1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click Activate.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click Edit and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time. After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

Task 8: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

Important:

If you want to use a single FastConnect to connect your existing network to multiple DRGs and VCNs, you must set up a different private virtual circuit for each VCN. Each virtual circuit must have a different VLAN and a different set of BGP IP addresses. For more information, see FastConnect with Multiple DRGs and VCNs on page 3689.

Instructions:

1. In the Console, return to the connection you created earlier. Under Resources, click Virtual Circuits.
2. Click Add Virtual Circuit.
3. Enter the following for your virtual circuit:
   - **Name**: A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment**: Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.

4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering (where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 4052.
   - For a private virtual circuit, enter the following:
     - **Dynamic Routing Gateway**: Select the DRG to route the FastConnect traffic to.
     - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4097).
     - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
     - **Customer BGP IP Address**: The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
     - **Oracle BGP IP Address**: The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
     - **Enable IPv6 Address Assignment**: Available only in the US Government Cloud. For more information, see FastConnect and IPv6 on page 3772.
     - **Customer BGP ASN**: The public or private ASN for your network.
     - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

   - For a public virtual circuit, enter the following:
     - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4097).
     - **Public IP Prefixes**: The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
     - **Route Filtering**: Choose a Route Filtering option. This selects the routes included in BGP advertisements to your on-premises network.
     - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
     - **Customer BGP ASN**: The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
     - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click Create.

The virtual circuit is created.

The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

**Task 9: Configure your edge**

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.
For a public virtual circuit: Your existing network can receive advertisements for Oracle’s public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 3818.

If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.
- If the third-party provider is performing any media conversion, LACP must be configured on the provider's device instead of your device.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

**Task 10: Ping the Oracle BGP IP address**

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

**Task 11: Confirm that the BGP session is established**

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

**Task 12: Test the connection**

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance on page 1023. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified at least one of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that only the public prefixes that Oracle has successfully verified so far are advertised on the connection.

**Managing Your Connection**

*To get the status of your connection*

Look at the icon for the particular part of the connection that you're interested in (cross-connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

**Cross-Connect: PENDING CUSTOMER**

- You need to submit the LOA and request cabling at the FastConnect location. See Task 4: Submit LOA and request cabling in the FastConnect location on page 4093.
• Or, you need to activate a cross-connect after confirming it's ready to use. See Task 7: Activate each cross-connect on page 4094, but make sure you've performed tasks 5 and 6 first.

Virtual circuit: DOWN

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:
• You need to configure your edge. See Task 9: Configure your edge on page 4095.
• Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).

The following table summarizes the different states of each component involved in the connection at different points during setup:

<table>
<thead>
<tr>
<th>Task in Setup Process</th>
<th>CCG Icon</th>
<th>CC Icon</th>
<th>VC Icon</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection to view its details.
   c. Click Add Cross-Connect.
   d. Enter the following items:
      • Name: A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.
      • Reference Name: Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.
   e. Click Add.

      The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.
   f. Print the new cross-connect's LOA. You submit it with your cabling order in the next step.
2. Perform tasks 4-7 in Getting Started with FastConnect on page 4091. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:
• The name
• The bandwidth
• Which DRG it uses (for a private virtual circuit)
• Which VLAN it uses
• The BGP session information
• The public IP prefixes (for a public virtual circuit)

Important:

Notes About Editing a Virtual Circuit

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Edit and make your changes. Avoid entering confidential information.
5. Click Save Changes.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

Important:

Also terminate the connection with the data center or third-party provider, or else they may continue to bill you.

To terminate a virtual circuit

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Delete.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the last provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Cross-Connects, and then click the cross-connect to view its details.
4. Click Delete.
5. Confirm when prompted.
The cross-connect's status changes to TERMINATING and then to TERMINATED.

**To terminate a cross-connect group**

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.

The cross-connect group's status changes to TERMINATING and then to TERMINATED.

**To manage public IP prefixes for a public virtual circuit**

For general information about the prefixes, see Basic Network Diagrams on page 4054.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit on page 4094.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 4097. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

**To move a connection to a different compartment**

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see To move a resource to a different compartment on page 3139.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 3542 for more information.

**Monitoring Your Connection**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring your connection, see FastConnect Metrics on page 4108.

**Troubleshooting**

See FastConnect Troubleshooting on page 4112.

**FastConnect Public Peering Advertised Routes**

This topic discusses the public IP address ranges (routes) that are advertised to your on-premises network by way of FastConnect public peering (a public virtual circuit).
When you connect with FastConnect to Oracle Cloud Infrastructure in a particular region, the routes advertised over the public virtual circuit may include routes for other Oracle Cloud Infrastructure regions, and for specific Oracle Cloud Infrastructure Classic regions.

If you do not own a Public ASN or Public IP Address, you may need to review this section: To use FastConnect if you do not own a Public ASN or Public IP Address on page 4060.

Using Route Filtering on page 3821 you can choose to advertise routes at the region, market, or global (all regions in all markets) scope, or only allow connection to Oracle Services Network (OSN). The following tables show which regions are in the same market scope.

Links are also provided to lists below of Oracle Cloud Infrastructure Classic regional routes that can be advertised over the public virtual circuit.

**Downloading the JSON File**

Use this link to download the current list of public IP ranges. This list is formatted in JSON, and provides the most current list of the actual routes advertised by a region, and you can concatenate several regional lists into market lists if needed.

You can poll the published file to check for new IP address ranges as frequently as every 24 hours. We recommend that you poll the published file at least weekly. More information on reading and using this JSON file is at IP Address Ranges on page 222.

**Security considerations for FastConnect public peering**

You should always consider FastConnect public peering as an untrusted interface, and put in place firewalls and other access controls as you would for any network interface connected to the Internet. FastConnect public peering is unusual in that it is a market-level rather than region-level resource in Oracle Cloud Infrastructure.

When your on-premises network is connected to Oracle Cloud Infrastructure using FastConnect public peering without access controls, your on-premises network can potentially receive packets from:

- All VCNs in the same market in your tenancy (or tenancies, if you have more than one) with internet access
- Any VCN resources with internet access operated by other Oracle Cloud Infrastructure customers in the same market
- Oracle Cloud Infrastructure public services such as Object Storage, the Console, or APIs

When your on-premises network is connected to Oracle Cloud Infrastructure using FastConnect public peering without access controls, your on-premises network can not receive packets from:

- Routers used by other Oracle Cloud Infrastructure customers’ on-premises networks that are also connected with FastConnect public peering
- Internet users and resources

**FastConnect Metrics**

You can monitor the health, capacity, and performance of your FastConnect connection by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

This topic describes the metrics emitted by the metric namespace `oci_fastconnect`.

Resources: cross-connect groups, virtual circuits

**Overview of Metrics: oci_fastconnect**

Metrics are available for multiple resources in the FastConnect connection. The metrics help you determine quickly whether your FastConnect connection is up, how much data is flowing over the connection, and whether packets are being dropped for unexpected errors.

FastConnect offers different connectivity models:

• **Connect with an Oracle partner:** Metrics are available for virtual circuits in the connection.
• **Connect with a third-party provider:** Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.

• **Colocate with Oracle:** Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.

A cross-connect group (LAG) contains one or more cross-connects. If there are multiple and one goes down, the cross-connect group stays up, but the group might experience a lower overall bandwidth.

**Required IAM Policy**

To monitor resources, you must be given the required type of access in a *policy* written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_fastconnect**

The metrics listed in the following table are automatically available for each virtual circuit or cross-connect group that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

**COMPONENT**

Possible values are `crossconnectgroup` and `virtualcircuit`. If you *connect through an Oracle partner*, only the `virtualcircuit` component is available.

**RESOURCEID**

The *OCID* of the resource (either a cross-connect group or virtual circuit).

<table>

<td></td>
</tr>
</tbody>
</table>

**Using the Console**

The instructions depend on which FastConnect connectivity model you use.

**If You Use an Oracle Partner**

To view default metric charts for a single FastConnect connection

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Click the connection you're interested in.
3. The default metrics charts for the connection's virtual circuit are displayed on the resulting page.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for all FastConnect connections in a compartment

2. For Compartment, select the compartment that you're interested in.
3. For Metric Namespace, select oci_fastconnect.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

If there are multiple FastConnect connections in the compartment, by default the charts show a separate line for each one (each virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**If You Use a Third-Party Provider or Colocate with Oracle**

In this situation, you manage both the physical connection (cross-connects) and logical connection (virtual circuit).

For the physical connection, metrics are available for the cross-connect group (LAG), but not the individual cross-connects. If you are using only a single cross-connect with no cross-connect group, then no metrics are available for the physical connection.
Networking

For the logical connection, metrics are available for each virtual circuit.

To view default metric charts for a single FastConnect connection
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Click the connection you're interested in.
3. View the metrics for the resource you're interested in:
   • For a cross-connect group: Under Resources, click Metrics. The default metrics charts are displayed on the resulting page.
   • For a virtual circuit:
     a. Under Resources, click Virtual Circuits.
     b. Click the virtual circuit you're interested in. If it's a private virtual circuit, the default metrics charts are displayed on the resulting page. If it's a public virtual circuit, click Metrics to view the charts.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for all FastConnect connections in a compartment
2. For Compartment, select the compartment that you're interested in.
3. For Metric Namespace, select oci_fastconnect.
   The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

By default the charts show a separate line for each resource in the compartment (each cross-connect group and virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:
• Monitoring API for metrics and alarms
• Notifications API for notifications (used with alarms)

FastConnect Troubleshooting

This topic covers troubleshooting techniques for a FastConnect connection that has issues.

Some of the troubleshooting techniques assume that you are a network engineer with access to your CPE's configuration.

Microsoft Azure Connection Issues

Problems terminating the Azure connection

The connection components must be terminated in a specific order. If you don't follow this order, the FastConnect virtual circuit switches to a "Failed" state and cannot be deleted.

To fix a virtual circuit in the "Failed" state, go to the Azure portal and confirm the following items:
• The ExpressRoute circuit is not in the "Failed" state. If it is, click the ExpressRoute circuit's Refresh button. The circuit should return to its normal state.
• The ExpressRoute circuit has no connections. Delete all its connections and then retry terminating the connection.

After you've confirmed the preceding items, you can continue with the termination process in the following steps:
1. In the Oracle Console, delete your FastConnect virtual circuit. Ensure that it is deleted before proceeding.
2. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not Provisioned".

3. In the Azure portal, delete the ExpressRoute circuit.

**General Issues**

*FastConnect is DOWN*

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you're working with an Oracle partner or a third-party provider, contact both the provider and Oracle to help troubleshoot the issue. If you're colocated with Oracle, contact Oracle.</td>
</tr>
</tbody>
</table>

Cross-connect and physical connection (layer 1)

Check these items:

- **Port allocation**: Verify that your connection is using the correct port, and the port is UP and activated.
- **Optical signal**: Verify that your connection is using the correct optics and transceiver, and the port is sending and receiving an optimal signal. For more information, see FastConnect Requirements on page 4061.
- **Fiber strands**: Try rolling or flipping the Tx/Rx fiber strands.
- **End-to-end physical connectivity**: Verify the end-to-end physical connectivity. Also verify the Tx/Rx optic signal between your CPE, the provider's network device (if you're working with a provider), and the Oracle FastConnect router.

Data-link (layer 2)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

- **BGP address**: Verify that the router is configured with the correct BGP peering IP address under the correct VLAN on the interface.
- **MAC address**: Verify that the router is receiving the MAC address from the Oracle FastConnect router, and that the MAC address has an entry in the router's address resolution protocol (ARP) table.
- **LAG and LACP**: Verify that the router has LAG configured and LACP is enabled on the interface (the Oracle FastConnect router requires both). For more information, see FastConnect Requirements on page 4061.

Network and transport (layers 3 and 4)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

- **BGP address**: Verify that the router is configured with the correct BGP peering IP address.
- **ASN**: Verify that the router is configured with the correct BGP local ASN and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180.
- **MD5**: If you're using MD5 authentication, verify that the authentication string (the password) is correct.
- **Maximum prefixes**: Verify that you are advertising less than the maximum allowed number of prefixes for virtual circuits. If you're advertising more prefixes than allowed, BGP establishment fails. Here are the limits:
  - Public virtual circuits: maximum 200 prefixes
  - Private virtual circuits: maximum 2000 prefixes
- **Firewalls**: Verify that your on-premises firewall or access control lists are not blocking TCP port 179 (BGP) or any high-numbered TCP ports.

*FastConnect virtual circuit is UP, but BGP session is DOWN*

The Oracle Console displays an alert if the virtual circuit is in the PROVISIONED state, but the BGP session is DOWN.

Typically, the alert indicates one of the following issues:

- You have not yet configured your CPE with the required information for the FastConnect connection. After you configure the CPE, the alert should no longer appear.
• You have configured your CPE with incorrect information. Verify that your CPE is configured with the correct information.

The CPE configuration information includes these items:

• BGP address for each side of the connection
• ASN for your network and for Oracle's network
• MD5 authentication string (if you're using MD5 authentication)
• Maximum number of allowed prefixes

For more details, see the preceding information shown for network and transport (layers 3 and 4) in FastConnect is DOWN on page 4113.

Exception: The preceding information is not relevant if you're using an Oracle partner, and the BGP session from your CPE goes to that partner and not Oracle. In that case, contact your provider to confirm that the BGP session they have with Oracle is configured correctly.

FastConnect virtual circuit is UP, but no traffic is passing through

Check these items:

• VCN security lists: Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.

• Correct routes on both ends: Verify that you have received the correct VCN routes from FastConnect and the CPE is using those routes. Likewise, verify that you are advertising the correct on-premises network routes to FastConnect and the VCN route tables use those routes.

FastConnect virtual circuit is UP, but traffic is passing in only one direction

Check these items:

• VCN security lists: Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
• Firewalls: Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.
• Asymmetric routing: Oracle uses asymmetric routing. If you have multiple virtual circuits, ensure that your CPE is configured for asymmetric route processing.
• Redundant connections: If you have redundant FastConnect virtual circuits, ensure that they're both advertising the same routes.

Redundant Connections

Remember that FastConnect uses BGP dynamic routing, and IPSec connections can use either static routing or BGP, or a combination.

IPSec and FastConnect are both set up, but traffic is only passing through IPSec

Verify that the route tables use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in Routing for Site-to-Site VPN on page 3810.

Access to the Internet

See these topics for how to give your virtual cloud network (VCN) access to the internet:

• Internet Gateway on page 4114: For public resources that need to be reached from the internet
• NAT Gateway on page 4119: For resources that need to reach the internet but are not reachable from the internet
• Bastion: For resources that require Secure Shell (SSH) access but otherwise are not reachable from the internet

Internet Gateway

This topic describes how to set up and manage an internet gateway to give your VCN internet access.
Tip:
Oracle also offers a NAT gateway, which is recommended for subnets in your VCN that do not require ingress connections from the internet.

Highlights
- An internet gateway is an optional virtual router you can add to your VCN to enable direct connectivity to the internet.
- The gateway supports connections initiated from within the VCN (egress) and connections initiated from the internet (ingress).
- Resources that need to use the gateway for internet access must be in a public subnet and have public IP addresses. Resources that have private IP addresses can instead use a NAT gateway to initiate connections to the internet.
- Each public subnet that needs to use the internet gateway must have a route table rule that specifies the gateway as the target.
- You use security rules to control the types of traffic allowed in and out of resources in that subnet. Make sure to allow only the desired types of internet traffic.
- The internet gateway can be used only by resources in the gateway's VCN. Hosts in the connected on-premises network or in a peered VCN cannot use that internet gateway.
- You can't add or move an internet gateway to a VCN within a security zone. Security zones do not permit public subnets.

Overview of Internet Gateways
Before continuing, make sure you've read Access to the Internet on page 3609 and also understand how to set up security rules for the resources in a subnet.

An internet gateway as an optional virtual router that connects the edge of the VCN with the internet. To use the gateway, the hosts on both ends of the connection must have public IP addresses for routing. Connections that originate in your VCN and are destined for a public IP address (either inside or outside the VCN) go through the internet gateway. Connections that originate outside the VCN and are destined for a public IP address inside the VCN go through the internet gateway.

A given VCN can have only one internet gateway. You control which public subnets in the VCN can use the gateway by configuring the subnet's associated route table. You use security rules to control the types of traffic allowed in and out of resources in those public subnets.

The following diagram illustrates a simple VCN setup with two public subnets. The VCN has an internet gateway, and the two public subnets are both configured to use the VCN's default route table. The table has a route rule that sends all egress traffic from the subnets to the internet gateway. The gateway allows any ingress connections from the internet with a destination IP address equal to the public IP address of a resource in the VCN. However, the public subnet's security list rules ultimately determine the specific types of traffic that are allowed in and out of the resources in the subnet. Those specific security rules are not shown in the diagram.
Networking

Tip:
Traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure (such as Object Storage) is routed without being sent over the internet.

Working with Internet Gateways

You create an internet gateway in the context of a specific VCN. In other words, the internet gateway is automatically attached to a VCN. However, you can disable and re-enable the internet gateway at any time. Compare this with a dynamic routing gateway (DRG), which you create as a standalone object that you then attach to a particular VCN. DRGs use a different model because they're intended to be modular building blocks for privately connecting VCNs to your on-premises network.

For traffic to flow between a subnet and an internet gateway, you must create a route rule accordingly in the subnet's route table (for example, destination CIDR = 0.0.0.0/0 and target = internet gateway). If the internet gateway is disabled, that means no traffic will flow to or from the internet even if there's a route rule that enables that traffic. For more information, see VCN Route Tables on page 3702.

For the purposes of access control, you must specify the compartment where you want the internet gateway to reside. If you're not sure which compartment to use, put the internet gateway in the same compartment as the cloud network. For more information, see Access Control on page 3708.

You may optionally assign a friendly name to the internet gateway. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the internet gateway a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

To delete an internet gateway, it does not have to be disabled, but there must not be a route table that lists it as a target.
Using the Console
To set up an internet gateway

Prerequisites:

- You've determined which subnets in the VCN need access to the internet, and you've created those public subnets.
- You've determined the types of ingress and egress internet traffic that you want to enable for the resources in each public subnet (examples: ingress HTTPS connections, ingress ICMP ping connections).
- The required IAM policy is in place to allow you to work with Networking service resources. For administrators: see IAM Policies for Networking on page 3709.

Important:

If you've configured the public subnet to use the default security list, remember that the list includes several helpful default rules that enable basic required access (examples: ingress SSH, egress access to all destinations). Oracle recommends that you become familiar with the basic access that these default rules provide. If you choose not to use the default security list, make sure to provide this basic access by implementing these security rules either in network security groups (NSGs) or custom security lists.

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

1. For each public subnet that needs to use the internet gateway, set up the subnet's security list rules to allow the desired internet traffic.
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in (a security list associated with the public subnet).
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a new rule, click Add Ingress Rule (or Add Egress Rule).

Example

Imagine you have web servers in the public subnet. This example shows how to add an ingress rule for HTTPS connections (TCP port 443) coming from the internet to the web server. Without this rule, inbound HTTPS connections are not allowed.

1. Leave the Stateless check box unselected.
2. Source Type: CIDR
3. Source CIDR: 0.0.0.0/0
4. IP Protocol: Leave as TCP.
5. Source Port Range: Leave as All.
6. Destination Port Range: Enter 443.
7. Description: An optional description of the rule.
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.
2. Create the VCN's internet gateway:
   a. In the Console, while viewing the VCN you're interested in, click **Internet Gateways**
   b. Click **Create Internet Gateway**.
   c. Enter the following:
      • **Name**: A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • **Create in Compartment**: The compartment where you want to create the internet gateway, if different from the compartment you're currently working in.
      • **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
   d. Click **Create Internet Gateway**.
      Your internet gateway is created and displayed on the **Internet Gateways** page of the compartment you chose. It's already enabled, but you still need to add a route rule that allows traffic to flow to the gateway.

3. For each public subnet that needs to use the internet gateway, update the subnet's route table:
   a. While viewing the VCN's details, click **Route Tables**.
   b. Click the public subnet's route table to view its details.
   c. Click **Add Route Rule**.
   d. Enter the following:
      • **Target Type**: Internet Gateway
      • **Destination CIDR block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule)
      • **Compartment**: The compartment where the internet gateway is located.
      • **Target**: The internet gateway you just created.
      • **Description**: An optional description of the rule.
   e. Click **Save**.

An internet gateway is now enabled and working for your cloud network.

*To disable/enable an internet gateway*

This is available only through the API. If you don't have access to the API and need to disable or enable an internet gateway, contact Oracle Support. You can also easily delete and recreate the internet gateway if needed. Just make sure to update any route tables that refer to the internet gateway.

*To delete an internet gateway*

Prerequisite: The internet gateway does not have to be disabled, but there must not be a route table that lists it as a target.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Internet Gateways**.
4. Click the Actions icon (three dots) for the internet gateway, and then click **Terminate**.
5. Confirm when prompted.

*To manage tags for an internet gateway*

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Internet Gateways**.
4. Click the Actions icon (three dots) for the internet gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.
Networking

For more information, see Resource Tags on page 239.

To move an internet gateway to a different compartment

You can move an internet gateway from one compartment to another. When you move an internet gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Internet Gateways.
4. Click the the Actions icon (three dots) for the internet gateway, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage your internet gateways, use these operations:

- ListInternetGateways
- CreateInternetGateway
- GetInternetGateway
- UpdateInternetGateway
- DeleteInternetGateway
- ChangeInternetGatewayCompartment

NAT Gateway

This topic describes how to set up and manage a Network Address Translation (NAT) gateway. A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

Highlights

- You can add a NAT gateway to your VCN to give instances in a private subnet access to the internet.
- Instances in a private subnet don't have public IP addresses. With the NAT gateway, they can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.
- NAT gateways are highly available and support TCP, UDP, and ICMP ping traffic.

Overview of NAT

NAT is a networking technique commonly used to give an entire private network access to the internet without assigning each host a public IPv4 address. The hosts can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.

When a host in the private network initiates an internet-bound connection, the NAT device's public IP address becomes the source IP address for the outbound traffic. The response traffic from the internet therefore uses that public IP address as the destination IP address. The NAT device then routes the response to the host in the private network that initiated the connection.

Overview of NAT Gateways

The Networking service offers a reliable and highly available NAT solution for your VCN in the form of a NAT gateway.

Example scenario: Imagine you have resources that need to receive inbound traffic from the internet (for example, web servers). You also have private resources that need to be protected from inbound traffic from the internet. All of these resources need to initiate connections to the internet to request software updates from sites on the internet.
You set up a VCN and add a public subnet to hold the web servers. When launching the instances, you assign public IP addresses to them so they can receive inbound internet traffic. You also add a private subnet to hold the private instances. They cannot have public IP addresses because they are in a private subnet.

You add an internet gateway to the VCN. You also add a route rule in the public subnet's route table that directs internet-bound traffic to the internet gateway. The public subnet's instances can now initiate connections to the internet and also receive inbound connections initiated from the internet. Remember that you can use security rules to control the types of traffic that are allowed in and out of the instances at the packet level.

