information.
   - **Compartment**: Select the compartment the health check runs in.
   - **Target(s)**: The IP address or fully qualified domain name (FQDN) of the host being monitored. Additional targets can be added.
   - **Vantage Points**: Select the location from which the health of the target is monitored. No more than ten vantage points can be added.
   - **Request Type**: Select the type of request sent to monitor the target.
     - **HTTP** - Enter the following:
       - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
       - **Port**: The port for the monitor to look for a connection. The default is port 80 for HTTP. For HTTPS, use port 443.
       - **Path**: The specific path on the target to be monitored.
       - **Header Name**: (Optional) The name displayed in the request header as part of the health check. Avoid entering confidential information.
       - **Header Value**: (Optional) Specifies the data requested by the header. Click + Add Header to add multiple headers in succession.
       - **Method**: Select the HTTP method used for the health check.
       - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
       - **Interval**: Select the period of time between health checks of the target.
     - **Ping** - Enter the following:
       - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
       - **Port**: If you have selected the TCP protocol, enter the port for the monitor to look for a connection. The default port is 80.
       - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
       - **Interval**: Select the period of time between health checks of the target.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click Create Health Check.

The health check is added to the health check list. To view more details, click the health check name. It will take a few moments for results to display once the tests have been configured.

**To edit a health check**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Select the check box for the health check you want to edit.
3. Select Edit from the Actions drop-down menu.
4. In the Edit Health Check dialog box, make the needed changes, and then click Edit Health Check.
Health Checks

To disable a health check

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Select the check box for the health check you want to disable.

   Tip:
   To help find a health check, you can enter the name of the health check in the Search field.

3. Select Disable from the Actions drop-down menu.

   The status of the health check changes to Disabled in the health check list.

To duplicate a health check

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Select the check box for the health check you want to duplicate.
3. Select Duplicate from the Actions drop-down menu.
4. In the Create Health Check dialog box, make any updates to the duplicated health check, and then click Create Health Check.

To delete a health check

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Select the check box for the health check you want to delete.

   Tip:
   To help find a health check, you can enter the name of the health check in the Search field.

3. Select Delete from the Actions drop-down menu.
4. In the confirmation dialog box, click Delete.

To view the history of a health check

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Click the name of the health check you want to view.

   The Health Check history displays a list of results for the past 90 days.

   Tip:
   To help find a result, you can use the Start Date, Start Time, End Date, End Time, and Targets filter options.

3. Click the drop-down arrow beside the Timestamp to view the monitor result details. You can use the API to download the data.

To manage tags for a health check

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. Click the name of the health check you want to view.
3. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

   For more information, see Resource Tags on page 211.

To move a health check to a different compartment

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Health Checks.
2. In the Scope section, select a compartment.
3. Find the health check in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

   For more information, see Managing Compartments on page 2431.
Tip:
If your health checks are continually failing, please ensure that you have permission to monitor the host and that the ports on the host have been configured to receive traffic from Health Checks.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

• Use the CreateHTTPMonitor operation to create a Health Check monitor that uses the HTTP protocol.
• Use the CreatePingMonitor operation to create a Health Check monitor that uses the ping protocol.
• Use the ListHealthChecksVantagePoints to retrieve a list of available vantage points from which to execute monitors.
• Use the UpdateHttpMonitor operation to update the configuration of an HTTP health check monitor. You can also use this operation to disable an HTTP monitor by setting the isEnabled field to false.
• Use the UpdatePingMonitor operation to update the configuration of ping health check monitor. You can also use this operation to disable a ping monitor by setting the isEnabled field to false.
• Use the DeleteHttpMonitor operation to remove an HTTP health check monitor from your setup.
• Use the DeletePingMonitor operation to remove a ping health check monitor from your setup.
• Use the ListHttpProbeResults operation to retrieve the results of an HTTP health check monitor.
• Use the ListPingProbeResults operation to retrieve results of a ping health check monitor.

Health Checks Metrics

You can monitor the health, capacity, and performance of your health checks by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_healthchecks (the Health Checks service).

Overview of the Health Checks Service Metrics

Oracle Cloud Infrastructure Health Checks provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. The Health Checks service metrics help you monitor the performance of your endpoints over a 24 hour period.

Prerequisites

• IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_healthchecks

The metrics listed in the following table are automatically available for each health check that you create. You do not need to enable monitoring on the health check to get these metrics.

Each metric includes the following dimensions:

RESOURCEID

The OCID of the policy to which the metric applies.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PING.isHealthy</td>
<td>Ping Test Success Rate</td>
<td>percent</td>
<td>Displays availability of end point being monitored.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage icmpCode</td>
</tr>
<tr>
<td>HTTP.DNSLookupTime</td>
<td>HTTP(S) DNS Lookup Time</td>
<td>ms</td>
<td>The time taken for domain name lookup in milliseconds.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage icmpCode</td>
</tr>
<tr>
<td>HTTP.TCPConnectTime</td>
<td>HTTP(S) Connection Duration</td>
<td>ms</td>
<td>The total TCP connection duration for the test which applies to both HTTP and HTTPS protocols.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>HTTP.RequestTime</td>
<td>HTTP(S) Request Duration</td>
<td>ms</td>
<td>The total duration of the request in milliseconds.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>HTTP.ResponseTime</td>
<td>HTTP(S) Response Duration</td>
<td>ms</td>
<td>The total duration of response in milliseconds.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>HTTP.TotalDuration</td>
<td>HTTP(S) Total Duration</td>
<td>ms</td>
<td>The total duration of the test run in milliseconds.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>PING.Latency</td>
<td>Ping Latency Measurement</td>
<td>ms</td>
<td>Latency measurement for ping test in milliseconds.</td>
<td>target vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
</tbody>
</table>

**Using the Console**

To view metric charts for resources related to a health check monitor

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Click the name of the health check you want to view metrics for.
3. Click **Metrics**.

**To view health check metric charts using monitoring**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.

   For **Metric Namespace**, select **oci_healthchecks**.

2. Select a metric to view from the **Metric Name** field.

3. Select a qualifier specified in the Dimension Name field. For example, the dimension **resourceId** is specified in the metric definition for **BasicCount**.

4. Select the value you want to use for the specified dimension in the **Dimension Value** field. For example, the resource identifier for your instance of interest.

5. Click **Update Chart**.

   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**Using the API**

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
Chapter 21

I AM

This chapter explains how to set up administrators, users, and groups and specify their permissions.

Overview of Oracle Cloud Infrastructure Identity and Access Management

Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who has access to your cloud resources. You can control what type of access a group of users have and to which specific resources. This section gives you an overview of IAM components and an example scenario to help you understand how they work together.

Note:

This document uses the term "you" broadly to mean any administrator in your company who has access to work with IAM.

Components of IAM

IAM uses the components described in this section. To better understand how the components fit together, see Example Scenario on page 2126.

RESOURCE

The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure. For example: compute instances, block storage volumes, virtual cloud networks (VCNs), subnets, route tables, etc.

USER

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources. Users might need to launch instances, manage remote disks, work with your virtual cloud network, etc. End users of your application are not typically IAM users. Users have one or more IAM credentials (see User Credentials on page 2360).

GROUP

A collection of users who all need the same type of access to a particular set of resources or compartment.

DYNAMIC GROUP

A special type of group that contains resources (such as compute instances) that match rules that you define (thus the membership can change dynamically as matching resources are created or deleted). These instances act as "principal" actors and can make API calls to services according to policies that you write for the dynamic group.

NETWORK SOURCE

A group of IP addresses that are allowed to access resources in your tenancy. The IP addresses can be public IP addresses or IP addresses from a VCN within your tenancy. After you create the network source, you use policy to restrict access to only requests that originate from the IPs in the network source.
COMPARTMENT

A collection of related resources. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating your cloud resources. You use them to clearly separate resources for the purposes of measuring usage and billing, access (through the use of policies), and isolation (separating the resources for one project or business unit from another). A common approach is to create a compartment for each major part of your organization. For more information, see “Setting Up Your Tenancy” in the Oracle Cloud Infrastructure Getting Started Guide.

TENANCY

The root compartment that contains all of your organization's Oracle Cloud Infrastructure resources. Oracle automatically creates your company's tenancy for you. Directly within the tenancy are your IAM entities (users, groups, compartments, and some policies; you can also put policies into compartments inside the tenancy). You place the other types of cloud resources (e.g., instances, virtual networks, block storage volumes, etc.) inside the compartments that you create.

POLICY

A document that specifies who can access which resources, and how. Access is granted at the group and compartment level, which means you can write a policy that gives a group a specific type of access within a specific compartment, or to the tenancy itself. If you give a group access to the tenancy, the group automatically gets the same type of access to all the compartments inside the tenancy. For more information, see Example Scenario on page 2126 and How Policies Work on page 2136. The word "policy" is used by people in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named “policy” document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

HOME REGION

The region where your IAM resources reside. All IAM resources are global and available across all regions, but the master set of definitions reside in a single region, the home region. You must make changes to your IAM resources in your home region. The changes will be automatically propagated to all regions. For more information, see Managing Regions on page 2445.

FEDERATION

A relationship that an administrator configures between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

Services You Can Control Access To

You can write policies to control access to all of the services within Oracle Cloud Infrastructure.

The Administrators Group and Policy

When your company signs up for an Oracle account and Identity Domain, Oracle sets up a default administrator for the account. This person will be the first IAM user for your company and will be responsible for initially setting up additional administrators. Your tenancy comes with a group called Administrators, and the default administrator automatically belongs in this group. You can't delete this group, and there must always be at least one user in it.

Your tenancy also automatically has a policy that gives the Administrators group access to all of the Oracle Cloud Infrastructure API operations and all of the cloud resources in your tenancy. You can neither change nor delete this policy. Any other users you put into the Administrators group will have full access to all of the services. This means they can create and manage IAM resources such as, groups, policies, and compartments. And they can create and manage the cloud resources such as virtual cloud networks (VCNs), instances, block storage volumes, and any other new types of Oracle Cloud Infrastructure resources that become available in the future.
Example Scenario

The goal of this scenario is to show how the different IAM components work together, and basic features of policies.

In this scenario, Acme Company has two teams that will be using Oracle Cloud Infrastructure resources for infrastructure: Project A and Project B. In reality, your company may have many more.

Acme Company plans to use a single virtual cloud network (VCN) for both teams, and wants a network administrator to manage the VCN.

Acme Company also wants the Project A team and Project B team to each have their own set of instances and block storage volumes. The Project A team and Project B teams shouldn't be able to use each other's instances. These two teams also shouldn't be allowed to change anything about the VCN set up by the network administrator. Acme Company wants each team to have administrators for that team's resources. The administrators for the Project A team can decide who can use the Project A cloud resources, and how. Same for the Project B team.

Acme Company Gets Started with Oracle Cloud Infrastructure

Acme Company signs up to use Oracle Cloud Infrastructure and tells Oracle that an employee named Wenpei will be the default administrator. In response, Oracle:

- Creates a tenancy for Acme Company (see the following diagram).
- Creates an IAM user account for Wenpei in the tenancy.
- Creates the Administrators group in the tenancy and places Wenpei in that group.
- Creates a policy in Acme Company's tenancy that gives the Administrators group access to manage all of the resources in the tenancy. Here's that policy:

  Allow group Administrators to manage all-resources in tenancy

The default setup for a new tenancy:

<table>
<thead>
<tr>
<th>CompanyA Tenancy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policies attached to the tenancy:</td>
</tr>
<tr>
<td>Allow group Administrators to manage all-resources in tenancy</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Users</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wenpei</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Administrators</td>
</tr>
<tr>
<td>Wenpei</td>
</tr>
</tbody>
</table>

The Default Administrator Creates Some Groups and Another Administrator

Wenpei next creates several groups and users (see the following diagram). She:

- Creates groups called NetworkAdmins, A-Admins, and B-Admins (these last two are for Project A and Project B within the company)
- Creates a user called Alex and puts him in the Administrators group.
- Leaves the new groups empty.

To learn how to create groups, see Working with Groups on page 2420. To learn how to create users and put them in groups, see Working with Users on page 2415.
The Default Administrator Creates Some Compartments and Policies

Wenpei next creates compartments to group resources together (see the following diagram). She:

- Creates a compartment called Networks to control access to the Acme Company’s VCN, subnets, IPSec VPN, and other components from Networking.
- Creates a compartment called Project-A to organize Project A team’s cloud resources and control access to them.
- Creates a compartment called Project-B to organize Project B team’s cloud resources and control access to them.

To learn how to manage compartments, see Working with Compartments on page 2432.

Wenpei then creates a policy to give the administrators for each compartment their required level of access. She attaches the policy to the tenancy, which means that only users with access to manage policies in the tenancy can later update or delete the policy. In this scenario, that is only the Administrators group. The policy includes multiple statements that:

- Give the NetworkAdmins group access to manage networks and instances (for the purposes of easily testing the network) in the Networks compartment
- Give both the A-Admins and B-Admins groups access to use the networks in the Networks compartment (so they can create instances into the network).
- Give the A-Admins group access to manage all resources in the Project-A compartment.
- Give the B-Admins group access to manage all resources in the Project-B compartment.

Here’s what that policy looks like (notice it has multiple statements in it):

```
Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
Allow group NetworkAdmins to manage instance-family in compartment Networks
Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
Allow group A-Admins to manage all-resources in compartment Project-A
Allow group B-Admins to manage all-resources in compartment Project-B
```

Notice the difference in the verbs (manage, use), as well as the resources (virtual-network-family, instance-family, all-resources). For more information about them, see Verbs on page 2138 and Resource-Types on page 2139. To learn how to create policies, see To create a policy on page 2454.
Important:

A-Admins and B-Admins can use the virtual-network-family in the compartment Networks. However, they can't create instances in that compartment. They can only create instances in the Project-A or Project-B compartment. Remember, a compartment is a logical grouping, not a physical one, so resources that make up or reside on the same VCN can belong to different compartments.

Acme Company wants to let the administrators of the Project-A and Project-B compartments decide which users can use the resources in those compartments. So Wenpei creates two more groups: A-Users and B-Users. She then adds six more statements that give the compartment admins the required access they need in order to add and remove users from those groups:

- Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
- Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
- Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
- Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'
- Allow group A-Admins,B-Admins to inspect users in tenancy
- Allow group A-Admins,B-Admins to inspect groups in tenancy

Notice that this policy doesn't let the project admins create new users or manage credentials for the users. It lets them decide which existing users can be in the A-Users and B-Users groups. The last two statements are necessary for A-Admins and B-Admins to list all the users and groups, and confirm which users are in which groups.
An Administrator Creates New Users

At this point, Alex is in the Administrators group and now has access to create new users. So he provisions users named Leslie, Jorge, and Cheri and places them in the NetworkAdmins, A-Admins, and B-Admins groups,
respectively. Alex also creates other users who will eventually be put in the A-Users and B-Users groups by the admins for Project A and Project B.

### CompanyA Tenancy

**Policies attached to the tenancy:**

- Allow group `Administrators` to manage all-resources in tenancy
- Allow group `NetworkAdmins` to manage virtual-network-family in compartment Networks
- Allow group `NetworkAdmins` to manage instance-family in compartment Networks
- Allow group `A-Admins,B-Admins` to use virtual-network-family in compartment Networks
- Allow group `A-Admins` to manage all-resources in compartment Project-A
- Allow group `B-Admins` to manage all-resources in compartment Project-B
- Allow group `A-Admins` to use users in tenancy where target.group.name='A-Users'
- Allow group `A-Admins` to use groups in tenancy where target.group.name='A-Users'
- Allow group `B-Admins` to use users in tenancy where target.group.name='B-Users'
- Allow group `B-Admins` to use groups in tenancy where target.group.name='B-Users'
- Allow group `A-Admins,B-Admins` to inspect users in tenancy
- Allow group `A-Admins,B-Admins` to inspect groups in tenancy

<table>
<thead>
<tr>
<th>Users</th>
<th>Alex</th>
<th>Cheri</th>

<th>Networks</th>
<th>Project-A</th>
<th>Project-B</th>
</tr>
</thead>
</table>
The Network Admin Sets Up the Network

Leslie (in the NetworkAdmins group) has access to manage virtual-network-family and instance-family in the Networks compartment. She creates a virtual cloud network (VCN) with a single subnet in that compartment. She also sets up an Internet gateway for the VCN, and updates the VCN's route table to allow traffic via that gateway. To test the VCN's connectivity to the on-premises network, she launches an instance in the subnet in the VCN. As part of the launch request, she must specify which compartment the instance should reside in. She specifies the Networks compartment, which is the only one she has access to. She then confirms connectivity from the on-premises network to the VCN by logging in to the instance via SSH from the on-premises network.

Leslie terminates her test instance and lets Jorge and Cheri know that the VCN is up and running and ready to try out. She lets them know that their compartments are named Project-A and Project-B respectively. For more information about setting up a cloud network, see Networking on page 2746. For information about launching instances into the network, see Overview of the Compute Service on page 590.

Compartment Admins Set Up Their Compartments

Jorge and Cheri now need to set up their respective compartments. Each admin needs to do the following:

- Launch instances in their own compartment
- Put users in their "users" group (e.g., A-Users)
- Decide the type of access to give those users, and accordingly attach a policy to their compartment

Jorge and Cheri both launch instances into the subnet in the VCN, into their respective team's compartments. They create and attach block volumes to the instances. Only the compartment admins can launch/terminate instances or attach/detach block volumes in their respective team's compartments.

### Important:

Network Topology and Compartment Access Are Different Concepts

It's important to understand the difference between the network topology of the VCN and the access control that the compartments provide. The instances Jorge launched reside in the VCN from a network topology standpoint. But from an access standpoint, they're in the Project-A compartment, not the Networks compartment where the VCN is. Leslie (the Networks admin) can't terminate or reboot Jorge's instances, or launch new ones into the Project-A compartment. But Leslie controls the instances' network, so she controls what traffic will be routed to them. If Jorge had specified the Networks compartment instead of the Project-A compartment when launching his instances, his request would have been denied. The story is similar for Cheri and the Project-B compartment.

But it's also important to note that Wenpei and Alex in the Administrators group do have access to the resources inside the compartments, because they have access to manage all kinds of resources in the tenancy. Compartments inherit any policies attached to their parent compartment (the tenancy), so the Administrators access also applies to all compartments within the tenancy.

Next, Jorge puts several of the users that Alex created into the A-Users group. Cheri does the same for B-Users.

Then Jorge writes a policy that gives users the level of access they need in the Project-A compartment.

```java
Allow group A-Users to use instance-family in compartment Project-A
Allow group A-Users to use volume-family in compartment Project-A
Allow group A-Users to inspect virtual-network-family in compartment Networks
```

This lets them use existing instances (with attached block volumes) that the compartment admins already launched in the compartment, and stop/start/reboot them. It does not let A-Users create/delete or attach/detach any volumes. To give that ability, the policy would need to include manage volume-family.
Jorge attaches this policy to the Project-A compartment. Anyone with the ability to manage policies in the compartment can now modify or delete this policy. Right now, that is only the A-Admins group (and the Administrators group, which can do anything throughout the tenancy).

Cheri creates and attaches her own policy to the Project-B compartment, similar to Jorge's policy:

```
Allow group B-Users to use instance-family in compartment Project-B
Allow group B-Users to use volume-family in compartment Project-B
Allow group B-Users to inspect virtual-network-family in compartment Networks
```

Now the A-Users and B-Users can work with the existing instances and attached volumes in the Project-A and Project-B compartments, respectively. Here's what the layout looks like:
# CompanyA Tenancy

**Policies attached to the tenancy:**

- Allow group **Administrators** to manage all-resources in tenancy
- Allow group **NetworkAdmins** to manage virtual-network-family in compartment **Networks**
- Allow group **NetworkAdmins** to manage instance-family in compartment **Networks**
- Allow group **A-Admins,B-Admins** to use virtual-network-family in compartment **Networks**
- Allow group **A-Admins** to manage all-resources in compartment **Project-A**
- Allow group **B-Admins** to manage all-resources in compartment **Project-B**
- Allow group **A-Admins** to use users in tenancy where target.group.name='A-Users'
- Allow group **A-Admins** to use groups in tenancy where target.group.name='A-Users'
- Allow group **B-Admins** to use users in tenancy where target.group.name='B-Users'
- Allow group **B-Admins** to use groups in tenancy where target.group.name='B-Users'
- Allow group **A-Admins,B-Admins** to inspect users in tenancy
- Allow group **A-Admins,B-Admins** to inspect groups in tenancy

<table>

  - Policy attached and managed by Cheri
  - Allow group **B-Users** to use instance-family in compartment **Project-B**
  - Allow group **B-Users** to use volume-family in compartment **Project-B**
  - Allow group **B-Users** to inspect virtual-network-family in compartment **Networks**
  - Allow group **B-Users** to inspect virtual-network-family in compartment **Networks**
For more information about basic and advanced features of policies, see How Policies Work on page 2136. For examples of other typical policies your organization might use, see Common Policies on page 2142.

**Viewing Resources by Compartment in the Console**

In the Console, you view your cloud resources by compartment. This means that after you sign in to the Console, you'll choose which compartment to work in (there's a list of the compartments you have access to on the left side of the page). Notice that compartments can be nested inside other compartments. The page will update to show that compartment's resources that are within the current region. If there are none, or if you don't have access to the resource in that compartment, you'll see a message.

This experience is different when you're viewing the lists of users, groups, dynamic groups, and federation providers. Those reside in the tenancy itself (the root compartment), not in an individual compartment.

As for policies, they can reside in either the tenancy or a compartment, depending on where the policy is attached. Where it's attached controls who has access to modify or delete it. For more information, see Policy Attachment on page 2141.

**The Scope of IAM Resources**

Oracle Cloud Infrastructure uses the concepts of regions and availability domains (see Regions and Availability Domains). Some resources are available regionally, whereas others are available only within a certain availability domain. IAM resources (users, groups, dynamic groups, compartments, tag namespaces, federation providers, and policies) are global and available across all regions. See Managing Regions on page 2445.

**Creating Automation with Events**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

The following IAM resources emit events:

- Authentication policies
- Credentials
- Dynamic groups
- Groups
- Identity Providers
- Multi-factor Authentication TOTP Devices
- Policies
- Users

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later
For general information about using the API, see REST APIs on page 4368.

Limits on IAM Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Getting Started with Policies

If you're new to Oracle Cloud Infrastructure Identity and Access Management (IAM) policies, this topic gives guidance on how to proceed.

If You’re Doing a Proof-of-Concept

If you're just trying out Oracle Cloud Infrastructure or doing a proof-of-concept project with infrastructure resources, you may not need more than a few administrators with full access to everything. In that case, you can simply create any new users you need and add them to the Administrators group. The users will be able to do anything with any kind of resource. And you can create all your resources directly in the tenancy (the root compartment). You don't need to create any compartments yet, or any other policies beyond the Tenant Admin Policy, which automatically comes with your tenancy and can't be changed.

Note:
Don't forget to add your new users to the Administrators group; it's easy to forget to do that after creating them.

If You’re Past the Proof-of-Concept Phase

If you're past the proof-of-concept phase and want to restrict access to your resources, first:

• Make sure you're familiar with the basic IAM components, and read through the example scenario: Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124
• Think about how to organize your resources into compartments: See "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide
• Learn the basics of how policies work: How Policies Work on page 2136
• Check out some typical policies: Common Policies on page 2142
• Read the FAQs below

Policy FAQs

Which of the services within Oracle Cloud Infrastructure can I control access to through policies?

All of them, including IAM itself. You can find specific details for writing policies for each service in the Policy Reference on page 2167.

Can users do anything without an administrator writing a policy for them?

Yes. All users can automatically do these things without an explicit policy:

• Change or reset their own Console password.
• Manage their own API signing keys and other credentials.

Why should I separate resources by compartment? Couldn't I just put all the resources into one compartment and then use policies to control who has access to what?

You could put all your resources into a single compartment and use policies to control access, but then you would lose the benefits of measuring usage and billing by compartment, simple policy administration at the compartment level, and clear separation of resources between projects or business units.

Can I control or deny access to an individual user?

Yes. However, there are a couple things to know first:
• Enterprise companies typically have multiple users that need similar permissions, so policies are designed to give access to groups of users, not individual users. A user gains access by being in a group.
• Policies are designed to allow access; there’s no explicit “deny” when you write a policy.

If you need to grant access to a particular user, you can add a condition to the policy that specifies the user’s OCID in a variable. This construction restricts the access granted in the policy to only the user specified in the condition. For example:

```
allow any-user to read object-family in compartment ObjectStorage where request.user.id = 'ocid1.user.oc1..<user_OCID>'
```

For information about using conditions and variables in policies, see Conditions on page 2160.

If you need to restrict a particular user’s access, you can:
• Remove the user from the particular group of interest
• Delete the user entirely from IAM (you have to remove the user from all groups first)

**How do I delete a user?**

First ensure the user isn’t in any groups. Only then can you delete the user.

**How do I delete a compartment?**

See To delete a compartment on page 2444.

**How can I tell which policies apply to a particular group or user?**

You need to look at the individual statements in all your policies to see which statements apply to which group. There’s not currently an easy way to get this information.

**How can I tell which policies apply to a particular compartment?**

You need to look at the individual statements in all the policies in the tenancy to see if any apply to the particular compartment. You also need to look at any policies in the compartment itself. Policies in any of the sibling compartments cannot refer to the compartment of interest, so you don't need to check those policies.

**How Policies Work**

This topic describes how policies work and the basic features.

**Overview of Policies**

A policy is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a group to work in certain ways with specific types of resources in a particular compartment. If you’re not familiar with users, groups, or compartments, see Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124.

In general, here’s the process an IAM administrator in your organization needs to follow:

1. Define users, groups, and one or more compartments to hold the cloud resources for your organization.
2. Create one or more policies, each written in the policy language. See Common Policies on page 2142.
3. Place users into the appropriate groups depending on the compartments and resources they need to work with.
4. Provide the users with the one-time passwords that they need in order to access the Console and work with the compartments. For more information, see User Credentials on page 2360.

After the administrator completes these steps, the users can access the Console, change their one-time passwords, and work with specific cloud resources as stated in the policies.
Policy Basics

To govern control of your resources, your company will have at least one policy. Each policy consists of one or more policy statements that follow this basic syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

Notice that the statements always begin with the word Allow. Policies only allow access; they cannot deny it. Instead there's an implicit deny, which means by default, users can do nothing and have to be granted access through policies. (There's one exception to this rule; see Can users do anything without an administrator writing a policy for them? on page 2135)

An administrator in your organization defines the groups and compartments in your tenancy. Oracle defines the possible verbs and resource-types you can use in policies (see Verbs on page 2138 and Resource-Types on page 2139).

In some cases you'll want the policy to apply to the tenancy and not a compartment inside the tenancy. In that case, change the end of the policy statement like so:

```
Allow group <group_name> to <verb> <resource-type> in tenancy
```

For more details about the syntax, see Policy Syntax on page 2164.

For information about how many policies you can have, see Service Limits on page 215.

A Few Examples

Let's say your administrator creates a group called HelpDesk whose job is to manage users and their credentials. Here is a policy that enables that:

```
Allow group HelpDesk to manage users in tenancy
```

Notice that because users reside in the tenancy (the root compartment), the policy simply states the word tenancy, without the word compartment in front of it.

Next, let's say you have a compartment called Project-A, and a group called A-Admins whose job is to manage all of the Oracle Cloud Infrastructure resources in the compartment. Here's an example policy that enables that:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Be aware that the policy directly above includes the ability to write policies for that compartment, which means A-Admins can control access to the compartment's resources. For more information, see Policy Attachment on page 2141.

If you wanted to limit A-Admins' access to only launching and managing compute instances and block storage volumes (both the volumes and their backups) in the Project-A compartment, but the network itself lives in the Networks compartment, then the policy could instead be:

```
Allow group A-Admins to manage instance-family in compartment Project-A
Allow group A-Admins to manage volume-family in compartment Project-A
Allow group A-Admins to use virtual-network-family in compartment Networks
```

The third statement with the virtual-network-family resource-type enables the instance launch process, because the cloud network is involved. Specifically, the launch process creates a new VNIC and attaches it to the subnet where the instance resides.

For additional examples, see Common Policies on page 2142.
Details about Specifying Groups and Compartments

Typically you'll specify a group or compartment by name in the policy. However, you can use the OCID instead. Just make sure to add "id" before the OCID. For example:

```
Allow group
  id ocid1.group.oc1..aaaaaaaqjihfhvmumrl3isyrfw3n6c4rzwckawuc7i5xwe6s7qmsb6a
  to manage instance-family in compartment Project-A
```

You can specify multiple groups separated by commas:

```
Allow group A-Admins, B-Admins to manage instance-family in compartment Projects-A-and-B
```

Verbs

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. <strong>Important:</strong> The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td>read</td>
<td>Includes inspect plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the &quot;update&quot; operation has the same effective impact as the &quot;create&quot; operation (e.g., UpdatePolicy, UpdateSecurityList, etc.), in which case the &quot;update&quot; ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td>manage</td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

The verb gives a certain general type of access (e.g., inspect lets you list and get resources). When you then join that type of access with a particular resource-type in a policy (e.g., Allow group XYZ to inspect compartments in the tenancy), then you give that group access to a specific set of permissions and API operations (e.g., ListCompartments, GetCompartment). For more examples, see Details for Verbs + Resource-Type Combinations on page 2281. The Policy Reference on page 2167 includes a similar table for each service, giving you a list of exactly which API operations are covered for each combination of verb and resource-type.

There are some special exceptions or nuances for certain resource-types.

**Users:** Access to both manage users and manage groups lets you do anything with users and groups, including creating and deleting users and groups, and adding/removing users from groups. To add/remove users from groups without access to creating and deleting users and groups, only both use users and use groups are required. See Common Policies on page 2142.
**Policies:** The ability to update a policy is available only with manage policies, not use policies, because updating a policy is similar in effect to creating a new policy (you can overwrite the existing policy statements). In addition, inspect policies lets you get the full contents of the policies.

**Object Storage objects:** inspect objects lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, read objects lets you download the object itself.

**Load Balancing resources:** Be aware that inspect load-balancers lets you get all information about your load balancers and related components (backend sets, etc.).

**Networking resources:**

Be aware that the inspect verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).

Also, the following types of abilities are available only with the manage verb, not the use verb:

- Update (enable/disable) internet-gateways
- Update security-lists
- Update route-tables
- Update dhcp-options
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
- Peer VCNs

**Important:**

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to update that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you're implicitly trusting them with controlling the network's behavior.

**Resource-Types**

Oracle also defines the resource-types you can use in your policies. First, there are individual types. Each individual type represents a specific type of resource. For example, the vcn resource-type is specifically for virtual cloud networks (VCNs).

To make policy writing easier, there are family types that include multiple individual resource-types that are often managed together. For example, the virtual-network-family type brings together a variety of types related to the management of VCNs (e.g., vcn, subnets, route-tables, security-lists, etc.). If you need to write a more granular policy that gives access to only an individual resource-type, you can. But you can also easily write a policy to give access to a broader range of resources.

In another example: Block Volume has volumes, volume-attachments, and volume-backups. If you need to give access to only making backups of volumes, you can specify the volume-backups resource-type in your policy. But if you need to give broad access to all of the Block Volume resources, you can specify the family type called volume-family. For a full list of the family resource-types, see Resource-Types on page 2169.
Important: If a service introduces new individual resource-types, they will typically be included in the family type for that service. For example, if Networking introduces a new individual resource-type, it will be automatically included in the definition of the virtual-network-family resource type. For more information about future changes to the definitions of resource-types, see Policies and Service Updates on page 2142.

Note that there are other ways to make policies more granular, such as the ability to specify conditions under which the access is granted. For more information, see Advanced Policy Features on page 2160.

Access that Requires Multiple Resource-Types

Some API operations require access to multiple resource-types. For example, LaunchInstance requires the ability to create instances and work with a cloud network. The CreateVolumeBackup operation requires access to both the volume and the volume backup. That means you’ll have separate statements to give access to each resource-type (for an example, see Let volume backup admins manage only backups on page 2146). These individual statements do not have to be in the same policy. And a user can gain the required access from being in different groups. For example, George could be in one group that gives the required level of access to the volumes resource-type, and in another group that gives the required access to the volume-backups resource-type. The sum of the individual statements, regardless of their location in the overall set of policies, gives George access to CreateVolumeBackup.