You add a NAT gateway to the VCN. You also add a route rule in the private subnet's route table that directs internet-bound traffic to the NAT gateway. The private subnet's instances can now initiate connections to the internet. The NAT gateway allows responses, but it does not allow connections that are initiated from the internet. Without that NAT gateway, the private instances would instead need to be in the public subnet and have public IP addresses to get their software updates.

The following diagram illustrates the basic network layout for the example. The arrows indicate whether connections can be initiated in only one direction or both.

---

**Note:**

A NAT gateway can be used only by resources in the gateway's own VCN. If the VCN is peered with another, resources in the other VCN cannot access the NAT gateway.

Also, resources in an on-premises network connected to the NAT gateway's VCN with FastConnect or an Site-to-Site VPN cannot use the NAT gateway.

Here are a few basics about NAT gateways:

- The NAT gateway supports TCP, UDP, and ICMP ping traffic.
- The gateway supports a maximum of approximately 20,000 concurrent connections to a single destination address and port.
- The Networking service can either allocate a new public IP address for a new NAT Gateway, or you can specify a specific existing reserved public IP to use for a newly created NAT Gateway.
- There's a limit on the number of NAT gateways per VCN. You can request an increase to that limit. See Service Limits on page 243.
Routing for a NAT Gateway
You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use a NAT gateway. You can have more than one NAT gateway on a VCN (although you must request an increase in your limits). For example, if you want an external application to distinguish traffic from the VCN's different subnets, you could set up a different NAT gateway (and thus a different public IP address) for each subnet. A given subnet can route traffic to only a single NAT gateway.

Blocking Traffic Through a NAT Gateway
You create a NAT gateway in the context of a specific VCN. In other words, the NAT gateway is automatically always attached to only one VCN of your choice. However, you can block or allow traffic through the NAT gateway at any time. By default, the gateway allows traffic upon creation. Blocking the NAT gateway prevents all traffic from flowing, regardless of any existing route rules or security rules in your VCN. For instructions on how to block traffic, see To block/allow traffic for a NAT gateway on page 4123.

Transitioning to a NAT Gateway
If you’re switching from using a NAT instance in your VCN to a NAT gateway, consider that the public IP address for your NAT device will change.

If you’re switching from using an internet gateway to a NAT gateway, the instances with access to the NAT gateway no longer need public IP addresses to reach the internet. Also, the instances no longer need to be in a public subnet. You can’t switch a subnet from public to private. However, you can delete the ephemeral public IPs from your instances if you like.

Deleting a NAT Gateway
To delete a NAT gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. For instructions, see To delete a NAT gateway on page 4123.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Setting Up a NAT Gateway
Task 1: Create the NAT gateway
1. In the Console, confirm you’re viewing the compartment that contains the VCN that you want to add the NAT gateway to. For information about compartments and access control, see Access Control on page 3708.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click the VCN you’re interested in.
5. Click Create NAT Gateway.
6. Enter the following values:

- **Name**: A friendly name for the NAT gateway. It doesn't have to be unique. Avoid entering confidential information.
- **Create in compartment**: The compartment where you want to create the NAT gateway, if different from the compartment you're currently working in.
- **Choose IP Address Type**: Specify whether the public IP address is reserved or ephemeral.
  - **Ephemeral IP Address**: Choose this option to let Oracle specify an ephemeral IP address for you from the Oracle IP pool. This is the default.
  - **Reserved IP Address**: Choose this option to specify an existing reserved IP address by name, or to create a new reserved IP address by assigning a name and selecting a source IP pool for the address. If you don't select a pool you've created, the default Oracle IP pool is used.
- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create NAT Gateway**.

The NAT gateway is then created and displayed on the NAT Gateways page in the compartment you chose. The gateway allows traffic by default. At any time, you can block or allow traffic through it.

**Task 2: Update routing for the subnet**

When you create a NAT gateway, you must also create a route rule that directs the desired traffic from the subnet to the NAT gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the NAT gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following values:
      - **Target Type**: NAT Gateway.
      - **Destination CIDR Block**: 0.0.0.0/0
      - **Compartment**: The compartment where the NAT gateway is located.
      - **Target NAT Gateway**: The NAT gateway.
      - **Description**: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to the NAT gateway. For more information about setting up route rules, see VCN Route Tables on page 3702.

Later, if you no longer need the NAT gateway and want to delete it, you must first delete all the route rules in your VCN that specify the NAT gateway as the target.

**Tip:**

Without the required routing, traffic doesn't flow over the NAT gateway. If a situation occurs where you need to temporarily stop the traffic flow over the gateway, you can simply remove the route rule that enables traffic. Or you can block traffic through the gateway entirely. You do not need to delete it.

**Using the Console**

*To create a NAT gateway*

See the instructions in To create a NAT gateway on page 4122.
To block/allow traffic for a NAT gateway

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. For the NAT gateway you're interested in, click the Actions icon (three dots) and then click **Block Traffic** (or **Allow Traffic** if you're enabling traffic for the NAT gateway).
5. Confirm when prompted.

When the traffic is blocked, the NAT gateway's icon turns gray, and the label changes to BLOCKED. When the traffic is allowed, the NAT gateway's icon turns green, and the label changes to AVAILABLE.

To update a NAT gateway

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. For the NAT gateway you're interested in, click the Actions icon (three dots), and then click **Edit**.
5. Make your changes and click **Save Changes**.

To delete a NAT gateway

Prerequisite: There must not be a route table that lists the NAT gateway as a target.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. For the NAT gateway you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

To manage tags for a NAT gateway

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. Click the Actions icon (three dots) for the NAT gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 239.

To move a NAT gateway to a different compartment

You can move a NAT gateway from one compartment to another. When you move a NAT gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. In **Resources**, click **NAT Gateways**.
4. Find the NAT gateway in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

The NAT gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the NAT gateway.

For more information about using compartments and policies to control access to your cloud network, see **Access Control** on page 3708. For general information about compartments, see **Managing Compartments** on page 3126.

Using the API

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.
To manage your NAT gateways, use these operations:

- ListNatGateways
- CreateNatGateway
- GetNatGateway
- UpdateNatGateway
- DeleteNatGateway
- ChangeNatGatewayCompartment

To manage route tables, see VCN Route Tables on page 3702.

**Access to Your On-Premises Network**

The following topics have information about ways to privately connect your cloud network to your existing on-premises network. Regardless of which method you use, you need a dynamic routing gateway (DRG) attached to your cloud network.

- Dynamic Routing Gateways (DRGs) on page 3793
- Routing Details for Connections to Your On-Premises Network on page 3818

**Private Access**

This topic gives an overview of the options for enabling private access to services within Oracle Cloud Infrastructure. *Private access* means that traffic does not go over the internet. Access can be from hosts within your virtual cloud network (VCN) or your on-premises network.
Tip:
This topic does not discuss access to services through an internet gateway. However, remember that traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure is routed without being sent over the internet.

**Highlights**

- You can enable private access to certain services within Oracle Cloud Infrastructure from your VCN or on-premises network by using either a private endpoint or a service gateway. See the sections that follow.
- For each private access option, these services or resource types are available:
  - **With a private endpoint:**
    - Autonomous Database (shared Exadata infrastructure)
    - Streaming
    - Data Safe
    - Data Catalog
    - Oracle Analytics Cloud
    - Data Flow
  - **With a service gateway:** Available services
- With either private access option, the traffic stays within the Oracle Cloud Infrastructure network and does not traverse the internet. However, if you use a service gateway, requests to the service use a public endpoint for the service.
- If you do not want to access a given Oracle service through a public endpoint, Oracle recommends using a private endpoint in your VCN (assuming the service supports private endpoints). A private endpoint is represented as a private IP address within a subnet in your VCN.

**About Private Endpoints**

A private endpoint is a private IP address within your VCN that you can use to access a given service within Oracle Cloud Infrastructure. The service sets up the private endpoint in a subnet of your choice within the VCN. You can think of the private endpoint as just another VNIC in your VCN. You can control access to it like you would for any other VNIC: by using security rules. However, the service sets up this VNIC and maintains its availability on your behalf. You only need to maintain the subnet and the security rules.

The following diagram illustrates the concept.
The private endpoint gives hosts within your VCN and your on-premises network access to a **single resource** within the Oracle service of interest (for example, one Autonomous Database with shared Exadata infrastructure). Compare that private access model with a service gateway (see the next section): If you created five Autonomous Databases for a given VCN, all five would be accessible through a single service gateway by sending requests to a public endpoint for the service. However, with the private endpoint model, there would be five separate private endpoints: one for each Autonomous Database, and each with its own private IP address.

**Note:**
The service that sets up the private endpoint in your VCN might provide you a DNS name (fully qualified domain name, or FQDN) for the private endpoint, and not the private IP address itself. If you've configured your network setup for DNS, your hosts can access the private endpoint by using the FQDN. If the service supports the use of **network security groups (NSGs)** with its resources, you can request that the service set up the private endpoint in an NSG of your choice within your VCN. NSGs let you write **security rules** to control access to the private endpoint without knowing the private IP address assigned to the private endpoint.

If you have a private endpoint for a resource, hosts within the VCN can use the private endpoint's FQDN or private IP address to access the resource. You set up **security rules** to control access between hosts in the VCN and the private endpoint. For an example of how to do this with Autonomous Data Warehouse, see **Autonomous Database with Private Endpoint** on page 1687.

You can also set up **transit routing with your VCN** so that hosts in the on-premises network can use the private endpoint. To enable on-premises hosts to use the private endpoint's FQDN instead of its private IP address, you have two options:

- Set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see **Hybrid DNS Configuration**.
- Manage hostname resolution yourself manually.

You might have multiple VCNs with hosts that need access to the specific resource of interest. You can **peer the VCNs** so that hosts in the other VCNs can also use the private endpoint (the preceding diagram does not show any peered VCNs).
**About Service Gateways**

A service gateway gives resources in your VCN and on-premises network private access to *multiple* services within Oracle Cloud Infrastructure, without the traffic going over the internet.

The following diagram illustrates the concept. The diagram refers to the *Oracle Services Network*, which is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services.

To use a service gateway from a particular subnet within your VCN, you set up a route rule in the subnet's route table, and specify the service gateway as the target of the rule. You also set up security rules to control access between hosts in the VCN and the services available through the service gateway.

If you have more than one VCN in your tenancy, you can configure each with its own service gateway.

You can also set up transit routing for the *Oracle Services Network* so that hosts in your on-premises network can use a VCN's service gateway.

**Access to Oracle Services: Service Gateway**

This topic describes how to set up and manage a service gateway. A service gateway enables cloud resources without public IP addresses to privately access Oracle services.

**Access to Oracle Services**

The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the internet. However, you can access the Oracle Services Network *without the traffic going over the internet*. There are different ways, depending on which of your hosts need the access:

- **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or Site-to-Site VPN: The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the VCN's service gateway.
  - Public access with FastConnect public peering: The on-premises hosts use public IP addresses.

- **Hosts in your VCN:**
  - Private access through a service gateway: This is the scenario covered in this topic. The VCN's hosts use private IP addresses.

**Highlights**

- A service gateway lets your virtual cloud network (VCN) privately access specific Oracle services without exposing the data to the public internet. No internet gateway or NAT is required to reach those specific services.
The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the internet.

- The service gateway is regional and enables access only to supported Oracle services in the same region as the VCN.
- The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your workloads may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.
- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.
- The service gateway uses the concept of a service CIDR label, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, OCI PHX Object Storage is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service's public IP addresses change in the future, you don't have to adjust those rules.
- You can set up a VCN so that your on-premises network has private access to Oracle services by way of the VCN and the VCN's service gateway. The hosts in your on-premises network communicate with their private IP addresses and the traffic does not go over the internet. For more information, see Private Access to Oracle Services on page 3653

**Overview of Service Gateways**

A service gateway lets resources in your VCN privately access specific Oracle services, without exposing the data to an internet gateway or NAT. The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the service of interest travels over the Oracle network fabric and never traverses the internet.

The following simple diagram illustrates a VCN that has both a public subnet and a private subnet. Resources in the private subnet have only private IP addresses.

The VCN has three gateways:

- **Internet gateway:** To provide the public subnet direct access to public endpoints on the internet. Connections can be initiated from the subnet or from the internet. The resources in the public subnet must have public IP addresses. For more information, see Internet Gateway on page 4114.
- **Service gateway:** To provide the private subnet with private access to supported Oracle services within the region. Connections can be initiated only from the subnet.
- **NAT gateway:** To provide the private subnet with private access to public endpoints on the internet. Connections can be initiated only from the subnet. For more information, see NAT Gateway on page 4119.

You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use each gateway. In the diagram, the route table for the public subnet sends non-local traffic through the internet gateway. The route table for the private subnet sends traffic destined for the Oracle services through the service gateway. It sends all remaining traffic to the NAT gateway.
A service gateway can be used by resources in the gateway's own VCN. However, if the VCN is peered with another, resources in the other VCN cannot access the service gateway unless a service gateway is configured in both VCNs. You could configure traffic destined for Oracle Services Network that originates on a spoke to travel through a network virtual appliance (NVA) in the hub and then through the hub's service gateway. See Using a Private IP as a Route Target on page 3703 and Private Access to Oracle Services on page 3653 for more information.

Resources in your on-premises network that is connected to the service gateway's VCN with FastConnect or Site-to-Site VPN can also use the service gateway. For more information, see Private Access to Oracle Services on page 3653.

Notice that your on-premises network can also use FastConnect public peering for private access to public Oracle services. That means that your on-premises network could have multiple paths to access Oracle services public IP address ranges. If that is the case, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network on page 3818.

A VCN can have only one service gateway. For more information about limits, see Service Limits on page 243.

For instructions on setting up a service gateway, see Setting Up a Service Gateway in the Console on page 4131.

**About Service CIDR Labels**

Each Oracle service has a regional public endpoint that uses public IP addresses for access. When you set up a service gateway with access to an Oracle service, you also set up Networking service route rules and optionally security rules that control traffic with the service. That means you need to know the service's public IP addresses to set up those rules. To make it easier for you, the Networking service uses service CIDR labels to represent all the public CIDRs for a given Oracle service or a group of Oracle services. If a service's CIDRs change in the future, you don't have to adjust your route rules or security rules.

Examples:

- **OCI PHX Object Storage** is a service CIDR label that represents all the Object Storage CIDRs in the US West (Phoenix) region.
• **All PHX Services in Oracle Services Network** is a service CIDR label that represents all the CIDRs for the supported services in the Oracle Services Network in the US West (Phoenix) region. For a list of the services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

As you can see, a service CIDR label can be associated with either a single Oracle service (example: Object Storage), or multiple Oracle services.

The term *service* is often used in this topic in place of the more accurate term *service CIDR label*. The important thing to remember is that when you set up a service gateway (and related route rules), you specify the *service CIDR label* you're interested in. In the Console, you're presented with the available service CIDR labels. If you use the REST API, the ListServices operation returns the available Service objects. The Service object's `cidrBlock` attribute contains the service CIDR label (example: `all-phx-services-in-oracle-services-network`).

### Available Service CIDR Labels

Here are the available service CIDR labels:

- **OCI <region> Object Storage**: For information about the service, see Overview of Object Storage on page 4290
- **All <region> Services in Oracle Services Network**: For a list of supported services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

**Important:**

See this known issue for information about accessing Oracle YUM services through the service gateway.

### Enabling a Service CIDR Label for a Service Gateway

To give your VCN access to a given service CIDR label, you must *enable* that service CIDR label for the VCN's service gateway. You can do that when you create the service gateway, or later after it's created. You can also disable a service CIDR label for the service gateway at any time.

**Important:**

Because Object Storage is covered by both **OCI <region> Object Storage** and **All <region> Services in Oracle Services Network**, a service gateway can use only one of those service CIDR labels. Likewise, a route table can have a single rule for one of the service CIDR labels. It cannot have two separate rules, one for each label.

If the service gateway is configured to use **All <region> Services in Oracle Services Network**, the route rule can use either CIDR label. However, if the service gateway is configured to use **OCI <region> Object Storage** and the route rule uses **All <region> Services in Oracle Services Network**, traffic to services in the Oracle Services Network except Object Storage will be blackholed. The Console prohibits you from configuring the service gateway and corresponding route table in that manner.

If you want to switch the service gateway to use a different service CIDR label, see To switch to a different service CIDR label on page 4134.

### Blocking Traffic Through a Service Gateway

You create a service gateway in the context of a specific VCN. In other words, the service gateway is always attached to that one VCN. However, you can block or allow traffic through the service gateway at any time. By default, the gateway allows traffic flow upon creation. Blocking the service gateway traffic prevents all traffic from flowing, regardless of what service CIDR labels are enabled, or any existing route rules or security rules in your VCN. For instructions on how to block traffic, see To block or allow traffic for a service gateway on page 4135.
Networking

Route Rules and Security Rules for a Service Gateway

For traffic to be routed from a subnet in your VCN to a service gateway, you must add a rule accordingly to the subnet's route table. The rule must use the service gateway as the target. For the destination, you must use the service CIDR label that is enabled for the service gateway. This means that you don't have to know the specific public CIDRs, which could change over time.

Any traffic leaving the subnet and destined for the service's public CIDRs is then routed to the service gateway. If the service gateway traffic is blocked, no traffic flows through it even if there's a route rule that matches the traffic. For instructions on setting up route rules for a service gateway, see Task 2: Update routing for the subnet on page 4132.

The VCN's security rules must also allow the desired traffic. If you like, you can use a service CIDR label instead of a CIDR for the source or destination of the desired traffic. Again, this means that you don't have to know the specific public CIDRs for the service. For convenience, you can use a service CIDR label in security rules even if your VCN doesn't have a service gateway, and the traffic to the services uses an internet gateway.

You can use stateful or stateless security rules that use a service CIDR label:

- **For stateful rules**: Create an egress rule with the destination service = the service CIDR label of interest. As with any security rule, you can specify other items such as the IP protocol and source and destination ports.

- **For stateless rules**: You must have both egress and ingress rules. Create an egress rule with the destination service = the service CIDR label of interest. Also create an ingress rule with the source service = the service CIDR label of interest. As with any security rule, you can specify other items such as the IP protocol and source and destination ports.

For instructions on setting up security rules that use a service CIDR label, see Task 3: (Optional) Update security rules on page 4133.

Object Storage: Allowing Bucket Access from Only a Particular VCN or CIDR Range

If you use a service gateway to access Object Storage, you can write an IAM policy that allows access to a particular Object Storage bucket only if these requirements are met:

- The request goes through a service gateway.
- The request originates from the particular VCN that is specified in the policy.

For examples of this particular type of IAM policy, and important caveats about its use, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access on page 4133.

Alternatively, you can use IAM IP-based filtering to restrict access to an IP address or ranges of addresses. For more information, see Managing Network Sources on page 3123.

Deleting a Service Gateway

To delete a service gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. See To delete a service gateway on page 4135.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Setting Up a Service Gateway in the Console

Following is the process for setting up a service gateway. It assumes that you already have a VCN with a subnet (either private or public).
Networking

Important:
The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your applications may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.

Task 1: Create the service gateway

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the service gateway to. For information about compartments and access control, see Access Control on page 3708.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click the VCN you're interested in.
4. On the left side of the page, click Service Gateways.
5. Click Create Service Gateway.
6. Enter the following values:
   - **Name**: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - **Services**: Optionally select the service CIDR label you're interested in. If you don't select one now, you can later update the service gateway and add a service CIDR label then. Without at least one service CIDR label enabled for the gateway, no traffic flows through it.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose. The gateway allows traffic through it by default. At any time, you can block or allow the traffic through it.

Task 2: Update routing for the subnet

When you configure a service gateway for a particular service CIDR label, you must also create a route rule that specifies that label as the destination and the target as the service gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the service gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   - a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   - b. Click the VCN you're interested in.
   - c. Under Resources, click Route Tables.
   - d. Click the route table you're interested in.
   - e. Click Edit Route Rules.
   - f. Click Add Route Rule and enter the following values:
      - **Target Type**: Service Gateway.
      - **Destination Service**: The service CIDR label that is enabled for the gateway.
      - **Compartment**: The compartment where the service gateway is located.
      - **Target**: The service gateway.
      - **Description**: An optional description of the rule.
   - g. Click Save.

Any subnet traffic with a destination that matches the rule is routed to the service gateway. For more information about setting up route rules, see VCN Route Tables on page 3702.
Later, if you no longer need the service gateway and want to delete it, you must first delete all the route rules in your VCN that specify the service gateway as the target.

**Tip:**
Without the required routing, traffic doesn't flow over the service gateway. If a situation occurs where you want to temporarily stop the traffic flow over the gateway to a particular service, you can simply remove the route rule that enables traffic. You can also disable that particular service CIDR label for the gateway. Or you can **block all traffic through the service gateway** entirely. You do not have to delete the gateway.

**Task 3: (Optional) Update security rules**

When you configure a service gateway to access a service CIDR label, you must also ensure that the security rules are configured to allow the desired traffic. Your security rules might already allow this traffic, which is why this task is optional. The following procedure assumes you are using security lists to implement your security rules. The procedure describes how to set up a rule that uses the service CIDR label. You do this for each subnet that needs to access the gateway.

**Tip:**
Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

1. Determine which subnets in your VCN need to connect to the services you're interested in.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic with the particular service:
   a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
   b. Click the security list you're interested in.
   c. Click **Edit All Rules** and create one or more rules, each for the specific type of traffic you want to allow. See the following example for more details.

**Example**
Let's say you want to add a stateful rule that enables egress HTTPS (TCP port 443) traffic from the subnet to both Object Storage and Oracle YUM repos. Here are the basic steps you take when adding a rule:

1. In the **Allow Rules for Egress** section, click **+Add Rule**.
2. Leave the **Stateless** check box unselected.
3. **Destination Type:** Service.
4. **Destination Service:** The service CIDR label that you're interested in. To access both Object Storage and Oracle YUM repos, it's **All <region> Services in Oracle Services Network**.
5. **IP Protocol:** Leave as TCP.
6. **Source Port Range:** Leave as All.
7. **Destination Port Range:** Enter 443.
8. **Description:** An optional description of the rule.
   d. Click **Save Security List Rules** at the bottom of the dialog box.

For more information about setting up security rules, see **Security Rules** on page 3710.

**Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access**

This task is applicable only if you're using a service gateway to access Object Storage. You can optionally create a network source and write an IAM policy to allow only the resources in a specific VCN to write objects to a particular bucket.
**Important:**

If you use one of the following IAM policies to restrict access to a bucket, the bucket is *not accessible from the Console*. It's accessible only from within the specific VCN.

Also, the IAM policies allow requests to Object Storage only if they go from the specified VCN *through the service gateway*. If they go through the internet gateway, the requests are denied.

- Create a network source to specify the allowed VCN. For information on creating network sources, see [Managing Network Sources](#) on page 3123.
- Create the policy. The following example lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a compartment called ABC.

```
Allow group ObjectBackup to read buckets in compartment ABC
Allow group ObjectBackup to manage objects in compartment ABC where
  all {target.bucket.name='db-backup', request.networkSource.name='<VCN_NETWORK_SOURCE>',
    any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

You can specify multiple VCNs by creating and specifying multiple network sources in the policy. The next example has network sources for two VCNs. You might do this if you've set up your on-premises network with private access to Oracle services through a VCN, and you've also set up one or more other VCNs with their own service gateways. For more information, see [Overview of On-Premises Network Private Access to Oracle Services](#) on page 3654.

```
Allow group ObjectBackup to read buckets in compartment ABC
Allow group ObjectBackup to manage objects in compartment ABC where
  all {target.bucket.name='db-backup',
    request.networkSource.name='<NETWORK_SOURCE_FOR_VCN_1>',
    request.networkSource.name='<NETWORK_SOURCE_FOR_VCN_2>',
    any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

**Managing a Service Gateway in the Console**

*To create a service gateway*

See the instructions in [Task 1: Create the service gateway](#) on page 4132.

*To switch to a different service CIDR label*

To avoid disrupting your Object Storage connections while switching between the OCI `<region>` Object Storage service CIDR label and All `<region>` Services in Oracle Services Network, use the following process:

1. **Update the service gateway**: Remove the existing service CIDR label, and then add the one you want to switch to. You can't enable both labels for the service gateway.
2. **Update relevant route rules**: For each rule that uses the service gateway as the target, switch the rule's destination service from the existing service CIDR label to the one you want to switch to.
3. **Update relevant security rules**: Change any security rules that specify the existing service CIDR label to instead use the one you want to switch to. The rules can be in network security groups or security lists.

If you instead delete your existing service gateway and create a new one, your Object Storage connections will be disrupted. Remember that before you can delete a service gateway, you must delete any route rules that specify that gateway as a target.

*To update a service gateway*

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Edit**.
5. Make your changes and click **Save**.

**To block or allow traffic for a service gateway**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Block Traffic** (or **Allow Traffic** if you're enabling traffic for the service gateway).

When the traffic is blocked, the service gateway's icon turns gray, and the label changes to BLOCKED. When the traffic is allowed, the service gateway's icon turns green, and the label changes to AVAILABLE.

**To associate a route table with an existing service gateway**

You perform this task only if you're implementing an advanced transit routing scenario.

A service gateway can exist without a route table associated with it. However, after you associate a route table with a service gateway, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

**Prerequisite:** The route table must exist and belong to the VCN that the service gateway belongs to.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (**•••**), and then click either:
   - **Associate With Route Table:** If the service gateway has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the service gateway.
5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

**To delete a service gateway**

Prerequisite: The service gateway does not have to block traffic, but there must not be a route table that lists it as a target.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Delete**.
5. Confirm when prompted.

**To manage tags for a service gateway**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. For the service gateway you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 239.

**To move a service gateway to a different compartment**

You can move a service gateway from one compartment to another. When you move a service gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. In **Resources**, click **Service Gateways**.
Networking

4. Find the service gateway in the list, click the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

The service gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the service gateway.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

Managing a Service Gateway with the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Caution: If anyone in your organization implements a service gateway, be aware that you may need to update any client code that works with Networking service route rules and security lists. There are possible breaking API changes. For more information, see the service gateway release notes.

To manage your service gateways, use these operations:

- ListServiceGateways
- CreateServiceGateway
- GetServiceGateway
- UpdateServiceGateway
- DeleteServiceGateway
- ChangeServiceGatewayCompartment
- ListServices: Use this to determine the available service CIDR labels.
- GetService: Gets the details for a particular service CIDR label.
- AttachServiceId: Enables a service CIDR label for a service gateway.
- DetachServiceId: Disables a service CIDR label for a service gateway.

To manage route tables, see VCN Route Tables on page 3702. To manage security lists, see Security Lists on page 3727. To manage network security groups, see Network Security Groups on page 3718. To manage IAM policies, see Managing Policies on page 3144.

Access to Other VCNs: Peering

VCN peering is the process of connecting multiple virtual cloud networks (VCNs). There are four types of VCN peering:

- Local VCN peering (within region) using LPGs
- Remote VCN peering (across regions) using RPCs
- Peering VCNs in the same region through a DRG on page 4162
- Peering VCNs in different regions through a DRG on page 4169

You can use VCN peering to divide your network into multiple VCNs (for example, based on departments or lines of business), with each VCN having direct, private access to the others. There's no need for traffic to flow over the internet or through your on-premises network by way of an Site-to-Site VPN or FastConnect. You can also place shared resources into a single VCN that all the other VCNs can access privately.

Each VCN can have up to 10 local peering gateways and one DRG. A single DRG supports up to 300 VCN attachments. We recommend using the DRG if you need to peer with a large number of VCNs. In addition, if you want extremely high bandwidth and super low-latency traffic between two VCNs in the same region, use the scenario described in Local VCN Peering using Local Peering Gateways on page 4139. Peering VCNs in the same region through a DRG on page 4162 gives you more flexibility in your routing due to the greater number of attachments.
Because remote VCN peering crosses regions, you can use it (for example) to mirror or back up your databases in one region to another.

**Overview of Local VCN Peering**

*Local VCN peering* is the process of connecting two VCNs in the same region so that their resources can communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. The VCNs can be in the same Oracle Cloud Infrastructure *tenancy* or different ones. Without peering, a given VCN would need an *internet gateway* and public IP addresses for the instances that need to communicate with another VCN.

If you want extremely high bandwidth and super low-latency traffic between two VCNs in the same region, use the scenario described in *Local VCN Peering using Local Peering Gateways* on page 4139. *Peering VCNs in the same region through a DRG* on page 4162 gives you more flexibility in your routing, but comes at the cost of higher latency and potentially lower bandwidth.

**Important Implications of Peering**

This section summarizes some access control, security, and performance implications for peered VCNs. In general, you can control access and traffic between two peered VCNs by using IAM policies, route tables in each VCN, and security lists in each VCN.

**Controlling the Establishment of Peerings**

With IAM policies, you can control:

- Who can *subscribe your tenancy to another region* (required for remote VCN peering)
- Who in your organization has the authority to establish VCN peerings (for example, see the IAM policies in *Setting Up a Local Peering* on page 4143 and *Setting Up a Remote Peering* on page 4157). Deletion of these IAM policies does not affect any existing peerings, only the ability for future peerings to be created.
- Who can *manage route tables* and *security lists*

**Controlling Traffic Flow Over the Connection**

Even if a peering connection has been established between your VCN and another, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the other VCN.

Without terminating the peering, you can stop traffic flow to the other VCN by simply removing route rules that direct traffic from your VCN to the other VCN. You can also effectively stop the traffic by removing any security list rules that enable ingress or egress traffic with the other VCN. This doesn't stop traffic flowing over the peering connection, but stops it at the VNIC level.

For more information about the routing and security lists, see the discussions in these sections:

Local VCN peering using local peering groups:

- *Important Local Peering Concepts* on page 4141
- *Task E: Configure the route tables* on page 4149

• Task E: Configure the security rules on page 4177

Controlling the Specific Types of Traffic Allowed

It's important that each VCN administrator ensures all outbound and inbound traffic with the other VCN is intended or expected and well defined. In practice, this means implementing security list rules that explicitly state the types of traffic your VCN can send to the other and accept from the other.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your instances running platform images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:</td>
</tr>
<tr>
<td>• The rules in the network security groups that the instance is in</td>
</tr>
<tr>
<td>• The rules in the security lists associated with the instance's subnet</td>
</tr>
<tr>
<td>• The instance's OS firewall rules</td>
</tr>
</tbody>
</table>

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, Oracle Linux Cloud Developer 8, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```bash
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp

sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding --reload command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

In addition to security lists and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don't apply to your own VCN's CIDR, but inadvertently apply to the other VCN's CIDR.

Using Default Security List Rules

If your VCN's subnets use the default security list with the default rules it comes with, be aware that there are two rules that allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the other VCN):

• Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
• Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Evaluate these rules and whether you want to keep or update them. As stated earlier, ensure that all inbound or outbound traffic that you permit is intended/expected and well-defined.
Preparing for Performance Impact and Security Risks

In general, prepare your VCN for the ways it could be affected by the other VCN. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the other VCN.

Regarding performance: If your VCN is providing a service to another, be prepared to scale up your service to accommodate the demands of the other VCN. This might mean being prepared to launch more instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security list rules to limit the level of connection tracking your VCN must perform. Stateless security list rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: You can't necessarily control whether the other VCN is connected to the internet. If it is, your VCN can be exposed to bounce attacks in which a malicious host on the internet can send traffic to your VCN but make it look like it's coming from the VCN you're peered with. To guard against this, as mentioned earlier, use your security lists to carefully limit the inbound traffic from the other VCN to expected and well-defined traffic.

Local VCN Peering using Local Peering Gateways

This topic is about local VCN peering. In this case, local means that the VCNs reside in the same region. If the VCNs are in different regions, see Remote VCN Peering using an RPC on page 4152.

Local peering gateways are still supported. This scenario assumes you are using a legacy DRG. Oracle currently recommends routing traffic from one VCN to another through an upgraded DRG as described in Peering VCNs in the same region through a DRG on page 4162.

Overview of Local VCN Peering

Local VCN peering is the process of connecting two VCNs in the same region so that their resources can communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. The VCNs can be in the same Oracle Cloud Infrastructure tenancy or different ones. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN.

For more information, see Access to Other VCNs: Peering on page 4136.

Summary of Networking Components for Peering using an LPG

At a high level, the Networking service components required for a local peering include:

- Two VCNs with non-overlapping CIDRs, in the same region
- A local peering gateway (LPG) on each VCN in the peering relationship.
- A connection between those two LPGs.
- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if wanted).
- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.
Networking

Note:
A given VCN can use the peered LPGs to reach these resources:
• VNICs in the other VCN
• An on-premises network attached to the other VCN, if an advanced routing scenario called transit routing has been set up for the VCNs

A VCN can't use its peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could not use it to send traffic to endpoints on the internet. However, VCN-2 could receive traffic from the internet by way of VCN-1. For more information, see Important Implications of VCN Peering on page 4143.

Explicit Agreement Required from Both Sides
Peering involves two VCNs that might be owned by the same party or two different ones. The two parties might both be in your company but in different departments. Or the two parties might be in entirely different companies (for example, in a service-provider model).

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's compartment or tenancy. If the VCNs are in different tenancies, each administrator must provide their tenancy OCID and put in place special policy statements to enable the peering.

Advanced Scenario: Transit Routing
There's an advanced routing scenario called transit routing that enables communication between an on-premises network and multiple VCNs over a single Oracle Cloud Infrastructure FastConnect or Site-to-Site VPN. The VCNs must be in the same region and locally peered in a hub-and-spoke layout. As part of the scenario, the VCN that is acting as the hub has a route table associated with each LPG (typically route tables are associated with a VCN's subnets).

When you create an LPG, you can optionally associate a route table with it. Or if you already have an existing LPG without a route table, you can associate a route table with it. The route table must belong to the LPG's VCN. A route table associated with an LPG can contain only rules that use the VCN's attached DRG as the target.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all rules.
**Important Local Peering Concepts**

The following concepts help you understand the basics of VCN peering and how to establish a local peering.

**PEERING**

A *peering* is a single peering relationship between two VCNs. Example: If VCN-1 peers with three other VCNs, then there are three peerings. The *local* part of *local peering* indicates that the VCNs are in the same region. A given VCN can have a maximum of 10 local peerings at a time.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The two VCNs in the peering relationship must not have overlapping CIDRs. However, if VCN-1 is peered with three other VCNs, those three VCNs can have overlapping CIDRs with each other. You would set up the subnets in VCN-1 to have route rules that direct traffic to the targeted peered VCN.</td>
</tr>
</tbody>
</table>

**VCN ADMINISTRATORS**

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

- Share some basic information with each other.
- Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
- Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies.

For more information about the required policies and VCN configuration, see Setting Up a Local Peering on page 4143.

**ACCEPTOR AND REQUESTOR**

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the *requestor* and the other as the *acceptor*. The requestor must be the one to initiate the request to connect the two LPGs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to LPGs in the acceptor's *compartment*. Without that policy, the requestor's request to connect fails.

**LOCAL PEERING GATEWAY (LPG)**

A *local peering gateway* (LPG) is a component on a VCN for routing traffic to a locally peered VCN. As part of configuring the VCNs, each administrator must create an LPG for their VCN. A given VCN must have a separate LPG for each local peering it establishes (maximum 10 LPGs per VCN). To continue with the previous example: VCN-1 would have three LPGs to peer with three other VCNs. In the API, a `LocalPeeringGateway` is an object that contains information about the peering. You can't reuse an LPG to later establish another peering.

**PEERING CONNECTION**

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to *connect the two LPGs*. The requestor must have information to identify each LPG (such as the LPG's compartment and name, or the LPG's OCID). Each administrator must put the required IAM policies in place for their compartment or tenancy.

Either VCN administrator can terminate a peering by deleting their LPG. In that case, the other LPG's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules or security rules that enable traffic to flow across the connection (see the next sections).
ROUTING TO THE LPG

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. In practice, this looks just like routing you set up for any gateway (such as an internet gateway or dynamic routing gateway). For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your LPG as the target. Your LPG routes traffic that matches that rule to the other LPG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to LPG-1 based on the rule in Subnet A's route table. From there the traffic is routed to LPG-2, and then from there, on to its destination in Subnet X.

Note: As mentioned earlier, a given VCN can use the peered LPGs to reach VNICs in the other VCN, or the on-premises network if transit routing is set up for the VCNs. But a VCN can't use the peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.
SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCNs. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.

Important Implications of VCN Peering

If you haven't yet, read Important Implications of Peering on page 4137 to understand important access control, security, and performance implications for peered VCNs.

Setting Up a Local Peering

Here's the general process for setting up a peering between two VCNs in the same region:

1. **Create the LPGs**: Each VCN administrator creates an LPG for their own VCN.
2. **Share information**: The administrators share the basic required information.
3. **Set up the required IAM policies for the connection**: The administrators set up IAM policies to enable the connection to be established.
4. **Establish the connection**: The requestor connects the two LPGs.
5. **Update route tables**: Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as wanted.
6. **Update security rules**: Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as wanted.

If wanted, the administrators can perform tasks E and F before establishing the connection. In that case, each administrator must know the CIDR block or specific subnets from the other's VCN and share that in task B. After the connection is established, you can also get the CIDR block of the other VCN by viewing your own LPG's details in the Console. Look for **Peer Advertised CIDR**. Or if you're using the API, see the `peerAdvertisedCidr` parameter.

**Task A: Create the LPGs**

Each administrator creates an LPG for their own VCN. "You" in the following procedure means an administrator (either the acceptor or requestor).

### Note:

**Required IAM Policy to Create LPGs**

If the administrators already have broad network administrator permissions (see [Let network admins manage a cloud network](#)), then they have permission to create, update, and delete LPGs. Otherwise, here's an example policy giving the necessary permissions to a group called LPGAdmins. The second statement is required because creating an LPG affects the VCN it belongs to, so the administrator must have permission to manage VCNs.

```plaintext
Allow group LPGAdmins to manage local-peering-gateways in tenancy
Allow group LPGAdmins to manage vcns in tenancy
```

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the LPG to. For information about compartments and access control, see [Access Control](#) on page 3708.
2. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
3. Click the VCN you're interested in.
4. Under **Resources**, click **Local Peering Gateways**.
5. Click **Create Local Peering Gateway**.

6. Enter the following:

   - **Name**: A friendly name for the LPG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the LPG, if different from the compartment you're currently working in.
   - **Associate with Route Table (optional)**: Only if you're setting up the advanced routing scenario called transit routing. Select the compartment that contains the route table you want to associate with the LPG, and the route table itself. You can skip this part and associate the LPG with a route table later if you like.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create Local Peering Gateway**.

   The LPG is then created and displayed on the **Local Peering Gateways** page in the compartment you chose.

**Task B: Share information**

If you're the **requestor**, give this information to the acceptor (for example, by email or other out-of-band method):

- If the VCNs are in the **same tenancy**: Name of the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, the group is RequestorGrp.
- If the VCNs are in **different tenancies**: OCID for your tenancy, and OCID for the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, it's the OCID for the RequestorGrp.
- Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

If you're the **acceptor**, give this information to the requestor:

- If the VCNs are in the **same tenancy**: OCID for your LPG. Optionally, also the names of your VCN, LPG, and the compartment each is in.
- If the VCNs are in **different tenancies**: OCID for your LPG, and OCID for your tenancy.
- Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

**Task C: Set up the IAM policies (VCNs in same tenancy)**

In this version of task C, both VCNs are in the same tenancy. If they're in different tenancies, instead see Task C: Set up the IAM policies (VCNs in different tenancies) on page 4146.

Both the requestor and acceptor must ensure that the right policies are in place:

- **Policy R (implemented by the requestor):**

  ```
  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
  ```

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any LPG in the requestor's compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or to RequestorComp. For information about why you would attach it to one versus the other, see Policy Basics on page 2801.

- **Policy A (implemented by the acceptor):**

  ```
  Allow group RequestorGrp to manage local-peering-to in compartment AcceptorComp
  ```

  ```
  Allow group RequestorGrp to inspect vcnns in compartment AcceptorComp
  ```
Networking

**Allow group RequestorGrp to inspect local-peering-gateways in compartment AcceptorComp**

The first statement in the policy lets the requestor connect to any LPG in the acceptor's compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.

**Tip:**

The second and third statements in Policy A let the requestor list the VCNs and LPGs in AcceptorComp. The statements are required for the requestor to use the Console UI to select from a list of VCNs and LPGs in AcceptorComp and establish the connection. The following diagram focuses only on the first statement, which is the critical one that permits the connection.

Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called local-peering-from, and Policy A has a resource-type called local-peering-to. Together, these policies let someone in RequestorGrp establish the connection from an LPG in the requestor's compartment to an LPG in the acceptor's compartment. The API call to create the connection specifies which two LPGs.

**Tip:**

The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all Networking components in RequesterComp. For example, there might be a general Network Admin policy like this:

**Allow group NetworkAdmin to manage virtual-network-family in compartment RequestorComp**
If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes LPGs). And further, if the policy is instead written to cover the entire tenancy instead of only compartment RequestorComp, then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

**Task C: Set up the IAM policies (VCNs in different tenancies)**

In this version of task C, the VCNs are in different tenancies (in other words, it's a *cross-tenancy* peering). If the VCNs are in the same tenancy, instead see *Task C: Set up the IAM policies (VCNs in same tenancy)* on page 4144.

Both the requestor and acceptor must ensure that the right policies are in place:

- **Policy R (implemented by the requestor):**

  ```
  Define tenancy Acceptor as <acceptor_tenancy_OCID>
  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
  Endorse group RequestorGrp to manage local-peering-to in tenancy Acceptor
  Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp with local-peering-gateways in tenancy Acceptor
  ```

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in that group initiate a connection from any LPG in the requestor's compartment (RequestorComp).

  The first statement is a "define" statement that assigns a friendly label to the acceptor's tenancy OCID. The statement happens to use "Acceptor" as the label, but it could be a value of the requestor's choice. All "define" statements in a policy must be the first ones (at the top).

  The second statement lets the RequestorGrp establish a connection from an LPG in the requestor's compartment.

  The third and fourth statements are special ones required because the LPGs are in different tenancies. They let the RequestorGrp connect an LPG in the requestor's tenancy to an LPG in the acceptor's tenancy.

  If the intent is to give the RequestorGrp permission to connect to an LPG in any tenancy, the policy would instead look like this:

  ```
  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
  Endorse group RequestorGrp to manage local-peering-to in any-tenancy
  Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp with local-peering-gateways in any-tenancy
  ```

  Regardless, Policy R must be attached to the requestor's tenancy (root compartment), and not the requestor's compartment. Policies that enable cross-tenancy access must be attached to the tenancy. For more information about attachment of policies, see *Policy Basics* on page 2801.
• **Policy A (implemented by the acceptor):**

  Define tenancy Requestor as `<requestor_tenancy_OCID>`

  Define group RequestorGrp as `<RequestorGrp_OCID>`

  Admit group RequestorGrp of tenancy Requestor to manage local-peering-to
  in compartment AcceptorComp

  Admit group RequestorGrp of tenancy Requestor to associate local-peering-
  gateways in tenancy Requestor
    with local-peering-gateways in compartment AcceptorComp

Similar to the requestor's policy, this policy first uses "define" statements to assign friendly labels to the
requestor's tenancy OCID and the RequestorGrp OCID. As mentioned earlier, the acceptor could use other values
for those labels if wanted.

The third and fourth statements let the RequestorGrp connect to an LPG in the acceptor's compartment
(AcceptorComp). **These statements reflect the critical agreement required for the peering to be established.**
The word **Admit** indicates that the access applies to a group **outside the tenancy** where the policy resides.

Policy A must be attached to the acceptor's tenancy (root compartment), and not the acceptor's compartment.
Task D: Establish the connection

The requestor must perform this task.

Prerequisite: The requestor must have the OCID of the acceptor's LPG.

Tip:
If you're using the Console and the peering is between two VCNs in the same tenancy: Instead of specifying the acceptor's LPG OCID, you can instead pick the acceptor's VCN and LPG from lists of resources in the tenancy. However, you need to know both the name and compartment for the acceptor's VCN and LPG instead of the LPG's OCID. For reference, see Task B: Share information on page 4144.

1. In the Console, view the details for the requestor LPG that you want to connect to the acceptor LPG.
2. For the requestor LPG, click the Actions icon (three dots), and then click Establish Peering Connection.
3. Specify which LPG you want to peer with:
   - If the VCNs are in different tenancies: Select **Enter Local Peering Gateway OCID**, and enter the acceptor LPG's OCID.
   - If the VCNs are in the same tenancy: Do one of the following:
     - Select **Enter Local Peering Gateway OCID**, and enter the acceptor LPG's OCID.
     - Select **Browse Below**, and then select the acceptor's VCN and LPG from the lists provided. Remember that the VCN and LPG each might be in a different compartment than the one you're currently working in.
4. Click **Establish Peering Connection**.

The connection is established and the LPG's state changes to PEERED.

At this point, the details of each LPG update to show the **Peer VCN CIDR Block** for the other VCN. This is the CIDR of the other VCN across the peering from the LPG. Each administrator can use this information to update the route tables and security rules for their own VCN.

**Task E: Configure the route tables**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. If the connection is already established, look at the **Peer VCN CIDR Block** for your LPG in the Console. Otherwise, get the information from the other administrator by email or other method.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN's CIDR to your LPG:
   - Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   - Click the VCN you're interested in.
   - Under **Resources**, click **Route Tables**.
   - Click the route table you're interested in.
   - Click **Add Route Rule** and enter the following:
     - **Target Type:** Local Peering Gateway.
     - **Destination CIDR Block:** The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
     - **Target Compartment:** The compartment where the LPG is located, if not the current compartment.
     - **Target:** The LPG.
     - **Description:** An optional description of the rule.
   - Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your LPG. For more information about setting up route rules, see **VCN Route Tables** on page 3702.