Policy Inheritance

A basic feature of policies is the concept of inheritance: Compartments inherit any policies from their parent compartment. The simplest example is the Administrators group, which automatically comes with your tenancy (see The Administrators Group and Policy on page 2125). There’s a built-in policy that enables the Administrators group to do anything in the tenancy:

Allow group Administrators to manage all-resources in tenancy

Because of policy inheritance, the Administrators group can also do anything in any of the compartments in the tenancy.

To illustrate further, consider a tenancy with three levels of compartments: CompartmentA, CompartmentB, and CompartmentC, shown here:

![Compartment Hierarchy Diagram]

Policies that apply to resources in CompartmentA also apply to resources in CompartmentB and CompartmentC. So this policy:

Allow group NetworkAdmins to manage virtual-network-family in compartment CompartmentA

allows the group NetworkAdmins to manage VCNs in CompartmentA, CompartmentB, and CompartmentC.
**Policy Attachment**

Another basic feature of policies is the concept of attachment. When you create a policy you must attach it to a compartment (or the tenancy, which is the root compartment). **Where you attach it controls who can then modify it or delete it.** If you attach it to the tenancy (in other words, if the policy is in the root compartment), then anyone with access to manage policies in the tenancy can then change or delete it. Typically that's the Administrators group or any similar group you create and give broad access to. Anyone with access only to a child compartment cannot modify or delete that policy.

If you instead attach the policy to a child compartment, then anyone with access to manage the policies in that compartment can change or delete it. In practical terms, this means it's easy to give compartment administrators (i.e., a group with access to manage all-resources in the compartment) access to manage their own compartment's policies, without giving them broader access to manage policies that reside in the tenancy. For an example that uses this kind of compartment administrator design, see Example Scenario on page 2126. (Recall that because of policy inheritance, users with access to manage policies in the tenancy automatically have the ability to manage policies in compartments inside the tenancy.)

The process of attaching the policy is easy (whether attaching to a compartment or the tenancy): If you're using the Console, when you add the policy to IAM, simply make sure you're in the desired compartment when you create the policy. If you're using the API, you specify the OCID of the desired compartment (either the tenancy or other compartment) as part of the request to create the policy.

When you attach a policy to a compartment, you must be in that compartment and you must indicate directly in the statement which compartment it applies to. If you are not in the compartment, you'll get an error if you try to attach the policy to a different compartment. Notice that attachment occurs during policy creation, which means a policy can be attached to only one compartment. To learn how to attach a policy to a compartment, see To create a policy on page 2454.

**Policies and Compartment Hierarchies**

As described in the previous section, a policy statement must specify the compartment for which access is being granted (or the tenancy). Where you create the policy determines who can update the policy. If you attach the policy to the compartment or its parent, you can simply specify the compartment name. If you attach the policy further up the hierarchy, you must specify the path. The format of the path is each compartment name (or OCID) in the path, separated by a colon:

<compartment_level_1>:<compartment_level_2>:...<compartment_level_n>

For example, assume you have a three-level compartment hierarchy, shown here:

![Compartment Hierarchy Diagram]

You want to create a policy to allow NetworkAdmins to manage VCNs in CompartmentC. If you want to attach this policy to CompartmentC or to its parent, CompartmentB, write this policy statement:

Allow group NetworkAdmins to manage virtual-network-family in compartment CompartmentC
However, if you want to attach this policy to CompartmentA (so that only administrators of CompartmentA can modify it), write this policy statement that specifies the path:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentB:CompartmentC
```

To attach this policy to the tenancy, write this policy statement that specifies the path from CompartmentA to CompartmentC:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentA:CompartmentB:CompartmentC
```

**Policies and Service Updates**

It's possible that the definition of a verb or resource-type could change in the future. For example, let's say that the `virtual-network-family` resource-type changes to include a new kind of resource that's been added to Networking. By default, your policies automatically stay current with any changes in service definition, so any policy you have that gives access to `virtual-network-family` would automatically include access to the newly added resource.

**Writing Policies for Each Service**

The Policy Reference on page 2167 includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.

**Common Policies**

This section includes some common policies you might want to use in your organization.

**Note:**

These policies use example group and compartment names. Make sure to replace them with your own names.

**Let the Help Desk manage users**

*Type of access:* Ability to create, update, and delete users and their credentials. It does not include the ability to put users in groups.

*Where to create the policy:* In the tenancy, because users reside in the tenancy.

```
Allow group HelpDesk to manage users in tenancy
```

**Let auditors inspect your resources**

*Type of access:* Ability to list the resources in all compartments. Be aware that:

- The operation to list IAM policies includes the contents of the policies themselves
- The list operations for Networking resource-types return all the information (for example, the contents of security lists and route tables)
- The operation to list instances requires the `read` verb instead of `inspect`, and the contents include the user-provided metadata.
- The operation to view Audit service events requires the `read` verb instead of `inspect`.

*Where to create the policy:* In the tenancy. Because of the concept of `policy inheritance`, auditors can then inspect both the tenancy and all compartments beneath it. Or you could choose to give auditors access to only specific compartments if they don't need access to the entire tenancy.

```
Allow group Auditors to inspect all-resources in tenancy

Allow group Auditors to read instances in tenancy
```
Allow group Auditors to read audit-events in tenancy

Let network admins manage a cloud network

**Type of access:** Ability to manage all components in Networking. This includes cloud networks, subnets, gateways, virtual circuits, security lists, route tables, and so on. If the network admins need to launch instances to test network connectivity, see Let users launch compute instances on page 2143.

**Where to create the policy:** In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage a cloud network in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

Allow group NetworkAdmins to manage virtual-network-family in tenancy

Let network admins manage load balancers

**Type of access:** Ability to manage all components in Load Balancing. If the group needs to launch instances, see Let users launch compute instances on page 2143.

**Where to create the policy:** In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage load balancers in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

Allow group NetworkAdmins to manage load-balancers in tenancy

If the group uses the Console to manage load balancers, an additional policy to use the associated networking resources is required:

Allow group NetworkAdmins to manage load-balancers in tenancy
Allow group NetworkAdmins to use virtual-network-family in tenancy

If a particular group needs to update existing load balancers (for example, modify the backend set) but not create or delete them, use this statement:

Allow group LBUsers to use load-balancers in tenancy

Let users launch compute instances

**Type of access:** Ability to do everything with instances launched into the cloud network and subnets in compartment XYZ, and attach/detach any existing volumes that already exist in compartment ABC. The first statement also lets the group create and manage instance images in compartment ABC. If the group doesn't need to attach/detach volumes, you can delete the volume-family statement.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (ABC and XYZ) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2141.

Allow group InstanceLaunchers to manage instance-family in compartment ABC
Allow group InstanceLaunchers to read app-catalog-listing in tenancy
Allow group InstanceLaunchers to use volume-family in compartment ABC
Allow group InstanceLaunchers to use virtual-network-family in compartment XYZ

To allow users to create new cloud networks and subnets, see Let network admins manage a cloud network on page 2143.
Let users launch compute instances from a specific custom image

**Type of access:** Ability to launch instances into the cloud network and subnets in compartment XYZ using only the specified custom image. The policy also includes the ability to attach/detach any existing volumes that already exist in compartment ABC. If the group doesn't need to attach/detach volumes, you can delete the `volume-family` statement.

To specify multiple custom images, you can use conditions.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (ABC and XYZ) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2141.

```
Allow group ImageUsers to inspect instance-images in compartment ABC
Allow group ImageUsers to {INSTANCE_IMAGE_READ} in compartment ABC where target.image.id='<image_OCID>'
Allow group ImageUsers to manage instances in compartment ABC
Allow group ImageUsers to read app-catalog-listing in tenancy
Allow group ImageUsers to use volume-family in compartment ABC
Allow group ImageUsers to use virtual-network-family in compartment XYZ
```

Let image admins manage custom images

**Type of access:** Ability to do everything with custom images and compute instances. Also includes the ability to do everything with Object Storage buckets, objects, and namespaces in compartment Y (for creating images from objects and creating pre-authenticated requests to images); to attach/detach any existing volumes in compartment X; and to launch instances into the cloud network and subnets in compartment Z (for creating new instances to base an image on). If the group doesn't need to attach/detach volumes, you can delete the `volume-family` statement.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (X, Y, and Z) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2141.

```
Allow group ImageAdmins to manage instances in compartment X
Allow group ImageAdmins to manage instance-images in compartment X
Allow group ImageAdmins to read app-catalog-listing in tenancy
Allow group ImageAdmins to manage object-family in compartment Y
Allow group ImageAdmins to use volume-family in compartment X
Allow group ImageAdmins to use virtual-network-family in compartment Z
```

Let users manage Compute instance configurations, instance pools, and cluster networks

**Type of access:** Ability to do all things with instance configurations, instance pools, and cluster networks in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the instance configurations, instance pools, and cluster networks in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group InstancePoolAdmins to manage compute-management-family in tenancy
```

If a group needs to create instance configurations using existing instances as a template, and uses the API, SDKs, or command line interface (CLI) to do this, add the following statements to the policy:

```
Allow group InstancePoolAdmins to read instance-family in tenancy
Allow group InstancePoolAdmins to inspect volumes in tenancy
```
If a particular group needs to start, stop, or reset the instances in existing instance pools, but not create or delete instance pools, use this statement:

```
Allow group InstancePoolUsers to use instance-pools in tenancy
```

If resources used by the instance pool contain default tags, add the following statement to the policy to give the group permission to the tag namespace `Oracle-Tags`:

```
Allow group InstancePoolUsers to use tag-namespaces in tenancy where target.tag-namespace.name = 'oracle-tags'
```

### Let users manage Compute autoscaling configurations

**Type of access:** Ability to create, update, and delete autoscaling configurations.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the autoscaling configurations in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group AutoscalingAdmins to manage auto-scaling-configurations in tenancy
Allow group AutoscalingAdmins to manage instance-pools in tenancy
```

### Let users list and subscribe to images from the Partner Image catalog

**Type of access:** Ability to list and create subscriptions to images in the Partner Image catalog. It does not include the ability to create instances using images from the Partner Image catalog (see Let users launch compute instances on page 2143).

**Where to create the policy:** In the tenancy. To reduce the scope of access to just creating subscriptions in a particular compartment, specify that compartment instead of the tenancy in the third statement.

```
Allow group CatalogSubscribers to inspect app-catalog-listing in tenancy
Allow group CatalogSubscribers to read app-catalog-listing in tenancy
Allow group CatalogSubscribers to manage app-catalog-listing in tenancy
```

### Let users create Compute instance console connections

**Type of access:** Ability to create instance console connections.

**Where to create the policy:** In the tenancy.

```
Allow group <group_name> to manage instance-console-connection in tenancy
Allow group <group_name> to read instance in tenancy
```

### Let users manage Compute dedicated virtual machine hosts

**Type of access:** Ability to create, update, and delete dedicated virtual machine hosts as well as launch instances on dedicated virtual machine hosts.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group DedicatedVMHostAdmins to manage dedicated-vm-hosts in tenancy
Allow group DedicatedVMHostAdmins to manage instances in tenancy
```
Let users launch Compute instances on dedicated virtual machine hosts

Type of access: Ability to launch instances on dedicated virtual machine hosts.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

| Allow group DedicatedVMHostAdmins to use dedicated-vm-hosts in tenancy |
| Allow group DedicatedVMHostAdmins to manage instances in tenancy |

Let volume admins manage block volumes, backups, and volume groups

Type of access: Ability to do all things with block storage volumes, volume backups, and volume groups in all compartments with the exception of copying volume backups across regions. This makes sense if you want to have a single set of volume admins manage all the volumes, volume backups, and volume groups in all the compartments. The second statement is required in order to attach/detach the volumes from instances.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and instances in a particular compartment, specify that compartment instead of the tenancy.

| Allow group VolumeAdmins to manage volume-family in tenancy |
| Allow group VolumeAdmins to use instance-family in tenancy |

If the group needs to also copy volume backups and boot volume backups across regions, add the following statements to the policy:

| Allow group VolumeAdmins to use volume-backups in tenancy where request.permission='VOLUME_BACKUP_COPY' |
| Allow group VolumeAdmins to use boot-volume-backups in tenancy where request.permission='BOOT_VOLUME_BACKUP_COPY' |

Let volume backup admins manage only backups

Type of access: Ability to do all things with volume backups, but not create and manage volumes themselves. This makes sense if you want to have a single set of volume backup admins manage all the volume backups in all the compartments. The first statement gives the required access to the volume that is being backed up; the second statement enables creation of the backup (and the ability to delete backups). The third statement enables the creation and management of user defined backup policies; the fourth statement enables assignment and removal of assignment of backup policies.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and backups in a particular compartment, specify that compartment instead of the tenancy.

| Allow group VolumeBackupAdmins to use volumes in tenancy |
| Allow group VolumeBackupAdmins to manage volume-backups in tenancy |
| Allow group VolumeBackupAdmins to manage backup-policies in tenancy |
| Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy |

If the group will be using the Console, the following policy gives a better user experience:

| Allow group VolumeBackupAdmins to use volumes in tenancy |
Allow group VolumeBackupAdmins to manage volume-backups in tenancy
Allow group VolumeBackupAdmins to inspect volume-attachments in tenancy
Allow group VolumeBackupAdmins to inspect instances in tenancy
Allow group VolumeBackupAdmins to manage backup-policies in tenancy
Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy

The last two statements are not necessary in order to manage volume backups. However, they enable the Console to display all the information about a particular volume and the available backup policies.

Let boot volume backup admins manage only backups

**Type of access:** Ability to do all things with boot volume backups, but not create and manage boot volumes themselves. This makes sense if you want to have a single set of boot volume backup admins manage all the boot volume backups in all the compartments. The first statement gives the required access to the boot volume that is being backed up; the second statement enables creation of the backup (and the ability to delete backups). The third statement enables the creation and management of user defined backup policies; the fourth statement enables assignment and removal of assignment of backup policies.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the boot volumes and backups in a particular compartment, specify that compartment instead of the tenancy.

Allow group BootVolumeBackupAdmins to use volumes in tenancy
Allow group BootVolumeBackupAdmins to manage boot-volume-backups in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policies in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policy-assignments in tenancy

If the group will be using the Console, the following policy gives a better user experience:

Allow group BootVolumeBackupAdmins to use volumes in tenancy
Allow group BootVolumeBackupAdmins to manage boot-volume-backups in tenancy
Allow group BootVolumeBackupAdmins to inspect instances in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policies in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policy-assignments in tenancy

The last two statements are not necessary in order to manage volume backups. However, they enable the Console to display all the information about a particular boot volume and the available backup policies.

Let users create a volume group

**Type of access:** Ability to create a volume group from a set of volumes.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

Allow group VolumeGroupCreators to inspect volumes in tenancy
Allow group VolumeGroupCreators to manage volume-groups in tenancy

Let users clone a volume group

Type of access: Ability to clone a volume group from an existing volume group.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

Allow group VolumeGroupCloners to inspect volumes in tenancy
Allow group VolumeGroupCloners to manage volume-groups in tenancy
Allow group VolumeGroupCloners to manage volumes in tenancy

Let users create a volume group backup

Type of access: Ability to create a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.

Allow group VolumeGroupBackupAdmins to inspect volume-groups in tenancy
Allow group VolumeGroupBackupAdmins to manage volumes in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-group-backups in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-backups in tenancy

Let users restore a volume group backup

Type of access: Ability to create a volume group by restoring a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.

Allow group VolumeGroupBackupAdmins to inspect volume-group-backups in tenancy
Allow group VolumeGroupBackupAdmins to read volume-backups in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-groups in tenancy
Allow group VolumeGroupBackupAdmins to manage volumes in tenancy

Let users create, manage, and delete file systems

Type of access: Ability to create, manage, or delete a file system or file system clone. Administrative functions for a file system include the ability to rename or delete it or disconnect from it.

Where to create the policy: In the tenancy, so that the ability to create, manage, or delete a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

Allow group StorageAdmins to manage file-family in tenancy

Let users create file systems

Type of access: Ability to create a file system or file system clone.
**Where to create the policy:** In the tenancy, so that the ability to create a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

- Allow group Managers to manage file-systems in tenancy
- Allow group Managers to read mount-targets in tenancy

The second statement is required when users create a file system using the Console. It enables the Console to display a list of mount targets that the new file system can be associated with.

**Let Object Storage admins manage buckets and objects**

**Type of access:** Ability to do all things with Object Storage buckets and objects in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the buckets and objects in a particular compartment, specify that compartment instead of the tenancy.

- Allow group ObjectAdmins to manage buckets in tenancy
- Allow group ObjectAdmins to manage objects in tenancy

**Let users write objects to Object Storage buckets**

**Type of access:** Ability to write objects to any Object Storage bucket in compartment ABC (imagine a situation where a client needs to regularly write log files to a bucket). This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and create a new object in a bucket. Although the second statement gives broad access with the manage verb, that access is then scoped down to only the OBJECT_INSPECT and OBJECT_CREATE permissions with the condition at the end of the statement.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment on page 2141.

- Allow group ObjectWriters to read buckets in compartment ABC
- Allow group ObjectWriters to manage objects in compartment ABC where any 
  
  `{request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}`

**Access limited to a specific bucket:** To limit access to a specific bucket in a particular compartment, add the condition where target.bucket.name='<bucket_name>'. The following policy allows the user to list all the buckets in a particular compartment, but they can only list the objects in and upload objects to BucketA:

- Allow group ObjectWriters to read buckets in compartment ABC
- Allow group ObjectWriters to manage objects in compartment ABC where all 
  
  `{target.bucket.name='BucketA', any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}`

For more information about using conditions, see Advanced Policy Features on page 2160.

**Let users download objects from Object Storage buckets**

**Type of access:** Ability to download objects from any Object Storage bucket in compartment ABC. This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and read existing objects in a bucket.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment on page 2141.

- Allow group ObjectReaders to read buckets in compartment ABC

Oracle Cloud Infrastructure User Guide
IAM

**Allow group ObjectReaders to read objects in compartment ABC**

**Access limited to a specific bucket:** To limit access to a specific bucket in a particular compartment, add the condition `where target.bucket.name='<bucket_name>'`. The following policy allows the user to list all buckets in a particular compartment, but they can only read the objects in and download from BucketA:

```
Allow group ObjectReaders to read buckets in compartment ABC
Allow group ObjectReaders to read objects in compartment ABC where target.bucket.name='BucketA'
```

For more information about using conditions, see Advanced Policy Features on page 2160.

**Let database admins manage Oracle Cloud database systems**

**Type of access:** Ability to do all things with the following system types and their associated resources in all compartments:

- Exadata Cloud Service instances
- bare metal DB systems
- virtual machine DB systems

This makes sense if you want to have a single set of database admins manage all the bare metal, virtual machine, and Exadata systems in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the database systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group DatabaseAdmins to manage database-family in tenancy
```

**Let database admins manage Exadata Cloud@Customer instances**

**Type of access:** Ability to do all things with the Exadata Cloud@Customer resources in all compartments. This makes sense if you want to have a single set of database admins manage all the Exadata Cloud@Customer systems in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Exadata Cloud@Customer systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group ExaCCAdmins to manage database-family in tenancy
```

**Let database admins manage Oracle Cloud external database resources**

**Type of access:** Ability to do all things with the following OCI external database resources in all compartments:

- OCI external container database resources
- OCI external pluggable database resources
- OCI external non-container database resources
- OCI external database connectors

This makes sense if you want to have a single set of database admins manage all the OCI external database resources in all the compartments.
Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the OCI external database resources in a particular compartment, specify that compartment instead of the tenancy.

Allow group OnPremDatabaseAdmins to manage external-database-family in tenancy

Let database and fleet admins manage Autonomous Databases

Type of access: Ability to do all things with Autonomous Database instances in all compartments. Applicable if you want to have a single set of database administrators manage all the Autonomous Database databases in all the compartments.

Where to create the policy: In the tenancy, so that the access is granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Autonomous Databases in a particular compartment, specify that compartment instead of the tenancy.

Example 1: For fleet administrators. Enables Autonomous Database fleet administrator access to the various workload types (Autonomous Data Warehouse, Autonomous JSON Database, and Autonomous Transaction Processing), and to dedicated Exadata infrastructure resources (container databases and Autonomous Exadata Infrastructure instances).

Allow group DatabaseAdmins to manage autonomous-database-family in tenancy

If you must restrict access to the Autonomous Exadata Infrastructure and Autonomous Container Database resource types (applicable only to dedicated Exadata infrastructure systems), then you can do so by creating separate policy statements for database administrators that allow access to only Autonomous Databases and their backups. Because a policy statement can only specify one resource type, you must create separate statements for the database and backup resources.

Example 2: For database administrators. Enables Autonomous Database database administrators access to databases and backups of the various workload types, but denies access to Autonomous Container Databases and Autonomous Exadata Infrastructure instances.

Allow group ADB-Admins to manage autonomous-database in tenancy

Allow group ADB-Admins to manage autonomous-backup in tenancy

To reduce the scope of access to either the Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing workload types, use a where clause, as shown in the next example.

Example 3: For database administrators. Limits Autonomous Database access to Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing databases and backups.

Allow group ADB-Admins to manage autonomous-database in tenancy where target.workloadType = 'workload_type'

Allow group ADB-Admins to manage autonomous-backup in tenancy where target.workloadType = 'workload_type'

In the preceding code examples, workload_type can be DW, AJD, or OLTP for Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing, respectively.

Let security admins manage vaults, keys, and secrets

Type of access: Ability to do all things with the Vault service in all compartments. This makes sense if you want to have a single set of security admins manage all the vaults, keys, and secret components (including secrets, secret versions, and secret bundles) in all compartments.
**Where to create the policy:** In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the vaults, keys, and secret components in a particular compartment, specify that compartment instead of the tenancy. To reduce the scope of access to just vaults, keys, or secret components, include only the policy statement that pertains to the respective individual or aggregate resource-type, as appropriate.

| Allow group SecurityAdmins to manage vaults in tenancy |
| Allow group SecurityAdmins to manage keys in tenancy |
| Allow group SecurityAdmins to manage secret-family in tenancy |

**Let security admins manage all keys in a specific vault in a compartment**

**Type of access:** Ability to do all things with keys in a specific vault in compartment ABC.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2141.

| Allow group SecurityAdmins to manage keys in compartment ABC where target.vault.id='<vault_OCID>' |

**Let security admins use a specific key in a compartment**

**Type of access:** Ability to list, view, and perform cryptographic operations with a specific key in a compartment.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2141.

| Allow group SecurityAdmins to use keys in compartment ABC where target.key.id='<key_OCID>' |

**Let a user group delegate key usage in a compartment**

**Type of access:** Ability to associate an Object Storage bucket, Block Volume volume, File Storage file system, Kubernetes cluster, or Streaming stream pool with a specific key authorized for use in a specific compartment. With this policy, a user in the specified group does not have permission to use the key itself. Rather, by association, the key can be used by Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming on behalf of the user to:

- Create or update an encrypted bucket, volume, or file system and to encrypt or decrypt data in the bucket, volume, or file system.
- Create Kubernetes clusters with encrypted Kubernetes secrets at rest in the etcd key-value store.
- Create a stream pool to encrypt data in the streams in the stream pool.

This policy requires that you also have a companion policy that lets Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming use the key to perform cryptographic operations.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2141.

| Allow group ObjectWriters, VolumeWriters, FileWriters, ClusterWriters, StreamWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>' |
Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools

Type of access: Ability to list, view, and perform cryptographic operations with all keys in compartment ABC. Because Object Storage is a regional service, it has regional endpoints. As such, you must specify the regional service name for each region where you’re using Object Storage with Vault encryption. This policy also requires that you have a companion policy that allows a user group to use the delegated key that Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming will use.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2141.

Allow service blockstorage, objectstorage-<region_name>, FssOc1Prod, oke, streaming to use keys in compartment ABC where target.key.id = '<key_OCID>'

For Object Storage, replace <region_name> with the appropriate region identifier, for example:

- objectstorage-us-phoenix-1
- objectstorage-us-ashburn-1
- objectstorage-eu-frankfurt-1
- objectstorage-uk-london-1
- objectstorage-ap-tokyo-1

To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 180.

For File Storage, the service name used in the policy is FssOc1Prod.

For Container Engine for Kubernetes, the service name used in the policy is oke.

For Streaming, the service name used in the policy is streaming.

Let security admins manage all secrets in a specific vault in a compartment

Type of access: Ability to do all things with secrets in a specific vault in compartment ABC.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2141.

Allow group SecurityAdmins to manage secret-family in compartment ABC where target.vault.id='<vault_OCID>'

Let users read, update, and rotate all secrets

Type of access: Ability to read, update, and rotate all secrets in any vault in the tenancy.

Where to create the policy: In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the vaults, keys, and secrets in a particular compartment, specify that compartment instead of the tenancy.

Allow group SecretsUsers to use secret-family in tenancy

Let users manage their own passwords and credentials

No policy is required to let users manage their own credentials. All users have the ability to change and reset their own passwords, manage their own API keys, and manage their own auth tokens. For more information, see User Credentials on page 2360.
Let a compartment admin manage the compartment

**Type of access:** Ability to manage all aspects of a particular compartment. For example, a group called A-Admins could manage all aspects of a compartment called Project-A, including writing additional policies that affect the compartment. For more information, see Policy Attachment on page 2141. For an example of this kind of setup and additional policies that are useful, see Example Scenario on page 2126.

**Where to create the policy:** In the tenancy.

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Restrict admin access to a specific region

**Type of access:** Ability to manage resources in a specific region. Remember that IAM resources must be managed in the home region. If the specified region is not the home region, then the Admin will not be able to manage IAM resources. For more information about the home region, see Managing Regions on page 2445.

**Where to create the policy:** In the tenancy.

```
Allow group PHX-Admins to manage all-resources in tenancy where request.region='phx'
```

The preceding policy allows PHX-Admins to manage all aspects of all resources in US West (Phoenix).

Members of the PHX-Admins group can only manage IAM resources if the tenancy’s home region is US West (Phoenix).

Restrict user access to view only summary announcements

**Type of access:** Ability to view the summary versions of announcements about the operational status of Oracle Cloud Infrastructure services.

**Where to create the policy:** In the tenancy.

```
Allow group AnnouncementListers to inspect announcements in tenancy
```

The preceding policy allows AnnouncementListers to view a list of summary announcements.

Let users view details of announcements

**Type of access:** Ability to view the details of announcements about the operational status of Oracle Cloud Infrastructure services.

**Where to create the policy:** In the tenancy.

```
Allow group AnnouncementReaders to read announcements in tenancy
```

The preceding policy allows AnnouncementReaders to view a list of summary announcements and the details of specific announcements.

Let streaming users manage streams

**Type of access:** Ability to do all things with the Streaming service in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group StreamAdmins to manage streams in tenancy
```
Let streaming users publish messages to streams

**Type of access:** Ability to produce messages to streams with the Streaming service in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

.Allow group StreamUsers to use stream-push in tenancy

Let streaming users publish messages to a specific stream

**Type of access:** Ability to produce messages to a stream with the Streaming service.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

.Allow group StreamUsers to use stream-push in tenancy where target.stream.id = '<stream_ocid>'

Let streaming users publish messages to a stream in a specific stream pool

**Type of access:** Ability to produce messages to a stream with the Streaming service.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

.Allow group StreamUsers to use stream-push in tenancy where target.streampool.id = '<stream_ocid>'

Let streaming users consume messages from streams

**Type of access:** Ability to consume messages from streams with the Streaming service in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

.Allow group StreamUsers to use stream-pull in tenancy

Let users view metric definitions in a compartment

**Type of access:** Ability to view metric definitions in a specific compartment. For more information about metrics, see Metrics Feature Overview on page 2663.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metric definitions in a particular compartment, specify that compartment instead of the tenancy.

.Allow group MetricReaders to inspect metrics in compartment ABC

Let users access monitoring metrics in a compartment

**Type of access:** Ability to view and retrieve monitoring metrics for supported resources in a specific compartment. For more information about metrics, see Metrics Feature Overview on page 2663.
Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metrics in a particular compartment, specify that compartment instead of the tenancy.

Allow group MetricReaders to read metrics in compartment ABC

Restrict user access to a specific metric namespace

Type of access: Ability to view and retrieve monitoring metrics for resources under a specific metric namespace. For more information about metrics, see Metrics Feature Overview on page 2663.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just metrics in a particular compartment, specify that compartment instead of the tenancy.

Allow group MetricReaders to read metrics in compartment ABC where target.metrics.namespace='oci_computeagent'

The preceding policy allows MetricReaders to view and retrieve metric data points from all monitoring-enabled Compute instances in the ABC compartment.

Let users publish custom metrics

Type of access: Ability to publish custom metrics under a specific metric namespace to the Monitoring service. For instructions, see Publishing Custom Metrics on page 2717.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just metrics in a particular compartment, specify that compartment instead of the tenancy.

Allow group MetricPublishers to use metrics in tenancy where target.metrics.namespace='mycustomnamespace'

The preceding policy allows MetricPublishers to publish data points for the custom metric namespace mycustomnamespace in the tenancy.

Let instances make API calls to access monitoring metrics in the tenancy

Type of access: Ability to call the Monitoring API for access to monitoring metrics. The instances on which API requests originate must be members of the dynamic group indicated in the policy. For more information, see Calling Services from an Instance on page 2410 and Metrics Feature Overview on page 2663.

Where to create the policy: In the tenancy.

Allow dynamic-group MetricInstances to read metrics in tenancy

The preceding policy allows applications that are running on Compute instances in the dynamic group MetricInstances to send API requests to the Monitoring service in the tenancy.

Let users view alarms

Type of access: Ability to view alarms for supported resources in tenancy. Does not include the ability to create alarms or to create or delete topics. For more information about alarms, see Alarms Feature Overview on page 2664.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, AlarmUsers can then view alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

Allow group AlarmUsers to read alarms in tenancy
IAM

Allow group AlarmUsers to read metrics in tenancy

Let users manage alarms

**Type of access:** Ability to view and create *alarms* with existing notification topics for supported resources in the tenancy. Does not include the ability to create or delete topics. For more information about alarms, see *Alarms Feature Overview* on page 2664.

All statements are required to let AlarmUsers create alarms.

**Where to create the policy:** In the tenancy. Because of the concept of *policy inheritance*, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

<table>
<thead>
<tr>
<th>Allow group AlarmUsers to manage alarms in tenancy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group AlarmUsers to read metrics in tenancy</td>
</tr>
<tr>
<td>Allow group AlarmUsers to use ons-topics in tenancy</td>
</tr>
</tbody>
</table>

Let users manage alarms and create topics

**Type of access:** Ability to view and create *alarms* (with new or existing *topics*) for supported resources in tenancy. Also includes the ability to create *subscriptions* in the tenancy, to publish *messages* (broadcast notification messages) to all subscriptions in the tenancy, and to move alarms to different compartments in the tenancy. For more information about alarms, see *Alarms Feature Overview* on page 2664.

**Where to create the policy:** In the tenancy. Because of the concept of *policy inheritance*, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

<table>
<thead>
<tr>
<th>Allow group AlarmUsers to manage alarms in tenancy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group AlarmUsers to read metrics in tenancy</td>
</tr>
<tr>
<td>Allow group AlarmUsers to manage ons-topics in tenancy</td>
</tr>
</tbody>
</table>

Let users access usage reports

**Type of access:** Ability to view usage reports for your tenancy. For more information about usage reports, see *Cost and Usage Reports Overview* on page 278.

**Where to create the policy:** This is a special cross-tenancy policy and must be created in the tenancy. For more information, see *Cost and Usage Reports Overview* on page 278.

<table>
<thead>
<tr>
<th>define tenancy usage-report as</th>
</tr>
</thead>
<tbody>
<tr>
<td>ocid1.tenancy.oc1..aaaaaaaaned4fkpkisbwjlr56u7cj631f3wffb1vqknstgtvzub7vhqkggq</td>
</tr>
<tr>
<td>endorse group Administrators to read objects in tenancy usage-report</td>
</tr>
</tbody>
</table>

Let users analyze costs

**Type of access:** Ability to see costs for the tenancy. See *Checking Your Expenses and Usage* on page 55.

**Where to create the policy:** In the tenancy so that users in the *<Example_Group>* can see costs for the entire account.

| Allow group *<Example_Group>* to read usage-reports in tenancy |
### Allow a group to manage topics

**Type of access:** Ability to get, create, update, and delete *topics* in the tenancy, as well as move topics to different compartments in the tenancy. Also includes the ability to create *subscriptions* in the tenancy and to publish *messages* (broadcast notification messages) to all subscriptions in the tenancy.