Later, if you no longer need the peering and want to delete your LPG, you must first delete all the route rules in your VCN that specify the LPG as the target.

**Tip:**

Without the required routing, traffic doesn't flow between the peered LPGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the LPGs.

**Task F: Configure the security rules**

As mentioned earlier, each administrator can do this task before or after the connection is established.
Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in Task E: Configure the route tables on page 4149.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

**Note:**
The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the intended egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a rule, click Add Ingress Rule (or Add Egress Rule).

   **Example**
   Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:
   1. Leave the Stateless check box unselected.
   2. **Source Type:** Leave as CIDR.
   3. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task E: Configure the route tables on page 4149).
   4. **IP Protocol:** Leave as TCP.
   5. **Source Port Range:** Leave as All.
   6. **Destination Port Range:** Enter 443.
   7. **Description:** An optional description of the rule.
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

For more information about security rules, see Security Rules on page 3710.

**Using the Console**

*To create a local peering gateway*

See the instructions in Task A: Create the LPGs on page 4143.

*To associate a route table with an existing local peering gateway*

This task is related to an advanced routing scenario called transit routing.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

**Prerequisite:** The route table must exist and belong to the VCN that the LPG belongs to.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. For the LPG you're interested in, click the Actions icon (three dots), and then click either:
   - **Associate With Route Table**: If the LPG has no route table associated with it yet.
   - **Replace Route Table Association**: If you're changing which route table is associated with the LPG.
5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

**To delete a local peering gateway**

Prerequisite: First delete all the route rules in your VCN that specify the LPG as the target. Deleting those rules stops the routing in your VCN to the LPG. However, the LPG's state may still be PEERED if the other LPG still exists. Whenever an LPG is deleted, the LPG at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Local Peering Gateways**.
4. For the LPG you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

**Note:**

After deleting an LPG (and thus terminating a peering), it's recommended you review your security rules to remove any rules that enabled traffic with the other VCN.

**To manage tags for a local peering gateway**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. Click the Actions icon (three dots) for the local peering gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 239.

**To move a local peering gateway to a different compartment**

You can move a local peering gateway from one compartment to another. When you move a local peering gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. Click the Actions icon (three dots) for the local peering gateway, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see **Access Control** on page 3708. For general information about compartments, see **Managing Compartments** on page 3126.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

To manage your LPGs and create connections, use these operations:

- **ListLocalPeeringGateways**
- **CreateLocalPeeringGateway**
- **GetLocalPeeringGateway**
Remote VCN Peering using an RPC

This topic is about remote VCN peering. In this case, remote means that the VCNs reside in different regions. If the VCNs you want to connect are in the same region, see Local VCN Peering using Local Peering Gateways on page 4139.

This scenario assumes you are using a legacy DRG, but the approach used in Peering VCNs in different regions through a DRG on page 4169 using an upgraded DRG is the current recommendation from Oracle.

Overview of Remote VCN Peering

Remote VCN peering is the process of connecting two VCNs in different regions (but the same tenancy). The peering allows the VCNs' resources to communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN in a different region.

Summary of Networking Components for Remote Peering

At a high level, the Networking service components required for a remote peering include:

- Two VCNs with non-overlapping CIDRs, in different regions that support remote peering.
- A dynamic routing gateway (DRG) attached to each VCN in the peering relationship. Your VCN already has a DRG if you're using a Site-to-Site VPN IPSec tunnel or an Oracle Cloud Infrastructure FastConnect private virtual circuit.
- A remote peering connection (RPC) on each DRG in the peering relationship.
- A connection between those two RPCs.
- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if desired).
- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.
Note:

A given VCN can use the connected RPCs to reach only VNICs in the other VCN or your on-premises network, and not destinations outside of the VCNs such as the internet. For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could NOT use it to send traffic to endpoints on the internet. For more information, see Important Implications of Peering on page 4137.

Spoke-to-Spoke: Remote Peering with Transit Routing

Note:

The scenario this section mentions is still supported, but is deprecated. Oracle recommends you use the DRG Transit routing method described in Using a DRG to route traffic through a centralized network virtual appliance on page 3644.

Imagine that in each region you have multiple VCNs in a hub-and-spoke layout, as shown in the following diagram. This type of layout within a region is discussed in detail in Transit Routing inside a hub VCN on page 3667. The spoke VCNs in a given region are locally peered with the hub VCN in the same region, using local peering gateways.

You can set up remote peering between the two hub VCNs. You can then also set up transit routing for the hub VCN's DRG and LPGs, as discussed in Transit Routing inside a hub VCN on page 3667. This setup allows a spoke VCN in one region to communicate with one or more spoke VCNs in the other region without needing a remote peering connection directly between those VCNs.

For example, you could configure routing so that resources in VCN-1-A could communicate with resources in VCN-2-A and VCN-2-B by way of the hub VCNs. That way, VCN 1-A is not required to have a separate remote peering with each of the spoke VCNs in the other region. You could also set up routing so that VCN-1-B could communicate with the spoke VCNs in region 2, without needing its own remote peerings to them.
Explicit Agreement Required from Both Sides

Peering involves two VCNs in the same tenancy that might be administered by the same party or two different ones. The two parties might both be in your company but in different departments.

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN’s compartment.

Important Remote Peering Concepts

The following concepts help you understand the basics of VCN peering and how to establish a remote peering.

PEERING

A peering is a single peering relationship between two VCNs. Example: If VCN-1 peers with two other VCNs, then there are two peerings. The remote part of remote peering indicates that the VCNs are in different regions. For this method of remote peering, the VCNs must be in the same tenancy.

VCN ADMINISTRATORS

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

• Share some basic information with each other.
• Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
• Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies. The VCNs must be in the same tenancy.

For more information about the required policies and VCN configuration, see Setting Up a Remote Peering on page 4157.
**ACCEPTR AND REQUESTOR**

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the requestor and the other as the acceptor. The requestor must be the one to initiate the request to connect the two RPCs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to RPCs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

**REGION SUBSCRIPTION**

To peer with a VCN in another region, your tenancy must first be subscribed to that region. For information about subscribing, see Managing Regions on page 3140.

**REMOTE PEERING CONNECTION (RPC)**

A remote peering connection (RPC) is a component you create on the DRG attached to your VCN. The RPC's job is to act as a connection point for a remotely peered VCN. As part of configuring the VCNs, each administrator must create an RPC for the DRG on their VCN. A given DRG must have a separate RPC for each remote peering it establishes for the VCN (maximum 10 RPCs per tenancy). To continue with the previous example: the DRG on VCN-1 would have two RPCs to peer with two other VCNs. In the API, a RemotePeeringConnection is an object that contains information about the peering. You can't reuse an RPC to later establish another peering with it.

**CONNECTION BETWEEN TWO RPCS**

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to connect the two RPCs. This means the requestor must have information to identify each RPC (such as the RPC's region and OCID).

Either VCN administrator can terminate a peering by deleting their RPC. In that case, the other RPC's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules that enable traffic to flow across the connection (see the next section).

**ROUTING TO THE DRG**

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your DRG as the target. Your DRG routes traffic that matches that rule to the other DRG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in Subnet A's route table. From there the traffic is routed through the RPCs to DRG-2, and then from there, on to the destination in Subnet X.
Note:
As mentioned earlier, a given VCN can use the connected RPCs to reach only VNICs in the other VCN, and not destinations outside of the VCNs (such as the internet or your on-premises network). For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.

Important Implications of Peering

If you haven’t yet, read Important Implications of Peering on page 4137 to understand important access control, security, and performance implications for peered VCNs.
Setting Up a Remote Peering

This section covers the general process for setting up a peering between two VCNs in different regions.

**Important:**
The following procedure assumes that:

- Your tenancy is subscribed to the other VCN's region. If it's not, see Managing Regions on page 3140.
- You already have a DRG attached to your VCN. If you don't, see Dynamic Routing Gateways (DRGs) on page 3793.

1. **Create the RPCs:** Each VCN administrator creates an RPC for their own VCN's DRG.
2. **Share information:** The administrators share the basic required information.
3. **Set up the required IAM policies for the connection:** The administrators set up IAM policies to enable the connection to be established.
4. **Establish the connection:** The requestor connects the two RPCs (see Important Remote Peering Concepts on page 4154 for the definition of the requestor and acceptor).
5. **Update route tables:** Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as desired.
6. **Update security rules:** Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as desired.

If desired, the administrators can perform tasks E and F before establishing the connection. Each administrator needs to know the CIDR block or specific subnets from the other's VCN and share that in task B.

**Task A: Create the RPCs**

Each administrator creates an RPC for their own VCN's DRG. "You" in the following procedure means an administrator (either the acceptor or requestor).

**Note:**
Required IAM Policy to Create RPCs

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network on page 2807), then they have permission to create, update, and delete RPCs. Otherwise, here's an example policy giving the necessary permissions to a group called RPCAdmins. The second statement is required because creating an RPC affects the DRG it belongs to, so the administrator must have permission to manage DRGs.

```plaintext
Allow group RPCAdmins to manage remote-peering-connections in tenancy
Allow group RPCAdmins to manage drgs in tenancy
```

1. In the Console, confirm you're viewing the compartment that contains the DRG that you want to add the RPC to. For information about compartments and access control, see Access Control on page 3708.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
3. Click the DRG you're interested in.
5. Click Create Remote Peering Connection.
6. Enter the following:
   - **Name**: A friendly name for the RPC. It doesn’t have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the RPC, if different from the compartment you’re currently working in.

7. Click **Create Remote Peering Connection**.
   - The RPC is then created and displayed on the **Remote Peering Connections** page in the compartment you chose.

8. If you’re the acceptor, record the RPC’s region and OCID to later give to the requestor.

**Task B: Share information**

- If you’re the acceptor, give this information to the requestor (for example, by email or other out-of-band method):
  - The region your VCN is in (the requestor’s tenancy must be subscribed to this region).
  - Your RPC’s OCID.
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The requestor needs this information when setting up routing for the requestor VCN.

- If you’re the requestor, give this information to the acceptor:
  - The region your VCN is in (the acceptor’s tenancy must be subscribed to this region).
  - The name of the IAM group that should be granted permission to create a connection in the acceptor’s compartment (in the example in the next task, the group is RequestorGrp).
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The acceptor needs this information when setting up routing for the acceptor VCN.

**Task C: Set up the IAM policies (VCNs in same tenancy)**

Both the requestor and acceptor must ensure the right policies are in place. These consist of:

- **Policy R (implemented by the requestor):**

```
Allow group RequestorGrp to manage remote-peering-from in compartment RequestorComp
```

The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any RPC in the requestor’s compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or to RequestorComp. For information about why you would attach it to one versus the other, see [Policy Basics](#) on page 2801.

- **Policy A (implemented by the acceptor):**

```
Allow group RequestorGrp to manage remote-peering-to in compartment AcceptorComp
```

This policy lets the requestor connect to any RPC in the acceptor’s compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.
Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called remote-peering-from, and Policy A has a resource-type called remote-peering-to. Together, these policies let someone in RequestorGrp establish the connection from an RPC in the requestor's compartment to an RPC in the acceptor's compartment. The API call to actually create the connection specifies which two RPCs.

**Tip:**

The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all of the Networking components in RequesterComp. For example, there might be a general Network Admin policy like this: Allow group NetworkAdmin to manage virtual-network-family in compartment RequestorComp. If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes RPCs). And further, if the policy is instead written to cover the entire tenancy (Allow group NetworkAdmin to manage virtual-network-family in tenancy), then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

**Task D: Establish the connection**

The requestor must perform this task.

Prerequisite: The requestor must have:

- The region the acceptor's VCN is in (the requestor's tenancy must be subscribed to the region).
- The OCID of the acceptor's RPC.

1. In the Console, view the details for the requestor RPC that you want to connect to the acceptor RPC.
2. Click **Establish Connection**.
3. Enter the following:
   - **Region**: The region that contains the acceptor's VCN. The drop-down list includes only those regions that both support remote VCN peering and your tenancy is subscribed to.
   - **Remote Peering Connection OCID**: The OCID of the acceptor's RPC.
4. Click **Establish Connection**.

The connection is established and the RPC's state changes to PEERED.

**Task E: Configure the route tables**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN to your DRG:
   a. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      * **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      * **Destination CIDR Block**: The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
      * **Description**: An optional description of the rule.
   f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see [VCN Route Tables](#) on page 3702.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without the required routing, traffic doesn't flow between the peered DRGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the RPCs.</td>
</tr>
</tbody>
</table>

**Task F: Configure the security rules**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in **Task E: Configure the route tables** on page 4160.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.</td>
</tr>
</tbody>
</table>

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a new rule, click Add Ingress Rule (or Add Egress Rule).
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

For more information about security rules, see Security Rules on page 3710.

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

1. In the Allow Rules for Ingress section, click +Add Rule.
2. Leave the Stateless checkbox unchecked.
3. Source Type: Leave as CIDR.
4. Source CIDR: Enter the same CIDR block that the route rules use (see Task E: Configure the route tables on page 4160).
5. IP Protocol: Leave as TCP.
6. Source Port Range: Leave as All.
7. Destination Port Range: Enter 443.
8. Description: An optional description of the rule.

Using the Console

To create a remote peering connection

See the instructions in Task A: Create the RPCs on page 4157.

To delete a remote peering connection

Deleting an RPC terminates the peering. The RPC at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in.
4. Click the RPC you're interested in.
5. Click Terminate.
6. Confirm when prompted.

Note:

After deleting an RPC (and thus terminating a peering), it's recommended you review your route tables and security rules to remove any rules that enabled traffic with the other VCN.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage your RPCs and create connections, use these operations:

- ListAllowedPeerRegionsForRemotePeering
- ListRemotePeeringConnections
- CreateRemotePeeringConnection
Peering VCNs in the same region through a DRG
This scenario describes using a mutual connection to a DRG to enable traffic between VCNs.

Overview
Instead of using local peering connections, you can establish private network communications between two or more virtual cloud networks (VCNs) in the same region by attaching them to a common dynamic routing gateway (DRG) and making appropriate adjustments to VCN and DRG route tables.

This scenario is only available to an upgraded DRG.

If you want extremely high bandwidth and super low-latency traffic between two VCNs in the same region, use the scenario described in Local VCN Peering using Local Peering Gateways on page 4139. Peering two VCNs in the same region through a DRG gives you more flexibility in your routing, but comes at the cost of higher latency and potentially lower bandwidth.

This sample scenario peers two VCNs. Before you attempt to implement this scenario, be sure that:

- VCN-A is not attached to a DRG
- VCN-B is not attached to a DRG
- VCN-A and VCN-B have non-overlapping CIDRs

Peering VCNs in different tenancies requires more IAM policies for cross-tenancy authorization. See IAM policies related to DRG peering on page 3806 for details on the permissions needed.

Steps
Here's the general process for setting up a peering between two VCNs in the same region using a DRG:

1. Create the DRG: See Task A: Create a DRG on page 4165.
2. Attach VCN A to the DRG: See Task B: Attach VCN-A to the DRG on page 4165.
3. Attach VCN B to the DRG: See Task C: Attach VCN-B to the DRG on page 4166.
4. Configure route tables in VCN A to send traffic destined to VCN B's CIDR to the DRG: See Task D: Configure route tables in VCN-A to send traffic destined to VCN-B's CIDR to the DRG attachment on page 4166.
5. Configure route tables in VCN B to send traffic destined to VCN A's CIDR to the DRG: See Task E: Configure route tables in VCN-B to send traffic destined to VCN-A's CIDR to the DRG attachment on page 4167.
6. Update security rules: Update each VCN's security rules to enable traffic between the peered VCNs as intended. See Task F: Update security rules on page 4168.

This page summarizes some access control, security, and performance implications for peered VCNs. You can control access and traffic between two peered VCNs by using IAM policies, route tables in each VCN, route tables in the DRG, and security lists in each VCN.

Summary of Networking components for peering through a DRG
At a high level, the Networking service components required for a local peering through a DRG include:

- Two VCNs with non-overlapping CIDRs, in the same region
- A single dynamic routing gateway (DRG) attached to each peer VCN.
- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if wanted).
- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.
The following diagram illustrates the components.

![Diagram of VCNs and DRG]

**Note:**
A given VCN can reach these resources:
- VNICs in the other VCN
- An on-premises network attached to the other VCN, if an advanced routing scenario called transit routing has been set up for the VCNs

Two VCNs interconnected with a DRG cannot reach other cloud gateways (such as an internet Gateway or NAT Gateway) except for transit routing via an LPG. For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could not use it to send traffic to endpoints on the internet. However, VCN-2 could receive traffic from the internet by way of VCN-1. For more information, see Important Implications of VCN Peering on page 4143.

**Important Local Peering Concepts**

The following concepts help you understand the basics of VCN peering using a DRG and how to establish a local peering.

**PEERING**

A *peering* is a relationship between two VCNs that both connect to the same DRG and can mutually route traffic. The *local* part of local peering indicates that the VCNs are in the same region. A given DRG can have a maximum of 300 local DRG attachments at a time.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peer VCNs must not have overlapping CIDRs.</td>
</tr>
</tbody>
</table>

**ADMINISTRATORS**

In general, VCN peering can occur only if all involved VCN administrators and DRG administrators agree to it. Depending on the situation, a single administrator might be responsible for all involved DRGs, VCNs, and the related policies.

For more information about the required policies and VCN configuration, see IAM policies related to DRG peering on page 3806.

**ROUTING TO THE DRG**

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. In practice, this looks just like routing you set up for any gateway (such as an internet gateway or dynamic routing gateway). For each subnet that needs to communicate with the other VCN, you
Networking

update the subnet's route table. The route rule specifies the destination traffic's CIDR and your DRG as the target. Your VCN routes traffic that matches that rule to the DRG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) destined for an instance in VCN-2 (192.168.0.15) is routed to the DRG based on the rule in Subnet A's route table. From there the traffic is routed to VCN-2, and then from there, on to its destination in Subnet X.

SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you can write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.

Setting up this scenario in the console
**Task A: Create a DRG**

A DRG created before May 2021 is not able to perform routing between on-premises networks and multiple VCNs, or provide local peering between VCNs. If you require that functionality and you see an Upgrade DRG button, click it.

**Note:**

Clicking the Upgrade DRG button also resets all existing BGP sessions and temporarily interrupt traffic from the on-premises network while the DRG upgrades. Be aware you can't roll back the upgrade.

While working in the same region as the VCNs you want to peer, perform the following steps:

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.
3. Click Create Dynamic Routing Gateway.
4. Enter the following items:
   - **Name:** A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** The compartment where you want to create the DRG, which could be different from the compartment you're currently working in.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create Dynamic Routing Gateway.

The new DRG is created and then displayed on the Dynamic Routing Gateways page of the compartment you chose. The DRG is in the "Provisioning" state for a short period. You can connect it to other parts of your network only after provisioning is complete.

Provisioning includes creating two route tables: one route table for connected VCNs and one for other resources such as virtual circuits and IPSec tunnels. The default route tables can't be deleted, but they can be edited. If left unmodified, the default routing policies in a DRG allow traffic to be routed between all VCNs attached to it.

**Note:**

The default upgraded DRG routing tables implement the same routing behavior as legacy DRGs for backward compatibility.

**Task B: Attach VCN-A to the DRG**

- A DRG can be attached to many VCNs, but VCN can be attached to only one DRG at a time. The attachment is automatically created in the compartment that holds the VCN. A VCN does not need to be in the same compartment or tenancy as the DRG.

You can eliminate local peering connections from your overall network design if you connect several VPNs in the same region to the same DRG and configure the DRG routing tables appropriately.

The following instructions have you navigate to the DRG and then choose which VCN to attach. You could instead navigate to the VCN and then choose which DRG to attach.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to attach to VCN A.
3. Under **Resources**, click **Virtual cloud network attachments**.

4. Click **Create VCN attachment**.
   - (Optional) Give the attachment point a friendly name. If you don't specify a name, one is created for you.
   - Select VCN A from the list. You can also click **Change compartment** and choose a different compartment if VCN is not in the current compartment, then select VCN A from the list.

5. (Optional) If you're setting up an **advanced scenario for transit routing**, you can associate a VCN route table with the DRG attachment (you can do this later):
   - Click **Show Advanced Options**.
   - Click the **VCN route table** tab.
   - Select the route table that you want to associate with the VCN attachment on the DRG. If you select **None**, the default VCN route table is used.

6. Click **Create VCN attachment**.

The attachment is in the "Attaching" state for a short period.

When the attachment is ready, create a route rule that directs subnet traffic to this DRG. See **To route a subnet's traffic to a DRG** on page 3802.

**Task C: Attach VCN-B to the DRG**

```plaintext
Note:

A DRG can be attached to many VCNs, but VCN can be attached to only one DRG at a time. The attachment is automatically created in the compartment that holds the VCN. A VCN does not need to be in the same compartment as the DRG.
```

You can eliminate local peering connections from your overall network design if you connect several VPNs in the same region to the same DRG and configure the DRG routing tables appropriately.

The following instructions have you navigate to the DRG and then choose which VCN to attach. You could instead navigate to the VCN and then choose which DRG to attach.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you want to attach to VCN B.
3. Under **Resources**, click **Virtual cloud network attachments**.
4. Click **Create VCN attachment**.
   - (Optional) Give the attachment point a friendly name. If you don't specify a name, one is created for you.
   - Select VCN B from the list. You can also click **Change compartment** and choose the compartment that contains VCN B, then select VCN B from the list.

5. (Optional) If you're setting up an **advanced scenario for transit routing**, you can associate a VCN route table with the DRG attachment (you can do this later):
   - Click **Show Advanced Options**.
   - Click the **VCN route table** tab.
   - Select the route table that you want to associate with the VCN attachment on the DRG. If you select **None**, the default VCN route table is used.

6. Click **Create VCN attachment**.

The attachment is in the "Attaching" state for a short period.

When the attachment is ready, create a route rule that directs subnet traffic to this DRG. See **To route a subnet's traffic to a DRG** on page 3802.

**Task D: Configure route tables in VCN-A to send traffic destined to VCN-B’s CIDR to the DRG attachment**

As mentioned earlier, each administrator can do this task before or after the VCN is attached to the DRG.
Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN.

For VCN A:

1. Determine which subnets in VCN-A need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN's CIDR to your DRG:
   
   a. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in, VCN-A.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      
      • **Target Type**: Dynamic Routing Gateway.
      • **Destination CIDR Block**: VCN-B's CIDR block. If you want, you can specify a subnet or particular subset of VCN-B's CIDR.
      • **Target Compartment**: The compartment where the other VCN is located, if not the current compartment.
      • **Target**: The DRG.
      • **Description**: An optional description of the rule.
   
   f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see [VCN Route Tables](#) on page 3702.

If in the future you no longer need the peering and want to end the peering relationship, first delete all the route rules in your VCN that specify the other as the target.

---

**Tip:**

Without the required routing, traffic doesn't flow between the peered VCNs. If a situation occurs where you need to temporarily stop the peering relationship, remove the route rules that enable traffic.

---

**Task E: Configure route tables in VCN-B to send traffic destined to VCN-A's CIDR to the DRG attachment**

As mentioned earlier, each administrator can do this task before or after the VCN is attached to the DRG.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN.

For VCN-B:

1. Determine which subnets in VCN B need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN's CIDR to your DRG:
   
   a. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in, VCN-B.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      
      • **Target Type**: Dynamic Routing Gateway.
      • **Destination CIDR Block**: VCN-A's CIDR block. If you want, you can specify a subnet or particular subset of VCN A's CIDR block.
      • **Target Compartment**: The compartment where the other VCN is located, if not in the current compartment.
      • **Target**: The DRG.
      • **Description**: An optional description of the rule.
   
   f. Click **Add Route Rule**.
Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see VCN Route Tables on page 3702.

If later on you no longer need the peering and want to end the peering relationship, delete all the route rules in your VCN that specify the other VCN as the target.

Tip:
Without the required routing, traffic doesn't flow between the peered VCNs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic.

**Task F: Update security rules**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, use the same CIDR block you used in the route table rule in Task E: Configure the route tables on page 4149.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

Note:
The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create the subnet's resources in that NSG.

For each VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the intended egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a rule, click Add Ingress Rule (or Add Egress Rule).

Example
Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

1. Leave the Stateless check box unselected.
2. Source Type: Leave as CIDR.
3. Source CIDR: Enter the same CIDR block that the route rules use (see Task E: Configure the route tables on page 4149).
4. IP Protocol: Leave as TCP.
5. Source Port Range: Leave as All.
6. Destination Port Range: Enter 443.
7. Description: An optional description of the rule.

   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

For more information about security rules, see Security Rules on page 3710.
Peering VCNs in different regions through a DRG

This topic is about remote VCN peering. In this case, remote means that the virtual cloud networks (VCNs) are each attached to a different dynamic routing gateway (DRG) that resides in a different region. If the VCNs you want to connect are in the same region, see Peering VCNs in the same region through a DRG on page 4162.

This scenario is available to an upgraded or legacy DRG, though legacy DRGs will not support connecting DRGs in different tenancies.

Before you attempt to implement this scenario, ensure that:

• VCN A is attached to DRG A in region 1
• VCN B is attached to DRG B in region 2
• Routing configuration in both DRGs is unchanged
• Appropriate IAM permissions are applied for VCNs that are either in the same or different tenancies

Overview of Remote VCN Peering

Remote VCN peering is the process of connecting two VCNs in different regions. The peering allows the VCNs' resources to communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. The VCNs can be in the same Oracle Cloud Infrastructure tenancy or different ones. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN in a different region.

Summary of Networking Components for Remote Peering

At a high level, the Networking service components required for a remote peering include:

• Two VCNs with non-overlapping CIDRs, in different regions.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>No VCN CIDRs can overlap</td>
</tr>
<tr>
<td>The two VCNs in the peering relationship cannot have overlapping CIDRs.</td>
</tr>
<tr>
<td>Also, if a particular VCN has multiple peering relationships, those other VCNs must not have overlapping CIDRs with each other. For example, if VCN-1 is peered with VCN-2 and also VCN-3, then VCN-2 and VCN-3 must not have overlapping CIDRs.</td>
</tr>
<tr>
<td>If you are configuring this scenario, you have to meet this requirement in the planning stage. Routing problems are likely when overlapping CIDRs occur, but you aren't prevented by the Console or API operations from creating a configuration that causes issues.</td>
</tr>
</tbody>
</table>

• A dynamic routing gateway (DRG) attached to each VCN in the peering relationship. Your VCN already has a DRG if you're using a Site-to-Site VPN IPSec tunnel or an Oracle Cloud Infrastructure FastConnect private virtual circuit.
• A remote peering connection (RPC) on each DRG in the peering relationship.
• A connection between those two RPCs.
• Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if wanted).
• Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.
A given VCN can use the connected RPCs to reach only VNICs in the other VCN, or your on-premises network if the DRG has a connection to an on-premises CPE. For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could NOT use it to send traffic to endpoints on the internet. For more information, see Important Implications of Peering on page 4137.

**Important Implications of Peering**

If you haven't yet, read Important Implications of Peering on page 4137 to understand important access control, security, and performance implications for peered VCNs.

Peering VCNs in different tenancies has some permissions complications that need to be resolved in both tenancies. See IAM policies related to DRG peering on page 3806 for details on the permissions needed.

**Spoke-to-Spoke: Remote Peering with Transit Routing (Legacy DRGs Only)**

Imagine that in each region you have multiple VCNs in a hub-and-spoke layout, as shown in the following diagram. This type of layout within a region is discussed in detail in Transit Routing inside a hub VCN on page 3667. The spoke VCNs in a given region are locally peered with the hub VCN in the same region, using local peering gateways.

You can set up remote peering between the two hub VCNs. You can then also set up transit routing for the hub VCN's DRG and LPGs, as discussed in Transit Routing inside a hub VCN on page 3667. This setup allows a spoke VCN in one region to communicate with one or more spoke VCNs in the other region without needing a remote peering connection directly between those VCNs.

For example, you could configure routing so that resources in VCN-1-A could communicate with resources in VCN-2-A and VCN-2-B by way of the hub VCNs. That way, VCN 1-A is not required to have a separate remote peering with each of the spoke VCNs in the other region. You could also set up routing so that VCN-1-B could communicate with the spoke VCNs in region 2, without needing its own remote peerings to them.
Imagine that in each region you have multiple VCNs in a hub-and-spoke layout, as shown in the following diagram. This type of layout within a region is discussed in detail in Transit Routing inside a hub VCN on page 3667. The spoke VCNs in a given region are locally peered with the hub DRG/VCN pair in the same region by mutual connection to the DRG.

You can set up remote peering between the two hub VCNs. You can then also set up transit routing for the hub VCN’s DRG, as discussed in Using a DRG to route traffic through a centralized network virtual appliance on page 3644. This setup allows a spoke VCN in one region to communicate with one or more spoke VCNs in the other region without needing a remote peering connection directly between those VCNs.

For example, you could configure routing so that resources in VCN-1-A could communicate with resources in VCN-2-A and VCN-2-B by way of the hub VCNs. That way, VCN 1-A is not required to have a separate remote peering with each of the spoke VCNs in the other region. You could also set up routing so that VCN-1-B could communicate with the spoke VCNs in region 2, without needing its own remote peerings to them.
Important Remote Peering Concepts

The following concepts help you understand the basics of VCN peering and how to establish a remote peering.

**PEERING**

A peering is a single peering relationship between two VCNs. Example: If VCN-1 peers with two other VCNs, two peerings exist. The remote part of remote peering indicates that the VCNs are in different regions. For this method of remote peering, the VCNs can be in the same tenancy or in different tenancies.

**VCN ADMINISTRATORS**

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, the two administrators must:

- Share some basic information with each other.
- Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
- Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies. The VCNs can be in the same tenancy or in different tenancies.

For more information about the required policies and VCN configuration, see IAM policies related to DRG peering on page 3806.

**ACCEPTOR AND REQUESTOR**

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the requestor and the other as the acceptor. The requestor must be the one to initiate the request to connect the two RPCs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to RPCs in the acceptor’s compartment. Without that policy, the requestor's request to connect fails.
REGION SUBSCRIPTION

To peer with a VCN in another region, your tenancy must first be subscribed to that region. For information about subscribing, see Managing Regions on page 3140.

REMOTE PEERING CONNECTION (RPC)

A remote peering connection (RPC) is a component you create on the DRG attached to your VCN. The RPC’s job is to act as a connection point for a remotely peered VCN. As part of configuring the VCNs, each administrator must create an RPC for the DRG on their VCN. A given DRG must have a separate RPC for each remote peering it establishes for the VCN (maximum 300 RPCs per tenancy). To continue with the previous example: the DRG on VCN-1 would have two RPCs to peer with two other VCNs. In the API, a RemotePeeringConnection is an object that contains information about the peering. You can't reuse an RPC to later establish another peering with it.

CONNECTION BETWEEN TWO RPCS

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to connect the two RPCs. The requestor must have information to identify each RPC (such as the RPC's region and OCID).

Either VCN administrator can terminate a peering by deleting their RPC. In that case, the other RPC’s status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules that enable traffic to flow across the connection (see the next section).

ROUTING TO THE DRG

As part of configuring the VCNs, each administrator must update the VCN’s routing to enable traffic to flow between the VCNs. For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic’s CIDR and your DRG as the target. Your DRG routes traffic that matches that rule to the other DRG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in Subnet A's route table. From there the traffic is routed through the RPCs to DRG-2, and then from there, on to the destination in Subnet X.
Note:
As mentioned earlier, a given VCN can use the connected RPCs to reach only VNICs in the other VCN or your on-premises network, and not destinations on the internet. For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

SECURITY RULES
Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you can write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.

Important Implications of Peering
If you haven't yet, read Important Implications of Peering on page 4137 to understand important access control, security, and performance implications for peered VCNs.
Setting Up a Remote Peering

This section covers the general process for setting up a peering between two VCNs in different regions.

Important:

The following procedure assumes that:

- Your tenancy is subscribed to the other VCN's region. If not, see Managing Regions on page 3140.
- You already have a VCN attached to your DRG. If you don't, see Dynamic Routing Gateways (DRGs) on page 3793.
- You have already set up the required IAM policies for the connection. IAM policies for remote peering in the same tenancy and between tenancies are different. See IAM policies related to DRG peering on page 3806.

Overview of required steps:

1. Create the RPCs: Each VCN administrator creates an RPC for their own VCN's DRG.
2. Share information: The administrators share the basic required information.
3. Establish the connection: The requestor connects the two RPCs (see Important Remote Peering Concepts on page 4154 for the definition of the requestor and acceptor).
4. Update route tables: Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as intended.
5. Update security rules: Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as intended.

If you want, the administrators can perform tasks 4 and 5 before establishing the connection. Each administrator needs to know the CIDR block or specific subnets from the other's VCN and share that in task 2.

Task A: Create the RPCs

Each administrator creates an RPC for their own VCN's DRG. "You" in the following procedure means an administrator (either the acceptor or requestor).

Note:

Required IAM Policy to Create RPCs

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network on page 2807), then they have permission to create, update, and delete RPCs. Otherwise, here's an example policy giving the necessary permissions to a group called RPCAdmins. The second statement is required because creating an RPC affects the DRG it belongs to, so the administrator must have permission to manage DRGs.

```
Allow group RPCAdmins to manage remote-peering-connections in tenancy
Allow group RPCAdmins to manage drgs in tenancy
```

1. In the Console, confirm you're viewing the compartment that contains the DRG that you want to add the RPC to. For information about compartments and access control, see Access Control on page 3708.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
3. Click the DRG you're interested in.
5. Click Create Remote Peering Connection.
6. Enter the following:
   • **Name**: A friendly name for the RPC. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   • **Create in compartment**: The compartment where you want to create the RPC, if different from the compartment you're currently working in.

7. Click **Create Remote Peering Connection**.

   The RPC is then created and displayed on the **Remote Peering Connections** page in the compartment you chose.

8. If you're the acceptor, record the RPC's region and OCID to later give to the requestor.

9. If the two VCNs are in different tenancies, record your tenancy OCID (found on the bottom of the page in the Console). Give the OCID to the other administrator later.

**Task B: Share information**

- If you're the acceptor, give this information to the requestor (for example, by email or other out-of-band method):
  - The region your VCN is in (the requestor's tenancy must be subscribed to this region).
  - Your RPC's OCID.
  - The CIDR blocks for subnets in your VCN you want available to the other VCN. The requestor needs this information when setting up routing for the requestor VCN.
  - If the VCNs are in different tenancies: the OCID for your tenancy.

- If you're the requestor, give this information to the acceptor:
  - The region your VCN is in (the acceptor's tenancy must be subscribed to this region).
  - If the VCNs are in the same tenancy: The name of the IAM group that will be granted permission to create a connection in the acceptor's compartment (in the example in the next task, the group is RequestorGrp).
  - If the VCNs are in different tenancies: the OCID for your tenancy.
  - The CIDR blocks for subnets in your VCN you want available to the other VCN. The acceptor needs this information when setting up routing for the acceptor VCN.

**Task C: Establish the connection**

The requestor must perform this task.

**Prerequisite**: The requestor must have:

- The region the acceptor's VCN is in (the requestor's tenancy must be subscribed to the region).
- The OCID of the acceptor's RPC.
- The OCID of the acceptor's tenancy (only if the acceptor's VCN is in a different tenancy)

1. In the Console, view the details for the requestor RPC that you want to connect to the acceptor RPC.
2. Click **Establish Connection**.
3. Enter the following:
   - **Region**: The region that contains the acceptor's VCN. The list includes only regions that both support remote VCN peering and that your tenancy is subscribed to.
   - **Peer Tenancy OCID (if cross-tenancy peering)**: The OCID of the acceptor's tenancy (only if the acceptor's VCN is in a different tenancy than the requestor's VCN).
   - **Remote Peering Connection OCID**: The OCID of the acceptor's RPC.
4. Click **Establish Connection**.

   The connection is established and the RPC's state changes to PEERED.

**Task D: Configure the route tables**

As mentioned earlier, each administrator can do this task before or after the connection is established.

**Prerequisite**: Each administrator must have the CIDR block or specific subnets for the other VCN.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN to your DRG:
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following:
      • Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • Destination CIDR Block: The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
      • Description: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see VCN Route Tables on page 3702.

Tip:

Without the required routing, traffic doesn't flow between the peered DRGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the RPCs.

Task E: Configure the security rules

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, use the same CIDR block you used in the route table rule in Task E: Configure the route tables on page 4160.

What rules should you add?

• Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
• Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

Note:

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the intended egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a rule, click Add Ingress Rule (or Add Egress Rule).
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

For more information about security rules, see Security Rules on page 3710.
Access to Oracle Cloud Infrastructure Classic

There are two ways to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN):

• **Option 1: Connection over the Oracle network**
  - You file a ticket with My Oracle Support and Oracle provisions a connection between the IP network's private gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over Oracle's network and not the internet.
  - The two environments must be in the same geographical area, and the connection is available only between the specific regions listed in Overview on page 4178.
  - The two environments must belong to the same company. Oracle validates ownership when setting up the connection.

• **Option 2: Connection over Site-to-Site VPN**
  - You set up Site-to-Site VPN between the IP network's VPN as a Service (VPNaaS) gateway and the VCN's attached DRG. The connection runs over the internet.
  - The two environments do not have to be in the same geographical area or regions.
  - The two environments do not have to belong to the same company.

**Connection Over Oracle Network**

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over Oracle’s network.

Another option is to connect the two clouds with Site-to-Site VPN. For more information, see Connection Over Site-to-Site VPN on page 4183.

**Highlights**

• You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
• Oracle connects the IP network's private gateway to the VCN's attached dynamic routing gateway (DRG). The connection runs over the Oracle network. You configure routing and security rules in the environments to enable traffic.
• The two environments must belong to the same company and not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
• The two environments must both be in the Ashburn area, the London area, or the Sydney area, and in specific regions listed in the next section. Connectivity to other regions is not supported.
• The connection is free of charge.

**Overview**

You can request Oracle to provision a connection between your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to Site-to-Site VPN: the resources in the two environments have a more reliable and consistent network connection, with better throughput, because the traffic uses Oracle's internal links. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.
Here are other important details to know:

- The connection is supported only between these regions:
  - Oracle Cloud Infrastructure Australia East (Sydney) region and the Sydney Classic region
  - Oracle Cloud Infrastructure US East (Ashburn) region and the Ashburn Classic region
  - Oracle Cloud Infrastructure UK South (London) region and the Slough Classic region
- The connection enables communication that uses private IP addresses only.
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- The IP network and VCN must belong to the same company. Oracle validates this when setting up the connection.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

<table>
<thead>
<tr>
<th>Component</th>
<th>Oracle Cloud Infrastructure Classic</th>
<th>Oracle Cloud Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud network</td>
<td>IP network</td>
<td>VCN</td>

</tr>
</tbody>
</table>

**Prerequisites:**

You must already have:

- An Oracle Cloud Infrastructure Classic IP network.
- An Oracle Cloud Infrastructure VCN with subnets.

**Task 1: Set up a private gateway for your IP network**

If you do not already have a private gateway for your IP network, create one.
Task 2: Set up a dynamic routing gateway (DRG) for your VCN

If you do not already have a DRG attached to your VCN, create a DRG and attach it:

- Creating a DRG on page 3799
- Attaching a VCN to a DRG on page 3800

Task 3: Configure route tables

For the IP network

When you create the private gateway and attach an IP network to it, traffic from cloud resources in the IP network uses the private gateway as the next hop. You do not need to update any routes for the IP network.

For the VCN

You must add a route rule that directs traffic from the VCN's subnets to the DRG:

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following:
      - Destination CIDR Block: The IP network's CIDR block.
      - Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - Description: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see VCN Route Tables on page 3702.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

Task 4: Configure the security rules

To ensure traffic flows between the IP network and VCN, the IP network security rules and the VCN's security rules must be set to allow traffic.

Here are the types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow traffic.

For the VCN

Note:

The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow egress or ingress traffic specifically with the CIDR block of the IP network:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.

   Under Resources, you can click Ingress Rules or Egress Rules to switch between the different types of rules.
   c. Add one or more rules, each for the specific type of traffic you want to allow.

For more information about setting up security rules, see Security Rules on page 3710.

**Important:**
The VCN's default security list does not allow ICMP echo reply and echo request (ping). You must add rules to enable that traffic. See Rules to Enable Ping on page 3718

Example:
Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

2. Leave the Stateless check box unselected.
3. Source CIDR: Enter the same CIDR block that the route rules use (see Task 3: Configure route tables on page 4181).
4. IP Protocol: Leave as TCP.
5. Source Port Range: Leave as All.
6. Destination Port Range: Enter 443.
7. Description: Optionally enter a description of the rule.
8. Click Add Ingress Rule.

**Task 5: Create a My Oracle Support ticket**
To have Oracle set up the connection, create a ticket at My Oracle Support and provide the following information:

- Ticket name: Create IP Network - VCN Connection - <your_company_name> - Ashburn
- OCI-C identity domain
- OCI-C private gateway name
- Region
- OCI tenancy OCID
- OCI DRG OCID

For example:

- Ticket name: Create IP Network - VCN Connection - ACME - Ashburn
- OCI-C identity domain: 123456789, uscom-east-1
- OCI-C private gateway name: Compute-acme/jack.jones@example.com/privategateway1
- Region: uscom-east-1 (OCI-C) / us-ashburn-1 (OCI)
- OCI tenancy OCID: ocid1.tenancy.oc1..examplefbpnm5cmdh7gk6kgcakfqmvhnvbpcv
- OCI DRG OCID: ocid1.drg.oc1.iad.exampleutg6cmdf3fqwqbea7ctadcatm

It can take three to four business days before your My Oracle Support ticket is complete and the connection is ready to test.

**Task 6: Test the connection**
After you receive confirmation from your support person that the connection is ready, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to launch an instance in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.
Terminating the Connection

If you want to terminate the connection, file a ticket at My Oracle Support.

Connection Over Site-to-Site VPN

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over Site-to-Site VPN.

Another option is to have Oracle set up a connection over the Oracle network. For more information, see Connection Over Oracle Network on page 4178.

Highlights

• You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
• You set up Site-to-Site VPN between the IP network's VPN as a Service (VPNaaS) gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over the internet. You configure routing and security rules in the environments to enable traffic.
• The two environments must not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
• The two environments do not have to be in the same geographical area or region.
• The connection is free of charge.

Overview

You can connect your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment with Site-to-Site VPN. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to using the Oracle network for the connection: you can set up Site-to-Site VPN yourself in a matter of minutes. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.
Here are other important details to know:

- The connection is supported in any of the Oracle Cloud Infrastructure and Oracle Cloud Infrastructure Classic regions. The two environments do not need to be in the same geographical area.
- The connection enables communication that uses private IP addresses only.
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

<table>
<thead>
<tr>
<th>Component</th>
<th>Oracle Cloud Infrastructure Classic</th>
<th>Oracle Cloud Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud network</td>
<td>IP network</td>
<td>VCN</td>
</tr>
<tr>

<tr>
<td>Security rules</td>
<td>security rules</td>
<td>network security groups, security lists</td>
</tr>
</tbody>
</table>
Setting Up Site-to-Site VPN Between Your IP Network and VCN

The following flow chart shows the overall process of connecting your IP network and VCN with Site-to-Site VPN.

Prerequisites:

You must already have:

- An Oracle Cloud Infrastructure Classic IP network.
- An Oracle Cloud Infrastructure VCN with subnets.
Task 1: Set up a VPNaaS gateway for your IP network

1. Use these values when setting up the VPNaaS gateway:

   - **IP Network:** The Oracle Cloud Infrastructure Classic IP network you want to connect to your VCN. You can only specify a single IP network.
   - **Customer Gateway:** A placeholder value such as 129.213.240.51. Using this placeholder value lets you move forward in the process. You update the value later with the Oracle Cloud Infrastructure VPN router’s IP address.
   - **Customer Reachable Routes:** The CIDR block for the VCN. You can specify only a single VCN.
   - **Specify Phase 2 ESP Proposal:** Check box selected.
   - **ESP Encryption:** AES 256
   - **ESP Hash:** SHA1
   - **IPSec Lifetime:** 1800
   - **Require Perfect Forward Secrecy:** Check box selected.

2. Record the resulting public IP address of the VPNaaS gateway.

Task 2: Set up the VCN's components and IPSec tunnel

Task 2a: Set up a dynamic routing gateway (DRG) for your VCN

If you do not already have a DRG attached to your VCN, create a DRG and attach it:

- **Creating a DRG** on page 3799
- **Attaching a VCN to a DRG** on page 3800

Task 2b: Configure routing to the DRG

Add a route rule that directs traffic from the VCN's subnets to the DRG. Use the IP network's CIDR block as the destination for the rule.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:

   a. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      - **Destination CIDR Block:** The IP network's CIDR block.
      - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Description:** An optional description of the rule.
   f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see **VCN Route Tables** on page 3702.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

Task 2c: Configure the security rules

To ensure traffic flows between the IP network and VCN, set the IP network security rules and the VCN's security rules to allow the wanted traffic.

Here are the types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
Networking

- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow the wanted traffic.

For the VCN

```
Note:
The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.
```

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow the wanted egress or ingress traffic specifically with the CIDR block of the IP network:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, you can click Ingress Rules or Egress Rules to switch between the different types of rules.
   d. Add one or more rules, each for the specific type of traffic you want to allow.