**Where to create the policy:** In the tenancy.

| Allow group A-Admins to manage ons-topics in tenancy |

### Allow a group to manage topic subscriptions

**Type of access:** Ability to list, create, update, and delete *subscriptions* for topics in the tenancy. Ability to move subscriptions to different compartments in the tenancy.

**Where to create the policy:** In the tenancy.

| Allow group A-Admins to manage ons-subscriptions in tenancy |

### Allow a group to publish messages to topics

**Type of access:** Ability to broadcast notification *messages* to all *subscriptions* in the tenancy, as well as list, create, update, and delete subscriptions in the tenancy.

**Where to create the policy:** In the tenancy.

| Allow group A-Admins to use ons-topics in tenancy |

### Let users create, deploy, and manage functions and applications using Cloud Shell

**Type of access:** Ability to create, deploy, and manage Functions applications and functions using Cloud Shell. These policy statements give the group access to Cloud Shell, repositories in Oracle Cloud Infrastructure Registry, logs, metrics, functions, and networks.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the resources in a particular compartment, you can specify the compartment instead of the tenancy in the to manage logging-family, to read metrics, to manage functions-family, and to use virtual-network-family policy statements. However, the remaining policy statements (to use cloud-shell, to manage repos, to read objectstorage-namespaces, and to read logging-family) must always be scoped to the tenancy.

| Allow group functions-developers to use cloud-shell in tenancy |
| Allow group functions-developers to manage repos in tenancy |
| Allow group functions-developers to read objectstorage-namespaces in tenancy |
| Allow group functions-developers to manage logging-family in tenancy |
| Allow group functions-developers to read metrics in tenancy |
| Allow group functions-developers to manage functions-family in tenancy |
| Allow group functions-developers to use virtual-network-family in tenancy |

### Let users list Events rules in a compartment

**Type of access:** Ability to list Events rules.

**Where to create the policy:** In the tenancy.

| Allow group RuleReaders to read cloudevents-rules in tenancy |
The preceding policy allows RuleReaders to list rules in the tenancy.

**Let admins manage Events rules in a compartment**

**Type of access:** Ability to manage Events rules, including creating, deleting and updating rules.

**Where to create the policy:** In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

```
allow group <RuleAdmins> to inspect compartments in tenancy
```

This line gives the user access to defined tags to apply filter tags to rules.

```
allow group <RuleAdmins> to use tag-namespaces in tenancy
```

These lines give the user access to Streaming resources for actions.

```
allow group <RuleAdmins> to inspect streams in tenancy
allow group <RuleAdmins> to use stream-push in tenancy
allow group <RuleAdmins> to use stream-pull in tenancy
```

These lines give the user access to Functions resources for actions.

```
allow group <RuleAdmins> to use virtual-network-family in tenancy
allow group <RuleAdmins> to manage function-family in tenancy
```

This line give the user access to Notifications topics for actions.

```
allow group <RuleAdmins> to use ons-topic in tenancy
```

This line gives the user manage access to rules for Events.

```
allow group <RuleAdmins> to manage cloudevents-rules in tenancy
```

**Allow a group to access all of Cloud Guard**

**Type of access:** Read-only access to all of Cloud Guard. In the example policy, the group is "CloudGuard_ReadOnly."

```
allow group CloudGuard_ReadOnly to read cloud-guard-family in tenancy
allow group CloudGuard_ReadOnly to read compartments in tenancy
allow group CloudGuard_ReadOnly to read announcements in tenancy
```

**Allow a group to access Cloud Guard problems**

**Type of access:** Read-only access to Cloud Guard problems. In the example policy, the group is "CloudGuard_ReadOnlyProblems."

```
allow group CloudGuard_ReadOnlyProblems to read cloud-guard-family in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-detectors in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-targets in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-resource-types in tenancy
allow group CloudGuard_ReadOnlyProblems to read announcements in tenancy
allow group CloudGuard_ReadOnlyProblems to read compartments in tenancy
```
allow group CloudGuard_ReadOnlyProblems to read cloud-guard-config in tenancy

**Allow a group to access Cloud Guard detector recipes**

**Type of access:** Read-only access to Cloud Guard detector recipes. In the example policy, the group is "CloudGuard_ReadOnlyDetectors."

allow group CloudGuard_ReadOnlyDetectors to read cloud-guard-detector-recipes in tenancy
allow group CloudGuard_ReadOnlyDetectors to read announcements in tenancy
allow group CloudGuard_ReadOnlyDetectors to read compartments in tenancy
allow group CloudGuard_ReadOnlyDetectors to read cloud-guard-config in tenancy

**Allow a group to access Cloud Guard in a single compartment**

**Type of access:** Read-only access to Cloud Guard in a single compartment. In the example policy, the group is "CloudGuard_ReadOnly_SingleCompartment" and the compartment name is "cgDemo_RestrictedAccess."

allow group CloudGuard_ReadOnly_SingleCompartment to read compartments in tenancy where target.compartment.name = 'cgDemo_RestrictedAccess'
allow group CloudGuard_ReadOnly_SingleCompartment to read cloud-guard-family in compartment cgDemo_RestrictedAccess
allow group CloudGuard_ReadOnly_SingleCompartment to read announcements in compartment cgDemo_RestrictedAccess
allow group CloudGuard_ReadOnly_SingleCompartment to read cloud-guard-config in tenancy

**Allow a group to manage service connectors**

**Type of access:** Ability to list, create, update, and delete service connectors in the tenancy. Ability to move service connectors to different compartments in the tenancy.

**Where to create the policy:** In the tenancy.

Allow group A-Admins to manage serviceconnectors in tenancy

**Allow a group to call Operations Insights ingest operations at tenancy**

**Type of access:** Ability to call ingest operations at the tenancy level only.

**Where to create the policy:** In the tenancy.

allow group opsi-users to use opsi-database-insights in tenancy where any
{request.operation='IngestSqlBucket',
request.operation='IngestSqlText',
request.operation='IngestSqlPlanLines'}

**Advanced Policy Features**

This section describes policy language features that let you grant more granular access.

**Conditions**

As part of a policy statement, you can specify one or more conditions that must be met in order for access to be granted.
Each condition consists of one or more predefined variables that you specify values for in the policy statement. Later, when someone requests access to the resource in question, if the condition in the policy is met, it evaluates to true and the request is allowed. If the condition is not met, it evaluates to false and the request is not allowed.

There are two types of variables: those that are relevant to the request itself, and those relevant to the resource being acted upon in the request, also known as the target. The name of the variable is prefixed accordingly with either request or target followed by a period. For example, there's a request variable called request.operation to represent the API operation being requested. This variable lets you write a broad policy statement, but add a condition based on the specific API operation. For an example, see Let users write objects to Object Storage buckets on page 2149.

**Important:**
Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment. If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

Variables that Aren't Applicable to a Request Result in a Declined Request

If the variable is not applicable to the incoming request, the condition evaluates to false and the request is declined. For example, here are the basic policy statements that together let someone add or remove users from any group except Administrators:

```
Allow group GroupAdmins to use users in tenancy
   where target.group.name != 'Administrators'
```

```
Allow group GroupAdmins to use groups in tenancy
   where target.group.name != 'Administrators'
```

Given the above policy, if GroupAdmins tried to call a general API operation for users such as `ListUsers` or `UpdateUser` (which lets you change the user's description), the request would be declined, even though those API operations are covered by `use users`. This is because the above policy statement for `use users` also includes the `target.group.name` variable, but the `ListUsers` or `UpdateUser` request doesn't involve specifying a group. There is no `target.group.name` for those requests, so the request is declined.

If you want to also grant access to general user API operations that don't involve a particular group, you would need an additional statement that gives the level of access you want to grant, but without the condition. For example, if you want to grant access to `ListUsers`, you need this additional statement:

```
Allow group GroupAdmins to inspect users in tenancy
```

Or if you want to grant access to `UpdateUser`, you need this additional statement (which also covers `ListUsers` because the `use` verb includes the capabilities of the `inspect` verb):

```
Allow group GroupAdmins to use users in tenancy
```

This general concept also applies to groups (e.g., `ListGroups` and `UpdateGroup`), and any other resource type with target variables.

For more information about the syntax of conditions, see Conditions on page 2166. For a list of all the variables you can use in policies, see the tables in the Policy Reference on page 2167.

**Tag-Based Access Control**

Using conditions and a set of tag variables, you can write policy to scope access based on the tags that have been applied to a resource. Access can be controlled based on a tag that exists on the requesting resource (the group or dynamic group in the policy) or on the target of the request (resource or compartment). Tag-based access control provides additional flexibility to your policies by allowing you to define access that spans compartments, groups, and
resources. For details about how to write policies to scope access by tags, see Using Tags to Manage Access on page 3932.

**Permissions**

Permissions are the atomic units of authorization that control a user's ability to perform operations on resources. Oracle defines all the permissions in the policy language. When you write a policy giving a group access to a particular verb and resource-type, you're actually giving that group access to one or more predefined permissions. The purposes of verbs is to simplify the process of granting multiple related permissions that cover a broad set of access or a particular operational scenario. The next sections give more details and examples.

**Relation to Verbs**

To understand the relationship between permissions and verbs, let's look at an example. A policy statement that allows a group to inspect volumes actually gives the group access to a permission called VOLUME_INSPECT (permissions are always written with all capital letters and underscores). In general, that permission enables the user to get information about block volumes.

As you go from inspect > read > use > manage, the level of access generally increases, and the permissions granted are cumulative. The following table shows the permissions included with each verb for the volumes resource-type. Notice that no additional permissions are granted going from inspect to read.

<table>
<thead>
<tr>
<th>Inspect Volumes</th>
<th>Read Volumes</th>
<th>Use Volumes</th>
<th>Manage Volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLUME_INSPECT</td>
<td>VOLUME_INSPECT</td>
<td>VOLUME_INSPECT</td>
<td>VOLUME_INSPECT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VOLUME_UPDATE</td>
<td>VOLUME_UPDATE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VOLUME_WRITE</td>
<td>VOLUME_WRITE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VOLUME_CREATE</td>
<td>VOLUME_CREATE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VOLUME_DELETE</td>
<td>VOLUME_DELETE</td>
</tr>
</tbody>
</table>

The policy reference lists the permissions covered by each verb for each given resource-type. For example, for block volumes and other resources covered by the Core Services, see the tables in Details for Verb + Resource-Type Combinations on page 2183. The left column of each of those tables lists the permissions covered by each verb. The other sections of the policy reference include the same kind of information for the other services.

**Relation to API Operations**

Each API operation requires the caller to have access to one or more permissions. For example, to use either ListVolumes or GetVolume, you must have access to a single permission: VOLUME_INSPECT. To attach a volume to an instance, you must have access to multiple permissions, some of which are related to the volumes resource-type, some to the volume-attachments resource-type, and some related to the instances resource-type:

- VOLUME_WRITE
- VOLUME_ATTACHMENT_CREATE
- INSTANCE_ATTACH_VOLUME

The policy reference lists which permissions are required for each API operation. For example, for the Core Services API operations, see the table in Permissions Required for Each API Operation on page 2225.

**Understanding a User's Access**

The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the desired permissions in the statement. However, there may be situations where a security team member or auditor wants to understand the specific permissions a particular user has. The tables in the policy reference show each verb and the associated permissions. You can look at the groups the user is in and the policies applicable to those groups, and from there compile a list of the permissions granted. However, having a list of the permissions isn't the complete picture. Conditions in a policy statement can scope a user's access beyond individual
permissions (see the next section). Also, each policy statement specifies a particular compartment and can have conditions that further scope the access to only certain resources in that compartment.

**Scoping Access with Permissions or API Operations**

In a policy statement, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (i.e., change their description), but not delete them. To list, get, create, and update groups, you need a policy with manage groups as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations on page 2281, the permissions covered are:

- GROUP_INSPECT
- GROUP_UPDATE
- GROUP_CREATE
- GROUP_DELETE

To restrict access to only the desired permissions, you could add a condition that explicitly states the permissions you want to allow:

Allow group XYZ to manage groups in tenancy where any 
{request.permission='GROUP_INSPECT',
request.permission='GROUP_CREATE',
request.permission='GROUP_UPDATE'}

An alternative would be a policy that allows all permissions except GROUP_DELETE:

Allow group XYZ to manage groups in tenancy where request.permission != 'GROUP_DELETE'

However, with this approach, be aware that any new permissions the service might add in the future would automatically be granted to group XYZ. Only GROUP_DELETE would be omitted.

Another alternative would be to write a condition based on the specific API operations. Notice that according to the table in Permissions Required for Each API Operation on page 2288, both ListGroups and GetGroup require only the GROUP_INSPECT permission. Here's the policy:

Allow group XYZ to manage groups in tenancy where any 
{request.operation='ListGroups',
request.operation='GetGroup',
request.operation='CreateGroup',
request.operation='UpdateGroup'}

It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-based policy above, that policy will already control XYZ group's access to that new API operation.

But notice that you can further scope a user's access to a permission by also specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to ListGroups.

Allow group XYZ to manage groups in tenancy

where all 
{request.permission='GROUP_INSPECT',
request.operation='ListGroups'}
Scoping Policy by the IP Address of the Requestor

You can scope access to only a set of allowed IP addresses. For example, you can write policy to allow only requests from a given public IP range to access a specific Object Storage bucket; or, you can allow only specific subnets of a specific VCN to make requests over a service gateway.

To restrict access to a set of IP addresses, do the following:

1. Create a network source object that specifies the allowed IP addresses. See Managing Network Sources on page 2427 for details.
2. Write a policy that uses the network source object in a condition.

Use the following variable in your policy:

```
request.networkSource.name='<network_source_name>'
```

For example:

```
allow group GroupA to manage object-family in tenancy where request.networkSource.name='corpnet'
```

Policy Syntax

The overall syntax of a policy statement is as follows:

```
Allow <subject> to <verb> <resource-type> in <location> where <conditions>
```

Spare spaces or line breaks in the statement have no effect.

For limits on the number of policies and statements, see Service Limits on page 215.

Subject

Specify one or more comma-separated groups by name or OCID. Or specify any-user to cover all users in the tenancy.

**Syntax:**

```
group <group_name> | group id <group_ocid> | dynamic-group <dynamic-group_name> | dynamic-group id<dynamic-group_ocid> | any-user
```

**Examples:**

- To specify a single group by name:

```
Allow

group A-Admins

to manage all-resources in compartment Project-A
```

- To specify multiple groups by name (a space after the comma is optional):

```
Allow

group A-Admins, B-Admins

to manage all-resources in compartment Projects-A-and-B
```

- To specify a single group by OCID (the OCID is shortened for brevity):

```
Allow group

id ocid1.group.oc1..aaaaaaaqjihfhvxmlm...awuc7i5xwe6s7qmnsbc6a
```
to manage all-resources in compartment Project-A

- To specify multiple groups by OCID (the OCIDs are shortened for brevity):

  Allow group

  id ocid1.group.oc1..aaaaaaaaqjihfhvxmlr1...wuc7i5xwe6s7qmnsbc6a,
  id ocid1.group.oc1..aaaaaaavhea5mellwzb...66yfxv1462tdgx20eczyq

to manage all-resources in compartment Projects-A-and-B

- To specify any user in the tenancy:

  Allow any-user to inspect users in tenancy

**Verb**

Specify a single verb. For a list of verbs, see Verbs on page 2169. Example:

Allow group A-Admins to manage all-resources in compartment Project-A

**Resource-Type**

Specify a single resource-type, which can be one of the following:

- An individual resource-type (e.g., vcns, subnets, instances, volumes, etc.)
- A family resource-type (e.g., virtual-network-family, instance-family, volume-family, etc.)
- **all-resources**: Covers all resources in the compartment (or tenancy).

A family resource-type covers a variety of components that are typically used together. This makes it easier to write a policy that gives someone access to work with various aspects of your cloud network.

For a list of the available resource-types, see Resource-Types on page 2169.

**Syntax:** `<resource_type> | all-resources`

**Examples:**

- To specify a single resource-type:

  Allow group HelpDesk to manage users in tenancy

- To specify multiple resource-types, use separate statements:

  Allow group A-Users to manage instance-family in compartment Project-A

  Allow group A-Users to manage volume-family in compartment Project-A

- To specify all resources in the compartment (or tenancy):

  Allow group A-Admins to manage all-resources in compartment Project-A

**Location**

Specify a single compartment or compartment path by name or OCID. Or simply specify tenancy to cover the entire tenancy. Remember that users, groups, and compartments reside in the tenancy. Policies can reside in (i.e., be attached to) either the tenancy or a child compartment.

**Note:**

Granting Access to Specific Regions or availability domains
To create a policy that gives access to a specific region or availability domain, use the `request.region` or `request.ad` variable with a condition. See Conditions on page 2166.

The location is required in the statement. If you want to attach a policy to a compartment, you must be in that compartment when you create the policy. For more information, see Policy Attachment on page 2141.

To specify a compartment that is not a direct child of the compartment you are attaching the policy to, specify the path to the compartment, using the colon (:) as a separator. For more information, see Policies and Compartment Hierarchies on page 2141.

**Syntax:**
```plaintext
[ tenancy | compartment <compartment_name> | compartment id <compartment_ocid> ]
```

**Examples:**

- To specify a compartment by name:
  ```plaintext
  Allow group A-Admins to manage all-resources in compartment Project-A
  ```

- To specify a compartment by OCID:
  ```plaintext
  Allow group id ocid1.group.oc1..aaaaaaaaexampleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaaaaaexampleocid
  ```

- To specify multiple compartments, use separate statements:
  ```plaintext
  Allow group InstanceAdmins to manage instance-family in compartment Project-A
  Allow group InstanceAdmins to manage instance-family in compartment Project-B
  ```

- To specify multiple compartments by OCID, use separate statements:
  ```plaintext
  Allow group id ocid1.group.oc1..aaaaaaaavheexampleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaaaaayzexampleocid
  Allow group id ocid1.group.oc1..aaaaaaaaexampleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaaexampledocid
  ```

- To specify a compartment that is not a direct child of the compartment where you are attaching the policy, specify the path:
  ```plaintext
  Allow group InstanceAdmins to manage instance-family in compartment Project-A:Project-A2
  ```

**Conditions**

Specify one or more conditions. Use any or all with multiple conditions for a logical OR or AND, respectively.

**Syntax for a single condition:**
```plaintext
variable =|!= value
```

**Syntax for multiple conditions:**
```plaintext
any|all {<condition>,<condition>,...}
```

**Important:**
Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment.
If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

For a list of variables supported by all the services, see General Variables for All Requests on page 2169. Also see the details for each service in the Policy Reference on page 2167. Here are the types of values you can use in conditions:

<table>
<thead>
<tr>
<th>Type</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>'<a href="mailto:johnsmith@example.com">johnsmith@example.com</a>'</td>
</tr>
<tr>
<td></td>
<td>'ocid1.compartment.oc1..aaaaaaaph...ctehnqg756a'</td>
</tr>
<tr>
<td></td>
<td>(single quotation marks are required around the value)</td>
</tr>
<tr>
<td>Pattern</td>
<td>/HR*/ (matches strings that start with &quot;HR&quot;)</td>
</tr>
<tr>
<td></td>
<td>/*HR/ (matches strings that end with &quot;HR&quot;)</td>
</tr>
<tr>
<td></td>
<td>/<em>HR</em>/ (matches strings that contain &quot;HR&quot;)</td>
</tr>
</tbody>
</table>

Examples:

Note:

In the following examples, the statements that specify the condition do not let GroupAdmins actually list all the users and groups, therefore statements including the inspect verb are added for completeness. To understand why this is required, see Variables that Aren't Applicable to a Request Result in a Declined Request on page 2161.

- A single condition.

The following policy enables the GroupAdmins group to create, update, or delete any groups with names that start with "A-Users-":

Allow group GroupAdmins to manage groups in tenancy where target.group.name = /A-Users-*/
Allow group GroupAdmins to inspect groups in tenancy

The following policy enables the NetworkAdmins group to manage cloud networks in any compartment except the one specified:

Allow group NetworkAdmins to manage virtual-network-family in tenancy where target.compartment.id != 'ocid1.compartment.oc1..aaaaaaexampleocid'

- Multiple conditions.

The following policy lets GroupAdmins create, update, or delete any groups whose names start with "A-", except for the A-Admins group itself:

Allow group GroupAdmins to manage groups in tenancy where all {target.group.name=/A-*/,target.group.name!=A-Admins}'
Allow group GroupAdmins to inspect groups in tenancy

**Verbs**

The verbs are listed in order of least amount of ability to most. The exact meaning of a each verb depends on which resource-type it's paired with. The tables later in this section show the API operations covered by each combination of verb and resource-type.

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. <strong>Important:</strong> The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td>read</td>
<td>Includes inspect plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the &quot;update&quot; operation has the same effective impact as the &quot;create&quot; operation (e.g., UpdatePolicy, UpdateSecurityList, etc.), in which case the &quot;update&quot; ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td>manage</td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

**Resource-Types**

The family resource-types are listed below. For the individual resource-types that make up each family, follow the links.

- all-resources: All Oracle Cloud Infrastructure resource-types
- cluster-family: See Details for Container Engine for Kubernetes on page 2177
- compute-management-family: See Details for the Core Services on page 2181
- data-catalog-family: See Data Catalog Policies
- database-family: See Details for the Database Service on page 2240
- dns: See Details for the DNS Service on page 2262
- file-family: See Details for the File Storage Service on page 2273
- instance-family: See Details for the Core Services on page 2181
- object-family: See Details for Object Storage, Archive Storage, and Data Transfer on page 2324
- virtual-network-family: See Details for the Core Services on page 2181
- volume-family: See Details for the Core Services on page 2181

IAM has no family resource-type, only individual ones. See Details for IAM on page 2280.

**General Variables for All Requests**

You use variables when adding conditions to a policy. For more information, see Conditions on page 2160. Here are the general variables applicable to all requests.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request.user.id</td>
<td>Entity (OCID)</td>
<td>The OCID of the requesting user.</td>
</tr>
<tr>
<td>request.user.mfaTotpVerified</td>
<td>Boolean</td>
<td>Whether the user has been verified by multi-factor authentication (MFA). To restrict access to only MFA-verified users, add the condition where request.user.mfaTotpVerified = 'true' See Managing Multi-Factor Authentication on page 2470 for information on setting up MFA.</td>
</tr>
<tr>
<td>request.groups.id</td>
<td>List of entities (OCIDs)</td>
<td>The OCIDs of the groups the requesting user is in.</td>
</tr>
<tr>
<td>request.permission</td>
<td>String</td>
<td>The underlying permission being requested (see Permissions on page 2162).</td>
</tr>
<tr>
<td>request.operation</td>
<td>String</td>
<td>The API operation name being requested (for example, ListUsers).</td>
</tr>
<tr>
<td>request.networkSource.name</td>
<td>String</td>
<td>The name of the network source group that specifies allowed IP addresses the request may come from. See Managing Network Sources on page 2427 for information.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>request.region</td>
<td>String</td>
<td>The 3-letter key for the region the request is made in. Allowed values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AMS - use for Netherlands Northwest (Amsterdam)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• BOM - use for India West (Mumbai)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CWL - use for UK West (Newport)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DXB - use for UAE East (Dubai)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FRA - use for Germany Central (Frankfurt)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GRU - use for Brazil East (Sao Paulo)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HYD - use for India South (Hyderabad)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IAD - use for US East (Ashburn)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ICN - use for South Korea Central (Seoul)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• JED - use for Saudi Arabia West (Jeddah)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• KIX - use for Japan Central (Osaka)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LHR - use for UK South (London)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MEL - use for Australia Southeast (Melbourne)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NRT - use for Japan East (Tokyo)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PHX - use for US West (Phoenix)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SCL - use for Chile (Santiago)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SJC - use for US West (San Jose)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SYD - use for Australia East (Sydney)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• YNY - use for South Korea North (Chuncheon)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• YUL - use for Canada Southeast (Montreal)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• YYZ - use for Canada Southeast (Toronto)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ZRH - use for Switzerland North (Zurich)</td>
</tr>
<tr>
<td>request.ad</td>
<td>String</td>
<td>The name of the availability domain the request is made in. To get a list of availability domain names, use the ListAvailabilityDomains operation.</td>
</tr>
<tr>
<td>request.principal.compartment.tag</td>
<td>String</td>
<td>The tags applied to the compartment that the requesting resource belongs to are evaluated for a match. For usage instructions, see Using Tags to Manage Access on page 3932.</td>
</tr>
<tr>
<td>request.principal.group.tag</td>
<td>String</td>
<td>The tags applied to the groups that the user belongs to are evaluated for a match. For usage instructions, see Using Tags to Manage Access on page 3932.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>target.compartment.name</td>
<td>String</td>
<td>The name of the compartment specified in target.compartment.id.</td>
</tr>
<tr>
<td>target.compartment.id</td>
<td>Entity (OCID)</td>
<td>The OCID of the compartment containing the primary resource. Note: target.compartment.id and target.compartment.name cannot be used with a &quot;List&quot; API operation to filter the list based on the requesting user's access to the compartment.</td>
</tr>
<tr>
<td>target.resource.compartment.tag</td>
<td></td>
<td>The tag applied to the target compartment of the request is evaluated. For usage instructions, see Using Tags to Manage Access on page 3932.</td>
</tr>
<tr>
<td>target.resource.tag</td>
<td></td>
<td>The tag applied to the target resource of the request is evaluated. For usage instructions, see Using Tags to Manage Access on page 3932.</td>
</tr>
</tbody>
</table>

**Details for the Announcements Service**

This topic covers details for writing policies to control access to the Announcements service.

**Resource-Types**

- announcements

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2169).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the announcements resource-type includes the same permissions and API operations as the inspect verb, plus the ANNOUNCEMENT_READ permission and an additional API operation, GetAnnouncement. However, the use verb and manage verbs cover no extra permissions or API operations compared to read.

**announcements**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>ANNOUNCEMENT_LIST</td>
<td>ListAnnouncements</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>INSPECT +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>ANNOUNCEMENT_READ</td>
<td>GetAnnouncement</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>
Permissions Required for Each API Operation
The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2162.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListAnnouncements</td>
<td>ANNOUNCEMENT_LIST</td>
</tr>
<tr>
<td>GetAnnouncement</td>
<td>ANNOUNCEMENT_READ</td>
</tr>
</tbody>
</table>

Details for API Gateway
This topic covers details for writing policies to control access to API Gateway.

Resource-Types

Aggregate Resource-Type
api-gateway-family

Individual Resource-Types
- api-gateways
- api-deployments
- api-definitions
- api-workrequests
- api-certificates

Comments
A policy that uses <verb> api-gateway-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2173 for details of the API operations covered by each verb, for each individual resource-type included in api-gateway-family.

Supported Variables
API Gateway supports all the general variables (see General Variables for All Requests on page 2169).

Details for Verb + Resource-Type Combinations
The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the api-gateways resource-type includes the same permissions and API operations as the inspect verb, plus the API_GATEWAY_READ permission and a number of API operations (e.g., GetGateway, etc.). The use verb covers additional permissions and API operations compared to read. Lastly, manage covers more permissions and operations compared to use.

Details for the Audit Service

This topic covers details for writing policies to control access to the Audit service.

**Resource-Types**

audit-events

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2169).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use and manage verbs for the audit-events resource-type cover no extra permissions or API operations compared to the read verb.

**audit-events**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>none</td>
<td>none</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>AUDIT_EVENT_READ</td>
<td>ListEvents</td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>

**Permissions Required for Each API Operation**

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2162.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListEvents</td>
<td>AUDIT_EVENT_READ</td>
</tr>
</tbody>
</table>

**Details for Container Engine for Kubernetes**

This topic covers details for writing policies to control access to Container Engine for Kubernetes.
Resource-Types

Aggregate Resource-Type

• cluster-family

Individual Resource-Types

• clusters
• cluster-node-pools
• cluster-work-requests

Comments

A policy that uses `<verb> cluster-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2178 for details of the API operations covered by each verb, for each individual resource-type included in `cluster-family`.

Supported Variables

Container Engine for Kubernetes supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The `clusters` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.cluster.id</code></td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

The `cluster-node-pools` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.nodepool.id</code></td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `clusters` resource-type includes the same permissions and API operations as the `inspect` verb, plus the CLUSTER_READ permission and a number of API operations (e.g., `GetCluster`, etc.). The `use` verb covers still another permission and API operation compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

<table>
<thead>
<tr>
<th><code>clusters</code></th>

</tbody>
</table>

Details for the Core Services

This topic covers details for writing policies to control access to the Core Services (Networking, Compute, and Block Volume).

Resource-Types

Networking

Aggregate Resource-Type

virtual-network-family

Individual Resource-Types

vcns
subnets
route-tables
network-security-groups
security-lists
dhcp-options
private-ips
public-ips
ipv6s
internet-gateways
nat-gateways
service-gateways
local-peering-gateways (which includes local-peering-from, and local-peering-to)
remote-peering-connections (which includes remote-peering-from, and remote-peering-to)
drgs
drg-attachments
cpes
ipsec-connections
cross-connects
cross-connect-groups
virtual-circuits
vnics
vnic-attachments
vlans
byoirrange
publicippool
Comments

A policy that uses `<verb> virtual-network-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2183 for details of the API operations covered by each verb, for each individual resource-type included in `virtual-network-family`.

Compute

**instance-family Aggregate Resource-Type**

The `instance-family` aggregate resource-type covers these individual resource-types:

- app-catalog-listing
- console-histories
- instances
- instance-console-connection
- instance-images
- volume-attachments (includes only the permissions required for attaching volumes to instances)

**compute-management-family Aggregate Resource-Type**

The `compute-management-family` aggregate resource-type covers these individual resource-types:

- instance-configurations
- instance-pools
- cluster-networks

**instance-agent-family Aggregate Resource-Type**

The `instance-agent-family` aggregate resource-type covers this individual resource-type:

- instance-agent-plugins

**instance-agent-command-family Aggregate Resource-Type**

The `instance-agent-command-family` aggregate resource-type covers this individual resource-type:

- instance-agent-commands

**Additional Individual Resource-Types**

- auto-scaling-configurations
- dedicated-vm-hosts
- instance-agent-commands
- work-requests

Comments

A policy that uses `<verb> instance-family` or `<verb> compute-management-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types in the family.

See the table in Details for Verb + Resource-Type Combinations on page 2183 for details of the API operations covered by each verb, for each individual resource-type.
Block Volume

Aggregate Resource-Type
volume-family

Individual Resource-Types
volumes
volume-attachments
volume-backups
boot-volume-backups
backup-policies
backup-policy-assignments
volume-groups
volume-group-backups

Comments
A policy that uses <verb> volume-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2183 for details of the API operations covered by each verb, for each individual resource-type included in volume-family.

Supported Variables
The Core Services support all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests on page 2169.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.boot-volume.kms-key.id</td>
<td>String</td>
<td>Use this variable to control whether Compute instances can be launched with boot volumes that were created without a Vault service master encryption key.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations
The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read and use verbs for the vcns resource-type cover no extra permissions or API operations compared to the inspect verb. However, the manage verb includes several extra permissions and API operations.

For virtual-network-family Resource Types
The following tables list the permissions and API operations covered by each of the individual resource-types included in virtual-network-family.
vcns

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>

**Note:** The above operations in this cell are covered with just manage virtual-network-family.

---

**For instance-family Resource Types**

The instance-family aggregate resource-type includes extra permissions beyond the sum of the permissions for the individual resource-types included in instance-family. For example: It includes a few permissions for vnics and volumes, even though those resource-types aren’t generally considered part of the instance-family. Why are there extras included? So you can write fewer policy statements to cover general use cases, like working with an instance that has an attached block volume. You can write one statement for instance-family instead of multiple statements covering instances, vnics, and volumes.

Here’s a list of the extra permissions:

**For inspect instance-family:**
- **VNIC_READ**
- **VNIC_ATTACHMENT_READ**
- **VOLUME_ATTACHMENT_INSPECT**

**For read instance-family:**
- **VOLUME_ATTACHMENT_READ**

**For use instance-family:**
- **VNIC_ATTACH**
- **VNIC_DETACH**
- **VOLUME_ATTACHMENT_UPDATE**

**For manage instance-family:**
- **VOLUME_ATTACHMENT_CREATE**
- **VOLUME_ATTACHMENT_DELETE**

The following tables list the permissions and API operations covered by each of the individual resource-types included in instance-family.
### instances

<table>

For volume-family Resource Types

The following tables list the permissions and API operations covered by each of the individual resource-types included in volume-family.