For more information about setting up security list rules, see Security Lists on page 3727.

```
Important:
The VCN's default security list does not allow ICMP echo reply and echo request (ping). Add rules to enable that traffic. See Rules to Enable Ping on page 3718
```

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

2. Leave the Stateless check box unselected.
3. Source CIDR: Enter the same CIDR block that the route rules use (see Task 2b: Configure routing to the DRG on page 4186).
4. IP Protocol: Leave as TCP.
5. Source Port Range: Leave as All.
6. Destination Port Range: Enter 443.
7. Click Add Ingress Rule.
8. Description: Optionally enter a description of the rule.

Task 2d: Create a CPE object

Create a CPE object. An IP address is required. Use the VPNaaS gateway's public IP address.

Task 2e: Create the IPSec connection

From your DRG, create an IPSec connection to the CPE object. You must provide one or more static routes. The values must match the IP network's subnets or aggregate.

The resulting IPSec connection consists of two tunnels. Record the IP address and shared secret for one of those tunnels. In the next task, you will provide those values.

Task 3: Update the VPNaaS connection with the tunnel information

Update the VPNaaS connection. Use these values:
• **Customer Gateway:** The tunnel's IP address from the preceding task.
• **Pre-shared Key:** The tunnel's shared secret from the preceding task.

After the IPsec connection is updated and provisioned, the state of your IPSec tunnel should change to Available. Provisioning might take a few minutes.

**Task 4: Test the connection**

After the tunnel state changes to Available, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to launch an instance in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.

**Terminating the Connection**

If you want to terminate the connection, delete the IPSec connection:

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.
   
   A list of the IPSec connections in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the IPSec connection you're interested in.
3. Click **Terminate**.
4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

**Access to Microsoft Azure**

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. This topic describes how to set up virtual networking infrastructure resources to enable this kind of cross-cloud deployment.

**Highlights**

• You can connect a Microsoft Azure virtual network (VNet) with an Oracle Cloud Infrastructure virtual cloud network (VCN) and run a cross-cloud workload. In the typical use case, you deploy your Oracle Database on Oracle Cloud Infrastructure, and deploy an Oracle, .NET, or custom application in Microsoft Azure.
• The two virtual networks must belong to the same company and not have overlapping CIDRs. The connection requires you to create an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit.
Currently, the connection is only available in these areas:

- Between the Oracle Cloud Infrastructure location in the US East (Ashburn) region and the Azure Washington DC and Washington DC2 locations.
- Between the Oracle Cloud Infrastructure location in the UK South (London) region and the Azure London location.
- Between the Oracle Cloud Infrastructure location in the Canada Southeast (Toronto) region and the Azure Canada Central location.
- Between the Oracle Cloud Infrastructure location in the Netherlands Northwest (Amsterdam) region and the Azure Amsterdam2 location.
- Between the Oracle Cloud Infrastructure location in the Japan East (Tokyo) region and the Azure Tokyo location.
- Between the Oracle Cloud Infrastructure location in the US West (San Jose) region and the Azure Silicon Valley location.
- Between the Oracle Cloud Infrastructure location in the Germany Central (Frankfurt) region and the Azure Frankfurt and Frankfurt2 locations.
- Between the Oracle Cloud Infrastructure location in the Brazil Southeast (Vinhedo) region and the Azure Campinas location.

Overview of Supported Traffic

Here are more details about the supported types of traffic.

**VNet-to-VCN Connection: Extension from One Cloud to Another**

You can connect your VNet and VCN so that traffic that uses private IP addresses goes over the cross-cloud connection.

For example, the following diagram shows a VNet that is connected to a VCN. Resources in the VNet are running a .NET application that access an Oracle database that runs on Database service resources in the VCN. The traffic between the application and database uses a logical circuit that runs on the cross-cloud connection between Azure and Oracle Cloud Infrastructure.
To enable the connection between the VNet and VCN, you set up an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit. The connection has built-in redundancy, which means you need to set up only a single ExpressRoute circuit and single FastConnect virtual circuit. The bandwidth for the connection is the bandwidth value you choose for the ExpressRoute circuit.

For instructions, see Setting Up a VNet-to-VCN Connection on page 4192.

**Peered VCNs**

The connection enables traffic to flow from the VNet through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

**Types of Traffic Not Supported by the Connection**

This cross-cloud connection does not enable traffic between your on-premises network through the VCN to the VNet, or from your on-premises network through the VNet to the VCN.

**Important Implications of Connecting Clouds**

This section summarizes some access control, security, and performance implications of connecting your VCN to a VNet. In general, you can control access and traffic by using IAM policies, route tables in the VCN, and security rules in the VCN.
The sections that follow discuss implications from the perspective of your VCN. Similar implications affect your VNet. As with your VCN, you can use Azure resources such as route tables and network security groups to secure your VNet.

**Controlling the Establishment of a Connection**

With Oracle Cloud Infrastructure IAM policies, you can control:

- Who in your organization has the authority to create a FastConnect virtual circuit (see Setting Up a VNet-to-VCN Connection on page 4192). Deletion of the relevant IAM policy does not affect any existing connections to a VNet, only the ability for a future connection to be created.
- Who can manage route tables, network security groups, and security lists.

**Controlling Traffic Flow Over the Connection**

Even if a connection has been established between your VCN and VNet, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the VNet.

Without terminating the connection, you can stop traffic flow to the VNet by simply removing route rules that direct traffic from your VCN to the VNet. You can also effectively stop the traffic by removing any security rules that enable ingress or egress traffic with the VNet. This doesn't stop traffic flowing over the connection, but stops it at the VNIC level.

**Controlling the Specific Types of Traffic Allowed**

It's important that you ensure that all outbound and inbound traffic with the VNet is intended or expected and well defined. Implement Azure network security group and Oracle security rules that explicitly state the types of traffic one cloud can send to the other and accept from the other.

---

**Important:**

Your Oracle Cloud Infrastructure instances running Linux or Windows platform images also have firewall rules that control access to the instance. When troubleshooting access to an instance, ensure that the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, Oracle Linux 7, or Oracle Linux Cloud Developer 8, you need to use `firewalld` to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

---

In addition to security rules and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don't apply to your own VCN's CIDR, but inadvertently apply to the VNet's CIDR.
**Using Default Security List Rules with Your VCN**

If your VCN's subnets use the default security list with the default rules, two rules in that list allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the VNet):

- Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
- Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Evaluate these rules and whether you want to keep or update them. As stated earlier, you should ensure that all permitted inbound or outbound traffic is intended or expected and well defined.

**Preparing for Performance Impact and Security Risks**

In general, you should prepare your VCN for the ways it could be affected by the VNet. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the VNet.

Regarding performance: If your VCN is providing a service to the VNet, be prepared to scale up your service to accommodate the demands of the VNet. This might mean being prepared to launch more instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security rules to limit the level of connection tracking your VCN must perform. Stateless security rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: If the VNet is connected to the internet, your VCN can be exposed to bounce attacks. A bounce attack involves a malicious host on the internet sending traffic to your VCN that looks like it's coming from the VNet. To guard against this, as mentioned earlier, use your security rules to carefully limit the inbound traffic from the VNet to expected and well-defined traffic.

**Setting Up a VNet-to-VCN Connection**

This section describes how to set up the logical connection between a VNet and VCN (for background, see Overview of Supported Traffic on page 4189).

**Prerequisites: Resources You Need**

You must already have:

- An Azure VNet with subnets and virtual network gateway
- An Oracle Cloud Infrastructure VCN with subnets and an attached dynamic routing gateway (DRG). It's easy to forget to attach the DRG to your VCN after you create it. If you already have Site-to-Site VPN or FastConnect between your on-premises network and VCN, then your VCN already has an attached DRG. You use that same DRG here when setting up the connection to Azure.

As a reminder, here is a table that lists the comparable networking components involved in each side of the connection.

<table>
<thead>
<tr>
<th>Component</th>
<th>Azure</th>
<th>Oracle Cloud Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual network</td>
<td>VNet</td>
<td>VCN</td>
</tr>
<tr>
<td>Virtual circuit</td>
<td>ExpressRoute circuit</td>
<td>FastConnect private virtual circuit</td>
</tr>
<tr>
<td>Gateway</td>
<td>virtual network gateway</td>
<td>dynamic routing gateway (DRG)</td>
</tr>
<tr>
<td>Routing</td>
<td>route tables</td>
<td>route tables</td>
</tr>
<tr>
<td>Security rules</td>
<td>network security groups (NSGs)</td>
<td>network security groups (NSGs), security lists</td>
</tr>
</tbody>
</table>
Prerequisites: BGP Information You Need

The connection between the VNet and VCN uses BGP dynamic routing. When you set up the Oracle virtual circuit, you provide the BGP IP addresses that will be used for the two redundant BGP sessions between Oracle and Azure:

- A primary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)
- A separate, secondary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)

For each pair, you must provide a separate /30 block of addresses (each /30 has four IP addresses).

The second and third addresses in each /30 are used for the BGP IP address pair. Specifically:

- The second address in the block is for the Oracle side of the BGP session
- The third address in the block is for the Azure side of the BGP session

The first and last addresses in the block are used for other internal purposes.

For example, if the /30 is 10.0.0.20/30, then the addresses in the block are:

- 10.0.0.20
- 10.0.0.21: Use this for the Oracle side (in the Oracle Console, enter the address as 10.0.0.21/30)
- 10.0.0.22: Use this for the Azure side (in the Oracle Console, enter the address as 10.0.0.22/30, and notice that this address is referred to as the "Customer" side in the Console)
- 10.0.0.23

Remember that you must also provide a /30 block for the secondary BGP addresses. For example: 10.0.0.24/30. In this case, 10.0.0.25 is for the Oracle side, and 10.0.0.26 is for the Azure side. In the Oracle Console, you must enter these as 10.0.0.25/30 and 10.0.0.26/30.

Prerequisites: Required IAM Policy

It's assumed that you have the necessary Azure Active Directory access and Oracle Cloud Infrastructure IAM access to create and work with the relevant Azure and Oracle networking resources. Specifically for IAM: If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this one generally covers all the Networking resources:

Allow group NetworkAdmins to manage virtual-network-family in tenancy

To only create and manage a virtual circuit, you must have a policy like this:

Allow group VirtualCircuitAdmins to manage drgs in tenancy
Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy

For more information, see IAM Policies for Networking on page 3709.
**Overall Process**

The following flow chart shows the overall process of connecting your VNet and VCN.

![Flow chart showing the overall process of connecting VNet and VCN]

**Task 1: Configure the network security groups and security rules**

The first task is to determine what traffic needs to flow between the relevant subnets within the VNet and VCN, and then configure the VNet security groups and VCN security rules accordingly. Here are the general types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's relevant subnets.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the traffic to the VNet. The VCN's default security list includes a broad default egress rule like this.

More specifically, here are recommended types of traffic to allow between the VNet and VCN:

- **Ping traffic** in both directions for testing the connection from each side
- SSH (TCP port 22)
- Client connections to an Oracle database (SQL*NET on TCP port 1521)

Only allow traffic to and from specific address ranges of interest (for example, the other cloud's relevant subnets).
For the VNet: Determine which subnets in your VNet need to communicate with the VCN. Then configure the network security groups for those subnets to allow traffic.

For the VCN:

Note:
The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's relevant resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the security list for each of those subnets to include rules to allow egress or ingress traffic specifically with the VNet's CIDR block or a subnet of the VNet:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Click Edit All Rules and create one or more rules, each for the specific type of traffic you want to allow.
   d. Click Save Security List Rules at the bottom of the dialog box.

For more information about setting up security rules, see Security Rules on page 3710.

Example: Outgoing ping from VCN to VNet

The following egress security rule lets an instance initiate a ping request to a host outside the VCN (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate ingress rule for echo reply ICMP type 0 is required.

1. In the Allow Rules for Egress section, click +Add Rule.
2. Leave the Stateless check box unselected.
3. Destination CIDR: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. IP Protocol: ICMP
5. Type and Code: 8
6. Description: An optional description of the rule.

Example: Incoming ping to VCN from VNet

The following ingress security rule lets an instance receive a ping request from a host in the VNet (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate egress rule for echo reply ICMP type 0 is required.

1. In the Allow Rules for Ingress section, click +Add Rule.
2. Leave the Stateless check box unselected.
3. Source CIDR: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. IP Protocol: ICMP
5. Type and Code: 8
6. Description: An optional description of the rule.

Example: Incoming SSH to VCN

The following ingress security rule lets an instance receive an SSH connection (TCP port 22) from a host in the VNet.

1. In the Allow Rules for Ingress section, click +Add Rule.
2. Leave the Stateless check box unselected.
3. Source CIDR: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. IP Protocol: TCP
5. Source Port Range: All
6. Destination Port Range: 22
7. Description: An optional description of the rule.
Example: SQL*Net connections to database

The following ingress security rule allows SQL*Net connections (TCP port 1521) from hosts in the VNet.

1. In the Allow Rules for Ingress section, click +Add Rule.
2. Leave the Stateless check box unselected.
3. Source CIDR: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. IP Protocol: TCP
5. Source Port Range: All
6. Destination Port Range: 1521
7. Description: An optional description of the rule.

Task 2: Set up Azure ExpressRoute circuit

Set up an ExpressRoute circuit to Oracle Cloud Infrastructure FastConnect. During the circuit setup, you receive a service key from Microsoft. Record that service key, because you must provide it to Oracle in the next task.

In the next task, you set up a FastConnect private virtual circuit to Microsoft Azure: ExpressRoute. When that virtual circuit finishes being provisioned, your ExpressRoute circuit updates to show that private peering is enabled.

Task 3: Set up an Oracle Cloud Infrastructure FastConnect virtual circuit

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to. This choice of compartment, along with a corresponding IAM policy, controls who can access the virtual circuit you're about to create.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect. The resulting FastConnect page is where you create a new virtual circuit and later return to when you need to manage the virtual circuit.
3. Click Create Connection.
4. Select FastConnect partner and choose Microsoft Azure: ExpressRoute from the list.
5. Enter the following for your virtual circuit:
   - Name: A friendly name of your choice. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - Create in Compartment: Leave as is (the compartment you're currently working in).
   - Virtual Circuit Type: Select Private Virtual Circuit.
   - Dynamic Routing Gateway Compartment: Select the compartment where the DRG resides (it should already be selected).
   - Dynamic Routing Gateway: Select the DRG.
   - Provisioned Bandwidth: Choose the same bandwidth level you chose for the ExpressRoute circuit (or the closest value available).
   - Partner Service Key: Enter the service key you received from Microsoft when you set up the ExpressRoute circuit.
   - Customer Primary BGP IP Address: This field is the Azure primary BGP IP address. Enter the third address in the primary /30 block that you provide, and include /30 at the end. For example: 10.0.0.22/30. For more information about this field and the next ones, see Setting Up a VNet-to-VCN Connection on page 4192.
   - Oracle Primary BGP IP address (optional): You can leave this field blank and Oracle infers the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.21/30.
   - Customer Secondary BGP IP Address: This field is the Azure secondary BGP IP address. Enter the third address in the secondary /30 block that you provide, and include /30 at the end. For example: 10.0.0.26/30.
   - Oracle Primary BGP IP Address (optional): You can leave this field blank and Oracle infers the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.25/30.
6. Click Continue.
   The virtual circuit is created.
7. Click Close.

After you create the Oracle virtual circuit, you do not need to contact Azure to request provisioning of the circuit. It happens automatically.

**Task 4: Confirm that both circuits are provisioned**

Within a few minutes, both circuits should be provisioned. To verify:

- For the ExpressRoute circuit, confirm that private peering is provisioned.
- For the FastConnect virtual circuit, confirm that its status is UP. See To get the status of your FastConnect virtual circuit on page 4197.

**Task 5: Configure the route tables**

**For the VNet:** Determine which subnets in your VNet need to communicate with the VCN. Then configure the route tables for those subnets to route traffic to the VNet gateway.

**For the VCN:**

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the VNet's CIDR to your DRG:
   a. In the Console, while viewing the VCN you're interested in, click Route Tables.
   b. Click the route table you're interested in.
   c. Click Edit Route Rules.
   d. Click + Another Route Rule and enter the following:
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram).
      - **Description**: An optional description of the rule.
   e. Click Save.

Any subnet traffic with a destination that matches the rule is routed to your DRG. The DRG then knows to route the traffic to the VNet based on the virtual circuit's BGP session information.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

For more information about setting up route rules, see VCN Route Tables on page 3702.

**Task 6: Test the connection**

Depending on how you've set up your VNet security groups and VCN security rules, you should be able to create an instance in your VCN and access it from a host in the VNet. Or you should be able to connect from the instance to a host in the VNet. If you can, your connection is ready to use.

**Important:**

If you decide to terminate the connection, you must follow a particular process. See To terminate the connection to Azure on page 4199.

**Managing a VNet-to-VCN Connection**

**To get the status of your FastConnect virtual circuit**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection you're interested in. If the icon for the virtual circuit is green and says UP, the virtual circuit is provisioned and BGP has been correctly configured. The virtual circuit is ready to use.
To edit a FastConnect virtual circuit

You can change these items for your virtual circuit:

- The name
- Which DRG it uses

**Caution:**

If your virtual circuit is in the PROVISIONED state, changing which DRG it uses switches the state to PROVISIONING and may cause the connection to go down. After Oracle reprovisions the virtual circuit, its state returns to PROVISIONED. Confirm that the connection is back up and working.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection.
3. Click the virtual circuit.
4. Click **Edit** and make your changes. Avoid entering confidential information.
5. Click **Save**.
To terminate the connection to Azure

The following flow chart shows the overall process of terminating a VNet-to-VCN connection.

1. In the Azure portal, view the ExpressRoute circuit, and then view its Connections. Confirm that there are no Connections still in existence for the ExpressRoute circuit. Delete all Connections before proceeding.
2. In the Oracle portal, delete your FastConnect virtual circuit:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection.
   c. Click the virtual circuit.
   d. Click Delete.
   e. Confirm when prompted.

   The virtual circuit's Lifecycle State switches to TERMINATING.
3. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not Provisioned".
4. In the Azure portal, delete the ExpressRoute circuit.

The connection between Azure and Oracle Cloud Infrastructure is terminated.
Access to Other Clouds with Libreswan

Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. This topic shows how to connect your Oracle Cloud Infrastructure virtual cloud network (VCN) with another cloud provider by using Site-to-Site VPN with a Libreswan VM as the customer-premises equipment (CPE).

In the example shown here, the other cloud provider is Amazon Web Services (AWS). Site-to-Site VPN provides a secure and encrypted site-to-site IPSec connection between the Oracle and Amazon environments. It enables resources in the two clouds to communicate with each other using their private IP addresses as if they are in the same network segment.

A Libreswan CPE guide is also available for all other use cases.

Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

Architecture

The following diagram shows the general layout of the connection.

![Diagram showing connection between third-party cloud and Oracle Cloud Infrastructure]

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

Configuration

Important:
The configuration instructions in this section are provided by Oracle Cloud Infrastructure for Libreswan. If you need support or further assistance, consult the Libreswan documentation.

Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

Refer to Supported IPSec Parameters on page 4200 for more details about the specific parameters used in this document.
Default Libreswan Configuration Files

The default Libreswan installation creates the following files:

- **`etc/ipsec.conf`**: The root of the Libreswan configuration.
- **`/etc/ipsec.secrets`**: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- **`/etc/ipsec.d/`**: A directory for storing the `.conf` and `.secrets` files for your Oracle Cloud Infrastructure tunnels (for example: `oci-ipsec.conf` and `oci-ipsec.secrets`). Libreswan encourages you to create these files in this folder.

The default `etc/ipsec.conf` file includes this line:

```
include /etc/ipsec.d/*.*.conf
```

The default `etc/ipsec.secrets` file includes this line:

```
include /etc/ipsec.d/*.*.secrets
```

The preceding lines automatically merge all the `.conf` and `.secrets` files in the `/etc/ipsec.d` directory into the main configuration and secrets files that Libreswan uses.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

You specify the IKE version when setting up the IPSec configuration file in task 4 in the next section. In that example file, there’s a comment showing how to configure IKEv1 versus IKEv2.

Configuration Process

**Task 1: Prepare the AWS Libreswan instance**

1. Using the AWS Console or APIs, create a Libreswan VM by using its provisioning process. Use Oracle Linux, CentOS, or Red Hat as the main operating system.
2. After the new instance starts, connect to it with SSH and install the Libreswan package:

```
sudo yum -y install libreswan
```

3. In the AWS Console, disable the source and destination checks on the Libreswan VM instance by right-clicking the instance, clicking Networking, and then clicking Change Source/Dest. Check. When prompted, click Yes, Disable.
4. On the Libreswan VM, configure IP_forward to allow AWS clients to send and receive traffic through the Libreswan VM. In the `/etc/sysctl.conf` file, set the following values and apply the updates with `sudo sysctl -p`.

```
net.ipv4.ip_forward=1
net.ipv4.conf.all.accept_redirects = 0
net.ipv4.conf.all.send_redirects = 0
net.ipv4.conf.default.send_redirects = 0
net.ipv4.conf.eth0.send_redirects = 0
net.ipv4.conf.default.accept_redirects = 0
net.ipv4.conf.eth0.accept_redirects = 0
```

5. In the AWS Console, edit your AWS route table. Add a rule with the VCN CIDR (172.0.0.0/16) as the destination and the AWS Libreswan instance ID (i-016ab864b43cb368e in this example) as the target.

6. In the AWS Console, enable inbound TCP and UDP traffic on ports 4500 and 500 to allow an Oracle Cloud Infrastructure Site-to-Site VPN IPSec connection with the AWS Libreswan VM. This task includes editing both
Networking

the AWS security groups and network ACLs. You can set the source value can be the Oracle public IP (the Oracle VPN headend IPSec tunnel endpoint) instead of 0.0.0.0/0.

For security groups:

For network ACLs:
Task 2: Configure the Oracle Cloud Infrastructure DRG and CPE object

1. In the Oracle Console, create a customer-premises equipment (CPE) object that points to the Libreswan AWS instance public IP address (34.200.255.174).

2. If you don’t already have a DRG attached to your VCN: in the Oracle Console, create a DRG and then attach it to the VCN (172.0.0.0/16).
3. In the Oracle Console, create an IPSec connection and point it to the AWS VPC CIDR (10.0.0.0/16). In other words, when you create the IPSec connection, set its static route to the AWS VPC CIDR.

For each configured IPSec connection, Oracle creates two tunnels and assigns these items to each one:

- Oracle VPN headend IPSec tunnel endpoint
- Oracle VPN tunnel shared secret

You can view the IPSec tunnel status and Oracle VPN headend IP by clicking the Actions icon (three dots) for the IPSec connection, and then clicking View Details. Initially each tunnel is in the DOWN state (offline) because you still have some additional configuration to do later on the AWS Libreswan VM.

4. In the Oracle Console, edit the VCN's security rules to enable ingress TCP and UDP traffic on ports 4500 and 500 like you did for the AWS security groups and network ACLs. You can use the AWS Libreswan VM public IP address instead of 0.0.0.0/0 if it's a persistent public IP. Also open all protocols and ports for ingress traffic from the AWS VPC CIDR (10.0.0.0/16). Remember: Security lists are associated with a subnet, so edit the security
list associated with each subnet that needs to communicate with the AWS VPC. Or, if you’re using VCN network security groups, edit the rules in the relevant NSGs.