### volumes

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>VOLUME_INSPECT</td>
<td>ListVolumes, GetVolume</td>
<td>ListVolumeBackups, GetVolumeBackup, UpdateVolumeBackup, DeleteVolumeBackup, GetVolumeAttachment (also need inspect instances and inspect volume-attachments). If you need to get the CHAP secret if it exists, read volume-attachments is required. CreateInstanceConfiguration (if using the CreateInstanceConfigurationFromInstanceDetails subtype. Also need read instances, inspect vnic, inspect vnic-attachments, and inspect volume-attachments.)</td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>no extra</td>
</tr>
<tr>
<td>use</td>
<td>READ +</td>
<td>no extra</td>
<td>READ + CreateVolumeBackup and DetachVolume (both also need manage volume-attachments, use instances)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>manage</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>
### IAM

#### Verbs

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>manage</strong></td>
<td>USE +</td>
<td>USE +</td>
<td>USE +</td>
</tr>
<tr>
<td></td>
<td>VOLUME_CREATE</td>
<td>CreateVolume</td>
<td></td>
</tr>
<tr>
<td></td>
<td>VOLUME_DELETE</td>
<td>DeleteVolume</td>
<td>If creating a volume <em>from a backup</em>, also need read volume-backups.</td>
</tr>
<tr>
<td></td>
<td>VOLUME_MOVE</td>
<td>ChangeVolumeCompartment</td>
<td>If creating a volume <em>encrypted with a Vault service master encryption key</em>, also need use key-delegate (for the caller) and read keys (for the service principal). For more information, see Details for the Vault Service on page 2347.</td>
</tr>
</tbody>
</table>

When moving volumes between compartments, the move volume permission is needed for both source and destination compartments.

#### volume-attachments

<table>
<thead>
<tr>

<tr>
<td></td>
<td>VOLUME_GROUP_DELETE</td>
<td></td>
<td>CreateVolumeGroup</td>
</tr>
<tr>
<td></td>
<td>VOLUME_GROUP_MOVE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If creating a volume group from a list of volumes, also need inspect volume for the volumes to include in the group.

If creating a volume group from another volume group, also need the following:

- inspect volume group for the source volume group
- create volume group for the destination volume group
- write volume for the source volumes
- create volume for the destination volumes
- write volume for the destination volumes

If creating a volume group from a volume group backup, also need the following:

- inspect volume group backup for the source volume group
- create volume group for the destination volume group
- read volume backup or read boot volume backup for the source volumes
- create volume for the destination volumes
- write volume for the destination volumes

When moving volume groups between compartments, the move volume group and move volume permissions are needed for both source and destination compartments.

### Details for the Database Service

See the following topics for details for writing policies to control access to Oracle Cloud Infrastructure Database service resources:

- Policy Details for Autonomous Database on page 2241
- Policy Details for Bare Metal, Virtual Machine, and Exadata DB Systems on page 2246
- Policy Details for Exadata Cloud@Customer
- Policy Details for External Database on page 2252
Policy Details for Autonomous Database

This topic covers details for writing policies to control access to Autonomous Database resources.

Tip:

For a sample policy, see Let database and fleet admins manage Autonomous Databases on page 2151.

Resource-Types

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the autonomous-database-family is equivalent to writing four separate policies for the group that would grant access to the autonomous-databases, autonomous-backups, autonomous-container-databases, and autonomous-exadata-infrastructures resource-types. For more information, see Resource-Types on page 2139.

Resource-Types for Autonomous Database

Aggregate Resource-Type

autonomous-database-family

Individual Resource-Types:

autonomous-databases
autonomous-backups
autonomous-container-databases
autonomous-exadata-infrastructures

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the autonomous-databases resource-type covers the same permissions and API operations as the inspect verb, plus the AUTONOMOUS_DATABASE_CONTENT_READ permission. The read verb partially covers the CreateAutonomousDatabaseBackup operation, which also needs manage permissions for autonomous-backups.

For autonomous-database-family Resource Types

</tbody>
</table>

For autonomous-data-warehouse-family Resource Types

Note:
The autonomous-data-warehouse-family permissions are deprecated. You can use the resource family autonomous-database-family to grant access to the Autonomous Database resources used by both Autonomous Data Warehouse databases and Autonomous Transaction Processing databases.

Policy Details for Bare Metal, Virtual Machine, and Exadata DB Systems

This topic covers details for writing policies to control access to bare metal, virtual machine, and Exadata DB system resources.
**Tip:**
For a sample policy, see Let database admins manage Oracle Cloud database systems on page 2150.

**Resource-Types**
An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the database-family is equivalent to writing five separate policies for the group that would grant access to the db-systems, db-nodes, db-homes, databases, and backups resource-types. For more information, see Resource-Types on page 2139.

**Resource-Types for Bare Metal, Virtual Machine, and Exadata DB Systems**

**Aggregate Resource-Type**
database-family

**Individual Resource-Types:**
db-systems
db-nodes
db-homes
databases
backups

**Supported Variables**
Only the general variables are supported (see General Variables for All Requests on page 2169).

**Details for Verb + Resource-Type Combinations**
The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read and use verbs for the db-systems resource-type cover no extra permissions or API operations compared to the inspect verb. However, the manage verb includes two more permissions and partially covers two more API operations.

**For database-family Resource Types**
db-systems

<table>
<thead>

|        | DB_HOME_CREATE |                   | TerminateDbSystem |
|        | DB_HOME_DELETE |                   | (both also need manage
db-systems, manage
databases, use
vnics, and use
subnets). If automatic
backups are enabled on the
default database, also needs
manage backups
CreateDbHome,
(also needs use db-
systems and manage
databases). If creating
the Database Home
by restoring from a
backup, also needs read
backups
DeleteDbHome,
(also needs use db-
systems and manage
databases). If automatic
backups are enabled on the
default database, also needs
manage backups. If the
performFinalBackup
option is selected, also
needs manage backups
and read databases.

</tbody>
</table>

**Policy Details for External Database**

This topic covers details for writing policies to control access to external database resources.

**Tip:**

For a sample policy, see Let database admins manage Oracle Cloud external database resources on page 2150.

**Resource-Types**

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the external-database-family is equivalent to writing four separate policies for the group that would grant access to the external-container-databases, external-pluggable-databases, external-non-container-databases, and external-database-connectors resource-types. For more information, see Resource-Types on page 2139.

**Aggregate Resource-Type**

external-database-family

**Individual Resource-Types:**

external-container-databases
external-pluggable-databases
external-non-container-databases
external-database-connectors

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2169).
**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the `external-container-databases` resource-type covers the same permissions and API operations as the read verb, plus the `EXTERNAL_CONTAINER_DATABASE_UPDATE` permission. The use verb partially covers the `ScanPluggableDatabases` operation, which also needs read permissions for `external-pluggable-databases`.

**external-container-databases**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td><code>EXTERNAL_CONTAINER_DATABASE_INSPECT</code></td>

**Details for Database Management**

This topic covers details for writing policies to control access to the Database Management service.

**Resource-Types**

**Aggregate Resource-Type**

dbmgmt-family

**Individual Resource-Types**

- dbmgmt-jobs
- dbmgmt-managed-database-groups
- dbmgmt-managed-databases
**Comments**

A policy that uses `<verb> dbmgmt-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types in the family.

See the table in **Details for Verb + Resource-Type Combinations** on page 2259 for details of the API operations covered by each verb, for each individual resource-type.

**Supported Variables**

Only the general variables are supported (see **General Variables for All Requests** on page 2169).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

### dbmgmt-jobs

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td><code>DBMGMT_JOB_INSPECT</code></td>
<td><code>ListJobs</code></td>

</table>
Details for the DNS Service

This topic covers details for writing policies to control access to the DNS service.

Aggregate Resource-Type
dns

Individual Resource-Types
dns-zones
dns-records
dns-steering-policies
dns-steering-policy-attachments
dns-tsig-keys
dns-views
dns-resolvers

Comments

A policy that uses `<verb> dns` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2265 for details of the API operations covered by each verb, for each individual resource-type included in `dns`.

Supported Variables

The DNS service supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The `dns-zones` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-zone.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific DNS zones by OCID.</td>
</tr>
<tr>
<td>target.dns-zone.name</td>
<td>String</td>
<td>Use this variable to control access to specific DNS zones by name.</td>
</tr>
<tr>
<td>target.dns-zone.apex-label</td>
<td>String</td>
<td>The most significant DNS label for the target zone. Example: If the target zone's name is &quot;service.example.com&quot;, the value of this variable would be &quot;service&quot;.</td>
</tr>
<tr>
<td>target.dns-zone.parent-domain</td>
<td>String</td>
<td>The domain name of the target zone's parent zone.</td>
</tr>
<tr>
<td>target.dns.scope</td>
<td>String</td>
<td>Valid values are &quot;public&quot; and &quot;private&quot;.</td>
</tr>
</tbody>
</table>
The **dns-records** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-zone.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific DNS zones by OCID.</td>
</tr>
<tr>
<td>target.dns-zone.name</td>
<td>String</td>
<td>Use this variable to control access to specific DNS zones by name.</td>
</tr>
<tr>
<td>target.dns-record.type</td>
<td>List (String)</td>
<td>Use this variable to control access to specific DNS records by type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values in the list can be any supported DNS resource type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, &quot;A&quot;, &quot;AAAA&quot;, &quot;TXT&quot;, and so on. See Supported Resource Records on page 1686.</td>
</tr>
<tr>
<td>target.dns-domain.name</td>
<td>List (String)</td>
<td>Use this variable to control access to specific domain names.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Applicable to the following API operations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GetDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PatchDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UpdateDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DeleteRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GetRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PatchRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UpdateRRSet</td>
</tr>
<tr>
<td>target.dns-zone.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of the DNS zone by OCID.</td>
</tr>
<tr>
<td>target.dns-zone.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the DNS zone by OCID.</td>
</tr>
</tbody>
</table>

**Note:**

Use the target.dns-record.type and target.dns-domain.name variables in your authorization policy to restrict users when modifying records of a specific type in a specific subdomain. A policy like this would allow a specific group of users to modify "A" records in the "example.com" domain: Allow group <GroupName> to use dns in compartment <CompartmentName> where all {target.dns-record.type='A', target.dns-domain.name = 'example.com'} Users will only be authorized to use RRSet API operations with this type of authorization policy.

The **dns-steering-policies** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-steering-policy.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific steering policies by OCID.</td>
</tr>
<tr>
<td>Variable</td>
<td>Variable Type</td>
<td>Comments</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>target.dns-steering-policy.display-name</td>
<td>String</td>
<td>Use this variable to control access to specific steering policies by name.</td>
</tr>
<tr>
<td>target.dns-steering-policy.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of the steering policy by OCID.</td>
</tr>
<tr>
<td>target.dns-steering-policy.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the steering policy by OCID.</td>
</tr>
</tbody>
</table>

The **dns-tsig-keys** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-tsig-key.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific TSIG keys by OCID.</td>
</tr>
<tr>
<td>target.dns-tsig-key.name</td>
<td>String</td>
<td>Use this variable to control access to specific TSIG keys by name.</td>
</tr>
<tr>
<td>target.dns-tsig-key.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific TSIG key by OCID.</td>
</tr>
<tr>
<td>target.dns-tsig-key.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the specific TSIG key by OCID.</td>
</tr>
</tbody>
</table>

The **dns-view** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-view.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific view by OCID.</td>
</tr>
<tr>
<td>target.dns-view.display-name</td>
<td>String</td>
<td>Use this variable to control access to specific view by name.</td>
</tr>
<tr>
<td>target.dns-view.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific view by OCID.</td>
</tr>
<tr>
<td>target.dns-view.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the specific view by OCID.</td>
</tr>
</tbody>
</table>

The **dns-resolver** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-resolver.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific resolver by OCID.</td>
</tr>
<tr>
<td>target.dns-resolver.display-name</td>
<td>String</td>
<td>Use this variable to control access to specific resolver by name.</td>
</tr>
<tr>
<td>target.dns-resolver.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific resolver by OCID.</td>
</tr>
</tbody>
</table>
The `target.dns-resolver.destination-compartment.id` variable type is used to control access to the destination compartment of the specific resolver by OCID.

The `target.dns-resolver-endpoint.name` variable allows you to control access to specific resolver endpoints by name.

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the manage verb for the `dns-records` resource-type covers no extra permissions or API operations compared to the use verb.

### dns-zones

**Details for the Email Service**

This topic covers details for writing policies to control access to the Email service.

**Resource-Types**

- approved-senders
- suppressions

**Supported Variables**

The Email Service supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The approved-senders resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.approved-sender.id</td>
<td>Entity (OCID)</td>
<td></td>
</tr>
<tr>
<td>target.approved-sender.emailaddress</td>
<td>String</td>
<td>Use this variable with the APPROVED_SENDER_USE permissions only.</td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the suppressions resource-type covers no extra permissions or API operations compared to the read verb.
approved-senders

</tbody>
</table>
## Details for the Events Service

This topic covers details for writing user IAM policies that control access to rules for the Events service.

### Resource-Types

cloadevents-rules

### Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for cloadevents-rules includes the same permissions and API operations as the inspect verb, plus the EVENTRULE_READ permissions and the corresponding API operation GetEventRule. The use verb adds no extra permissions or API operations compared to read. However, manage adds more permissions and operations compared to use.

### Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2162.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListRules</td>
<td>EVENTRULE_LIST</td>
</tr>
<tr>
<td>CreateRule</td>
<td>EVENTRULE_CREATE</td>
</tr>
</tbody>
</table>
### API Operation | Permissions Required to Use the Operation
---|---
GetRule | EVENTRULE_READ
DeleteRule | EVENTRULE_DELETE
UpdateRule | EVENTRULE_MODIFY
ChangeRuleCompartment | EVENTRULE_MODIFY

## Details for the File Storage Service

This topic covers details for writing policies to control access to the File Storage Service.

### Aggregate Resource-Type

- file-family

### Individual Resource-Types

- file-systems
- mount-targets
- export-sets

### Comments

A policy that uses `<verb> file-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in [Details for Verb + Resource-Type Combinations](#) on page 2273 for details of the API operations covered by each verb, for each individual resource-type included in file-family.

### Supported Variables

Only the general variables are supported (see [General Variables for All Requests](#) on page 2169).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the file-systems resource-type includes the same permissions and API operations as the inspect verb, plus the FILE_SYSTEM_READ permission and a number of API operations (e.g., GetFileSystem, ListMountTargets, etc.). The use verb covers still another permission and set of API operations compared to read. Lastly, manage covers two more permissions and operations compared to use.

### export-sets

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>EXPORT_SET_INSPECT</td>
<td>ListExportSets</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>INSPECT +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>EXPORT_SET_READ</td>
<td>GetExportSet</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListExports</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>
## IAM

### Verbs

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>

</thead>
<tbody>
<tr>
<td>manage</td>
<td>USE +</td>
<td>USE +</td>
<td>CreateExport</td>
</tr>
<tr>
<td></td>
<td>EXPORT_SET_CREATE</td>
<td>CreateExportSet</td>
<td>DeleteExport</td>
</tr>
<tr>
<td></td>
<td>EXPORT_SET_UPDATE</td>
<td>UpdateExportSet</td>
<td>(both also need use file-systems.)</td>
</tr>
<tr>
<td></td>
<td>EXPORT_SET_DELETE</td>
<td>DeleteExportSet</td>
<td></td>
</tr>
</tbody>
</table>

### file-systems

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>FILE_SYSTEM_INSPECT</td>
<td>ListFileSystems</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>INSPECT +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_READ</td>
<td>GetFileSystem</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetSnapshot</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListSnapshots</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>READ +</td>
<td>no extra</td>
<td>DeleteExport</td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_NFSv3_EXPORT</td>
<td>(both also need manage export-sets.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_NFSv3_UNEXPORT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>USE +</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_CREATE</td>
<td>CreateFileSystem</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_UPDATE</td>
<td>UpdateFileSystem</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_DELETE</td>
<td>DeleteFileSystem</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_MOVE</td>
<td>ChangeFileSystemCompartment</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_CREATE_SNAPSHOT</td>
<td>CreateSnapshot</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FILE_SYSTEM_DELETE_SNAPSHOT</td>
<td>DeleteSnapshot</td>
<td></td>
</tr>
</tbody>
</table>

If creating a file system or clone encrypted with a Key Management master encryption key, also need use key-delegate (for the caller) and read keys (for the service principal). For more information, see Details for the Vault Service on page 2347.

### mount-targets

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>

### Details for Functions

This topic covers details for writing policies to control access to Oracle Functions.

#### Resource-Types

**Aggregate Resource-Type**
- functions-family

**Individual Resource-Types**
- fn-app
- fn-function
- fn-invocation

#### Comments

A policy that uses `<verb> functions-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2277 for details of the API operations covered by each verb, for each individual resource-type included in functions-family.

#### Supported Variables

Oracle Functions supports all the general variables (see General Variables for All Requests on page 2169).
**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `fn-app` resource-type includes the same permissions and API operations as the `inspect` verb, plus the `FN_APP_READ` permission and the `GetApp` API operation. In the case of the `fn-app` resource-type, the `use` verb covers no additional permissions or API operations compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

### fn-app

<table>
<thead>
<tr>
<th>Verbs</th>

</tbody>
</table>

Details for the Health Checks Service

This topic covers details for writing policies to control access to the Health Checks service.

Resource-Types

- health-check-monitor
- health-check-results
- on-demand-probe
- vantage-points
- health-check-family

Supported Variables

The Health Checks Service supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here. Values in the list can be any valid test type. For example, HTTP, HTTPS, ICMP, etc.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.health-check-monitor.test-type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>target.on-demand-probe.test-type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>target.health-check-results.test-type</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.
For example, the `use` verb for the `health-check-monitor` resource-type covers no extra permissions or API operations compared to the `read` verb.

### health-check-monitor

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>

<td>HEALTH_CHECK_MONITOR_MANAGE</td>
</tr>
<tr>
<td>GetOHCMonitor</td>
<td>HEALTH_CHECK_MONITOR_READ</td>
</tr>
<tr>
<td>UpdateOHCMonitor</td>
<td>HEALTH_CHECK_MONITOR_MANAGE</td>
</tr>
<tr>
<td>DeleteOHCMonitor</td>
<td>HEALTH_CHECK_MONITOR_MANAGE</td>
</tr>
<tr>
<td>ListOHCProbeResults</td>
<td>HEALTH_CHECK_RESULTS_READ</td>
</tr>
<tr>
<td>ListOHCProbeResultsForTarget</td>
<td>HEALTH_CHECK_RESULTS_READ</td>
</tr>
<tr>
<td>ListVantagePoints</td>
<td>VANTAGE_POINTS_INSPECT</td>
</tr>
<tr>
<td>CreateOnDemandOHCProbe</td>
<td>ON_DEMAND_PROBE_MANAGE</td>
</tr>
<tr>
<td>MoveOHCMonitor</td>
<td>HEALTH_CHECK_MONITOR_MOVE</td>
</tr>
</tbody>
</table>

**Details for IAM**

This topic covers details for writing policies to control access to IAM.

**Resource-Types**

authentication-policies  
compartments  
credentials  
dynamic-groups  
groups  
identity-providers  
network-sources  
policies  
tag-defaults  
tag-namespaces  
tenancies  
users  
workrequest
**Supported Variables**

IAM supports all the general variables (see [General Variables for All Requests](#) on page 2169), plus additional ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use These Variables...</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>users</strong></td>
<td>target.user.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreateUser.</td>
</tr>
<tr>
<td></td>
<td>target.user.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><strong>groups</strong></td>
<td>target.group.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreateGroup.</td>
</tr>
<tr>
<td></td>
<td>target.group.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td></td>
<td>target.group.member</td>
<td>Boolean</td>
<td>True if request.user is a member of target.group.</td>
</tr>
<tr>
<td><strong>policies</strong></td>
<td>target.policy.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreatePolicy.</td>
</tr>
<tr>
<td></td>
<td>target.policy.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><strong>compartments</strong></td>
<td>target.compartment.id</td>
<td>Entity (OCID)</td>
<td>For CreateCompartment, this will be the value of the parent compartment (e.g., the root compartment). This is a universal variable available to use with any request across all services (see <a href="#">General Variables for All Requests</a> on page 2169).</td>
</tr>
<tr>
<td></td>
<td>target.compartment.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><strong>tag-namespace</strong></td>
<td>target.tag-namespace.id</td>
<td>Entity (OCID)</td>
<td>This variable is supported only in statements granting permissions for the tag-namespaces resource-type. For an example, see <a href="#">Required Permissions for Working with Defined Tags</a> on page 3915. Not available to use with CreateTagNamespace.</td>
</tr>
<tr>
<td></td>
<td>target.tag-namespace.name</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

**Details for Verbs + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for compartments covers no extra permissions or API operations compared to the inspect verb. The use verb includes the same ones as the read verb, plus the COMPARTMENT_UPDATE permission and UpdateCompartment API operation. The manage verb includes the same permissions and
API operations as the use verb, plus the COMPARTMENT_CREATE permission and two API operations: CreateCompartment and DeleteCompartment.

**authentication-policies**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>AUTHENTICATION_POLICY_INSPECT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>USE + AUTHENTICATION_POLICY_UPDATE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**compartments**

To move a compartment (that is, use the MoveCompartment operation) you must belong to a group that has manage all-resources permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>

**credentials**

The credentials resource type refers to only the SMTP credentials. Permissions to work with other credentials that can be added to a user (such as auth tokens, API keys, and customer secret keys) are included with users resource permissions.

Details for Load Balancing

This topic covers details for writing policies to control access to the Load Balancing service.

Resource-Types

load-balancers

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for load-balancers includes the same permissions and API operations as the inspect verb, plus the LOAD_BALANCER_READ permission and a number of API operations (e.g., GetLoadBalancer, ListWorkRequests, etc.). The use verb covers still another permission and set of API operations compared to read. And manage covers two more permissions and operations compared to use.

**Permissions Required for Each API Operation**

The following table lists the API operations in a logical order, grouped by resource type.

**Tip:**

If a group uses the Console to manage load balancers, permissions to use the associated networking resources are required. See the load balancing policy examples for further guidance.

For information about permissions, see [Permissions](#) on page 2162.

**Details for Logging**

This topic covers details for writing policies to control access to Logging.

**Resource-Types**

**Aggregate Resource-Type**
- logging-family
Individual Resource-Ttypes

- log-objects
- log-groups
- log-content

Comments

A policy that uses `<verb> logs` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in logs.

Supported Variables

Logging supports all the general variables (see General Variables for All Requests on page 2169), plus additional ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use These Variables...</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>log-groups</td>
<td>target.loggroup.id</td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the log-groups resource-type includes the same permissions and API operations as the inspect verb, plus the LOG_GROUPS_READ permission and the corresponding API operations GetLog and GetLogGroup.

log-objects

<table>
<thead>
<tr>

<tr>
<td>GetLogGroup</td>
<td>LOG_GROUP_READ</td>
</tr>
<tr>
<td>UpdateLogGroup</td>
<td>LOG_GROUP_UPDATE</td>
</tr>
<tr>
<td>CreateLogGroup</td>
<td>LOG_GROUP_CREATE</td>
</tr>
<tr>
<td>DeleteLogGroup</td>
<td>LOG_GROUP_DELETE</td>
</tr>
<tr>
<td>ChangeLogGroupCompartment</td>
<td>LOG_GROUP_UPDATE</td>
</tr>
</tbody>
</table>

**Details for Logging Analytics**

This topic covers details for writing policies to control access to the Logging Analytics service.

**Resource-Types**

**Individual Resource-Types**

loganalytics-config-work-request
loganalytics-entity
loganalytics-entity-type
loganalytics-field
loganalytics-label
loganalytics-lifecycle
loganalytics-log-group
loganalytics-lookup
loganalytics-object-collection-rule
loganalytics-ondemand-upload
loganalytics-parser
loganalytics-query
loganalytics-queryjob-work-request
loganalytics-scheduled-task
loganalytics-source
loganalytics-storage
loganalytics-storage-work-request

**Aggregate Resource-Types**

The loganalytics-features-family aggregate resource-type covers these individual resource-types (resource kinds that are not modeled as resources; that is, resource kinds that do not belong to a compartment):

loganalytics-entity-type
loganalytics-field
loganalytics-label
loganalytics-lifecycle
loganalytics-lookup
loganalytics-ondemand-upload
loganalytics-parser
loganalytics-query
loganalytics-source
loganalytics-storage
loganalytics-storage-work-request

The loganalytics-resources-family aggregate resource-type covers these individual resource-types (resource kinds that are modeled as resources; that is, resource kinds that belong to a compartment):

loganalytics-config-work-request
loganalytics-entity
loganalytics-log-group
loganalytics-object-collection-rule
loganalytics-queryjob-work-request
loganalytics-scheduled-task
loganalytics-storage-work-request

Comments

A policy that uses <verb> loganalytics-features-family or <verb> loganalytics-resources-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types in the family.

See the table in Permissions Required for Each API Operation on page 2308 for details of the API operations covered by each verb, for each individual resource-type.

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

**Details for Management Agent**

This topic covers details for writing policies to control access to the Management Agent service.

**Resource-Types**

management-agents

management-agent-install-keys

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2169).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for Management Dashboard

This topic covers details for writing policies to control access to Management Dashboard.

Resource-Types

Individual Resource-Types

- management-dashboard
- management-saved-search

Aggregate Resource-Type

- management-dashboard-family

Comments

A policy that uses `<verb>` management-dashboard-family is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual resource-types. The resource-type management-dashboard allows a user group to work with dashboards while the resource-type management-saved-search allows a user group to work with saved searches (widgets) that are displayed in dashboards.

See the table in Details for Verb + Resource-Type Combinations on page 2316 for details of the API operations covered by each verb, for each individual resource-type included in management-dashboard-family.

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

</tbody>
</table>

**Example Policies**

This section provides example policies for use with Management Dashboard.

**Dashboard Policies**

Here are examples of policy statements that authorize access to dashboards (management-dashboard resource-type):

- To allow a user group to list the dashboards in a compartment, use the inspect verb:

  ```
  Allow group dashboard-users to inspect management-dashboard in compartment myCompartment1
  ```

- To allow a user group to list dashboards and obtain details regarding the dashboards in a compartment, use the read verb:

  ```
  Allow group dashboard-users to read management-dashboard in compartment myCompartment1
  ```

- To allow a group of administrators to list dashboards, obtain details regarding dashboards, and update the dashboards in a compartment, use the use verb:

  ```
  Allow group dashboard-admins to use management-dashboard in compartment myCompartment1
  ```

- To allow a group of administrators to list dashboards, obtain details regarding dashboards, update dashboards, and manage (create, move, and delete) the dashboards in a compartment, use the manage verb:

  ```
  Allow group dashboard-admins to manage management-dashboard in compartment myCompartment1
  ```

**Saved Search Policies**

Here are examples of policy statements that authorize access to saved searches (management-saved-search resource-type):

- To allow a user group to list the saved searches in a compartment, use the inspect verb:

  ```
  Allow group saved-search-users to inspect management-saved-search in compartment myCompartment1
  ```

- To allow a user group to list saved searches and obtain details regarding the saved searches in a compartment, use the read verb:

  ```
  Allow group saved-search-users to read management-saved-search in compartment myCompartment1
  ```
- To allow a group of administrators to list saved searches, obtain details regarding saved searches, update the saved searches in a compartment, use the use verb:

```
Allow group saved-search-admins to use management-saved-search in compartment myCompartment1
```

- To allow a group of administrators to list saved searches, obtain details regarding saved searches, update saved searches, and manage (create, move, and delete) the saved searches in a compartment, use the manage verb:

```
Allow group saved-search-admins to manage management-saved-search in compartment myCompartment1
```

**Aggregate Policies**

Here's an example of a policy that simultaneously authorizes access to both dashboards and saved searches by using the aggregate `management-dashboard-family` resource-type. In this example, the inspect verb is used to allow a user group to list both the dashboards and saved searches in a compartment:

```
Allow group dashboard-family-admins to inspect management-dashboard-family in compartment myCompartment1
```

Similarly, the other Oracle Cloud Infrastructure verbs can be used to allow user groups to perform the corresponding tasks for dashboards and saved searches in one policy.

**Details for the Marketplace Service**

This topic covers details for writing policies to control access to the Marketplace service.

**Individual Resource-Type**

`marketplace-listings`

**Supported Variables**

Marketplace supports all the general variables, plus the ones listed here. Specifically, you can use the variables listed here when writing policies that grant read, use, and manage verbs. You cannot use them with the inspect verb. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests on page 2169.

<table>
<thead>
<tr>
<th>Resource-Type</th>
<th>Variable</th>
<th>Variable Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>marketplace-listings</td>
<td>listing.id</td>
<td>String</td>
<td>Use this variable to control whether to return a specific listing (based on the given listing ID) in response to a request.</td>
</tr>
<tr>
<td>marketplace-listings</td>
<td>listing.publisher.id</td>
<td>String</td>
<td>Use this variable to control whether to return only listings from a specific publisher (based on the given publisher ID) in response to a request.</td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.
For example, the `use` verb for the `marketplace-listings` resource-type includes the same permissions and API operations as the `read` verb, plus the `MARKETPLACE_LISTING_LAUNCH` permission and an additional API operation, `LaunchListing`. However, the `manage` verb covers no extra permissions or API operations compared to `use`.

### `marketplace-listings`

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td><code>MARKETPLACE_LISTING_INSPECT</code></td>
<td>ListListings</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td><code>INSPECT + MARKETPLACE_LISTING_READ</code></td>
<td></td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td><code>READ + MARKETPLACE_LISTING_LAUNCH</code></td>
<td></td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>

**Permissions Required for Each API Operation**

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see [Permissions](#) on page 2162.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListListings</td>
<td><code>MARKETPLACE_LISTING_INSPECT</code></td>
</tr>
<tr>
<td>GetListing</td>
<td><code>MARKETPLACE_LISTING_READ</code></td>
</tr>
<tr>
<td>LaunchListing</td>
<td><code>MARKETPLACE_LISTING_LAUNCH</code></td>
</tr>
</tbody>
</table>

**Details for Monitoring**

This topic covers details for writing policies to control access to the Monitoring service.

**Resource-Types**

- alarms
- metrics

**Supported Variables**

Monitoring supports all the general variables (see [General Variables for All Requests](#) on page 2169), plus the one listed here:
Operations for This Resource-Type...

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.metrics.namespace</td>
<td>Use this variable to control access to specific resource types. Surround the namespace value with single quotes. For example, to control access to metrics for Compute instances, use the following phrase: where target.metrics.namespace='oci_computeagent'. For an example policy, see Restrict user access to a specific metric namespace on page 2156. For valid namespace values, see Supported Services on page 2669.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

**alarms**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>

Details for Object Storage, Archive Storage, and Data Transfer

This topic covers details for writing policies to control access to Archive Storage, Object Storage, and Data Transfer.

Tip:

The object lifecycle policies feature requires that you grant permissions to the Object Storage service to archive and delete objects on your behalf. See Using Object Lifecycle Policies for more information.

Resource-Types

Individual Resource-Types

objectstorage-namespaces
buckets
objects

Aggregate Resource-Type

object-family

A policy that uses <verb> object-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.
See the table in Details for Verb + Resource-Type Combinations on page 2325 for details of the API operations covered by each verb, for each individual resource-type included in object-family.

**Additional Individual Resource-Type for Data Transfer**

**data-transfer-jobs**

**Supported Variables**

Object Storage supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use This Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>buckets and objects</td>
<td>target.bucket.name</td>
<td>String</td>
<td>Use this variable to control access to a specific bucket. For an example policy, see Let users write objects to Object Storage buckets on page 2149. <strong>Important:</strong> Condition matching is case insensitive. If you have a bucket named &quot;BucketA&quot; and a bucket named &quot;bucketA&quot;, the condition where target.bucket.name=&quot;BucketA&quot; applies to both. To avoid potential issues with resource names in policy, give your resources distinct names.</td>
</tr>
</tbody>
</table>

**Note:**
The request.ipv4.ipaddress and the request.vcn.id variables are deprecated. Instead of using these variables, create a network source to specify either an IP address range or a specific VCN ID. You can then use the network source in your policy to restrict access to only requests coming from the allowed networks. For more information, see Managing Network Sources on page 2427.