### Ingress Rules

| Stateless | Source | IP Protocol | Source Port Range | Destination Port Range | Type and Code | Allow
|-----------|--------|-------------|-------------------|--------------------|--------------|------
| No        | 10.0.0.0/16 | All Protocols |                  |                    | All traffic for all ports |   |
| No        | 0.0.0.0/0   | TCP         | All              | 4500               | TCP traffic for ports 4500 |   |
| No        | 0.0.0.0/0   | TCP         | All              | 500                | TCP traffic for ports 500  |   |
| No        | 0.0.0.0/0   | UDP         | All              | 4500               | UDP traffic for ports 4500 |   |
| No        | 0.0.0.0/0   | UDP         | All              | 500                | UDP traffic for ports 500  |   |

5. In the Oracle Console, edit the VCN’s route tables to add a rule that has the AWS VPC CIDR (10.0.0.0/16) as the destination CIDR block and the DRG you created earlier as the target. Remember: Route tables are associated with a subnet, so edit the route table associated with each subnet that needs to communicate with the AWS VPC. The following screenshot shows the route table for the VCN with an added route for the AWS VPC CIDR.

### Route Rules

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target Type</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Dynamic Routing Gateways</td>
<td>AWS DRG</td>
</tr>
</tbody>
</table>

### Task 3: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- **${cpeLocalIP}**: The IP address of your Libreswan device.
- **${cpePublicIpAddress}**: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from **${cpeLocalIP}**.
- **${oracleHeadend1}**: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- **${oracleHeadend2}**: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- **${vti1}**: The name of the first VTI used. For example, vti1.
- **${vti2}**: The name of the second VTI used. For example, vti2.
- **${sharedSecret1}**: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- **${sharedSecret2}**: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- **${vcnCidrNetwork}**: The VCN IP range.

### Task 4: Set up the configuration file: /etc/ipsec.d/oci-ipsec.conf

Libreswan configuration uses the concept of **left** and **right** to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the **conn** in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **Left**: Your local Libreswan CPE
- **Right**: The Oracle VPN headend

Use the following template for your /etc/ipsec.d/oci-ipsec.conf file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.

Oracle Cloud Infrastructure User Guide 4206
Important:
If your CPE is behind a 1–1 NAT device, uncomment the leftid parameter and set it equal to the ${cpePublicIpAddress}.

```plaintext
conn oracle-tunnel-1
  left=${cpeLocalIP}
  right=${oracleHeadend1}
  leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
  authby=secret
  leftsubnet=0.0.0.0/0
  rightsubnet=0.0.0.0/0
  auto=start
  mark=5/0xffffffff # Needs to be unique across all tunnels
  vti-interface=${vti1}
  vti-routing=no
  ikev2=no # To use IKEv2, change to ikev2=insist
  ike=aes_cbc256-sha2_384;modp1536
  phase2alg=aes_gcm256;modp1536
  encapsulation=yes
  ikelifetime=28800s
  salifetime=3600s

conn oracle-tunnel-2
  left=${cpeLocalIP}
  right=${oracleHeadend2}
  leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
  authby=secret
  leftsubnet=0.0.0.0/0
  rightsubnet=0.0.0.0/0
  auto=start
  mark=6/0xffffffff # Needs to be unique across all tunnels
  vti-interface=${vti2}
  vti-routing=no
  ikev2=no # To use IKEv2, change to ikev2=insist
  ike=aes_cbc256-sha2_384;modp1536
  phase2alg=aes_gcm256;modp1536
  encapsulation=yes
  ikelifetime=28800s
  salifetime=3600s
```

Task 5: Set up the secrets file: /etc/ipsec.d/oci-ipsec.secrets

Use the following template for your /etc/ipsec.d/oci-ipsec.secrets file. It contains two lines per IPSec connection (one line per tunnel).

```plaintext
${cpePublicIpAddress} ${ipAddress1}: PSK "${sharedSecret1}"
${cpePublicIpAddress} ${ipAddress2}: PSK "${sharedSecret2}"
```

Task 6: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service with the following command.

Important:
Restarting the Libreswan service may impact existing tunnels.

```
service ipsec restart
```
Task 7: Configure IP routing

Use the following `ip` command to create static routes that send traffic to your VCN through the IPSec tunnels. If you’re logged in with an unprivileged user account, you might need to use `sudo` before the command.

**Important:**

Static routes created with the `ip route` command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.

```
ip route add ${VcnCidrBlock} nexthop dev ${vti1} nexthop dev ${vti2}
ip route show
```

Verification

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

Checking the Libreswan Status

Check the current state of your Libreswan tunnels by using the following command:

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you’re using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

Checking the Tunnel Interface Status

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as tcpdump with the interfaces.

Here’s an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>
vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
        inet6 2001:db8::1 prefixlen 64 scopeid 0x20<link>
        tunnel txqueuelen 1000 (IPIP Tunnel)
        RX packets 0 bytes 0 (0.0 B)
        RX errors 0 dropped 0 overruns 0 frame 0
        TX packets 0 bytes 0 (0.0 B)
        TX errors 10 dropped 0 overruns 0 carrier 10 collisions 0
vti02: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
        inet6 2001:db8::2 prefixlen 64 scopeid 0x20<link>
        tunnel txqueuelen 1000 (IPIP Tunnel)
        RX packets 0 bytes 0 (0.0 B)
```
Networking

RX errors 0 dropped 0 overruns 0 frame 0
TX packets 0 bytes 0 (0.0 B)
TX errors 40 dropped 0 overruns 0 carrier 40 collisions 0

Here's an example of the `ip link show` output:

```
ip link show
<output trimmed>
9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
  state UNKNOWN mode DEFAULT group default qlen 1000
  link/ipip 10.1.2.3 peer 192.168.0.51
10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
  state UNKNOWN mode DEFAULT group default qlen 1000
  link/ipip 10.1.2.3 peer 192.168.0.49
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.

Network Performance

The content in the sections below apply to Category 7 and Section 3.c of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation. You can download a PDF from the Oracle Cloud Infrastructure Service Level Agreement page.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for network throughput between instances in the same availability domain in a virtual cloud network (VCN). You might think of this as a measurement of LAN performance.

**Important:**

This SLA applies only to bare metal instances.

To meet the SLA, the network throughput for instances within the same availability domain and VCN must be at least 90% of the stated maximum for at least 99.9% of the billing month. Network throughput is measured in megabits per second (Mbps) or gigabits per second (Gbps).

For information about the average network round-trip latency between regions, see Inter-Region Latency on page 4211.

Testing Methodology

Launch two bare metal instances in the same availability domain and VCN. Install and run the `iperf3` utility, with one instance as server and the other as client. Look at the `iperf3` bandwidth results to determine your VCN's network throughput.

1. Launch two bare metal instances in the same availability domain in a single VCN. Designate one as the server and the other as the client. For launch instructions, see Creating an Instance on page 1023.
2. Install `iperf3` on both instances. Example Linux command:

```
sudo yum install -y iperf3
```
3. Enable communication to the server instance on TCP port 5201 (for `iperf3`):
   a. For the subnet that the server instance is in, add a rule to the subnet's security list to allow stateless ingress traffic on TCP port 5201 from any source IP address (0.0.0.0/0) and any source port. For instructions, see
To update rules in an existing security list on page 3730. If you are instead using network security groups (NSGs) with the instance, add the rule to the instance's NSG.

b. On the instance itself, open the firewall to allow iperf3 traffic. Example Linux commands:

```
Caution:

For instances with an iSCSI boot volume, the following --reload command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

```
sudo firewall-cmd --zone=public --permanent --add-port 5201/tcp
sudo firewall-cmd --reload

4. Start the iperf3 test:

a. On the server instance, run iperf3 in server mode. Example Linux command:

iperf3 -s

b. On the client instance, run iperf3 in client mode and specify the private IP address of the server instance. Example Linux command:

iperf3 -c <server_instance_private_ip_address>

5. Look at the iperf3 results on the client instance. The network throughput between the two instances is shown under "Bandwidth" in the last five lines of the client's iperf3 test output. For example:

```
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
[ ID] Interval         Transfer      Bandwidth        Retr
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec  752
    sender
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec
    receiver
iperf Done.
```

Automated Testing

The script included in perf-check.zip automates the commands used in the previous section. To use the script:

1. Ensure that TCP/UDP port 5201 is open by reviewing the security rules and route tables, making changes if necessary.
2. Extract the script perf-check.py from the perf-check.zip file.
3. Start a copy of the script on your server endpoint by entering:

   ```bash
   ./perf-check.py server
   ```
4. Start a copy of the script on your client endpoint by entering:

   ```bash
   ./perf-check.py client <server address>
   ```

The script will produce an archive on both endpoints (default names: perf-results-client.tar.gz and perf-results-server.tar.gz). These archives should be provided to Oracle support for further analysis.

**Frequently Asked Questions**

**Q: My VCN isn’t meeting the bandwidth SLA. What should I do?**

**A:** Ensure that the CPU on the instance isn't loaded heavily with other services or applications. Confirm with a utility such as `top` to look at the average CPU utilization. It should be less than one.
Q: Can I use the preceding iperf instructions to test performance between hosts that are not in the same availability domain, or between a host in the VCN and a host in the on-premises network?

A: Yes. The instructions can be used to test performance between any two endpoints. For accurate results, when transferring data outside an availability domain, you must add `--parallel 5` at the end of the client connection command.

**Inter-Region Latency**

The Inter-Region Latency dashboard in the Console provides the average network round-trip latency (round-trip time or RTT) for all pairs of `regions` in an Oracle Cloud Infrastructure `realm`. In realms with only one region, the Inter-Region Latency dashboard is not available. The dashboard shows a current snapshot view and lets you view historic snapshots including up to a 30-day history. The latency information provided is not specific to your `tenancy's` workloads: these global statistics provide visibility into latency between all regions to help you plan scenarios such as backup and data transfers. This dashboard is not intended for use in troubleshooting.

The Inter-Region Latency dashboard shows two charts:

1. The **Current Inter-Region Round-Trip Time** is a current snapshot expressed in milliseconds. This snapshot is an average of values over the last five minutes. This view updates every minute.
2. The **Inter-Region Round-Trip Time (ms) for the last 30 days** is a historical view of the last 30 days

**Using the Console**

Both dashboards are on the same console screen. To view the dashboards:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Inter-Region Latency**.
2. The **Current Inter-Region Round-Trip Time** chart is at the top of the page. With this chart you can:
   - Select two regions (one is the "from" region and one is the "to" region) and click **Show**. The relevant cell is highlighted and displays the RTT in milliseconds for the origin/destination pair.
   - Hover over the three-letter code in the heading row or column to see the region name associated with the code.
   - Click a cell in the table corresponding to a pair of regions to highlight the cell. The cell displays the RTT in milliseconds for the origin/destination pair.
3. Scroll to the bottom of the page to see the **Inter-Region Round-Trip Time (ms) for the last 30 days** chart. With this chart you can:
   - Select two regions (one is the "from" region and one is the "to" region) and click **Show**. The relevant graph of latency times between the origin/destination pair displays. The graph covers the last 30 days by default.
   - Slide the beginning and end of the bar to change the time period covered by the chart using the date bar under the chart.
   - Hover over a point on the graph to get the values in milliseconds for that point in time.

**Using the API**

This feature is not available using API operations.

**Networking Metrics**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

There are multiple Monitoring service metric namespaces related to networking resources.

For instance connectivity:

- **oci_vcn**: Metrics related to VNICs. See VNIC Metrics on page 4212.

For cloud connectivity:

- **oci_fastconnect**: Metrics related to FastConnect. See FastConnect Metrics on page 4108.
Networking

- **oci_vpn**: Metrics related to an **IPSec connection**. See Site-to-Site VPN Metrics on page 4042.
- **oci_service_gateway**: Metrics related to a **service gateway**. See Service Gateway Metrics on page 4217.
- **oci_nat_gateway**: Metrics related to a **NAT gateway**. See NAT Gateway Metrics on page 4219.

**VNIC Metrics**

You can monitor the health, capacity, and performance of your Networking service VNICs by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace **oci_vcn** (the Networking service).

Resources: virtual network interface cards (VNICs).

**Overview of Metrics for an Instance and Its Network Devices**

If you're not already familiar with the different types of metrics available for an instance and its storage and network devices, see Compute Instance Metrics on page 1158.

**Overview of Metrics: oci_vcn**

Each Compute instance has one or more Networking service **VNICs**. A VNIC connects the instance to a subnet in a virtual cloud network (VCN). A given VNIC controls how the instance communicates with endpoints inside the VCN (other instances) and endpoints outside the VCN (hosts on the internet, in your on-premises network, in another VCN, and so on).

With the Networking service metrics (in metric namespace **oci_vcn**), you can get this information for a VNIC:

- **Traffic to and from the network**: Per-VNIC traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of your instances
- **Packets dropped due to security list violations**: Per-VNIC drops (dropped packets), which can help you identify changes in traffic caused by security list changes

The following diagram illustrates the general concept. A given instance resides in a subnet within a VCN that has one or more gateways to communicate with other networks. The instance is enlarged to show its VNIC, which the instance uses to communicate with the network. In this context, the term **network** means both the other instances in the VCN and hosts outside the VCN available through the gateways.

The VNIC receives traffic from the network and sends traffic to the network. The Networking service drops packets according to security list rules you set up for the instance's subnet. Traffic coming to the VNIC from the network is measured **after** the Networking service drops the packets that violate the subnet's security list rules. Traffic leaving the VNIC is measured **before** the Networking service drops the packets that violate the subnet's security list rules.
The Compute service separately reports network-related metrics as measured on the instance itself and aggregated across all the attached VNICs. Those metrics are available in the `oci_computeagent` metric namespace. For more information, see Compute Instance Metrics on page 1158.

**Raw Data Point Frequency**

For every 1-minute interval, the Networking service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, 1-hour (60-minute), and 1-day intervals. Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the `1h` or `1d` interval values are supported. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

- The mean for each 5-minute interval is calculated over five raw data points.
The mean for each 60-minute interval is calculated over 60 raw data points.

**Required IAM Policy**

When writing an IAM policy for viewing VNIC metrics, it's important to remember that:

- The VNIC and the VNIC's metrics (emitted by the `oci_vcn` metric namespace) reside in the subnet's compartment, and not the instance's compartment.
- The VNIC attachment (which is an object different from the VNIC itself) resides in the instance's compartment.

If the instance and subnet are in the same compartment, these details aren't so important when you write the IAM policy.

**Minimum required policy for getting VNIC metrics**

The following policy contains the one statement required to get VNIC metrics, which are part of the `oci_vcn` metric namespace.

If you're using the Console, this policy lets you go to the Monitoring tab in the Console and view the metrics for one or more VNICs in the specified compartment. The policy uses an example group called VnicMetricReaders. The condition at the end (`where target.metrics.namespace='oci_vcn'`) allows the group to view only the metrics in the `oci_vcn` metric namespace.

```
Allow group VnicMetricReaders to read metrics in
  compartment <subnet_compartment> where target.metrics.namespace='oci_vcn'
```

**Policy for viewing a VNIC's details and metrics in the Console**

The following policy lets you view an instance in the Console, click through to a specific VNIC, and then view that VNIC's details and metrics.

```
Allow group VnicMetricReaders to read metrics in
  compartment <subnet_compartment> where target.metrics.namespace='oci_vcn'

Allow group VnicMetricReaders to read instance-family in
  compartment <instance_compartment>

Allow group VnicMetricReaders to inspect virtual-network-family in
  compartment <subnet_compartment>
```

The second and third statements let you view the instance's details and the VNIC's details, respectively.

**Available Metrics: oci_vcn**

The metrics listed in the following table are automatically available for any VNIC on any instance you create. You do not need to enable monitoring on the instance to get these metrics for the VNIC or VNICs on the instance.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimension:

**RESOURCENAME**

The `OCID` of the VNIC.

* The Compute service separately reports network-related metrics as measured on the instance itself and aggregated across all the attached VNICs. Those metrics are available in the oci_computeagent metric namespace. For more information, see [Compute Instance Metrics](#) on page 1158.

**Tips for Working with VNIC Metrics**

Here are some tips to help you use VNIC metrics.

**Default Metric Charts for One VNIC Versus Multiple VNICs**

The default charts for VNIC metrics use these default settings:

- Time range = the last hour
- Interval = 1 minute
- Statistic displayed: Sum
- Aggregation of metric streams = not selected (which means each VNIC is displayed as a separate line on the chart)

You can view the default charts with data for only a single VNIC by viewing the VNIC’s details in the Console. When looking at a single VNIC, these statistics are the most useful: sum, mean, max, and min.

You can view the default charts with data for multiple VNICs by going to the Service Metrics page in the Console. Select the necessary compartment and metric namespace (oci_vcn) at the top of the page. For all the charts, you can either show each VNIC as a separate line, or show a single line that aggregates the data for all the VNICs in your selected compartment. To aggregate the data, select the check box for Aggregate Metric Streams.

When viewing aggregated data, you can use the P90 - P99.9 statistics to help identify typical behavior of your instance fleet and outliers. To view these statistics over an even larger number of data points, expand the chart’s start and end time (for example, view the last 7 days instead of the last hour), and set the interval to 1 hour.

For general information about how to work with and modify the default metric charts, see [Using the Console](#) on page 3471 in the Monitoring documentation.

**Alarms for VNIC Metrics**

You can set up alarms for a given metric. For VNICs, an alarm makes the most sense for the egress security list drops metric (VnicEgressDropsSecurityList). In a normal situation, you shouldn't have egress security list drops. If you do, it might be due to one of the following causes:

- An application is behaving in an unexpected manner
- Your security list is incorrectly configured

In either case, an alarm is warranted.

**Using the Console**

To view default metric charts for a single VNIC

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance to view its details.
3. Under **Resources**, click **Attached VNICs**.
4. Click the VNIC to view its details.
5. Under **Resources**, click **Metrics**.
For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for multiple VNICs

2. For Compartment, select the compartment that contains the VNICs you're interested in. Remember that a given VNIC resides in its subnet's compartment.
3. For Metric Namespace, select oci_vcn.

The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

Tip:

If the compartment has multiple VNICs, the charts default to show a separate line for each VNIC. By selecting the check box for Aggregate Metric Streams on the right side of the page, you can show a single line aggregated across all the VNICs.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

• Monitoring API for metrics and alarms
• Notifications API for notifications (used with alarms)

Service Gateway Metrics

You can monitor the health, capacity, and performance of your service gateways by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

This topic describes the metrics emitted by the metric namespace oci_service_gateway.

Resources: Service gateways

Overview of Metrics: oci_service_gateway

A service gateway is used to enable on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

The available metrics help you determine quickly if your service gateway is up, how much data is flowing through the gateway, and if packets are being dropped for unexpected errors.

• Traffic to and from the service gateway: Per-gateway traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of the gateway.
• Packets dropped: Per-gateway drops (dropped packets), which can help you identify changes in traffic caused by issues such as gateway misconfiguration or unrecognized packet protocol.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
Available Metrics: oci_service_gateway

The metrics listed in the following table are automatically available for each service gateway that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes one or more of the following dimensions:

**RESOURCEID**

The *OCID* of the service gateway.

**DROPTYPE**

The type of packet drop:

- `sgwDisabledDrops`: Packets dropped because the service gateway is disabled.
- `sgwMtuExceededDrops`: Packets dropped because the Maximum Transmission Unit (MTU) has been exceeded.
- `sgwServiceDestUnknown`: Packets dropped because of an unknown or incorrect service destination.
- `sgwTtlExpiryDrops`: Packets dropped because the TTL (Time To Live) value in the IPv4 header of the packet has expired.
- `sgwMisconfigurationDrops`: Packets dropped because the gateway service moniker is misconfigured. For example, the gateway's associated route table points to a different CIDR service than the one specified in the gateway configuration.
- `sgwUnknownProtocolDrops`: Packets dropped because the protocol in the IPv4 header of the packet is not recognized.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>packetsToService</td>
<td>Packets to Service</td>
<td>Packets</td>
<td>The number of packets successfully sent from the service gateway toward Oracle services.</td>
<td>resourceId</td>

<td>Packets Dropped to Service</td>
<td>Packets</td>
<td>The number of packets dropped while sending packets from the service gateway toward Oracle services.</td>
<td>resourceId, dropType</td>
</tr>
</tbody>
</table>

**Using the Console**

To view default metric charts for all service gateways in a compartment

2. In *Compartment*, select the compartment you're interested in.
3. For Metric *Namespace*, select *oci_service_gateway*.
4. The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

By default, the charts show a separate line for each resource in the compartment.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:
- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

NAT Gateway Metrics

You can monitor the health, capacity, and performance of your NAT gateways by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

This topic describes the metrics emitted by the metric namespace `oci_nat_gateway`.

Resources: NAT gateways

Overview of Metrics: `oci_nat_gateway`

A NAT gateway is used to give an entire private network access to the internet without assigning each host a public IPv4 address. The hosts can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.

The available metrics help you determine quickly if your NAT gateway is up, how much data is flowing through the gateway, and if packets are being dropped for unexpected errors.

- **Traffic to and from the NAT gateway**: Per-gateway traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of the gateway.
- **Packets dropped**: Per-gateway drops (dropped packets), which can help you identify changes in traffic caused by issues such as NAT port exhaustion.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: `oci_nat_gateway`

The metrics listed in the following table are automatically available for each NAT gateway that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes one or more of the following dimensions:

**RESOURCEID**

The OCID of the NAT gateway.

**DROPTYPE**

The type of packet drop:
- `noPorts`: Packets dropped due to NAT port exhaustion.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>BytesToNATgw</td>
<td>Bytes from OCI resources to NAT gateway</td>
<td>Bytes</td>
<td>Number of bytes sent from Oracle Cloud Infrastructure (OCI) resources to NAT gateway.</td>
<td>resourceId</td>
</tr>
<tr>
<td>BytesFromNATgw</td>
<td>Bytes from NAT gateway to OCI resources</td>
<td>Bytes</td>
<td>Number of bytes sent from NAT gateway to OCI resources.</td>
<td></td>
</tr>
<tr>
<td>PacketsToNATgw</td>
<td>Packets from OCI resources to NAT gateway</td>
<td>Packets</td>
<td>Number of packets sent from OCI resources to NAT gateway.</td>

</tr>
<tr>
<td>DropsToNATgw</td>
<td>Packet Drops from OCI resource to NAT gateway</td>
<td>Packets</td>
<td>Number of packets from OCI resources to NAT Gateway that were dropped by NAT Gateway.</td>
<td>resourceId, dropType</td>
</tr>
</tbody>
</table>

**Using the Console**

To view default metric charts for all NAT gateways in a compartment

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. In **Compartment**, select the compartment you’re interested in.
3. For Metric **Namespace**, select **oci_nat_gateway**.
4. The **Service Metrics** page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

By default, the charts show a separate line for each resource in the compartment.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

**Troubleshooting**

These topics cover some common issues and how to address them:

- **Hanging Connection** on page 4221
- **Subnet or VCN Deletion** on page 4227
- **Redundancy Remedies** on page 4229
- **Site-to-Site VPN Troubleshooting** on page 4044
- **FastConnect Troubleshooting** on page 4112
Hanging Connection

This topic covers one of the most common issues seen with communications between your cloud network and on-premises network: a hanging connection, even though you can ping hosts across the connection.