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

## Details for Operations Insights

This topic covers details for writing policies to control access to the Operations Insights service.

### Resource-Types

**Individual Resource-Types**

.opsi-database-insights

**Aggregate Resource-Types**

.opsi-family

### Comments

See the table in Permissions Required for Each API Operation on page 2331 for details of the API operations covered by each verb, for each individual resource-type.

### Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2169).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for Oracle Cloud VMware Solution

This topic covers details for writing policies to control access to Oracle Cloud VMware Solution resources.

**Resource-Types**

sddcs

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2169).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for sddcs includes the same permissions and API operations as the inspect verb, plus the SDDC_READ permission and a number of API operations (e.g., GetSddc, ListWorkRequests, etc.). The use verb covers two more permissions and set of API operations compared to read. And manage covers five more permissions and operations compared to use.

**sddcs**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Details for the Quotas Service

This topic covers details for writing policies to control access to the Quotas service.

**Supported Variables**

The Quotas service supports all the general variables (see General Variables for All Requests on page 2169) plus the following:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.quota.id</td>
<td>Entity</td>
<td>Request/OCID</td>
</tr>
<tr>
<td>target.quota.name</td>
<td>String</td>
<td>Request/Stored</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>

</table>

Details for Registry
This topic covers details for writing policies to control access to the Registry.

Resource-Types
- repos

Supported Variables
Oracle Cloud Infrastructure Registry supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The repos resource-type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.repo.name</td>
<td>String</td>
<td>Use this variable to control access to specific repositories. For an example policy, see Policies to Control Repository Access on page 3527.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations
The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the repos resource-type includes the same permissions and API operations as the inspect verb, plus the REPOSITORY_READ permission and a number of API operations (e.g., GetContainerRepository, etc.). The use verb covers still another permission and API operation compared to read. Lastly, manage covers more permissions and operations compared to use.

repos
### Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2162.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListContainerRepositories</td>
<td>REPOSITORY_INSPECT</td>
</tr>
<tr>
<td>CreateContainerRepository</td>
<td>REPOSITORY_CREATE</td>
</tr>
<tr>
<td>GetContainerRepository</td>
<td>REPOSITORY_READ</td>
</tr>
<tr>
<td>UpdateContainerRepository</td>
<td>REPOSITORY_MANAGE</td>
</tr>
<tr>
<td>DeleteContainerRepository</td>
<td>REPOSITORY_DELETE</td>
</tr>
<tr>
<td>ChangeContainerRepositoryCompartment</td>

<td>REPOSITORY_INSPECT</td>
</tr>
<tr>
<td>GetContainerImage</td>
<td>REPOSITORY_READ</td>
</tr>
<tr>
<td>DeleteContainerImage</td>
<td>REPOSITORY_UPDATE</td>
</tr>
<tr>
<td>RestoreContainerImage</td>
<td>REPOSITORY_UPDATE</td>
</tr>
<tr>
<td>RemoveContainerVersion</td>
<td>REPOSITORY_UPDATE</td>
</tr>
<tr>
<td>GetContainerConfiguration</td>
<td>REPOSITORY_INSPECT</td>
</tr>
<tr>
<td>UpdateContainerConfiguration</td>
<td>REPOSITORY_MANAGE</td>
</tr>
</tbody>
</table>

### Details for Resource Manager

This topic covers details for writing policies to control access to the Resource Manager service.
Aggregate Resource-Type

orm-family

Individual Resource-Types

orm-config-source-providers
orm-jobs
orm-stacks
orm-template
orm-work-requests

Supported Variables

Resource Manager supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The orm-jobs resource type can use the following variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.job.operation</td>
<td>String</td>
<td>Use this variable to control access for running specified job types. For example, to limit access to PLAN and APPLY jobs, use the following phrase: where any {target.job.operation = 'PLAN', target.job.operation = 'APPLY'}</td>
</tr>
<tr>
<td>target.stack.id</td>
<td>String</td>
<td>Use this variable to limit access to specified stacks. For example, use the following phrase: where any {target.stack.id = ocid1.ormstack.uniqueid1, target.stack.id = ocid1.ormstack.uniqueid2}</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

### Details for Search

The Search service does not require permissions for its API operations. You do not need to write policies specifically to control access to Search. However, what you can see in search or query results depends on the permissions you have. If a policy exists to give you access to the `inspect` verb for a particular resource type, you have access to the permissions needed to view that resource type and its associated metadata in search results. If a service does not recognize the `inspect` verb or if the resource type's `inspect` verb does not fully cover list operations, permissions to view the service's supported resource types are granted by the `read` verb instead.

For more information about permissions, see the Permissions section of Advanced Policy Features.

### Permissions Required to View Each Resource Type

The following table lists the resource types grouped by service, which are listed in alphabetical order. The Search API operations that can access the metadata for these resource types with these permissions are `GetResourceType`, `ListResourceTypes`, and `SearchResources`.

<table>
<thead>
<tr>

Details for Service Connector Hub

This topic covers details for writing policies to control access to the Service Connector Hub service.

**Individual Resource-Types**

`serviceconnectors`

**Supported Variables**

Service Connector Hub supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

The `serviceconnectors` resource type can use the following variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.serviceconnector.id</code></td>
<td>OCID</td>
<td>Use this variable to control access for service connectors.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.
### serviceconnectors

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>

### Details for the Streaming Service

This topic covers details for writing policies to control access to the Streaming service.
**Resource-Types**

- streams
- stream-pull
- stream-push
- connect-harnesses
- stream-pools

**Supported Variables**

The Streaming service supports all the general variables (see General Variables for All Requests on page 2169) plus the following:

The **streams** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.stream.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

The **connect-harnesses** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.connectharness.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

The **stream-pools** resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.streampool.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

**streams**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>STREAM_INSPECT</td>
<td>ListStreams</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT + STREAM_READ</td>
<td>GetStream</td>
<td>none</td>
</tr>
</tbody>
</table>
### IAM

**Verbs** | **Permissions** | **APIs Fully Covered** | **APIs Partially Covered**
---|---|---|---
**use** | READ + | UpdateStream | none
STREAM_UPDATE | MoveStream
STREAM_MOVE | PutMessages
STREAM_PRODUCE | GetMessages
STREAM_CONSUME | CreateCursor

</table>

**Details for the Vault Service**

This topic covers details for writing policies to control access to the Vault service.

**Individual Resource-Types**

- vaults
- keys
- key-delegate
- secrets
- secret-versions
- secret-bundles

**Aggregate Resource-Type**

- secret-family

A policy that uses `<verb> secret-family` is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual secret resource-types. (Secret resource-types include only secrets, secret-versions, and secret-bundles.)

See the table in **Details for Verb + Resource-Type Combinations** on page 2348 for details of the API operations covered by each verb, for each individual resource-type included in `secret-family`.

**Supported Variables**

Vault supports all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see **General Variables for All Requests** on page 2169.
### Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>request.includePlainTextKey</td>
<td>String</td>
<td>Use this variable to control whether to return the plaintext key, in addition to the encrypted key, in response to a request to generate a data encryption key.</td>
</tr>
<tr>
<td>request.kms-key.id</td>
<td>String</td>
<td>Use this variable to control whether block volumes or buckets can be created without a Vault master encryption key.</td>
</tr>
<tr>
<td>target.boot-volume.kms-key.id</td>
<td>String</td>
<td>Use this variable to control whether Compute instances can be launched with boot volumes that were created without a Vault master encryption key.</td>
</tr>
<tr>
<td>target.key.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific keys by OCID.</td>
</tr>
<tr>
<td>target.vault.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific vaults by OCID.</td>
</tr>
<tr>
<td>target.secret.name</td>
<td>String</td>
<td>Use this variable to control access to specific secrets, secret versions, and secret bundles by name.</td>
</tr>
<tr>
<td>target.secret.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific secrets, secret versions, and secret bundles by OCID.</td>
</tr>
</tbody>
</table>

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the keys resource-type includes the same permissions and API operations as the read verb, plus the KEY_ENCRYPT and KEY_DECRYPT permissions and a number of API operations (Encrypt, Decrypt, and GenerateDataEncryptionKey). The manage verb allows even more permissions and API operations when compared to the use verb.

### Details for the WAF Service

This topic covers details for writing policies to control access to the WAAS service.

#### Aggregate Resource-Type

waas-family

#### Individual Resource-Types

- waas-policy
- waas-certificate
- waas-work-request
- waas-metering
- waas-custom-protection-rule
- waas-address-list
- http-redirects

#### Comments

A policy that uses `<verb> waas` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2354 for details of the API operations covered by each verb, for each individual resource-type included in `waas`.

#### Supported Variables

The WAF Service supports all the general variables (see General Variables for All Requests on page 2169), plus the ones listed here.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.waas-policy.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific WAAS policies by OCID.</td>
</tr>
<tr>
<td>target.waf-rule-key</td>
<td>String</td>
<td>Use this variable to control access to specific WAF rules by name.</td>
</tr>
<tr>
<td>target.waas-work-request.id</td>
<td>Entity (OCID)</td>
<td>The OCID of WAAS work requests.</td>
</tr>
<tr>
<td>target.waas-policy-certificate.id</td>
<td>Entity (OCID)</td>
<td>The OCID of SSL certificates configured in a WAAS policy.</td>
</tr>
<tr>
<td>target.certificate.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>The OCID of a compartment.</td>
</tr>
<tr>
<td>target.certificate.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>The OCID of a compartment.</td>
</tr>
</tbody>
</table>
### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` and `manage` verbs for the `waas-policy` resource-type cover no extra permissions or API operations compared to the `read` verb.

### User Credentials

There are several types of credentials that you manage with Oracle Cloud Infrastructure Identity and Access Management (IAM):

- **Console password**: For signing in to the Console, the user interface for interacting with Oracle Cloud Infrastructure. Note that federated users can't have Console passwords because they sign in through their identity provider. See [Federating with Identity Providers](#) on page 2362.
- **API signing key (in PEM format)**: For sending API requests, which require authentication.
- **Auth token**: An Oracle-generated token that you can use to authenticate with third-party APIs. For example, use an auth token to authenticate with a Swift client when using Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage.
- **Customer Secret Keys**: For using the Amazon S3 Compatibility API with Object Storage. See [Amazon S3 Compatibility API](#) on page 3493.
- **OAuth 2.0 Client Credentials**: For interacting with the APIs of those services that use OAuth 2.0 authorization. See [OAuth 2.0 Client Credentials](#) on page 2362.
- **SMTP Credentials**: For using the Email Delivery service.

#### Important:

API signing keys are different from the SSH keys you use to access a compute instance (see [Security Credentials](#) on page 179). For more information about API signing keys, see [Required Keys and OCIDs](#) on page 4179. For more information about instance SSH keys, see [Managing Key Pairs](#).

### User Password

The administrator who creates a new user in IAM also needs to generate a one-time Console password for the user (see [To create or reset another user's Console password](#) on page 2460). The administrator needs to securely deliver the password to the user by providing it verbally, printing it out, or sending it through a secure email service.
When the user signs in to the Console the first time, they'll be immediately prompted to change the password. If the user waits more than 7 days to initially sign in and change the password, it will expire and an administrator will need to create a new one-time password for the user.

Once the user successfully signs in to the Console, they can use Oracle Cloud Infrastructure resources according to permissions they've been granted through policies.

**Note:**
A user automatically has the ability to change their password in the Console. An administrator does not need to create a policy to give a user that ability.

### Changing a Password

If a user wants to change their own password *sometime after* they change their initial one-time password, they can do it in the Console. Remember that a user can automatically change *their own* password; an administrator does not need to create a policy to give the user that ability.

For more information, see To change your Console password on page 2459.

### If a User Needs Their Console Password Reset

If a user forgets their Console password and also has no access to the API, they can use the Console’s **Forgot Password** link to have a temporary password sent to them. This option is available if the user has an email address in their user profile.

If the user does not have an email address in their user profile, then they need to ask an administrator to reset their password for them. All administrators (and anyone else who has permission to the tenancy) can reset Console passwords. The process of resetting the password generates a new one-time password that the administrator needs to deliver to the user. The user will need to change their password the next time they sign in to the Console.

If you're an administrator who needs to reset a user's Console password, see To create or reset another user's Console password on page 2460.

### If a User Is Blocked from Signing In to the Console

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further attempts. They'll need to contact an administrator to get unblocked (see To unblock a user on page 2460).

### API Signing Keys

A user who needs to make API requests must have an **RSA public key in PEM format (minimum 2048 bits)** added to their IAM user profile and sign the API requests with the corresponding private key (see Required Keys and OCIDs on page 4179).

**Important:**
A user automatically has the ability to generate and manage *their own* API keys in the Console or API. An administrator does not need to write a policy to give the user that ability. Remember that a user can't use the API to change or delete their own credentials until they themselves save a key in the Console, or an administrator adds a key for that user in the Console or the API.

If you have a non-human system that needs to make API requests, an administrator needs to create a user for that system and then add a public key to the IAM service for the system. There's no need to generate a Console password for the user.

For instructions on generating an API key, see To add an API signing key on page 2461.
OAuth 2.0 Client Credentials

**Note:**

OAuth 2.0 Client Credentials are not available in the United Kingdom Government Cloud (OC4).

OAuth 2.0 client credentials are required to interact programmatically with those services that use the OAuth 2.0 authorization protocol. The credentials enable you to obtain a secure token to access those service REST API endpoints. The allowed actions and endpoints granted by the token depend on the scopes (permissions) that you select when you generate the credentials. For more information, see Working with OAuth 2.0 Client Credentials on page 2457.

Auth Tokens

Auth tokens are authentication tokens generated by Oracle. You use auth tokens to authenticate with third-party APIs that do not support the Oracle Cloud Infrastructure signature-based authentication, for example, the Swift API. If your service requires an auth token, the service-specific documentation instructs you to generate one and how to use it.

Federating with Identity Providers

This topic describes identity federation concepts. Oracle Cloud Infrastructure supports federation with Oracle Identity Cloud Service, and Microsoft Active Directory (via Active Directory Federation Services (AD FS)), Microsoft Azure Active Directory, Okta, and other identity providers that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

Overview

Enterprise companies commonly use an *identity provider (IdP)* to manage user login/passwords and to authenticate users for access to secure websites, services, and resources.

When someone in your company wants to use Oracle Cloud Infrastructure resources in the Console, they must sign in with a user login and password. Your administrators can federate with a supported IdP so that each employee can use an existing login and password and not have to create a new set to use Oracle Cloud Infrastructure resources.

To federate, an administrator goes through a short process to set up a relationship between the IdP and Oracle Cloud Infrastructure (commonly referred to as a *federation trust*). After an administrator sets up that relationship, any person in your company who goes to the Oracle Cloud Infrastructure Console is prompted with a "single sign-on" experience provided by the IdP. The user signs in with the login/password that they’ve already set up with the IdP. The IdP authenticates the user, and then that user can access Oracle Cloud Infrastructure.

When working with your IdP, your administrator defines groups and assigns each user to one or more groups according to the type of access the user needs. Oracle Cloud Infrastructure also uses the concept of groups (in conjunction with IAM policies) to define the type of access a user has. As part of setting up the relationship with the IdP, your administrator can map each IdP group to a similarly defined IAM group, so that your company can re-use the IdP group definitions when authorizing user access to Oracle Cloud Infrastructure resources. Here’s a screenshot from the mapping process:
For information about the number of federations and group mappings you can have, see Service Limits on page 215. There’s no limit on the number of federated users.

**Note:**

Any users who are in more than 50 IdP groups cannot be authenticated to use the Oracle Cloud Infrastructure Console.

**Automated User Provisioning and Synchronization with SCIM**

Tenancies federated with Oracle Identity Cloud Service or the third-party provider Okta, can also leverage SCIM (System for Cross-domain Identity Management) to enable provisioning of federated users in Oracle Cloud Infrastructure. Federated users that have been provisioned in Oracle Cloud Infrastructure through this process can have the additional user credentials such as API keys and auth tokens that are managed in the User Settings page. This enables federated users to use the SDK and CLI, and other features that require the additional user credentials. For more information, see User Provisioning for Federated Users on page 2404.

**General Concepts**

Here’s a list of the basic concepts you need to be familiar with.

**IDP**

IdP is short for identity provider, which is a service that provides identifying credentials and authentication for users.

Tenancies created after December 18, 2017 are automatically federated with Oracle Identity Cloud Service as the IdP. Oracle Cloud Infrastructure can be federated with any IdP that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

**SERVICE PROVIDER (SP)**

A service (such as an application, website, and so on) that calls upon an IdP to authenticate users. In this case, Oracle Cloud Infrastructure is the SP.

**FEDERATION TRUST**

A relationship that an administrator configures between an IdP and SP. You can use the Oracle Cloud Infrastructure Console or API to set up that relationship. Then, the specific IdP is "federated" to that SP. In the Console and API, the process of federating is thought of as adding an identity provider to the tenancy.
SAML METADATA DOCUMENT

An IdP-provided XML-based document that provides the required information to an SP to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. Depending on which IdP you are federating with, you must either provide the metadata URL (see below) to this document or upload the document to Oracle Cloud Infrastructure.

METADATA URL

An IdP-provided URL that enables an SP to get required information to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. The metadata URL points to the SAML metadata document the SP needs.

FEDERATED USER

Someone who signs in to use the Oracle Cloud Infrastructure Console by way of a federated IdP.

LOCAL USER

A non-federated user. In other words, someone who signs in to use the Oracle Cloud Infrastructure Console with a login and password created in Oracle Cloud Infrastructure.

GROUP MAPPING

A mapping between an IdP group and an Oracle Cloud Infrastructure group, used for the purposes of user authorization.

SCIM

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. Using a SCIM client to provision users in Oracle Cloud Infrastructure enables you to assign credentials to the users in Oracle Cloud Infrastructure.

PROVISIONED (OR SYNCHRONIZED) USER

A user provisioned by the identity provider's SCIM client in Oracle Cloud Infrastructure. These users can be listed in the Oracle Cloud Infrastructure Console and can have all the Oracle Cloud Infrastructure user credentials except for a Console password.

Encrypt Assertion

Some IdPs support the encryption of the SAML assertion. When enabled, the service provider expects the SAML assertion to be encrypted by the identity provider, using the service provider's encryption key. In this case, the service provider is Oracle Cloud Infrastructure authentication service. If you choose to enable this feature of your IdP, you must also enable the feature when you set up your Federation provider in the IAM service. Note that Microsoft AD FS enables the encryption of the SAML assertion by default. If your IdP is Microsoft AD FS, you must either enable this feature in IAM or disable it for Microsoft AD FS.

Experience for Federated Users

Federated users can use the Console to access Oracle Cloud Infrastructure (according to IAM policies for the groups the users are in).

They'll be prompted to enter their Oracle Cloud Infrastructure tenant (for example, ABCCorp).

They then see a page with two sets of sign-in instructions: one for federated users and one for non-federated (Oracle Cloud Infrastructure) users. See the following screenshot.
The tenant name is shown on the left. Directly below is the sign-in area for federated users. On the right is the sign-in area for non-federated users.

Federated users choose which identity provider to use for sign-in, and then they're redirected to that identity provider's sign-in experience for authentication. After entering their login and password, they are authenticated by the IdP and redirected back to the Oracle Cloud Infrastructure Console.

The federated users (without SCIM configuration) cannot access the "User Settings" page in the Console. This page is where a user can change or reset their Console password and manage other Oracle Cloud Infrastructure credentials such as API signing keys and auth tokens.

**Experience for Federated Users with SCIM Configuration**

If your IdP has also been configured with a SCIM client, a user signed in through their identity provider can access the User Settings page and have user capabilities such as API keys, auth tokens, and other user credentials. *(Note: This is currently available for Oracle Identity Cloud Service and Okta federations only.)*

**Required IAM Policy**

To add and manage identity providers in your tenancy, you must be authorized by an IAM policy. If you're in the Administrators group, then you have the required access.

Here's a more limited policy that restricts access to only the resources related to identity providers and group mappings:

```
Allow group IdPAdmins to manage identity-providers in tenancy
Allow group IdPAdmins to manage groups in tenancy
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.
Supported Identity Providers

**Important:**

Oracle Cloud Infrastructure tenancies created December 18, 2017 or later are automatically federated with Oracle Identity Cloud Service.

If your tenancy was created before December 18, 2017, and you want to set up a federation with Oracle Identity Cloud Service, see Federating with Oracle Identity Cloud Service on page 2366.

For instructions for federating with other identity providers, see the following:

Federating with Microsoft Active Directory on page 2385
Federating with Microsoft Azure Active Directory on page 2391
Cloud Infrastructure Okta Configuration for Federation and Provisioning (white paper)
Federating with SAML 2.0 Identity Providers on page 2401

**Federating with Oracle Identity Cloud Service**

This topic points to the appropriate topics for federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service depending on when you activated your tenancy.

**Tenancies created December 21, 2018 and after**

These tenancies are automatically federated with Oracle Identity Cloud Service and configured to provision federated users in Oracle Cloud Infrastructure.

To manage your federated users and groups, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372.

For information about the federation, see Frequently Asked Questions for Oracle Identity Cloud Service Federated Users on page 2383.

**Tenancies created between December 18, 2017 and December 20, 2018**

These tenancies are automatically federated with Oracle Identity Cloud Service but are not configured to provision federated users in Oracle Cloud Infrastructure to allow these users to have additional credentials (API keys, auth tokens, etc.).

To enable this feature for users, you need to perform a one-time upgrade, see: User Provisioning for Federated Users on page 2404.

After you have performed this upgrade, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372 to manage your federated users and groups.

**Tenancies created before December 18, 2017**

These tenancies must be manually federated with Oracle Identity Cloud Service. See Federating with Oracle Identity Cloud Service on page 2366 described below.

**Manually Federating with Oracle Identity Cloud Service**

Your organization can have multiple Oracle Identity Cloud Service accounts (e.g., one for each division of the organization). You can federate multiple Identity Cloud Service accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Identity Cloud Service account.

**Note:**

Before following the steps in this topic, see Federating with Identity Providers on page 2362 to ensure that you understand general federation concepts.
Components of the Manual Federation to Understand

Web Application and Client Credentials

For each trust, you must set up a web application in Oracle Identity Cloud Service (also called a trusted application); instructions are in Instructions for Federating with Oracle Identity Cloud Service on page 2367. The resulting application has a set of client credentials (a client ID and client secret). When you federate your Identity Cloud Service account with Oracle Cloud Infrastructure, you must provide these credentials.

COMPUTEBAREMETAL application

A trusted application in Oracle Identity Cloud Service that contains the set of client credentials (a client ID and client secret) you'll need to provide when you federate your Identity Cloud Service account with Oracle Cloud Infrastructure.

Required URLs

The easiest way to federate with Oracle Identity Cloud Service is through the Oracle Cloud Infrastructure Console, although you could do it programmatically with the API. If you're using the Console, you're asked to provide a base URL instead of the metadata URL. The base URL is the left-most part of the URL in the browser window when you're signed in to the Identity Cloud Service console:

- **Base URL:** `<Identity Cloud Service account name>.identity.oraclecloud.com`

If you're using the API to federate, you need to provide the metadata URL, which is the base URL with /fed/v1/ metadata appended, like so:

- **Metadata URL:** `<Identity Cloud Service account name>.identity.oraclecloud.com/fed/v1/metadata`

The metadata URL links directly to the IdP-provided XML required to federate. If you're using the API, you need to provide both the metadata URL and the metadata itself when federating. For more information, see Managing Identity Providers in the API on page 2371.

OCI-V2-<tenancy_name> app

When you manually federate an Oracle Identity Cloud Service account with Oracle Cloud Infrastructure, a new SAML application called OCI-V2-<tenancy_name> is automatically created in that Oracle Identity Cloud Service account. If you later need to delete the Oracle Identity Cloud Service identity provider from your Oracle Cloud Infrastructure tenancy, make sure to also delete the OCI-V2-<tenancy_name> from Oracle Identity Cloud Service. If you don't, and you later try to federate the same Oracle Identity Cloud Service account again, you'll get a 409 error saying that an application with the same name already exists (that is, OCI-V2-<tenancy_name>).

Provisioned User

A provisioned user is provisioned by Oracle Identity Cloud Service in Oracle Cloud Infrastructure and is synched to a federated user that is managed in Oracle Identity Cloud Service. The provisioned user can have the special Oracle Cloud Infrastructure credentials like API keys and auth tokens to enable programmatic access. Provisioned users cannot have Console passwords.

Instructions for Federating with Oracle Identity Cloud Service

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

1. Sign in to Oracle Identity Cloud Service. Perform one of the following, as appropriate:
   - **Option A:** Get the required information from the COMPUTEBAREMETAL application you'll need to perform the set up steps in Oracle Cloud Infrastructure.
   - **Option B:** If Oracle Identity Cloud Service does not include the COMPUTEBAREMETAL application, set up a trusted application.

2. In Oracle Cloud Infrastructure, set up the federation:
   - **a.** Set up Oracle Identity Cloud Service as an identity provider.
   - **b.** Map Oracle Identity Cloud Service groups to IAM groups.
3. In Oracle Cloud Infrastructure, set up the IAM policies for the IAM groups to define the access you want the members of the mapped groups to have.

   **Step 1: Get required information from Oracle Identity Cloud Service**

**Option A: Get information from the COMPUTEBAREMETAL application**

1. Go to the Oracle Identity Cloud Service console and sign in with admin privileges. Make sure you're viewing the Admin Console.
2. In the Identity Cloud Service console, click **Applications**. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL. If your instance does not include the COMPUTEBAREMETAL application, perform **Step 1 Option B**, instead.
4. Click **Configuration**.
5. Expand **General Information**. The client ID is displayed. Click **Show Secret** to display the client secret.

   ![Oracle Identity Cloud Service Console](image)

6. Record the Client ID and Client Secret. They look similar to this:
   - Client ID: de06b81cb45a45a8acdcde923402a9389d8
   - Client Secret: 8a297afd-66df-49ee-c67d-39fcdf3d1c31

**Option B: Set up a trusted application and get required information from Oracle Identity Cloud Service**

Perform this step only if you were unable to complete Step 1 Option A.

**Summary**: For Oracle Identity Cloud Service, you need to create a confidential application (also referred to as a trusted application) with particular properties described in the following instructions. For the general Oracle Identity Cloud Service documentation, see Add a Confidential Application.

**Instructions for Oracle Identity Cloud Service**:

1. Go to the Oracle Identity Cloud Service console and sign in with privileges to create the application. Make sure you're viewing the Admin Console.
2. **Add a confidential (or trusted) application**, which enables secure, programmatic interaction between Oracle Cloud Infrastructure and Oracle Identity Cloud Service. Specify these items when setting up the application:

   a. On the first page:
      1. Enter an application a name (e.g., Oracle Cloud Infrastructure Federation).
      2. Leave other fields empty or unselected.
   b. On the next page:
      1. Select **Configure this application as a client now**.
      2. For the **Allowed Grant Types**, select the check box for **Client Credentials**.
      3. Leave other fields empty.
      4. At the bottom of the page:
         a. Select the check box for **Grant the client access to Identity Cloud Service Admin APIs**.
         b. Select **Identity Domain Administrator** from the list of roles.
   c. On the next page, leave any fields empty or unselected and continue until you click **Finish**.
   d. Copy and paste the displayed client credentials so you can later give them to Oracle Cloud Infrastructure when federating. You can view the application's client credentials any time in the Oracle Identity Cloud Service console. They look similar to this:
      - Client ID: de06b81cb45a45a8adcdce923402a9389d8
      - Client Secret: 8a297af6-6d6f-49ee-c67d-39fedf3d1c31

3. Record the **Oracle Identity Cloud Service base URL**, which you'll need when federating.

4. **Activate the application**.

**Step 2: Add Oracle Identity Cloud Service as an identity provider in Oracle Cloud Infrastructure**

1. Go to the **Console** and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Click **Add identity provider**.
4. Enter the following:
   a. **Name**: A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console (for example, **ABCCorp_IDCS** as shown in the screenshot in **Experience for Federated Users** on page 2364). The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. **Description**: A friendly description.
   c. **IDCS Base URL**: See **Required URLs** on page 2367.
   d. **Client ID**: From Step 1 Option A or Option B.
   e. **Client secret**: From Step 1 Option A or Option B.
   f. **Encrypt Assertion**: Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in IDCS. For more information, see **General Concepts** on page 2363. For information about setting this feature up in the IDCS, see **Managing Oracle Identity Cloud Service Applications**.
   g. **Force Authentication**: Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   h. **Authentication Context Class References**: This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party) expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.
   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Continue.

6. Set up the mappings between Oracle Identity Cloud Service groups and IAM groups in Oracle Cloud Infrastructure. A given Oracle Identity Cloud Service group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Oracle Identity Cloud Service group and a single IAM group. Changes to group mappings take effect typically within seconds.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you don't want to set up the group mappings now, you can simply click Create and come back to add the mappings later.</td>
</tr>
</tbody>
</table>

To create a group mapping:

a. Select the Oracle Identity Cloud Service group from the list under Identity Provider Group.
b. Choose the IAM group you want to map this group to from the list under OCI Group.

c. Repeat the above sub-steps for each mapping you want to create, and then click Create.

After the Federation Set Up

The identity provider is now added to your tenancy and appears in the list on the Federation page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the Federation page if you want to edit the group mappings or delete the identity provider from your tenancy.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users on page 2408 for more information on assigning these users additional credentials.

Step 3: Set up IAM policies for the groups

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Step 4: Give your federated users the name of the tenant and URL to sign in

Give your federated users need the URL for the Oracle Cloud Infrastructure Console, https://cloud.oracle.com), and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

To add an Oracle Identity Cloud Service as an identity provider

See Instructions for Federating with Oracle Identity Cloud Service on page 2367.

To delete the identity provider

All the group mappings will also be deleted.
1. Delete the identity provider from your tenancy:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click Delete.
   d. Confirm when prompted.

2. Delete the OCI-V2-<tenancy_name> from your Oracle Identity Cloud Service account:
   a. Go to Oracle Identity Cloud Service and sign in to the federated account.
   b. Click Applications. The list of applications is displayed.
   c. Locate the OCI-V2-<tenancy_name> and click its name to view its details page.
   d. In the upper right of the page, click Deactivate. Confirm when prompted.
   e. Click Remove. Confirm when prompted.

To add group mappings for Oracle Identity Cloud Service

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. A list of the identity providers in your tenancy is displayed.
2. Click the name you chose for your Oracle Identity Cloud Service federation to view its details.
3. Click Add Mappings.
   a. Select the Oracle Identity Cloud Service group from the list under Identity Provider Group.
   b. Choose the IAM group you want to map this group to from the list under OCI Group.
   c. To add more mappings, click +Another Mapping.
   d. When you are finished, click Add Mappings.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users on page 2408 for more information on assigning these users additional credentials.

To update or delete a group mapping

You can't update a group mapping, but you can delete the mapping and add a new one.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click Delete.
4. Confirm when prompted.
5. Add a new mapping, if wanted.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations:

Identity providers:
IAM

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

**Group mappings:**
- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

**Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console**

This topic describes how to use the Oracle Cloud Infrastructure Console to manage your Oracle Identity Cloud Service users and groups. Before you get started, understand basic federation concepts. See Federating with Identity Providers on page 2362.

**Overview of Working with Oracle Identity Cloud Service Users and Groups in the Console**

The Oracle Cloud Infrastructure Console provides an integration with Oracle Identity Cloud Service (IDCS) that lets you perform many management tasks for your IDCS users and groups in the Console.

**User Management Tasks**

In the Console, you can do the following user management tasks:
- Add users
- Remove users
- Add users to groups
- Assign roles to users to access services and instances
- Reset user password

For information on more user management tasks, see Managing Oracle Identity Cloud Service Users in Administering Oracle Identity Cloud Service.

**Group Management Tasks**

In the Console, you can do the following group management tasks:
- Add groups
- Remove groups
- Add users to groups
- Map IDCS groups to IAM groups

For information on more group management tasks, see Managing Oracle Identity Cloud Service Groups in Administering Oracle Identity Cloud Service.

**Required Policies and Permissions**

To manage Oracle Identity Cloud Service users and groups in the Console, you'll need to be granted permissions in both the Oracle Cloud Infrastructure IAM service and in Oracle Identity Cloud Service.

Members of the OCI_Administrators group have the required permissions to create groups and policies in Oracle Cloud Infrastructure.

**Important:** To create users and groups in the Oracle Identity Cloud Service federation, you'll need the Identity Domain Administrator role, or be a member of a group that has been granted that role. For information on Oracle Identity Cloud Service roles, see Administering Oracle Identity Cloud Service.
To quickly create a user with the required permissions, see Add a User with Oracle Cloud Administrator Permissions on page 58.

**Navigating to Your Oracle Identity Cloud Service Users and Groups in the Console**

In the Console, you can add users and groups to Oracle Identity Cloud Service from the Identity Provider Details page.

To view your identity provider details:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.

![Identity Provider Details](image)

From the Identity Provider Details page, click **Users** to display the users created in Oracle Identity Cloud Service. Click **Groups** to display the groups created in Oracle Identity Cloud Service.

**Working with Oracle Identity Cloud Service Groups**

The Console lets you perform the following tasks to manage groups in Oracle Identity Cloud Service:

- Add groups
- Delete groups
- Edit the name and description
- Add users to groups
- Remove users from groups
- Map groups to Oracle Cloud Infrastructure groups

Some tasks you can't perform in the Oracle Cloud Infrastructure Console. To add the predefined application roles for some Oracle Cloud products, you need to assign roles in the Identity Cloud Service console. For more information about using Oracle Identity Cloud Service, see Administering Oracle Identity Cloud Service.

For the members of a group in Oracle Identity Cloud Service to have permissions in Oracle Cloud Infrastructure, you must map the IDCS group to a group in IAM. Before you set up any new groups in IDCS, ensure that you understand how to assign permissions to groups in Oracle Cloud Infrastructure. See Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124.

**Working with Oracle Identity Cloud Service Users**

The Console lets you perform the following tasks to manage users in Oracle Identity Cloud Service:

- Add users
- Delete users
- Edit user details
- Add users to groups
- Add roles to users
- Remove users from groups
- Reset user passwords

**User Management Tasks You Can’t Perform in the Console**

The Oracle Cloud Console does not support management of the following Oracle Identity Cloud Service user features and tasks:

- Manage multi-factor authentication

For information about managing these tasks, see *Administering Oracle Identity Cloud Service*.

*Managing Oracle Identity Cloud Service Groups in the Console*

To create a group in Oracle Identity Cloud Service

This procedure creates a new group in Oracle Identity Cloud Service. Optionally, you can add users to the group at the time you create it. This group will not have any permissions in Oracle Cloud Infrastructure until you map it to an Oracle Cloud Infrastructure group.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**. A list of the federations in your tenancy is displayed.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.

The list of existing groups is displayed.

4. Click **Create IDCS Group**.

5. Enter the following:
   - **Name**: A unique name for the group. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Users**: Add Oracle Identity Cloud Service users to this group. You can add users when you create the group, or later. Select users from the list. To find a specific user, you can start typing the user name to filter the list as you type.

6. Click **Create**.

After you create a group in Oracle Identity Cloud Service, you'll want to give the group permissions to user services:

- To grant the group access to map it to an Oracle Cloud Infrastructure group as described in the next procedure.
- To add roles to this group, see *Managing Oracle Identity Cloud Service Roles for Groups* on page 2381.

To map an Oracle Identity Cloud Service group to an IAM group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.
3. Click **Edit Mapping**.
4. In the **Edit Identity Provider** dialog, click **+ Add Mapping**.
5. Select the **Identity Provider Group** you want to map from the list. To find a specific group, you can start typing the group name to filter the list as you type.
6. Select the **OCI Group** you want to map this Identity Cloud Service group to. To find a specific group, you can start typing the group name to filter the list as you type.
7. To add more mappings, click **Add Mapping** and continue adding the mappings.
8. Select the group you want to map this group to from the list under **OCI Mapped User Group**.

Members of this group now have the permissions granted to the OCI Mapped User Group.

To add roles to a group
Oracle Cloud Infrastructure services use policies to control access to services. However, some Oracle Cloud services use roles to manage access. This procedure describes how to add roles to an IDCS group.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. A list of the identity providers in your tenancy is displayed.
2. Click the Oracle Identity Cloud Service Console link.
   The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the Navigation Drawer, and then click Applications.
   The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in.
   The Details page is displayed.
5. Click Application Roles.
   The roles are displayed.
6. Click the menu for the role you want to assign and select Assign Groups.
7. Select the group you want to assign to the role, and click OK.
8. Click the Applications breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to assign to this group.

To remove roles from a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. A list of the identity providers in your tenancy is displayed.
2. Click the Oracle Identity Cloud Console link.
   The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the Navigation Drawer, and then click Applications.
   The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in.
   The Details page is displayed.
5. Click Application Roles.
   The roles are displayed.
6. Click the menu for the role you want to remove from the group and select Revoke Groups.
7. Select the group you want to remove the role from, and click OK.
8. Click the Applications breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to remove from this group.

To edit details for an Oracle Identity Cloud Service group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
   The list of existing groups in the federation is displayed.
4. Find the group you want to edit and click its name.
   The Group Details page is displayed.
5. Click Edit.
6. You can update the **Group Name** or the **Description**: Avoid entering confidential information.

   **Caution:**
   
   Changing the group name will break mappings to Oracle Cloud Infrastructure (OCI) groups. If you change the group name, ensure that you delete any existing group mappings and add new mappings with the new name. See the previous task on editing mappings.

7. Click **Update** to save your changes.

To add users to a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   
   The list of existing groups is displayed.
4. Find the group you want to add a user to.
   
   The **User Group Details** page is displayed.
5. Click **Add IDCS User**.
6. Select the user you want to add to this group from the **Users** list.
7. Click **Add**.

To remove users from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   
   The list of existing groups is displayed.
4. Find the group you want to remove the user from.
   
   The list of users is displayed in the **Group Details** page.
5. Find the user you want to remove, and then click the the Actions icon (three dots).
6. Click **Remove User**.
7. Confirm when prompted.

To delete a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   
   The list of existing groups is displayed.
4. Find the group you want to edit and click its name.
   
   The **Group Details** page is displayed.
5. Click **Delete**.
6. Confirm when prompted.

Create a policy to grant the group permissions on Oracle Cloud Infrastructure resources

The group you created in Oracle Identity Cloud Service gets permissions to access resources in Oracle Cloud Infrastructure through the policy you assign to the Oracle Cloud Infrastructure group. Before you complete this step, you need to decide what permissions you want to give your new group. For more information, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142.

Prerequisite: The group and compartment that you're writing the policy for must already exist.
1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.

2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see **Policy Attachment** on page 2141).

3. Click **Create Policy**.

4. Enter the following:

   - **Name**: A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Statement**: A policy statement. For the correct format to use, see **Policy Basics** on page 2137 and also **Policy Syntax** on page 2164. If you want to add more than one statement, click +.

For example:

To allow your group to manage all resources within a specified compartment enter a statement like the following:

```
Allow group <OCI_group_name> to manage all-resources in compartment <compartment_name>
```

For more policy examples, see **Common Policies** on page 2142.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

**Managing Oracle Identity Cloud Service Users in the Console**

After you add a user in Oracle Identity Cloud Service, a user is also automatically provisioned in Oracle Cloud Infrastructure. This provisioned user can have the Oracle Cloud Infrastructure credentials, such as API keys and auth tokens. To understand this provisioning, see **User Provisioning for Federated Users** on page 2404.

To create a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.

3. Click **Create IDCS User**.

4. In the **Create IDCS User** dialog enter the following:

   - **User Name**: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Email**: Enter an email address for this user. The initial sign-in credentials will be sent to this email address.
   - **First Name**: Enter the user's first name.
   - **Last Name**: Enter the user's last name.
   - **Phone Number**: Optionally, enter a phone number.
   - **Groups**: Optionally, select groups to add this user to.

5. Click **Create User**.

**Important:**

For the user to have permissions in Oracle Cloud Infrastructure, you must assign the user to a group that is mapped to an Oracle Cloud Infrastructure group. Or, if you are also creating a new group, you can perform this mapping later. The user will not be able to sign in to the Console until the mapping is accomplished.
The user creation process generates an email that is sent to the address provided that you entered. The email includes the new user’s username and password to use with the Oracle Cloud Infrastructure Console.

To add API keys, auth tokens, customer secret keys, or SMTP credentials for this user, see Managing User Capabilities for Federated Users on page 2408.

To edit a user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
   - The list of existing users is displayed.
4. Find the user you want to edit and click its name.
   - The User Details page is displayed.
5. Click Edit.
6. Update the fields.
7. Click Save when finished.

To reset a user’s password

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
   - The list of existing user groups in the federation is displayed.
4. Find the user you want to reset the password for and click the name.
   - The User Details page is displayed.
5. Click Reset Password.
   - The user's password is reset. This user can't access their account until they complete the password reset steps.
6. Click Email Password Instructions to send the password link and instructions to the user.
   - The password link is good for 24 hours. If the user does not reset their password in time, you can generate a new password link by clicking Reset Password for the user again.

To manage roles for services managed through IDCS

See see Managing Oracle Identity Cloud Service Roles for Users on page 2379.

To add API keys, auth tokens, or other Oracle Cloud Infrastructure credentials

1. View the user's details:
   - If you're adding credentials for yourself:
     Open the Profile menu (🔗) and click User Settings.
   - If you're an administrator adding credentials for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
     Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
     Find the user in the list and click the OCI Synched User link.
2. Add the credentials for the user.
   - For more details about these credentials, see Managing User Credentials on page 2456.

To delete a user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.

   The list of existing user groups in the federation is displayed.

4. Find the user you want to delete and click the name.

   The User Details page is displayed.

5. Click Delete.

Managing Group Mappings

To add group mappings for Oracle Identity Cloud Service

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.

3. Click Edit Provider Details.

4. Add at least one mapping:
   a. Click + Add Mapping.
   b. Select the Oracle Identity Cloud Service group from the list under Identity Provider Group.
   c. Choose the IAM group you want to map this group to from the list under OCI Group.
   d. Repeat the above sub-steps for each mapping you want to create, and then click Submit.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users on page 2408 for more information on assigning these users additional credentials.

To update or delete a group mapping

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.

2. Click the identity provider to view its details.

3. Click Edit Mapping.

4. Update the mappings (or click the X to delete a mapping), and then click Submit.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

Managing Oracle Identity Cloud Service Roles for Users

This topic describes managing user roles for users created in Oracle Identity Cloud Service.

About User Roles in Oracle Identity Cloud Service

You can assign roles to a user to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- Service access roles - grant access to use the service.
- Instance access roles - grant access to specific instances of a service. These can only be granted after the instances are created

For information about more complex role management including assigning other administrative privileges, see Managing Oracle Identity Cloud Service Users.
**Available Roles for Each Service**

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See About Service Administrator Roles for more information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

**Required Permissions to Manage Roles**

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

```
Allow group GroupA to inspect identity-providers in tenancy
```

where you replace GroupA with the name of the group you want to grant the permission to.

To manage the service roles for another user, you must be assigned the appropriate role in Oracle Identity Cloud Service. See Understanding Administrator Roles.

**Managing Roles User Roles in the Console**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.

   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.

2. Click the name of the user you want to edit.

3. On the user details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this user has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.

4. Find the service you want to edit this user's access to, click the Actions icon (three dots), and then click Manage service access or Manage instance access, as appropriate. The list of roles for the selected service is displayed.

5. Edit the user's access as follows:
   - Select each role you want to give to the user.
   - Click the x next to each role you want remove from the user. Note that you can't remove a role that has been granted through a group. These roles are read only.

   **Note:**

   If a user is assigned the Cloud Account Administrator role, then you can’t remove the individual entitlement roles for the user.

6. Click Apply Role Settings or Update Instance Settings, as appropriate.

7. If you are granting roles to a user, in the confirmation dialog, click Send Email to User to send an email to the user to notify them of this change.

8. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.

9. Return to the Console and click Close.

**Managing Instance Roles in the Console**

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage individual user access to the instance.

**Managing User Access to an Instance**
1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.

   A list of the users in your tenancy is displayed.

   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.

2. Click the name of the user you want to edit.

3. On the user details page, click **Manage Roles**. The **Manage Roles** page displays the list of services for which you have Administrator access. The service and instance roles that this user has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.

4. Find the service with instances that you want to edit this user's access to, click the Actions icon (three dots), and then click **Manage instance access**. The list of instances for the selected service is displayed.

5. On the **Manage Access to Instances** page, find the name of the instance you want to edit this user's access to.

   To grant access to this instance:

   In the **Instance Role** column, select the role you want to grant to the user. You can select multiple roles from the list.

   To remove access to this instance:

   In the **Instance Role** column, click the x next to the role you want to remove from the user.

6. When you are finished editing roles, click **Update Instance Settings**.

7. On the **Manage Roles** page, click **Apply Role Settings**.

8. If you are granting roles to a user, in the confirmation dialog, click **Send Email to User** to send an email to the user to notify them of this change.

9. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.

10. Return to the Console and click **Close**.

### Managing Oracle Identity Cloud Service Roles for Groups

This topic describes managing roles for groups created in Oracle Identity Cloud Service.

**About Group Roles in Oracle Identity Cloud Service**

You can assign roles to groups to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- Service access roles - grant access to use the service.
- Instance access roles - grant access to specific instances of a service. These can only be granted after the instances are created.

For information about more complex role management, see **Manage Oracle Identity Cloud Service Groups**.

**Available Roles for Each Service**

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See **About Service Administrator Roles** for more information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

**Required Permissions to Manage Roles**

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

```
Allow group GroupA to inspect identity-providers in tenancy
```
where you replace GroupA with the name of the group you want to grant the permission to.

To manage service roles, you must be assigned the Administrator role for that service.

**Managing Group Roles in the Console**

To add roles to a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Click Groups.

   The list of groups is displayed.

4. Click the name of the group you want to add roles to.
5. On the group details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click Manage service access. The list of roles for the selected service is displayed.
7. Select each role that you want to assign to the group.
8. Click Save Role Selections.
9. To add more service roles to this group, repeat steps 6 - 8.
10. Click Apply Role Settings.
11. In the confirmation dialog, click Send Email to Group to send an email to each member of the group to notify them of this change.

   Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending.
12. Return to the Console and click Close.

To revoke roles from a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Click Groups.

   The list of groups is displayed.

4. Click the name of the group you want to remove roles from.
5. On the group details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click Manage service access or Manage instance access, as appropriate. The list of roles for the selected service is displayed.
7. Clear the check box for each role you want remove from the group.
8. Click Save Role Selections or Update Instance Settings, as appropriate.
9. To revoke more service or instance roles from this group, repeat steps 6 - 8.
10. Click Apply Role Settings.
11. A confirmation dialog displays the services that you modified access to in this session. Click Close.

**Managing Instance Roles in the Console**

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage group access to the instance.

**Managing Group Access to an Instance**
1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.

3. Click **Groups**.

   The list of groups is displayed.

4. On the group details page, click **Manage Roles**. The **Manage Roles** page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.

5. Find the service with instances that you want to edit this group's access to, click the Actions icon (three dots), and then click **Manage instance access**. The list of instances for the selected service is displayed.

6. On the **Manage Access to Instances** page, find the name of the instance you want to edit this group's access to.

   - To grant access to this instance: In the **Instance Role** column, select the role you want to grant to the group. You can select multiple roles from the list.
   - To remove access to this instance: In the **Instance Role** column, click the **x** next to the role you want to remove from the group.

7. When you are finished editing roles for this service, click **Update Instance Settings**.

8. To edit more instance roles for this group, repeat steps 6 - 7.

9. On the **Manage Roles** page, click **Apply Role Settings**.

10. If you added roles, in the confirmation dialog, click **Send Email to Group** to send an email to each member of the group to notify them of this change. Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending. Return to the Console and click **Close**.

   If you revoked roles, a confirmation dialog displays the services that you modified access to in this session. Click **Close**.

**Frequently Asked Questions for Oracle Identity Cloud Service Federated Users**

When you sign up for Oracle Cloud Infrastructure, your account is automatically federated with Oracle Identity Cloud Service as your identity provider. This topic answers some frequently asked questions about the federation.

**What resources are created in Oracle Identity Cloud Service?**

**The following resources are created in Identity Cloud Service:**

- **Applications:**
  - **OCI-V2-<tenancy_name>**
    This SAML application that creates the federation with Oracle Cloud Infrastructure.
  - **COMPUTEAREMETA** application
    A supporting application for the federation.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not delete these applications.</td>
</tr>
</tbody>
</table>

- **Group:**
  - **OCI_Administrators group**
    This group is mapped to the Administrators group in Oracle Cloud Infrastructure. Members of this group have full administrator privileges in Oracle Cloud Infrastructure.

- **User:**
  - A default administrator user (e.g., user@example.com) who is a member of the OCI_Administrators group.
What resources are created in Oracle Cloud Infrastructure?

The following resources are created in Oracle Cloud Infrastructure:

- **Identity Provider**: OracleIdentityCloudService
- **Group Mappings**: The federation is created with one group mapping:
  - OCI_Administrators group (from Oracle Identity Cloud Service) is mapped to the Administrators group (in Oracle Cloud Infrastructure).
- **Users**:
  - The default administrator user created in Oracle Identity Cloud Service is provisioned in Oracle Cloud Infrastructure. This user can have the Oracle Cloud Infrastructure credentials, but not a Console password.
  - A default administrator local-user with the same user name (user@example.com) is also created in Oracle Cloud Infrastructure's IAM service. Customers who choose not to use the Oracle Identity Cloud Service federation can use this user to administer Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The default administrator created in Oracle Identity Cloud Service and the local default administrator created in Oracle Cloud Infrastructure exist independently in their respective identity systems. Ensure that you manage passwords for them separately.</td>
</tr>
</tbody>
</table>

Why is my account federated with Oracle Identity Cloud Service?

Oracle Identity Cloud Service is the identity provider for multiple Oracle services. Federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service allows you to have a seamless connection between services, without having to create a separate username and password for each one.

How do I know if I am signed in through Oracle Identity Cloud Service?

Click the **Profile** menu to display your username. Users signed in through an identity provider will see their username prefaced with their identity provider name, for example:

oracleidentitycloudservice/user@example.com

How do I add a user to Oracle Identity Cloud Service (a federated user)?

See Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372.

Can I add a user just for Oracle Cloud Infrastructure?

Yes. If you don't want to manage the user in Oracle Identity Cloud Service, you can add a user directly to the Oracle Cloud Infrastructure IAM service. See Adding Users on page 57. Using this procedure, you can create users who can sign in directly to the Oracle Cloud Infrastructure Console. Users created with this procedure do not have access to any other Oracle services.

How do I manage groups?

In short, managing groups requires actions in both Oracle Identity Cloud Service and Oracle Cloud Infrastructure. Groups you create in Oracle Identity Cloud Service have no privileges in Oracle Cloud Infrastructure until you map them to a group in Oracle Cloud Infrastructure. You define the policies that permit access to Oracle Cloud Infrastructure resources in the IAM service in Oracle Cloud Infrastructure. For more information, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372.

How do I find the client ID and client secret?

To edit mappings of your user groups in Oracle Identity Cloud Service to user groups in Oracle Cloud Infrastructure, you'll need to supply the client ID and client secret. The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

1. Sign in to the Oracle Identity Cloud Service console.
2. In the Identity Cloud Service console, click **Applications**. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL.
4. Click **Configuration**.
5. Expand **General Information**. The client ID is displayed. Click **Show Secret** to display the client secret.

![Identity Cloud Service Console](image)

---

**If I delete the federation, can I later recreate it?**

Yes. To recreate the federation with Oracle Identity Cloud Service, follow the instructions in the topic Federating with Oracle Identity Cloud Service on page 2366.

### Federating with Microsoft Active Directory

This topic describes how to federate with Microsoft Active Directory using Microsoft Active Federation Services (AD FS).

**Note:**

Before following the steps in this topic, see Federating with Identity Providers on page 2362 to ensure that you understand general federation concepts.

### About Federating with Microsoft Active Directory

Your organization can have multiple Active Directory accounts (for example, one for each division of the organization). You can federate multiple Active Directory accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Active Directory account.

To federate with Active Directory, you set up a trust between Active Directory and Oracle Cloud Infrastructure. To set up this trust, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Active Directory Federation Services.

Following is the general process an administrator goes through to set up federation with Active Directory. Details for each step are given in the sections below.

1. Get required information from Active Directory Federation Services.
2. Federate Active Directory with Oracle Cloud Infrastructure:
   a. Add the identity provider (AD FS) to your tenancy and provide the required information.
   b. Map Active Directory groups to IAM groups.
3. In Active Directory Federation Services, add Oracle Cloud Infrastructure as a trusted, relying party.
4. In Active Directory Federation Services, add the claim rules required in the authentication response by Oracle Cloud Infrastructure.
5. Test your configuration by logging in to Oracle Cloud Infrastructure with your Active Directory credentials.

Federating with Active Directory

Prerequisites
You have installed and configured Microsoft Active Directory Federation Services for your organization.
You have set up groups in Active Directory to map to groups in Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Consider naming Active Directory groups that you intend to map to Oracle Cloud Infrastructure groups with a common prefix, to make it easy to apply a filter rule. For example, OCI_Administrators, OCI_NetworkAdmins, OCI_InstanceLaunchers.</td>
</tr>
</tbody>
</table>

Step 1: Get required information from Active Directory Federation Services

Summary: Get the SAML metadata document and the names of the Active Directory groups that you want to map to Oracle Cloud Infrastructure Identity and Access Management groups.

1. Locate the SAML metadata document for your AD FS federation server. By default, it is at this URL: https://<yourservername>/FederationMetadata/2007-06/FederationMetadata.xml
   Download this document and make a note of where you save it. You will upload this document to the Console in the next step.
2. Note all the Active Directory groups that you want to map to Oracle Cloud Infrastructure IAM groups. You will need to enter these in the Console in the next step.

Step 2: Add Active Directory as an identity provider in Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
3. Click Add identity provider.
4. Enter the following:
   a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. **Description:** A friendly description.
   c. **Type:** Select Microsoft Active Directory Federation Services (ADFS) or SAML 2.0 compliant identity provider.
   d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.
   e. Click **Show Advanced Options**.
   f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.

      To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.

   g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.
   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.

6. Set up the mappings between Active Directory groups and IAM groups in Oracle Cloud Infrastructure. A given Active Directory group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Active Directory group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

   **Note:**
   
   If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

   To create a group mapping:
   a. Under **Identity Provider Group**, enter the Active Directory group name. You must enter the name exactly, including the correct case.

      Choose the IAM group you want to map this group to from the list under **OCI Group**.

      **Tip:**

      Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

   b. Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

   The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.
Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the Federation page if you want to edit the group mappings or delete the identity provider from your tenancy.

**Step 3: Copy the URL for the Oracle Cloud Infrastructure Federation Metadata document**

**Summary:** The Federation page displays a link to the Oracle Cloud Infrastructure Federation Metadata document. Before you move on to configuring Active Directory Federation Services, you need to copy the URL.

1. On the Federation page, click **Download this document**.
2. Copy the URL. The URL looks similar to:

   https://auth.r2.oracleiaas.com/v1/saml/
   ocid1.tenancy.oc1..aaaaaaaaqdt2tvdmhsa3jmvc5dzulgs3pcv6imfwdgdy4aq/
   metadata.xml

**Step 4: In Active Directory Federation Services, add Oracle Cloud Infrastructure as a trusted relying party**

1. Go to the AD FS Management Console and sign in to the account you want to federate.
2. Add Oracle Cloud Infrastructure as a **trusted relying party**:
   a. From the AD FS Management Console, right-click AD FS and select **Add Relying Party Trust**.
   b. In the **Add Relying Party Trust Wizard**, click **Start**.
   c. Select **Import data about the relying party published online or on a local network**.
      Paste the Oracle Cloud Infrastructure Federation Metadata URL that you copied in Step 3. Click **Next**.
      AD FS will connect to the URL. If you get an error during the attempt to read the federation metadata, you can alternatively upload the Oracle Cloud Infrastructure Federation Metadata XML document.
      **To upload the federation metadata document**
      1. In a web browser, paste the Oracle Cloud Infrastructure Federation Metadata URL in the address bar.
      2. Save the XML document to a location that is accessible by your AD FS Management Console.
      3. In the **Select Data Source** step of the **Add Relying Party Trust Wizard**, select **Import data about the relying party from a file**.
         4. Click **Browse** and select the metadata.xml file that you saved.
         5. Click **Next**.
   d. Set the display name for the relying party (for example, Oracle Cloud Infrastructure) and then click **Next**.
   e. Select **I do not want to configure multi-factor authentication settings for this relying party trust at this time**.
   f. Choose the appropriate Issuance Authorization Rules to either permit or deny all users access to the relying party. Note that if you choose "Deny", then you must later add the authorization rules to enable access for the appropriate users.
      Click **Next**.
   g. Review the settings and click **Next**.
   h. Check **Open the Edit Claim Rules** dialog for this relying part trust when the wizard closes and then click **Close**.

**Step 5: Add the claim rules for the Oracle Cloud Infrastructure relying party**

**Summary:** Add the claim rules so that the elements that Oracle Cloud Infrastructure requires (Name ID and groups) are added to the SAML authentication response.

**Add the Name ID rule:**
1. In the **Add Transform Claim Rule Wizard**, select **Transform an Incoming Claim**, and click **Next**.
2. Enter the following:
   - **Claim rule name**: Enter a name for this rule, for example, nameid.
   - **Incoming claim type**: Select Windows account name.
   - **Outgoing claim type**: Select Name ID.
   - **Outgoing name ID format**: Select Persistent Identifier.
   - Select **Pass through all claim value**.
   - Click **Finish**.
3. The rule is displayed in the rules list. Click **Add Rule**.

### Add the groups rule:

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any users who are in more than 100 IdP groups cannot be authenticated to use the Oracle Cloud Infrastructure Console. To enable authentication, apply a filter to the groups rule, as described below.</td>
</tr>
</tbody>
</table>

**If your Active Directory users are in no more than 100 groups**

**Add the groups rule:**

1. Under Claim rule template, select **Send Claims Using a Custom Rule**. Click **Next**.
2. In the **Add Transform Claim Rule Wizard**, enter the following:
   a. **Claim rule name**: Enter groups.
   b. **Custom rule**: Enter the following custom rule:

   ```
c: [Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname", Issuer == "AD AUTHORITY"] => issue(store = "Active Directory", types = ("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;{0}", param = c.Value);
   ```
   c. Click **Finish**.

**If your Active Directory users are in more than 100 groups**

**Add the groups rule with a filter:**

To limit the groups sent to Oracle Cloud Infrastructure, create two custom claim rules. The first one retrieves all groups the user belongs to directly and indirectly. The second rule applies a filter to limit the groups passed to the service provider to only those that match the filter criteria.

Add the first rule:

1. In the Edit Claim Rules dialog, click **Add Rule**.
2. Under Claim rule template, select **Send Claims Using a Custom Rule**. Click **Next**.
3. In the **Add Transform Claim Rule Wizard**, enter the following:
   a. **Claim rule name**: Enter a name, for example, groups.
   b. **Custom rule**: Enter the following custom rule:

   ```
c: [Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname", Issuer == "AD AUTHORITY"] => add(store = "Active Directory", types = ("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;{0}", param = c.Value);
   ```

   Note that in this custom rule you use `add` instead of `issue`. This command passes the results of the rule to the next rule, instead of sending the results to the service provider.
   c. Click **Finish**.
4. Now add the filter rule.
   a. In the Edit Claim Rules dialog, click Add Rule.
   b. Under Claim rule template, select Send Claims Using a Custom Rule. Click Next.
   c. In the Add Transform Claim Rule Wizard, enter the following:
      1. Claim rule name: Enter groups.
      2. Custom rule: Enter an appropriate filter rule. For example to send only groups that begin with the string "OCI", enter the following:
         ```
         c:[Type == "https://auth.oraclecloud.com/saml/claims/groupName", Value =~ "(?i)OCI"] => issue(claim = c);
         ```
         This rule filters the list from the first rule to only those groups that begin with the string OCI. The issue command, sends the results of the rule to the service provider.
         You can create filters with the appropriate criteria for your organization.
         For information on AD FS syntax for custom rules, see the Microsoft document: Understanding Claim Rule Language in AD FS 2.0 and Higher.
      3. Click Finish.

Step 6: Set up IAM policies for the groups
If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Step 7: Give your federated users the name of the tenant and URL to sign in
Give federated users the URL for the Oracle Cloud Infrastructure Console, https://cloud.oracle.com, and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console
To add an identity provider
See About Federating with Microsoft Active Directory on page 2385.

To delete an identity provider
All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
      A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click Delete.
   d. Confirm when prompted.

To add group mappings for an identity provider
1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Add Mappings**.
   a. Under **Identity Provider Group**, enter the Active Directory group name. The name you enter here must match exactly the name in Active Directory.
   b. Choose the IAM group you want to map this group to from the list under **OCI Group**.
   c. To add more mappings, click **+ Another Mapping**.
   d. When you are finished, click **Add Mappings**.

Your changes take effect typically within seconds.

**To update a group mapping**

You can't update a group mapping, but you can delete the mapping and add a new one.

**To delete a group mapping**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click **Delete**.
4. Confirm when prompted.

Your changes take effect typically within seconds.

**Managing Identity Providers in the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations:

**Identity providers:**

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

**Group mappings:**

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

**Federating with Microsoft Azure Active Directory**

This topic describes how to federate with Microsoft Azure Active Directory (AD).

**Note:**

Before following the steps in this topic, see Federating with Identity Providers on page 2362 to ensure that you understand general federation concepts.

**About Federating with Azure AD**

To federate with Azure AD, you set up Oracle Cloud Infrastructure as a basic SAML single sign-on application in Azure AD. To set up this application, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Azure AD.
Following is the general process an administrator goes through to set up the federation. Details for each step are given in the next section.

1. In Oracle Cloud Infrastructure, download the federation metadata document.
2. In Azure AD, set up Oracle Cloud Infrastructure Console as an enterprise application.
3. In Azure AD, configure the Oracle Cloud Infrastructure enterprise application for single sign-on.
4. In Azure AD, set up the user attributes and claims.
5. In Azure AD, download the Azure AD SAML metadata document.
6. In Azure AD, assign user groups to the application.
7. In Oracle Cloud Infrastructure, set up Azure AD as an identity provider.
8. In Oracle Cloud Infrastructure, map your Azure AD groups to Oracle Cloud Infrastructure groups.
9. In Oracle Cloud Infrastructure, set up the IAM policies to govern access for your Azure AD groups.
10. Share the Oracle Cloud Infrastructure sign-in URL with your users.

**Steps to Federate with Azure AD**

**Prerequisites**

You have an Azure tenancy with groups and users set up in Azure AD.

**Step 1: In Oracle Cloud Infrastructure, download the federation metadata document**

**Summary:** The Oracle Cloud Infrastructure Console Federation page displays a link to the Oracle Cloud Infrastructure federation metadata document. Before you set up the application in Azure AD, you need to download the document.

1. Go to the **Federation** page: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. On the Federation page, click **Download this document**.

After you click the link, the metadata.xml document opens in your browser window. Use your browser's **Save page as** command to save the xml document locally where you can access it later.

**Step 2: In Azure AD, add Oracle Cloud Infrastructure as an enterprise application**

1. In the Azure portal, on the left navigation panel, select **Azure Active Directory**.
2. In the **Azure Active Directory** pane, select **Enterprise applications**. A sample of the applications in your Azure AD tenant is displayed.
3. At the top of the **All applications** pane, click **New application**.
4. In the **Add from gallery** region, enter **Oracle Cloud Infrastructure Console** in the search box.
5. Select the Oracle Cloud Infrastructure Console application from the results.
6. In the application-specific form, you can edit information about the application. For example, you can edit the name of the application.
7. When you are finished editing the properties, select **Create**.

The getting started page is displayed with the options for configuring the application for your organization.
Step 3: In Azure AD, configure Oracle Cloud Infrastructure as an enterprise application

1. Under the **Manage** section, select **Single sign-on**.

2. Select **SAML** to configure single sign-on. The **Set up Single Sign-On with SAML** page is displayed.

3. At the top of the page, click **Upload metadata file**.

4. Locate the federation metadata file (metadata.xml) you downloaded from Oracle Cloud Infrastructure in Step 1, and upload it here. After you upload the file, these **Basic SAML Configuration** fields are automatically populated:
   - Identifier (Entity ID)
   - Reply URL (Assertion Consumer Service URL)
5. In the **Basic SAML Configuration** section, click **Edit**. On the **Basic SAML Configuration** pane, enter the following required field:

   - **Sign on URL**: Enter the URL in the following format:
     
     ```
     https://console.<oci_home_region>.oraclecloud.com
     
     where `oci_home_region` is your tenancy's home region. For example, if you home region is Ashburn, enter:
     
     https://console.us-ashburn-1.oraclecloud.com
     
     [How do I find my tenancy home region?](page 136)
     ```

   ![Basic SAML Configuration Panel](image)

6. Click **Save**.

   **Step 4: Configure User Attributes & Claims**

   The Oracle Cloud Infrastructure Console enterprise application template is seeded with the required attributes, so you don't need to add any. However, you do need to make the following customizations:

   1. In the **User Attributes & Claims** section, click **Edit** in the upper-right corner. The **Manage claim** panel is displayed.
2. Next to the **Name identifier value** field, click **Edit**.
   - Under **Required claim**, select Unique User Identifier (Name ID).
   - Select **Email address** and change it to **Persistent**.
   - For **Source**, select Attribute.
   - For **Source attribute**, select user.userprincipalname.

3. Click **Add a group claim**.
4. In the Group Claims panel, configure the following:

- Select Security groups.
- **Source attribute**: Select Group ID.
- Under Advanced Options, select **Customize the name of the group claim**.
- In the Name field, enter: `groupName`.
  
  Ensure that you enter `groupName` with spelling and case exactly as given.

- In the Namespace field, enter: `https://auth.oraclecloud.com/saml/claims`

- Click Save.
Step 5: Download the SAML metadata document

1. In the SAML Signing Certificate section, click the download link next to Federation Metadata XML.

2. Download this document and make a note of where you save it. You will upload this document to the Console in the next step.

Step 6: Assign user groups to the application

To enable Azure AD users to sign in to Oracle Cloud Infrastructure, you need to assign the appropriate user groups to your new enterprise application.

1. On the left navigation pane, under Manage, select Users and Groups.
2. Click Add at the top of the Users and Groups list to open the Add Assignment pane.
3. Click the Users and groups selector.
4. Enter the name of the group you want to assign to the application into the Search by name or email address search box.
5. Hover over the group in the results list to display a check box. Select the check box to add the group to the Selected list.
6. When you are finished selecting groups, click Select to add them to the list of users and groups to be assigned to the application.
7. Click Assign to assign the application to the selected groups.

Step 7: Add Azure AD as an identity provider in Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure username and password.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
3. Click Add identity provider.
4. Enter the following:
   a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. **Description:** A friendly description.
   c. **Type:** Select SAML 2.0 compliant identity provider.
   d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.
   e. Click **Show Advanced Options**.
   f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.
      To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.
   g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.
   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.

Note: If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

**Step 8: Add group mappings**

Summary: Set up the mappings between Azure AD groups and IAM groups in Oracle Cloud Infrastructure. A given Azure AD group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Azure AD group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions. Note that the Azure AD groups that you choose to map must also be assigned to the enterprise application in Azure AD. See Step 6: Assign user groups to the application on page 2397.

Before you begin: Have your Azure AD groups page open. From the Azure Dashboard, under Manage, select Groups. From the list of groups, select the group you want to map to an Oracle Cloud Infrastructure group. In the group’s details page, click the Copy icon next to the Object ID for the group.

To create a group mapping:
1. For **Identity Provider Group**, enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: `aa0e7d64-5b2c-623g-at32-65058526179c`

![Edit Identity Provider](image)

2. Choose the IAM group you want to map this group to from the list under **OCI Group**.
3. Repeat the preceding steps for each mapping you want to create, and then click **Create**.

**Tip:**

Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit the group mappings or delete the identity provider from your tenancy.

**Step 9: Set up IAM policies for the groups**

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Step 10: Give your federated users the name of the tenant and URL to sign in**

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, `https://cloud.oracle.com`) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

**Managing Identity Providers in the Console**

*To add an identity provider*

See About Federating with Azure AD on page 2391.

*To delete an identity provider*

All the group mappings for the identity provider will also be deleted.
1. Delete the identity provider from your tenancy:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click Delete.
   d. Confirm when prompted.

To add group mappings for an identity provider

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click Add Mappings.
   a. Under Identity Provider Group, select Custom Group. Enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: aa0e7d64-5b2c-623g-at32-65058526179c. Note that for groups to be able to sign in to Oracle Cloud Infrastructure, they must also be assigned to the enterprise application in Azure AD. See Step 6: Assign user groups to the application on page 2397.
   b. Choose the IAM group you want to map this group to from the list under OCI Group.
   c. To add more mappings, click +Another Mapping.
   d. When you are finished, click Add Mappings.

Your changes take effect typically within seconds.

To update a group mapping

You can't update a group mapping, but you can delete the mapping and add a new one.

To delete a group mapping

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click Delete.
4. Confirm when prompted.

Your changes take effect typically within seconds.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations:

Identity providers:
- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIgpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:
- CreateIgpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIgpGroupMappings
- GetIgpGroupMapping
Federating with SAML 2.0 Identity Providers

This topic describes the general steps to federate Oracle Cloud Infrastructure with any identity provider that supports the Security Assertion Markup Language (SAML) 2.0 protocol. If you want specific instructions for Oracle Identity Cloud Service or Microsoft Active Directory, see Federating with Oracle Identity Cloud Service on page 2366 or Federating with Microsoft Active Directory on page 2385.

Tip:
Find detailed setup steps for more IdPs in the following white papers:

- Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning
- Federating Oracle Access Manager to Oracle Cloud Infrastructure

Instructions for Federating

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

Note:
Before following the steps in this topic, see Federating with Identity Providers on page 2362 to ensure that you understand general federation concepts.

1. In the Oracle Cloud Infrastructure Console, get the federation metadata required to establish a trust relationship with the Identity Provider (IdP).
2. In the IdP, configure Oracle Cloud Infrastructure as an application (sometimes called a trusted relying party).
3. In the IdP, assign users and groups to your new Oracle Cloud Infrastructure application.
4. In the IdP, get the required information needed by Oracle Cloud Infrastructure.
5. In Oracle Cloud Infrastructure:
   a. Add the identity provider to your tenancy and provide information you got from the IdP.
   b. Map the IdP's groups to IAM groups.
6. In Oracle Cloud Infrastructure, make sure you have IAM policies set up for the groups so you can control users' access to Oracle Cloud Infrastructure resources.

Step 1: Get information from Oracle Cloud Infrastructure

Summary: Download the federation metadata document.

The federation metadata document is a standard SAML 2.0 document, which provides information about Oracle Cloud Infrastructure you'll need to provide to your IdP. Depending on your provider's setup requirements, you may need to upload the entire document, or you may be asked to provide only specific metadata values from the document.

1. Sign in to the Oracle Cloud Infrastructure Console as an administrator.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
3. Right-click the Download this document link and save the document.

Step 2: Set up Oracle Cloud Infrastructure as a trusted application

Consult your IdP documentation for how to set up a trusted application. Refer to the metadata document you downloaded for required parameters.

Step 3: Assign users and groups to the new application.
Follow your IdP's procedures for adding users and groups to the application you set up for Oracle Cloud Infrastructure.

Step 4: Download the IdP's metadata document.

Your IdP should provide a SAML 2.0 document that contains the information Oracle Cloud Infrastructure needs to complete the federation. See your IdP documentation for instructions on downloading this document.

Step 5: Federate the IdP with Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

Details:

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
3. Click Add Identity Provider.
4. Enter the following:
   a. Name: A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console, so consider making this a friendly, intuitive name your users will understand. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. Description: A friendly description.
   c. Type: Select Microsoft Active Directory Federation Service (ADFS) or SAML 2.0 Compliant Identity Provider.
   d. XML: Upload the metadata.xml document that you downloaded from your IdP.
   e. Encrypt Assertion: Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in your IdP. For more information, see Encrypt Assertion under General Concepts on page 2363. See also your IdP's documentation.
   f. Force Authentication: Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   g. Authentication Context Class References: This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select Custom, then manually enter the class reference.
   h. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click Continue.
6. Set up the mappings between the IdP groups and IAM groups in Oracle Cloud Infrastructure. A given IdP group can be mapped to zero, one, or multiple IAM groups, and conversely. However, each individual mapping is
between only a single IdP group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you don't want to set up the group mappings now, you can simply click Create and come back to add the mappings later.</td>
</tr>
</tbody>
</table>

To create a group mapping:

**a.** Under **Identity Provider Group**, enter the name of the group in your IdP. You must enter the name exactly, including the correct case.

Choose the IAM group you want to map this group to from the list under **OCI Group**.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.</td>
</tr>
</tbody>
</table>

**b.** Repeat the above sub-steps for each mapping you want to create, and then click Create.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see **Resource Identifiers**.

In the future, come to the **Federation** page if you want to edit or add group mappings or delete the identity provider from your tenancy.

**Step 6: Set up IAM policies for the groups**

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142.

**Step 7: Give your federated users the name of the tenant and URL to sign in**

The federated users need the URL for the Oracle Cloud Infrastructure Console: https://cloud.oracle.com, and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

**Managing Identity Providers in the Console**

- **To add an identity provider**

  See **Instructions for Federating** on page 2401.

- **To delete an identity provider**

  All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
   **a.** Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

   A list of the identity providers in your tenancy is displayed.

   **b.** Click the identity provider to view its details.

   **c.** Click **Delete**.

   **d.** Confirm when prompted.

2. Follow your IdP's documentation to delete the application from your IdP.

- **To add group mappings for an identity provider**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

   A list of the identity providers in your tenancy is displayed.

2. Click the identity provider to view its details.
3. Click **Add Mappings**.
   a. Enter the IdP group name exactly in the **Identity Provider Group** text box.
   b. Choose the IAM group you want to map this group to from the list under **OCI Group**.
   c. To add more mappings, click **+Another Mapping**.
   d. When you are finished, click **Add Mappings**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

*To update a group mapping*

You can't update a group mapping, but you can delete the mapping and add a new one.

*To delete a group mapping*

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click **Delete**.
4. Confirm when prompted.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

**Managing Identity Providers in the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations:

**Identity providers:**
- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

**Group mappings:**
- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

**User Provisioning for Federated Users**

This topic describes how you can use SCIM to provision federated users in Oracle Cloud Infrastructure. Provisioned federated users can have API keys and other service-specific credentials.

**Overview**

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. If your IdP is Oracle Identity Cloud Service or Okta, you can set up SCIM user provisioning.
After you configure the SCIM integration between your IdP and Oracle Cloud Infrastructure, users that belong to groups mapped to Oracle Cloud Infrastructure groups are automatically provisioned in Oracle Cloud Infrastructure. Provisioned users are assigned a unique **OCID**, and can have API keys and other service-specific credentials.

The following functionality is supported for provisioned, federated users:

- Provisioned users are assigned a unique **OCID**
- Provisioned users can have API keys, auth tokens, and other service-specific credentials
- You can list the users in the Console
- Provisioned users can access the **User Settings** page to see and manage these credentials for themselves
- When you add or remove users to Oracle Cloud Infrastructure-mapped groups in your IdP, the updates are automatically synced with Oracle Cloud Infrastructure

**Understanding User Types**

The SCIM configuration introduces the concept of the *provisioned* or *synchronized* user. The following descriptions provide details to help you understand the user types you'll be managing.

- **Federated users**
  
  A federated user is created and managed in an identity provider. Federated users can sign in to the Console using a password managed in their identity provider. Federated users are granted access to Oracle Cloud Infrastructure based on their membership in groups that are mapped to Oracle Cloud Infrastructure groups.

- **Provisioned (or Synchronized) users**
  
  A synchronized user is systematically provisioned by the identity provider in Oracle Cloud Infrastructure. Synchronized users can have Oracle Cloud Infrastructure credentials, but not Console passwords. When listing users in the Console, you can identify synchronized users using the **User Type** filter.

- **Local users**
  
  A local user is a user created and managed in Oracle Cloud Infrastructure's IAM service. Federated tenancies typically would have few, if any, local users. When listing users in the Console, you can identify local users using the **User Type** filter.

The following graphic summarizes the characteristics of the user types:
Who Should Set Up This Integration?

Set up this integration if your IdP is Oracle Identity Cloud Service or Okta and your federated users need to have the specialized credentials required by some services and features. For example, if you need your federated users to access Oracle Cloud Infrastructure through the SDK or CLI, setting up this integration enables these users to get the API keys needed for this access.

Prerequisite

Perform this synchronization setup after you have successfully set up a federation between your IdP and Oracle Cloud Infrastructure. See Supported Identity Providers on page 2366.

Enabling User Provisioning

Instructions for Oracle Identity Cloud Service Federations

If your identity provider is Oracle Identity Cloud Service, you need to perform a one-time upgrade.

Important:

If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to provision your Oracle Identity Cloud Service users in Oracle Cloud Infrastructure. You do not need to perform the steps in this topic. See Understanding User Types on page 2405 and Managing User.
Upgrading Your Oracle Identity Cloud Service Federation

If your federation with Oracle Identity Cloud service was set up before December 21, 2018, perform this one-time upgrade task.

To upgrade your Oracle Identity Cloud Service federation:

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.

   A list of the identity providers in your tenancy is displayed.

2. Click your Identity Cloud Service federation to view its details. If your tenancy was auto-federated, it is listed as OracleIdentityCloudService.

3. Click Edit Mapping.

4. When prompted, provide the client ID and client secret for the Oracle Identity Cloud Service application, and then click Continue.

   Where do I find the client ID and client secret?

   The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

   a. 1. Sign in to the Oracle Identity Cloud Service console.
      2. In the Identity Cloud Service console, click Applications. The list of trusted applications is displayed.
      3. Click COMPUTEBAREMETAL.
      4. Click Configuration.
      5. Expand General Information. The client ID is displayed. Click Show Secret to display the client secret.

Allow several minutes for the changes to take effect.

Instructions for Okta Federations

If you do not have an existing federation with Okta, follow the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning. This paper includes instructions for both setting up your federation and provisioning with SCIM.

If you have an existing federation with Okta with group mappings that you want to maintain, you can add SCIM provisioning as follows:
1. In Okta, delete the existing SAML application you originally set up to federate with Oracle Cloud Infrastructure.
2. Set up a new SAML application in Okta according to the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning, with the following exceptions:
   - Skip the steps to Add Identity Provider to Oracle Cloud Infrastructure (you already have this resource in Oracle Cloud Infrastructure).
   - Instead, click Edit Identity Provider and upload the new metadata.xml document from the new Okta app you created.
   - Then, in Oracle Cloud Infrastructure, ensure that you Reset Credentials. Add the new Client ID and Secret to the API integration settings page in Okta (Step 7 in the white paper).

**What to Expect After the Upgrade**

When the system has had time to synchronize, you can manage user capabilities for federated users in the Console. Users that belong to a group mapped to a group in Oracle Cloud Infrastructure are listed on the Users page in the Console. Whenever you add new users to mapped groups in Oracle Identity Cloud Service, they will be available in the Console after the system synchronizes.

By default, the following user capabilities are enabled:

- API keys
- auth tokens
- SMTP credentials
- customer secret keys

Notice that you can't enable a local password. The Oracle Cloud Infrastructure console password is still managed only in your IdP.

For more information about user capabilities, see Managing User Capabilities for Federated Users on page 2408.

**Resetting Credentials**

Use the Reset Credentials button to reset your SCIM client credentials. You can perform this task periodically as a security measure to rotate your credentials. After you reset these credentials, you'll need to update the SAML app in your identity provider with the new credentials.

**Note:** If your IdP is Oracle Identity Cloud Service, Oracle Cloud Infrastructure automatically resets the credentials with Oracle Identity Cloud Service for you. You don't need to manually reset the configuration.

**Actions You Still Perform in Your Identity Provider**

After the integration is set up, continue to perform the following actions in your IdP:

- Create users and assign them to groups.
- Delete users.
  - Users that you delete from your IdP are removed from Oracle Cloud Infrastructure when the next synching cycle completes.
- Query for group membership.
- Manage sign-in passwords for users.

**Managing User Capabilities for Federated Users**

This topic describes managing user capabilities for federated users when your tenancy is federated and configured for user provisioning with a supported identity provider.

**About User Capabilities**

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console, must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.
User capabilities are managed by an Administrator in the user's details. Each user can see their capabilities, but only an Administrator can enable or disable them. The user capabilities available to federated users are:

- API keys
- auth tokens
- SMTP credentials
- customer secret keys
- OAuth 2.0 client credentials

By default, these capabilities are enabled when you provision new users, allowing users to create these credentials for themselves. For information about these user credentials, see Managing User Credentials on page 2456.

**Important:**

The capability "Console password" is not available for federated users. Federated users authenticate to the Console through their IdP, where their sign-in passwords are managed.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing user capabilities. A user can't enable or disable user capabilities for themselves (except for Administrators). However, a user can manage their own credentials that have been enabled for them.

**Prerequisites**

Management of user capabilities for federated users is supported for Oracle Identity Cloud Service and Okta federations only.

- Oracle Identity Cloud Service federations:
  
  If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to manage user capabilities. There are no prerequisites.

  If your tenancy was created before December 21, 2018, you must perform a one-time upgrade. See Enabling User Provisioning on page 2406.

- If your tenancy is federated with Okta, see User Provisioning for Federated Users on page 2404.

**Viewing Provisioned Federated Users in the Console**

After the prerequisites are satisfied, you can view users that you create in your IdP that belong to groups mapped to Oracle Cloud Infrastructure groups. Whenever you add a user to a group mapped to an Oracle Cloud Infrastructure group, the user automatically displays in the Console.

**To list users in the Console:**

Open the navigation menu. Under Governance and Administration, go to Identity and click Users.

Notice that you can filter the list by user type to include only users that belong to a specified identity provider. Local Users are users created in Oracle Cloud Infrastructure's IAM service. The filter list includes all identity providers you have set up.

**Using the Console**

**To edit user capabilities**

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.

2. Click the user to see its details.
3. Click **Edit User Capabilities**.
4. Select or clear the check box to add or remove a capability.
5. Click **Save**.

**To change a user's description**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.
4. Edit the description and save it. This description is maintained in Oracle Cloud Infrastructure and is not synched back to your identity provider.

**To apply tags to a user**

For instructions, see **Resource Tags** on page 211.

**To delete a user**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.
2. Find the user you want to delete and click the Actions icon (three dots).
3. Click **Delete**.

**Important:** Deleting a user here does not delete the user in your IdP. If you later want the federated user to have a provisioned user in Oracle Cloud Infrastructure, you must remove the user from all OCI-mapped groups in Oracle Identity Cloud Service and re-add the user.

For information about managing user credentials in the Console, see **Managing User Credentials** on page 2456.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage user capabilities:

- **ListUsers**
- **GetUser**
- **UpdateUser**: You can update the user capabilities and the user's description.
- **UpdateUserCapabilities**
- **DeleteUser**: This operation deletes the provisioned user in Oracle Cloud Infrastructure, but not the user in the identity provider.

For information about the API operations for managing user credentials, see **Managing User Credentials** on page 2456.

The following operations are **not** supported for federated users:

- **ListUserGroupMemberships**
- **AddUserToGroup**
- **GetUserGroupMembership**
- **RemoveUserFromGroup**

**Calling Services from an Instance**

This topic describes how you can authorize instances to call services in Oracle Cloud Infrastructure.
Introduction
This procedure describes how you can authorize an instance to make API calls in Oracle Cloud Infrastructure services. After you set up the required resources and policies, an application running on an instance can call Oracle Cloud Infrastructure public services, removing the need to configure user credentials or a configuration file.

Concepts

DYNAMIC GROUP
Dynamic groups allow you to group Oracle Cloud Infrastructure instances as principal actors, similar to user groups. You can then create policies to permit instances in these groups to make API calls against Oracle Cloud Infrastructure services. Membership in the group is determined by a set of criteria you define, called matching rules.

MATCHING RULE
When you set up a dynamic group, you also define the rules for membership in the group. Resources that match the rule criteria are members of the dynamic group. Matching rules have a specific syntax you follow. See Writing Matching Rules to Define Dynamic Groups on page 2424.

INSTANCE PRINCIPALS
The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

Security Considerations
Any user who has access to the instance (who can SSH to the instance), automatically inherits the privileges granted to the instance. Before you grant permissions to an instance using this procedure, ensure that you know who can access it, and that they should be authorized with the permissions you are granting to the instance.

All compute instance principals are granted the compartment_inspect permission. You cannot revoke this permission. This permission allows the instance to ListCompartments in the tenancy to retrieve the following information:

- Compartment names
- Compartment descriptions
- Free-form tags applied to compartments
- Automatic tag defaults applied to compartments. These tags, such as CreatedBy and CreatedOn, are in the Oracle-Tag namespace and are automatically added by Oracle.

Process Overview
The following steps summarize the process flow for setting up and using instances as principals. The subsequent sections provide more details.

1. Create a dynamic group. In the dynamic group definition, you provide the matching rules to specify which instances you want to allow to make API calls against services.
2. Create a policy granting permissions to the dynamic group to access services in your tenancy (or compartment).
3. A developer in your organization configures the application built using the Oracle Cloud Infrastructure SDK to authenticate using the instance principals provider. The developer deploys the application and the SDK to all the instances that belong to the dynamic group.
4. The deployed SDK makes calls to Oracle Cloud Infrastructure APIs as allowed by the policy (without needing to configure API credentials).
5. For each API call made by an instance, the Audit service logs the event, recording the OCID of the instance as the value of principalId in the event log.
Steps to Enable Instances to Call Services

Perform these tasks to enable an instance to call services:

Create a Dynamic Group and Matching Rules

Write Policies for Dynamic Groups

Configure the SDK, CLI, or Terraform

Creating a Dynamic Group and Matching Rules

See Managing Dynamic Groups on page 2422.

Writing Policies for Dynamic Groups

After you have created a dynamic group, you need to create policies to permit the dynamic groups to access Oracle Cloud Infrastructure services.

Policy for dynamic groups follows the syntax described in How Policies Work on page 2136. Review that topic to understand basic policy features.

The syntax to permit a dynamic group access to resources in a compartment is:

```
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in compartment <compartment_name>
```

The syntax to permit a dynamic group access to a tenancy is:

```
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in tenancy
```

Here are a few example policies:

To allow a dynamic group (FrontEnd) to use a load balancer in a specific compartment (ProjectA):

```
Allow dynamic-group FrontEnd to use load-balancers in compartment ProjectA
```

To allow a dynamic group to launch instances in a specific compartment:

```
Allow dynamic-group FrontEnd to manage instance-family in compartment ProjectA
Allow dynamic-group FrontEnd to use volume-family in compartment ProjectA
Allow dynamic-group FrontEnd to use virtual-network-family in compartment ProjectA
```

For more sample policies, see Common Policies on page 2142.

Configuring the SDK, CLI, or Terraform

For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For the SDK for Java:

In your SDK for Java, create an InstancePrincipalsAuthenticationDetailsProvider object. For example:

```java
public static void main(String[] args) throws Exception {
    InstancePrincipalsAuthenticationDetailsProvider provider =
        InstancePrincipalsAuthenticationDetailsProvider.builder().build();
    IdentityClient identityClient = new IdentityClient(provider);
}
For the SDK for Python:

In your SDK for Python, create an `oci.auth.signers.InstancePrincipalsSecurityTokenSigner` object. For example:

```python
# By default this will hit the auth service in the region returned by

signer = oci.auth.signers.InstancePrincipalsSecurityTokenSigner()
identity_client = oci.identity.IdentityClient(config={}, signer=signer)

...```

To refresh the token without waiting, use the following command:

```python
signer.refresh_security_token()
```

**Enabling Instance Principal Authorization for the CLI**

To enable instance principal authorization from the CLI, you can set the authorization option (`--auth`) for a command. For example:

```bash
oci os ns get --auth instance_principal
```

Alternatively, you can set the following environment variable:

```bash
OCI_CLI_AUTH=instance_principal
```

Note that if both are set, the value set for `--auth` takes precedence over the environment variable.

For information about using the CLI, see [Working with the Command Line Interface](#).

**Enabling Instance Principal Authorization for Terraform**

To enable instance principal authorization in Terraform, you can set the `auth` attribute to "InstancePrincipal" in the provider definition as shown in the following sample:

```hcl
variable "region" {}

provider "oci" {
  auth = "InstancePrincipal"
  region = "${var.region}"
}
```

Note that when you use instance principal authorization you do not need to include the `tenancy_ocid`, `user_ocid`, `fingerprint`, and `private_key_path` attributes.

**FAQs**

**How do I query the instance metadata service to query the certificate on the instance?**

**How frequently is the certificate rotated on each instance?**

The certificate is rotated multiple times each day.

**What happens if I try to use an expired certificate?**

You will get a 401-Not Authenticated error.
Can I change the frequency at which the certificate is rotated?
No. You can't change the frequency at which the certificate is rotated. However, you can change the policy on the dynamic group. If you think an instance has been compromised, you can either change the policy on the dynamic group to revoke permissions for all members of the group, or you can remove the instance from the dynamic group. See Can I remove an instance from a dynamic group? on page 2414

What happens if the certificate is rotated in the middle of a long running operation?
The token expiration is independent of the certificate expiration period. And, it also depends on the application you are interacting with. For example, if Object Storage does not have a multipart PUT operation, then it does not matter how long the operation runs.

Are the certificates accessible for all users on an instance?
Yes. Ensure that only users who should be granted the access that you have granted to the dynamic group, have access to the instance.

Are dynamic groups created at the tenancy level?
Yes.

Can I remove an instance from a dynamic group?
Yes. You can remove it by modifying the matching rule to exclude it. See below for an example.

Can I exclude specific instances in a compartment from the dynamic group?
Yes. For example, assume you want to exclude two specific instances in a compartment from the dynamic group. Write a matching rule like this:

```text
All {instance.compartment.id = '<compartment_ocid>',
    instance.id != '<instance1_to_exclude_ocid>', instance.id !=
    '<instance2_to_exclude_ocid>'}
```

The above rule includes all instances in the compartment except those with the OCIDs specified.

Managing Users
This topic describes the basics of working with users.

Important:
If your tenancy is federated with Oracle Identity Cloud Service, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372 to manage users.

Required IAM Policy
If you're in the Administrators group, then you have the required access for managing users.

- You can create a policy that gives someone the power to create new users and credentials but not control which groups those users are in. See Let the Help Desk manage users on page 2142.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for users or other IAM components, see Details for IAM on page 2280.

Tagging Resources
You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.
Working with Users

When creating a user, you must provide a unique, unchangeable name for the user. The name must be unique across all users within your tenancy. This name is the user's login to the Console. You might want to use a name that's already in use by your company's own identity system (for example, Active Directory, LDAP, etc.). You must also provide the user with a description (although it can be an empty string), which is a non-unique, changeable description for the user. This value could be the user's full name, a nickname, or other descriptive information. Oracle also assigns the user a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note:
If you delete a user and then create a new user with the same name, the two users are considered different users, because they have different OCIDs.

Oracle recommends that you supply a password recovery email address for the user. If the user forgets their password, they can request to have a temporary password sent to them using the Forgot Password link on the sign-on page. If no email address is present for the user, an administrator must intervene to reset their password.

A new user has no permissions until you place the user in one or more groups and at least one policy gives that group permission to either the tenancy or to a compartment. Exception: each user can manage their own credentials they have been enabled to have. An administrator does not need to create a policy to give a user that ability. For more information, see User Credentials on page 2360.

Important:
After creating a user and putting them in a group, let them know which compartment(s) they have access to.

You also need to give the new user some credentials so they can access Oracle Cloud Infrastructure. A user can have one or both of the following credentials, depending on the type of access they need: A password for using the Console and an API signing key for using the API.

About User Capabilities

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.

Administrators manage user capabilities in the User details. Each user can see their capabilities, but only an Administrator can enable or disable those capabilities. The user capabilities are:

- Can use Console password (native users only)
- Can use API keys
- Can use auth tokens
- Can use SMTP credentials
- Can use customer secret keys

By default, all these capabilities are enabled when you create users, allowing users to create these credentials for themselves. For information about working with user credentials, see Managing User Credentials on page 2456.

Enabling Multi-Factor Authentication for a User

See Managing Multi-Factor Authentication on page 2470 for details.

Signing In to the Console

Users created through this procedure are created in IAM and are sometimes called "local users." If your tenancy is federated with another identity provider (such as Oracle Identity Cloud Service, Azure AD, or Okta), your sign-in page to the Console displays two options for signing in. The local users you create in IAM use the Oracle Cloud Infrastructure option to sign in, as shown in the following image:
If your tenancy is not federated, you only have one sign in option.

**Tracking Recent Sign-in Activity**

The Users list page displays information to assist administrators in determining whether user accounts are active. The **Last Sign In** field displays the date and time the user last signed in to Oracle Cloud Infrastructure using the Console. This field is displayed only on the list view of all users, it is not displayed on the individual user details page. This field only tracks sign in from the Console. If a user accesses Oracle Cloud Infrastructure through other access methods (for example, through the SDK), those occurrences are not tracked.

**Linking a User to a My Oracle Support Account**

To file support requests directly from the Console, each user must link their IAM user account with their My Oracle Support (MOS) account. You only need to complete this step once. For instructions, see To link a user to their My Oracle Support account on page 2418.

**Prerequisites**

- Before a user can create this link, they must set up an account in My Oracle Support. For information on setting up a My Oracle Support account, see Creating an Oracle Single Sign On (SSO) Account on page 130.
- Before a user can submit service requests for a tenancy, their My Oracle Support account must be associated to their tenancy CSI number. See Registering Your CSI for Oracle Cloud Infrastructure on page 131.

**Unblocking a User After Unsuccessful Sign-in Attempts**

If a user unsuccessfully tries to sign in to the Console 10 times in a row, they are blocked from further sign-in attempts. An administrator can unblock the user in the Console (see To unblock a user on page 2418) or with the UpdateUserState API operation.

**Deleting a User**

You can delete a user, but only if the user is not a member of any groups.

**Limits on Users**

For information about the number of users you can have, see Service Limits on page 215.
Using the Console
To create a user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click Create User.
3. Enter the following:
   - **Name:** A unique name or email address for the user. For tips about what value to use, see Working with Users on page 2415. The name must be unique across all users in your tenancy. You cannot change this value later. The name must meet the following requirements: No spaces. Only Basic Latin letters (ASCII), numerals, hyphens, periods, underscores, +, and @.
   - **Description:** This value could be the user's full name, a nickname, or other descriptive information. You can change this value later.
   - **Email:** Enter an email address for the user. This email address is used for password recovery. The email address must be unique in the tenancy.
     If the user forgets their password, they can click Forgot Password on the sign on page, and a temporary password is generated and sent to the email address provided here. The user or an administrator can also update the email address can also later.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click Create.

Next, you need to give the user permissions by adding them to at least one group. You also need to give the user the credentials they need (see Managing User Credentials on page 2456).

To add a user to a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user. The user's details are displayed.
4. Click Groups.
5. Click Add User to Group.
6. Select the group from the drop-down list, and then click Add.

Let the user know which compartment(s) they have access to.

To remove a user from a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user. The user's details are displayed.
4. Click Groups.
5. Click the Actions icon (three dots), and then click Remove.
6. Confirm when prompted.

To delete a user

Prerequisite: To delete a user, the user must not be in any groups.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. For the user you want to delete, click Delete.
3. Confirm when prompted.
To unblock a user

If you are an administrator, you can use the following procedure to unblock a user who has unsuccessfully tried to sign in to the Console 10 times in a row.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user. The user's details are displayed, including the current status.
3. Click Unblock.
4. Confirm when prompted.

To change a user's description

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.
4. Edit the description and save it.

To edit a user's email

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Under User Information, click the pencil next to Email.
4. Enter the email address and click the save icon. The email address must be unique in the tenancy.

To edit user capabilities

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user to see its details.
3. Click Edit User Capabilities.
4. Select or clear the check box to add or remove a capability.
5. Click Save.

To apply tags to a user

For instructions, see Resource Tags on page 211.

To link a user to their My Oracle Support account

Important: Ensure that you meet the prerequisites before linking your account. See Linking a User to a My Oracle Support Account on page 2416.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Click Link Support Account. The Oracle account sign in page prompts you to enter your Oracle credentials.
4. Enter the User name and Password of the Oracle support account that you want to link to this user and click Sign in. The I AM user account is linked to the Oracle support account. The e-mail address associated with the support account is displayed in the user details in the field My Oracle Support account.

To unlink a user a user from a My Oracle Support account

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Click **Unlink Support Account**.
4. In the confirmation prompt, click **Unlink**.

For information about managing user credentials in the Console, see Managing User Credentials on page 2456.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

**Note:**

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA is able to launch instances in your home region within a minute. However, UserA is not able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage users:

- CreateUser
- ListUsers
- GetUser
- UpdateUserState: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.
- UpdateUser: You can update the user's description, email, and tags.
- UpdateUserCapabilities
- DeleteUser
- ListUserGroupMemberships: Use this operation to get a list of which users are in a group, or which groups a user is in.
- AddUserToGroup: This operation results in a UserGroupMembership object with its own OCID.
- GetUserGroupMembership
- RemoveUserFromGroup: This operation deletes a UserGroupMembership object.

For information about the API operations for managing user credentials, see Managing User Credentials on page 2456.

**Managing Groups**

This topic describes the basics of working with groups.

**Important:**

If your tenancy is federated with Oracle Identity Cloud Service, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372 to manage groups.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing groups.
If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2280.

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

### Working with Groups

When creating a group, you must provide a unique, unchangeable name for the group. The name must be unique across all groups within your tenancy. You must also provide the group with a description (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

**Note:**

If you delete a group and then create a new group with the same name, they'll be considered different groups because they'll have different OCIDs.

A group has no permissions until you write at least one policy that gives that group permission to either the tenancy or a compartment. When writing the policy, you can specify the group by using either the unique name or the group's OCID. Per the preceding note, even if you specify the group name in the policy, IAM internally uses the OCID to determine the group. For information about writing policies, see Managing Policies on page 2450.

You can delete a group, but only if the group is empty.

For information about the number of groups you can have, see Service Limits on page 215.

If you're federating with an identity provider, you'll create mappings between the identity provider's groups and your IAM groups. For more information, see Federating with Identity Providers on page 2362.

### Using the Console

#### To create a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list of the groups in your tenancy is displayed.
2. Click Create Group.
3. Enter the following:
   - **Name**: A unique name for the group. The name must be unique across all groups in your tenancy. You cannot change this later. The name must be 1-100 characters long and can include the following characters: lowercase letters a-z, uppercase letters A-Z, 0-9, and the period (.), dash (-), and underscore (_). Spaces are not allowed. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click Create Group.

Next, you might want to add users to the group, or write a policy for the group. See To create a policy on page 2454.

#### To add a user to a group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group. Its details are displayed
4. Click **Add User to Group**.
5. Select the user from the drop-down list, and then click **Add User**.

**To remove a user from a group**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group to display its details. A list of users in the group is displayed.
4. Locate the user in the list.
5. For the user you want to remove, click **Remove**.
6. Confirm when prompted.

**To delete a group**

Prerequisite: To delete a group, it must not have any users in it.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. For the group you want to delete, click **Delete**.
4. Confirm when prompted.

**To update a group's description**

This is available only through the API. If you don't have access to the API and need to update a group's description, contact Oracle Support.

**To apply tags to a group**

For instructions, see **Resource Tags** on page 211.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

**Note:**

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage groups:

- **CreateGroup**
- **ListGroups**
- **GetGroup**
- **UpdateGroup**: You can update only the group's description.
- **DeleteGroup**
- **ListUserGroupMemberships**: Use to get a list of which users are in a group, or which groups a user is in.
• **AddUserToGroup**: This operation results in a `UserGroupMembership` object with its own OCID.
• **GetUserGroupMembership**
• **RemoveUserFromGroup**: This operation deletes a `UserGroupMembership` object.

For API operations related to group mappings for identity providers, see *Federating with Identity Providers* on page 2362.

**Managing Dynamic Groups**

This topic describes how to manage dynamic groups and define the rules to determine a dynamic group's members.

**About Dynamic Groups**

Dynamic groups allow you to group Oracle Cloud Infrastructure compute instances as "principal" actors (similar to user groups). You can then create policies to permit instances to make API calls against Oracle Cloud Infrastructure services. When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of matching rules to define the group members. For example, a rule could specify that all instances in a particular compartment are members of the dynamic group. The members can change dynamically as instances are launched and terminated in that compartment.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing dynamic groups.

If you're new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142. If you want to dig deeper into writing policies for dynamic groups or other IAM components, see *Details for IAM* on page 2280.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see *Resource Tags* on page 211.

**Working with Dynamic Groups**

When creating a dynamic group, you must provide a unique, unchangeable name for the dynamic group. The name must be unique across all groups within your tenancy. You must also provide the dynamic group with a description (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see *Resource Identifiers*.

**Note:**

If you delete a dynamic group and then create a new dynamic group with the same name, they'll be considered different groups because they'll have different OCIDs.

A dynamic group has no permissions until you write at least one policy that gives that dynamic group permission to either the tenancy or a compartment. When writing the policy, you can specify the dynamic group by using either the unique name or the dynamic group's OCID. Per the preceding note, even if you specify the dynamic group name in the policy, IAM internally uses the OCID to determine the dynamic group. For information about writing policies, see *Managing Policies* on page 2450.

You can delete a dynamic group, but only if the group is empty.

**Updating Dynamic Groups**

You can update the matching rules that define the members of a dynamic group. For example, you might change a matching rule that includes all instances in a compartment to exclude a particular instance. Or, you might update a rule to include a new tag value.
Important:

When you make a change to a matching rule you must allow about one hour for the updated policy to take effect. For example, if you update tags on an instance to either include or exclude that instance from a dynamic group, you must wait for that policy to take effect to include or exclude the instance.

Limits on Dynamic Groups

A single compute instance can belong to a maximum of 5 dynamic groups.

You can have a maximum of 50 dynamic groups in your tenancy.

Using the Console

To create a dynamic group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.
2. Click Create Dynamic Group.
3. Enter the following:
   - Name: A unique name for the group. The name must be unique across all groups in your tenancy (dynamic groups and user groups). You can't change this later. Avoid entering confidential information.
   - Description: A friendly description.
4. Enter the Matching Rules. Resources that meet the rule criteria are members of the group.
   - Rule 1: Enter a rule following the guidelines in Writing Matching Rules to Define Dynamic Groups on page 2424. You can manually enter the rule in the text box or launch the rule builder.
   - Enter additional rules as needed. To add a rule, click Additional Rule.
5. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
6. Click Create Dynamic Group.
   
   The matching rule syntax is verified, but the OCIDs are not. Be sure that the OCIDs you enter are correct.

Next, to give the dynamic group permissions, you need to write a policy. See Writing Policies for Dynamic Groups on page 2412.

To delete a dynamic group

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.
   
   A list of the dynamic groups in your tenancy is displayed.
2. Locate the dynamic group in the list.
3. For the dynamic group you want to delete, click Delete.
4. Confirm when prompted.

To update a dynamic group's description

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.
   
   A list of the groups in your tenancy is displayed.
2. Click the dynamic group you want to update. The dynamic's group's details are displayed.
3. Click Edit Dynamic Group.
4. Edit the description. When finished, click Save Changes.

To update a dynamic group's matching rules

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.
   
   A list of the dynamic groups in your tenancy is displayed.
2. Click the dynamic group you want to update. The dynamic group's details are displayed.
3. Click **Edit All Matching Rules**.
4. Edit the matching rule in the text box; or, you can use the rule builder if the change is **supported by the rule builder.**

### Writing Matching Rules to Define Dynamic Groups

Matching rules define the resources that belong to the dynamic group. In the Console, you can either enter the rule manually in the provided text box, or you can use the **rule builder**. The rule builder lets you make selections and entries in a dialog, then writes the rule for you, based on your entries.

You can define the members of the dynamic group based on the following:

- **compartment ID** - include (or exclude) the instances that reside in that compartment based on compartment OCID
- **instance ID** - include (or exclude) an instance based on its instance OCID
- **tag namespace and tag key** - include (or exclude) instances tagged with a specific tag namespace and tag key. All tag values are included. For example, include all instances tagged with tag namespace `department` and the tag key `operations`.
- **tag namespace, tag key, and tag value** - include (or exclude) instances tagged with a specific value for the tag namespace and tag key. For example, include all instances tagged with the tag namespace `department` and the tag key `operations` and with the value '45'.

A matching rule has the following syntax:

For a single condition:

```
variable =|!= 'value'
```

For multiple conditions:

```
any|all {<condition>,<condition>,...}
```

Supported variables are:

- `instance.compartment.id` - the OCID of the compartment where the instance resides
- `instance.id` - the OCID of the instance
- `tag.<tagnamespace>.<tagkey>.value` - the tag namespace and tag key. For example, `tag.department.operations.value`.
- `tag.<tagnamespace>.<tagkey>.value='tagvalue'` - the tag namespace, tag key, and tag value. For example, `tag.department.operations.value='45'`

Here are some examples:

#### Include All Instances in a Specific Compartment in the Dynamic Group

To include all instances that are in a specific compartment, add a rule with the following syntax:

```
instance.compartment.id = '<compartment_ocid>'
```

You can type the rule directly in the text box, or you can use the **rule builder**.

Example entry in text box:

```
instance.compartment.id =
'ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv'
```

To add the same rule using the Console rule builder:

- **For Include Instances That Match:** Select **All of the following**.
- **For Match Instances with:** Select **Compartment OCID**.
- **For Value:** Enter the compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`
All instances that currently exist or get created in the compartment (identified by the OCID) are members of this group.

### Include All Instances in Any of Two or More Compartments

To include all instances that reside in any of two (or more) compartments, add a rule with the following syntax:

```plaintext
Any {instance.compartment.id = '<compartment_ocid>', instance.compartment.id = '<compartment_ocid>'}
```

separating each compartment entry with a comma.

You can type the rule directly in the text box, or you can use the rule builder.

Example entry in the text box:

```plaintext
```

To add the same rule using the Console rule builder:

1. For **Include Instances That Match**: Select **Any of the following**.
2. For **Match Instances With**: Select **Compartment OCID**.
3. For **Value**: Enter the compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`
4. Click **+Additional Line**. Enter the following on the second line:
   - For **Match Instances With**: Select **Compartment OCID**.
   - For **Value**: Enter the additional compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocidythksk89ekslsoelu2`

Instances that currently exist or are later created in either of the specified compartments are members of this group.

### Include All Instances Tagged with a Specific Namespace and Tag Key

To include all instances that are tagged with a specific tag namespace and tag key, add a rule with the following syntax:

```plaintext
tag.<tagnamespace>.<tagkey>.value
```

All instances assigned the tagnamespace.tagkey combination are included. Note that the tag value is not evaluated, so all values are included.

**Example**: Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the namespace and tag key.

Enter the following rule in the text box:

```plaintext
tag.department.operations.value
```

All instances that currently exist or get created with the tag namespace and tag key `department.operations` are members of this group.

### Include All Instances In a Specific Compartment with a Specific Tag Namespace, Tag Key, and Tag Value

To include all instances in a specific compartment that are tagged with a specific tag namespace, key, and value, add a rule with the following syntax:

```plaintext
All {instance.compartment.id = '<compartment_ocid>', tag.<tagnamespace>.<tagkey>.value='<tagvalue>'}
```
All instances that are in the identified compartment and that are assigned the tagnamespace.tagkey with the specified tag value are included.

**Example:** Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the value 45, that are in a particular compartment.

Enter the following statement in the text box:

```java
All
{instance.compartment.id='ocid1:compartment:oc1:phx:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv,'
tag.department.operations.value='45'}
```

**Using the Rule Builder**

The rule builder is a tool available from the Console to help you write matching rules. The rule builder provides menus and text boxes for you to make entries and then writes the rule for you. The rule builder does have some limitations, so you can't use it for all cases.

**Limitations of the Rule Builder**

The rule builder does not support the following:

- Exclusion rules - the rule builder lets you select compartment IDs and instance IDs to include only.
- Rules based on tags - the rule builder does not allow you to select tags to include in your rule. To add a rule based on tag values, you need to enter the rule in the Rule text box using the syntax above.

**Launching the Rule Builder**

When you click **Create Dynamic Group**, the Rule Builder is displayed in the **Create Dynamic Group** dialog.

To create a matching rule using the rule builder:

1. Under the **Matching Rules** section, click **Rule Builder**.
2. From the **Include Instances That Match** menu, select **All of the following** or **Any of the following**.
   - **All of the following** includes only instances that match all of the statements in the rule.
   - **Any of the following** includes instances that match any of the statements in the rule.
3. Select a resource type from the **Match Instances With** menu, and then enter the OCID for the resource in the **Value** field:
   - **Compartment OCID** includes instances in the compartment you specify.
   - **Instance OCID** includes the instances with the OCIDs you specify.
4. Click **+Additional line** to add more statements to this rule.
   - When you add multiple statements to a rule, remember that **Any of the following** includes instances that match any of the statements. If you choose **All of the following**, instances must match all of the specifications in the statements to be included in the group.

**Examples Using the Rule Builder**

**Include All Instances in a Specific Compartment in the Dynamic Group**

To include all instances that are in a specific compartment, using the rule builder:

- Select **All of the following**.
- For **Match Instances With**: Select **Compartment OCID**.
- For **Value**: Enter the compartment OCID, for example,
  ocid1:compartment:oc1:phx:samplecompartmentocidythksk89ekslsoel1u2

All instances that currently exist or are later created in the compartment (identified by the OCID) are members of this group.

**Include All Instances in Any of Two or More Compartments**

To include all instances that reside in any of two (or more) compartments using the rule builder:
1. From the **Include Instances That Match** menu, select **Any of the following**.
2. In the first line, enter:
   - For **Match Instances With**, select **Compartment OCID**.
   - For **Value**, enter the compartment OCID, for example:
     `ocid1:compartment:oci:phx:samplecompartmentocid6q6igvfauxmima74jv`
3. Click **Additional Line**. Enter the following on the second line:
   - For **Match Instances With**, select **Compartment OCID**
   - For **Value**, enter the compartment OCID, for example:
     `ocid1:compartment:oci:phx:samplecompartmentocidythksk89ekslsoelu2`
4. Continue adding additional lines as needed for each compartment you want to include.

Instances that currently exist or get created in any of the specified compartments are members of this group.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage dynamic groups:

- CreateDynamicGroup
- ListDynamicGroups
- GetDynamicGroup
- UpdateDynamicGroup
- DeleteDynamicGroup

**Managing Network Sources**

This topic describes the basics of working with network sources.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing network sources. To write policies specifically for network sources, use the network-sources resource type, found with the other IAM components, in Details for IAM on page 2280.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

**Introduction to Network Sources**

A network source is a set of defined IP addresses. The IP addresses can be public IP addresses or IP addresses from VCNs within your tenancy. After you create the network source, you can reference it in policy or in your tenancy’s authentication settings to control access based on the originating IP address.

Network resources can only be created in the tenancy (or root compartment) and, like other Identity resources, reside in the home region. For information about the number of network sources you can have, see IAM Limits on page 225.

You can use network sources to help secure your tenancy in the following ways:
• Specify the network source in IAM policy to restrict access to resources.

When specified in a policy, IAM validates that requests to access a resource originate from an allowed IP address.

For example, you can restrict access to Object Storage buckets in your tenancy to only users that are signed in to Oracle Cloud Infrastructure through your corporate network. Or, you can allow only resources belonging to specific subnets of a specific VCN to make requests over a service gateway.

• Specify the network source in your tenancy's authentication settings to restrict sign in to the Console.

You can set up your tenancy's authentication policy to allow sign in to the Console from only those IP addresses specified in your network source. Users attempting to sign in from an IP address not on the allowed list in your network source will be denied access. For information on using a network source restriction in authentication policy, see Managing Authentication Settings on page 2468.

Support for Network Sources

The following services support using network sources in policy to restrict access to their resources:

Services that support network sources

• Analytics Cloud
• API Gateway
• Application Migration
• Audit
• Blockchain Platform Cloud
• Block Volume
• Budgets
• Compute
• Container Engine for Kubernetes
• Content and Experience
• Data Flow
• Data Safe
• Database
• Digital Assistant
• Events
• IAM
• Load Balancing
• Monitoring
• MySQL Database
• Notifications
• Object Storage
• Operations Insights
• OS Management
• Resource Manager
• Service Limits
• Streaming
• Tagging
• Unified Billing
• WAF

Allowing Access to Resources from Only Specified IP Addresses

To restrict access to requests made from a set of IP addresses, do the following:

1. Create a network source that specifies the allowed IP addresses.
2. Write a policy that uses the network source variable in a condition.
1. Create the Network Source

Follow the instructions provided for the Console or the API to create the network source.

A single network source can include IP addresses from a specific VCN, public IP addresses, or both.

To specify the VCN, you need the VCN OCID and the subnet IP ranges that you want to allow.

Examples:

- **Public IP addresses or CIDR blocks**: 192.0.2.143 or 192.0.2.0/24
- **VCN OCID**: ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID
  - **Subnet IP addresses or CIDR blocks**: 10.0.0.4, 10.0.0.0/16

To allow any IP address from a specific VCN, use 0.0.0.0/0.

2. Write the Policy

The IAM service includes a variable to use in policy that allows you to scope your policy using a condition. The variable is:

```
request.networkSource.name
```

After you have created your network source, you can scope policies by using this variable in a condition. For example, assume you create a network source named "corpnet". You can restrict users of the group "CorporateUsers" to access your Object Storage resources only when their requests originate from IP addresses you specified in corpnet.

To do this, write a policy like the following:

```allow group CorporateUsers to manage object-family in tenancy where
request.networkSource.name='corpnet'
```

This policy allows users in the CorporateUsers group to manage Object Storage resources only when their requests originate from an allowed IP address specified in the network source "corpnet". Requests made from outside the specified IP ranges are denied. For general information about writing policies, see How Policies Work on page 2136.

Using the Console to Manage Network Sources

To create a network source

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Network Sources.
   A list of the network sources in your tenancy is displayed.
2. Click Create Network Source.
3. Enter the following:
   - **Name**: A unique name for the network source. The name must be unique in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Allow OCI Services**: This check box is selected by default to allow Oracle Cloud Infrastructure services access, even if the request comes from outside the specified IP addresses. Typically, you want this option enabled, for example, to allow a service to interact with objects in a bucket.
   - **Network Type**: Select one of the following:
     - **Public Network**: Enter a specific IP address or CIDR block range. For example: 192.0.2.143.
       Click **Another IP Address/CIDR Block** to add another allowed address or range.
     - **Virtual Cloud Network**: Enter the following for this option:
       - **VCN OCID**: Enter the OCID from the VCN you want to allow. For example: ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID
       - **IP Address/CIDR Block**: Enter an IP address from the VCN or a subnet CIDR block. For example: 10.0.0.0/16 or 10.0.0.4.
         If you want to allow all subnets from the specified VCN, enter 0.0.0.0/0.
       Click **Another IP Address/CIDR Block** to add another allowed address or range from the same VCN.
   4. To add more IP ranges to this network source, click **Add Source**.
   5. **Show Advanced Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
   6. Click **Create**.

**To update a network source**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Network Sources**. A list of the network sources in your tenancy is displayed.
2. Locate the network source in the list and click its name to view its details.
3. Edit the network source:
   - To add more allowed IP addresses to this network source, click **Add Sources**. In the **Add Sources** dialog, click **Add Source** again, and enter the details for each IP address or CIDR block you want to add to this network source.
   - To remove an allowed source, click the Actions icon (three dots) and click **Delete**.
   - To change the setting of **Allow OCI Services**, click **Add Sources**. Update the check box setting and click **Update**.

**To delete a network source**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. The list of network sources in your tenancy is displayed.
2. Locate the network source in the list and click the Actions icon (three dots) for the item.
3. Click **Delete**.
4. Confirm when prompted.

**To apply tags to a network source**

For instructions, see **Resource Tags** on page 211.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.
Use these API operations to manage network sources:

- CreateNetworkSource
- ListNetworkSources
- GetNetworkSource
- UpdateNetworkSource
- DeleteNetworkSource

Creating the Network Source Object

A sample network source object looks like the following example:

```json
{
    "compartmentId" : "ocid1.tenancy.oc1..aaaaaaaabaexampleuniqueID",
    "description" : "Corporate IP ranges to be used for IP-based authorization",
    "name" : "corpnet",
    "virtualSourceList": [{
        "vcnId": "ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID",
        "ipRanges": [ "129.213.39.0/24" ]
    }],
    "publicSourceList": [ "192.0.2.5", "192.0.2.6" ],
    "services": ["all"]
}
```

The elements are:

- **virtualSourceList** - specifies the VCN (OCID) and subnet IP ranges within that VCN that are allowed access. The `virtualSourceList` must contain both the VCN OCID and the subnet IP ranges:
  - **vcnID** - the OCID of the VCN
  - **IpRanges** - comma-separated list of the IP addresses or CIDR blocks of the subnets belonging to the specified VCN that are allowed to access the resource. To allow all ranges in the specified VCN, enter 0.0.0.0/0.

- **publicSourceList** - comma-separated list of the public IP ranges that are allowed access.
- **services** - currently, "all" or "none" are the only supported values. The default is "all". Specifying "all" allows Oracle Cloud Infrastructure services to access the resource.

Example:

```json
{
    "virtualSourceList": [{
        "vcnId": "ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID",
        "ipRanges": [ "129.213.39.0/24" ]
    }],
    "publicSourceList": [ "192.0.2.0/25", "192.0.2.200" ],
    "services": ["all"]
}
```

Managing Compartments

This topic describes the basics of working with compartments.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing compartments.

For an additional policy related to compartment management, see Let a compartment admin manage the compartment on page 2154.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for compartments or other IAM components, see Details for IAM on page 2280.
Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Working with Compartments

When you first start working with Oracle Cloud Infrastructure, you need to think carefully about how you want to use compartments to organize and isolate your cloud resources. Compartments are fundamental to that process. Most resources can be moved between compartments. However, it’s important to think through your compartment design for your organization up front, before implementing anything. For more information, see "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide.

The Console is designed to display your resources by compartment within the current region. When you work with your resources in the Console, you must choose which compartment to work in from a list on the page. That list is filtered to show only the compartments in the tenancy that you have permission to access. If you're an administrator, you'll have permission to view all compartments and work with any compartment's resources, but if you're a user with limited access, you probably won't.

Compartments are tenancy-wide, across regions. When you create a compartment, it is available in every region that your tenancy is subscribed to. You can get a cross-region view of your resources in a specific compartment with the tenancy explorer. See Viewing All Resources in a Compartment on page 235.

For added security, you can associate a compartment with a security zone. For more information, see Security Zones.

Creating Compartments

When creating a compartment, you must provide a name for it (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores) that is unique within its parent compartment. You must also provide a description, which is a non-unique, changeable description for the compartment, from 1 through 400 characters. Oracle will also assign the compartment a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

You can create subcompartments in compartments to create hierarchies that are six levels deep.

For information about the number of compartments you can have, see Service Limits on page 215.

Access Control for Compartments

After creating a compartment, you need to write at least one policy for it, otherwise no one can access it (except administrators or users who have permissions set at the tenancy level). When creating a compartment inside another
compartment, the compartment inherits access permissions from compartments higher up its hierarchy. For more information, see Policy Inheritance on page 2140.

When you create an access policy, you need to specify which compartment to attach it to. This controls who can later modify or delete the policy. Depending on how you've designed your compartment hierarchy, you might attach it to the tenancy, a parent, or to the specific compartment itself. For more information, see Policy Attachment on page 2141.

Putting Resources in a Compartment
To place a new resource in a compartment, you simply specify that compartment when creating the resource (the compartment is one of the required pieces of information to create a resource). If you're working in the Console, you just make sure you're first viewing the compartment where you want to create the resource. Keep in mind that most IAM resources reside in the tenancy (this includes users, groups, compartments, and any policies attached to the tenancy) and can't be created in or managed from a specific compartment.

Moving Resources to a Different Compartment
Most resources can be moved after they are created. There are a few resources that you can't move from one compartment to another. Also, you can't move certain resources from a security zone to a standard compartment because it might be less secure. For details about restrictions for resources in security zones, see Restrict Resource Movement.

Some resources have attached resource dependencies and some don’t. Not all attached dependencies behave the same way when the parent resource moves.

For some resources, the attached dependencies move with the parent resource to the new compartment. The parent resource moves immediately, but in some cases attached dependencies move asynchronously and are not visible in the new compartment until the move is complete.

For other resources, the attached resource dependencies do not move to the new compartment. You can move these attached resources independently.

After you move the resource to the new compartment, the policies that govern the new compartment apply immediately and affect access to the resource. Depending on the structure of your compartment organization, metering, billing, and alarms can also be affected.

See the service documentation for individual resources to familiarize yourself with the behavior of each resource and its attachments.

Viewing Resources in a Compartment
It's not possible to get a list of all the resources in a compartment by using a single API call. Instead you can list all the resources of a given type in the compartment (e.g., all the instances, all the block storage volumes, etc.).

Tip:
In the Console, the tenancy explorer allows you to get a list of resources in a compartment, across regions, with some limitations. For more information, see Viewing All Resources in a Compartment on page 235.

Discovering Resources in Compartments
With Resource Manager you can capture deployed resources as Terraform configuration and state files using resource discovery. The created stack provides you with a Terraform configuration that you can use to programmatically manage, version, and persist your IT infrastructure as "infrastructure as code."

A stack created from a compartment represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.

Stack creation is supported from a single compartment only. Stacks cannot be created from nested compartments.

For instructions, see To create a stack on page 3557.
Deleting Compartments

To delete a compartment, it must be empty of all resources. Before you initiate deleting a compartment, be sure that all its resources have been moved, deleted, or terminated, including any policies attached to the compartment.

Important:

Some resource types can't be deleted, therefore, compartments containing these resource types can't be deleted. A resource type that can't be deleted is:

- Data transfer jobs

The delete action is asynchronous and initiates a work request. The state of the compartment changes to Deleting while the work request is executing. It typically takes several minutes for the work request to complete. While it is in the Deleting state it is not displayed on the compartment picker. If the work request fails, the compartment is not deleted and it returns to the Active state.

After a compartment is deleted, its state is updated to Deleted and a random string of characters is appended to its name, for example, CompartmentA might become CompartmentA.qR5hP2BD. Renaming the compartment allows you to reuse the original name for a different compartment. Oracle displays the deleted compartment on the Compartments page for 365 days. The deleted compartment is removed from the compartment picker. If any policy statements reference the deleted compartment, the name in the policy statement is updated to the new name.

Troubleshooting tips for when a compartment fails to delete

If the compartment fails to delete, verify that you have removed all the resources:

- For most resources, you can use the tenancy explorer to help you locate them. See Resources Supported by the Tenancy Explorer on page 236 for the list of supported resources.

To view resources in a compartment

Open the navigation menu. Under Governance and Administration, go to Governance and click Tenancy Explorer.

The tenancy explorer opens with a view of the root compartment. Select the compartment you want to explore from the compartment picker on the left side of the Console. After you select a compartment, the resources that you have permission to view are displayed. The Name and Description of the compartment you are viewing are displayed at the top of the page. To also list all resources in the subcompartments of the selected compartment, select Show resources in subcompartments. When viewing resources in all subcompartments, it is helpful to use the Compartment column in the results list to see the compartment hierarchy where the resource resides.

- Verify that there are no policies in the compartment (polices are not included in Search results).

To find policies in a compartment

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
2. From the compartments list on the left, select the compartment you want to delete.

Policies attached to the compartment are displayed.

- If you can't locate any resources in the compartment, check with your Administrator; you might not have permission to view all resources.

Important:

There is a known issue causing deleted compartments to continue to count against your service limit of compartments. See Deleted compartments continue to count against service limits.

Recovering Compartments

To recover a compartment, you must first select it from the list on the Compartment page. You may have to use the state filter to see the deleted compartment. Remember that deleted compartments are renamed by appending a random string of characters to the original compartment name. For example, CompartmentA might become CompartmentA.qR5hP2BD. Oracle displays the deleted compartment on the Compartments page for 365 days.
When you recover a deleted compartment, the name is not changed. For example, if you recover a deleted compartment named CompartmentA.qR5hP2BD, the name remains the same. Because policy statements are updated to use the new names of deleted compartments, any policy statements that had referenced the deleted compartment now reference the recovered compartment.

Adding Tag Defaults for a Compartment

Tag defaults let you specify tags to be applied automatically to all resources, at the time of creation, in the current compartment. For more information, see Managing Tag Defaults on page 3927.

Moving a Compartment to a Different Parent Compartment

You can move a compartment to a different parent compartment within the same tenancy. When you move a compartment, all its contents (subcompartments and resources) are moved with it. Moving a compartment has implications for the contents. These implications are described in the following sections. Ensure that you are aware of these before you move a compartment.

- Required IAM Policy on page 2431
- Restrictions on Moving Compartments on page 2435
- Understanding the Policy Implications When You Move a Compartment on page 2436
- Understanding Compartment Quota Implications When You Move a Compartment on page 2442
- Understanding Tagging Implications When You Move a Compartment on page 2442

Required IAM Policy

To move a compartment, you must belong to a group that has manage all-resources permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

Restrictions on Moving Compartments

- A security zone compartment can only have subcompartments that are also security zone compartments. You can't move a standard compartment that's not in a security zone to a destination compartment that is in a security zone. For more information, see Security Zones.
• You can't move a compartment to a destination compartment with the same name as the compartment being moved.

For example, assume compartment A and compartment B are both under the root compartment. Under compartment A is a subcompartment, also called compartment B. You cannot move the compartment B to the parent compartment B.

You can’t move a compartment under a parent compartment with the same name

• Two compartments within the same parent cannot have the same name. Therefore you can't move a compartment to a destination compartment where a compartment with the same name already exists.

Understanding the Policy Implications When You Move a Compartment

After you move a compartment to a new parent compartment, the access policies of the new parent take effect and the policies of the previous parent no longer apply. Before you move a compartment, ensure that:

• You are aware of the policies that govern access to the compartment in its current position.
• You are aware of the policies in the new parent compartment that will take effect when you move the compartment.
In some cases, when moving nested compartments with policies that specify the hierarchy, the policies are automatically updated to ensure consistency.

**Policy Examples**

**Groups with Permissions in the Current Compartment Lose Access; Groups with Permissions in the Destination Compartment Gain Access**

The following figure shows a compartment hierarchy in which compartment C, a child of A:B is moved to the hierarchy A:D.

![Diagram showing compartment hierarchy]

The tenancy has the following policies defined for compartments B and D:

**Policy1:** Allow group G1 to manage instance-family in compartment A:B

**Policy2:** Allow group G2 to manage instance-family in compartment A:D

Impact when compartment C is moved from B to D:
Group G1 can no longer manage instance-families in compartment C.
Group G2 can now manage instance-families in compartment C.

Ensure that you are aware not only of what groups lose permissions when you move a compartment, but also what groups will gain permissions.

**Automatic Update of Policies**

When you move a compartment, some policies will be automatically updated. Policies that specify the compartment hierarchy down to the compartment being moved will automatically be updated when the policy is attached to a shared ancestor of the current and target parent. Consider the following examples:

**Example 1: Policy automatically updated**

![Diagram showing policy automatically updated](Image)
In this example, you move compartment A from Operations:Test to Operations:Dev. The policy that governs compartment A is attached to the shared parent, Operations. When the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy

Allow group G1 to manage buckets in compartment Test:A

is updated to

Allow group G1 to manage buckets in compartment Dev:A

No manual intervention is required to allow group G1 to continue to access compartment A in its location.

**Example 2: Policy not updated**
In this example, you move compartment A from Operations:Test to Operations:Dev. However, the policy that governs compartment A here is attached directly to the Test compartment. When the compartment is moved, the policy is not automatically updated. The policy that specifies compartment A is no longer valid and must be manually removed. Group G1 no longer has access to compartment A in its new location under Dev. Unless another existing policy grants access to group G1, you must create a new policy to allow G1 to continue to manage buckets in compartment A.

Example 3: Policy attached to the tenancy is updated
In this example, you move compartment A from Operations:Test to HR:Prod. The policy that governs compartment A is attached to the tenancy, which is a shared ancestor by the original parent compartment and the new parent compartment. Therefore, when the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy statement:

| Allow group G1 to manage buckets in compartment Operations:Test:A |

is updated to

| Allow group G1 to manage buckets in compartment HR:Prod:A |

No manual intervention is required to allow group G1 to continue to access compartment A.
Understanding Compartment Quota Implications When You Move a Compartment