Summary of Problem and Solutions

Symptom: Your virtual cloud network (VCN) is connected to your existing on-premises network via Site-to-Site VPN, or Oracle Cloud Infrastructure FastConnect. Hosts on one side of the connection can ping hosts on the other side, but the connection hangs. For example:

- You can SSH to a host across the connection, but after you log in to the host, the connection hangs.
- You can start a Virtual Networking Computing (VNC) connection, but the session hangs.
- You can start an SFTP download, but the download hangs.

General problem: *Path Maximum Transmission Unit Discovery (PMTUD)* is probably not working on one or both sides of the connection. It must be working on both sides of the connection so that both sides can know if they're trying to send packets that are too large for the connection and adjust accordingly. For a brief overview of Maximum Transmission Unit (MTU) and PMTUD, see Overview of MTU on page 4222 and Overview of PMTUD on page 4224.

Solutions for fixing PMTUD:

1. Ensure that your hosts are configured to use PMTUD: If the hosts in your on-premises network don't use PMTUD (that is, if they don't set the Don't Fragment flag in the packets), they have no way to discover if they're sending packets that are too large for the connection. Your instances on the Oracle side of the connection use PMTUD by default. Do not change that configuration on the instances.

2. Ensure both the VCN security lists and the instance firewalls allow ICMP type 3 code 4 messages: When PMTUD is in use, the sending hosts receive a special ICMP message if they send packets that are too large for the connection. Upon receipt of the message, the host can dynamically update the size of the packets to fit the connection. However, your instances can't receive these important ICMP messages if both the security lists for the subnet in the VCN and the instance firewalls aren't configured to accept them.

   Tip:

   If you're using stateful security list rules (for TCP, UDP, or ICMP traffic), you don't need to ensure that your security list has an explicit rule to allow ICMP type 3 code 4 messages because the Networking service tracks the connections and automatically allows those messages. Stateless rules require an explicit ingress security list rule for ICMP type 3 code 4 messages. Confirm that the instance firewalls are set up correctly.

   To check to see if a host is receiving the messages, see Finding Where PMTUD Is Broken on page 4224.

3. Ensure that your router honors the Don't Fragment flag: If the router doesn't honor the flag and thus ignores the use of PMTUD, it sends fragmented packets to the instances in the VCN, which is bad (see Why Avoid Fragmentation? on page 4222). The VCN's security lists are most likely configured in such a way that they recognize only the initial fragment, and the remaining ones are dropped, causing the connection to hang. Instead, your router should use PMTUD and honor the Don't Fragment flag to determine the correct size of unfragmented packets to send through the connection.
The parts of the solution are numbered and called out in red italics in the following diagram. It shows an example scenario with your on-premises network connected to your VCN over Site-to-Site VPN.

Keep reading for a brief overview of MTU and PMTUD, and how to check if PMTUD is working on both sides of the network connection.

**Why Avoid Fragmentation?**

You may be wondering why you want to avoid fragmentation. First, it adversely affects the performance of your application. Fragmentation requires reassembly of the fragments and retransmission if fragments are lost. Reassembly and retransmission require time and CPU resources.

Second, only the first fragment contains the source and destination port information. This means that firewalls or your VCN’s security lists will probably drop the other packets, because they are typically configured to evaluate the port information. For fragmentation to work with your firewalls and security lists, you would have to configure them to be more permissive than usual, which is not desirable.

**Overview of MTU**

The communications between any two hosts across an Internet Protocol (IP) network use packets. Each packet has a source and destination IP address and a payload of data. Every network segment between the two hosts has a Maximum Transmission Unit (MTU) that represents the number of bytes that a single packet can carry.

The standard internet MTU size is 1500 bytes. This is also true for most home networks and many corporate networks (and their Wi-Fi networks). Some data centers, including those for Oracle Cloud Infrastructure, can have a larger MTU. The Compute instances use an MTU of 9000 by default. On a Linux host, you can use the `ifconfig` command to display the MTU of the host’s network connection. For example, here's the `ifconfig` output from an Ubuntu instance (the MTU is highlighted in red italics):

```
ifconfig
ens3 Link encap:Ethernet HWaddr 00:00:00:00:00:01
inet addr:10.0.6.9 Bcast:10.0.6.31 Mask:255.255.255.224
inet6 addr: 2001:db8::/32 Scope:Link
          UP BROADCAST RUNNING MULTICAST
          MTU: 9000
          Metric: 1
```

For comparison, here's the output from a machine connected to a corporate network:

```
ifconfig
en0: flags=8863<UP,BROADCAST,SMART,RUNNING,SIMPLEX, MULTICAST>
```
Notice that its MTU is the more typical 1500 bytes.

If the host is connected through a corporate VPN, the MTU is even smaller, because the VPN tunnel must encapsulate the traffic inside an IPSec packet and send it across the local network. For example:

```
ifconfig
utun0: flags=81d1<UP,POINTOPOINT,RUNNING,NOARP,PROMISC,MULTICAST>

mtu 1300
```

How do the two hosts figure out how large of a packet they can send to each other? For many types of network traffic, such as HTTP, SSH, and FTP, the hosts use TCP to establish new connections. During the initial three-way handshake between two hosts, they each send the **Maximum Segment Size (MSS)** for how large their payload can be. This is smaller than the MTU. (TCP runs inside the Internet Protocol (IP), which is why it’s referred to as TCP/IP. Segments are to TCP what packets are to IP.)

Using the `tcpdump` application, you can see the MSS value shared during the handshake. Here’s an example from `tcpdump` (with the MSS highlighted in red italics):

```
12:11:58.846890 IP 192.168.0.22 > 10.197.176.19.58824: Flags [S.], seq 2799552952, ack 258009593, win 26844, options [mss 1260,ts val 44858491,ecr 1321638674,nop,wscale 7], length 0
```

The preceding packet is from an SSH connection to an instance from a laptop connected to a corporate VPN. The local network the laptop uses for its internet connection has an MTU of 1500 bytes. The VPN tunnel enforces an MTU of 1300 bytes. Then when the SSH connection is attempted, TCP (running inside the IP connection) tells the Oracle Cloud Infrastructure instance that it supports TCP segments that are less than or equal to 1260 bytes. With a corporate VPN connection, the laptop connected to the VPN typically has the smallest MTU and MSS compared to anything it’s communicating with across the internet.

A more complex case is when the two hosts have a larger MTU than some network link between them that is not directly connected to either of them. The following diagram illustrates an example.

The example shows two servers, each directly connected to its own routed network that supports a 9000-byte MTU. The servers are in different data centers. Each data center is connected to the internet, which supports a 1500-byte MTU. A Site-to-Site VPN IPSec tunnel connects the two data centers. That tunnel crosses the internet, so the inside of the tunnel has a smaller MTU than the internet. In this diagram, the MTU is 1380 bytes.
Networking

If the two servers try to communicate (with SSH, for example), during the three-way handshake, they agree on an MSS around 8960. The initial SSH connection might succeed, because the maximum packet sizes during the initial SSH connection setup are usually less than 1380 bytes. When one side tries to send a packet larger than the smallest link between the two endpoints, Path MTU Discovery (PMTUD) becomes critical.

Overview of PMTUD

Path MTU Discovery is defined in RFC 1191. It works by requiring the two communicating hosts to set a Don't Fragment flag in the packets they each send. If a packet from one of these hosts reaches a router where the egress (or outbound) interface has an MTU smaller than the packet length, the router drops that packet. The router also returns an ICMP type 3 code 4 message to the host. This message specifically says "Destination Unreachable, Fragmentation Needed and Don't Fragment Was Set" (defined in RFC 792). Effectively the router tells the host: "You told me not to fragment packets that are too large, and this one's too large. I'm not sending it." The router also tells the host the maximum size packets allowed through that egress interface. The sending host then adjusts the size of its outbound packets so they're smaller than the value the router provided in the message.

Here's an example that shows the results when an instance tries to ping a host (203.0.113.2) over the internet with an 8000-byte packet and the Don't Fragment flag set (that is, with PMTUD in use). The returned ICMP message is highlighted in red italics:

```plaintext
ping 203.0.113.2 -M do -s 8000
PING 203.0.113.2 (203.0.113.2) 8000(8028) bytes of data.
From 10.0.0.2 icmp_seq=1
Frag needed and DF set (mtu = 1500)
```

The response is exactly what's expected. The destination host is across the internet, which has an MTU of 1500 bytes. Even though the sending host's local network connection has an MTU of 9000 bytes, the host can't reach the destination host with the 8000-byte packet and gets an ICMP message accordingly. PMTUD is working correctly.

For comparison, here's the same ping, but the destination host is across a Site-to-Site VPN IPSec tunnel:

```plaintext
ping 192.168.6.130 -M do -s 8000
PING 192.168.0.130 (192.168.0.130) 8000(8028) bytes of data.
From 192.0.2.2 icmp_seq=1 Frag needed and DF set
(mtus = 1358)
```

Here the VPN router sees that to send this packet to its destination, the outbound interface is a VPN tunnel. That tunnel goes across the internet, so the tunnel must fit inside the internet's 1500-byte MTU link. The result is that the inside of the tunnel only allows packets up to 1360 bytes (which the router then lowered to 1358, which can make things more confusing).

Finding Where PMTUD Is Broken

If PMTUD isn't working somewhere along the connection, you need to figure out why and where. Typically it's because the ICMP type 3 code 4 packet (from the router with the constrained link that can't fit the packet) never gets back to the sending host. This can happen if there's something blocking that kind of traffic between the host and the router. And it can happen on either side of the VPN tunnel (or other constrained MTU link).

Try Pinging From Each Side of the Connection

To troubleshoot the broken PMTUD, you must determine if PMTUD is working on each side of the connection. In this scenario, let's assume the connection uses Site-to-Site VPN.

**How to ping:** Like in Overview of PMTUD on page 4224, ping a host on the other side of the connection with a packet that you know is too large to fit through the VPN tunnel (for example, 1500 bytes or larger). Depending on which operating system the sending host uses, you might need to format the ping command slightly different.
to ensure the Don't Fragment flag is set. For both Ubuntu and Oracle Linux, you use the \(-M\) flag with the ping command.

Here's information about the \(-M\) flag:

```
-M pmtudisc_opt
Select Path MTU Discovery strategy. pmtudisc_option may be either do (prohibit fragmentation, even local one), want (do PMTU discovery, fragment locally when packet size is large), or dont (do not set DF flag).
```

Here's an example ping (with the \(-M\) flag and the resulting ICMP message highlighted in red italics)

```
ping
-M do
-s 1500 192.168.6.130
PING 192.168.0.130 (192.168.0.130) 1500(1528) bytes of data.
From 10.0.0.2 icmp_seq=1
Frag needed and DF set (mtu = 1358)
```

**Good: PMTUD is working**

If the result includes the line "From x.x.x.x icmp_seq=1 Frag needed and DF set (mtu = xxxx)", then PMTUD is working on that side of the tunnel. Note that the source address of the ICMP message is the public IP address of the tunnel the traffic is trying to go out (for example 203.0.113.13 in the preceding Ubuntu example).

Also, ping from the other side of the connection to confirm PMTUD is working from that side. Both sides of the connection must recognize that there is a tunnel between them that can't fit the large packets.

**Bad: If you're testing your side of the connection and the ping succeeds**

If you're sending the ping from a host in your on-premises network, and the ping succeeds, that probably means your edge router is not honoring the Don't Fragment flag. Instead the router is fragmenting the large packet. The first fragment reaches the destination host, so the ping succeeds, which is misleading. If you try to do more than just ping, the fragments after the first get dropped, and the connection will hang.

**Verify that your router configuration honors the Don't Fragment flag.** The router's default configuration is to honor it, but someone might have changed the default.

**Bad: If you're testing the VCN side of the connection and you don't see the ICMP message**

When testing from the VCN side of the connection, if you don't see the ICMP message in the response, there is probably something dropping the ICMP packet before it reaches your instance.

There could be two issues:

- **Security list:** The Networking security list could be missing an ingress rule that allows ICMP type 3 code 4 messages to reach the instance. This is an issue only if you're using stateless security list rules. If you're using stateful rules, your connections are tracked and the ICMP message is automatically allowed without needing a specific security list rule to allow it. If you're using stateless rules, ensure that the subnet the instance is in has a security list with an ingress rule that allows ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port. For more information, see Security Lists on page 3727, and specifically To update rules in an existing security list on page 3730.

- **Instance firewall:** The instance's firewall rules (set in the OS) could be missing a rule that allows ICMP type 3 code 4 messages to reach the instance. Specifically for a Linux instance, ensure that iptables or firewalld is configured to allow the ICMP type 3 code 4 messages.

**Avoiding the Need for PMTUD**

Oracle recommends using PMTUD. However, in some situations it's possible to configure servers so they don't need to rely on it. Consider the case of the instances in your VCN communicating across Site-to-Site VPN to hosts in your
on-premises network. You know the range of IP addresses for your on-premises network. You can add a special route to your instances that specifies the maximum MTU to use when communicating with hosts in that address range. The instance-to-instance communication within the VCN still uses an MTU of 9000 bytes.

The following information shows how to set that route on a Linux instance.

The default route table on the instance typically has two routes: the default route (for the default gateway), and a local route (for the local subnet). For example:

```
ip route show
default via 10.0.6.1 dev ens3
10.0.6.0/27 dev ens3 proto kernel scope link src 10.0.6.9
```

You can add another route that points to the same default gateway, but with the address range of the on-premises network and a smaller MTU. For example, in the following command, the on-premises network is 1.0.0.0/8, the default gateway is 10.0.6.1, and the maximum MTU size is 1300 for packets being sent to the on-premises network.

```
ip route add 1.0.0.0/8 via 10.0.6.1 mtu 1300
```

The updated route table looks like this:

```
ip route show
default via 10.0.6.1 dev ens3
1.0.0.0/8 via 10.0.6.1 dev ens3  mtu 1300
10.0.6.0/27 dev ens3  proto kernel  scope link  src 10.0.6.9
```

Within the VCN, the instance-to-instance communication continues to use 9000 MTU. However, communication to the on-premises network uses a maximum of 1300. This example assumes there's no part of the connection between the on-premises network and VCN that uses an MTU smaller than 1300.

**Important:**

The preceding commands do not persist if you reboot the instance. You can make the route permanent by adding it to a configuration file in the OS. Oracle Linux, for example, uses an interface-specific file called `/etc/sysconfig/network-scripts/route-<interface>`. For more information, see the documentation for your variant of Linux.

**VCN Troubleshooting**

**Breaking API Changes**

If anyone in your organization implements a regional subnet, be aware that you **may need to update any client code that works with Networking service subnets and private IPs**. There are possible breaking API changes. For more information, see the regional subnet release note.

**DNS Resolver Endpoints**

Network security groups (NSGs) act as a virtual firewall for your DNS resolver endpoints. An NSG consists of a set of ingress and egress security rules that apply only to the associated DNS resolver endpoints.

**Secondary IP Address**

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**DNS in Your VCN**
You use the Domain Name Server DHCP option to specify the DNS Type for the associated subnet. If you change the option's value, either restart the DHCP client on the instance or reboot the instance. Otherwise, the change does not get picked up until the DHCP client refreshes the lease (within 24 hours).

By default, the Internet and VCN Resolver does not let instances resolve the hostnames of hosts in your on-premises network connected to your VCN by Site-to-Site VPN or FastConnect. That functionality can be achieved either by using a custom resolver or by configuring the VCN's private DNS resolver.

Requirements for DNS Labels and Hostnames

- VCN and subnet labels: Max 15 alphanumeric characters and must start with a letter. Notice that hyphens and underscores are NOT allowed. The value cannot be changed later.
- Hostnames: Max 63 characters and must be compliant with RFCs 952 and 1123. The value can be changed later.

Don't confuse the DNS label or hostname with the friendly name you can assign to the object (that is, the display name), which doesn't have to be unique.

Firewalls

Your instances running platform images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance's subnet
- The instance's OS firewall rules

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, Oracle Linux 7, or Oracle Linux Cloud Developer 8, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```bash
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

Outbound SMTP is blocked

Tenancies made after June 23, 2021 are by default not allowed to send e-mail via outbound TCP port 25 to the internet. Tenancies made prior to June 23, 2021 are unaffected. If you require the ability to send email from your tenancy, open a service limits request to obtain an exemption.

Subnet or VCN Deletion

This topic covers reasons why deletion of a subnet or VCN might fail.

Remember:

- To delete a VCN, it must first be empty and have no related resources or attached gateways (for example: no internet gateway, dynamic routing gateway, and so on).
- To delete a VCN's subnets, they must first be empty.

Delete All Option

The Console has an easy "Delete all" process that deletes a VCN and its related Networking resources (subnets, route tables, security lists, sets of DHCP options, internet gateway, and so on). If the VCN is attached to a dynamic routing gateway (DRG), the attachment is deleted, but the DRG remains.

The "Delete All" process deletes one resource at a time and takes a minute or two. A progress report is displayed to show you what's been deleted so far.
Before using the "Delete All" process, verify there are no instances, load balancers, DB systems, or orphaned mount targets in any of the subnets. For more information, see Subnet or VCN Deletion on page 4227.

If there are still resources in any subnet, or if you don't have permission to delete a particular Networking resource, the "Delete All" process stops and an error message is displayed. Any resources deleted up to that point cannot be restored. You might need to contact your tenancy administrator to help you delete any remaining resources.

The Subnet Isn't Empty

The most common reason a subnet (and thus a VCN) can't be deleted is because the subnet contains one or more of these resources:

- Load balancer
- Mount target
- DB system

Note:

When you create one of the preceding resources, you specify a VCN and subnet for it. The relevant service creates at least one VNIC in the subnet and attaches the VNIC to the resource. The service manages the VNICs on your behalf, so they are not readily apparent to you in the Console. The VNIC enables the resource to communicate with other resources over the network. Although this documentation commonly talks about the resource itself being in the subnet, it's actually the resource's attached VNIC. This documentation uses the term parent resource to refer to this type of resource.

If the subnet is empty when you try to delete it, its state changes to TERMINATING briefly and then to TERMINATED.

If the subnet is not empty, you instead get an error indicating that there are still resources that you must delete first. The error includes the OCID of a VNIC that is in the subnet (there could be more, but the error returns only a single VNIC's OCID).

You can use the Oracle Cloud Infrastructure command line interface (CLI) or another SDK or client to call the GetVnic operation with the VNIC OCID. The response includes the VNIC's display name. Depending on the type of parent resource, the display name can indicate which parent resource the VNIC belongs to. You can then delete that parent resource, or you can contact your administrator to determine who owns the resource. When the VNIC's parent resource is deleted, the attached VNIC is also deleted from the subnet. If there are remaining VNICs in the subnet, repeat the process of determining and deleting each parent resource until the subnet is empty. Then you can delete the subnet.

For example, if you're using the CLI, use this command to get information about the VNIC.

oci network vnic get --vnic-id <VNIC_OCID>

Load balancer example

Here is an example CLI response for a VNIC that belongs to a load balancer. The display name shows the load balancer's OCID:

```json
{
  "data": {
    "availability-domain": "fooD:PHX-AD-1",
    "compartment-id": "ocidl.compartment.oc1..<unique_id_1>",
    "defined-tags": {},
    "display-name": "VNIC for LB ocidl.loadbalancer.oc1.phx.<unique_id_2>",
    "freeform-tags": {},
    "hostname-label": null,
    "id": "ocidl.vnic.oc1.phx.<unique_id_3>",
    "is-primary": false,
    "lifecycle-state": "AVAILABLE",
  }
}
```
Networking

File Storage example

Here's an example for a VNIC that belongs to a File Storage mount target:

```json
"display-name": "fss-<integer>",
```

Although the display name does not include an OCID, the `fss` characters indicate that the resource is for the File Storage service.

Database example

Here's an example of the display name for a VNIC that belongs to a DB system:

```json
"display-name": "ocid1.dbnode.oc1.phx.<unique_id>",
```

A Network Security Group Isn't Empty

Another reason a VCN can't be deleted is because it contains a one or more network security groups (NSGs) that are not yet empty. To delete an NSG, it must not contain any VNICs (or parent resources with VNICs). You can determine what parent resources are in an NSG by using either the Console or REST API. For more information, see To delete an NSG on page 3726.

There Are Resources in Compartments You Don't Have Access To

You might not be able to see all the resources in a subnet or VCN. This is because subnets and VCNs can contain resources in multiple compartments, and you might not have access to all the compartments. For example, the subnet might contain instances that your team manages but also DB systems that another team manages. Another example: The VCN might have security lists or a gateway in a compartment that another team manages. You might need to contact your tenancy administrator to help you determine who owns the resources in the subnet or VCN.

Redundancy Remedies

Oracle recommends setting up a redundant connection between your on-premises network and virtual cloud network (VCN) for high availability. This topic gives background and links to other topics that describe how to resolve some common redundancy issues with that connection.

About the DRG and Redundant Connections

When you connect your on-premises network to a virtual cloud network (VCN) in Oracle Cloud Infrastructure, you use a dynamic routing gateway (DRG). A DRG is a virtual representation of highly available hardware (physical routers) on the edge of the Oracle Cloud Infrastructure network. You attach a DRG to the VCN, and the DRG is the termination point for the connections from your on-premises network to that VCN. If you have multiple VCNs in your tenancy, each has a DRG. You can attach multiple VCNs to a single DRG. Each VCN can be in the same or different tenancies as the DRG.

A single DRG can have multiple connections to it from your on-premises network, which allows redundancy. Those connections could be the same type or different types. Here are the two types:
• FastConnect
• Site-to-Site VPN

For example, you might use FastConnect, but also set up Site-to-Site VPN to use as backup when FastConnect is temporarily unavailable because of maintenance. Or, you might have two VPN tunnels, with one as primary and the second as failover.

For high availability, the multiple connections to a DRG must not terminate on a single physical router in Oracle's edge network. If they do, your overall connection to Oracle Cloud Infrastructure is disrupted whenever Oracle performs maintenance on that router.

How to Identify and Fix a Redundancy Issue

You might have a redundancy issue in which a DRG in your tenancy has multiple on-premises connections that terminate on a single physical Oracle router. Or you might have only a single connection with no redundancy.

If you do, the Console displays an alert message when you view the DRG's details, or when you view the details of one of the connections (for example, the IPSec connection). The alert message includes a link to one of the following topics, which explain how to fix the particular issue:

• Case 1: Multiple FastConnect virtual circuits
• Case 2: FastConnect and Site-to-Site VPN
• Case 3: Multiple IPSec connections
• Case 4: Single FastConnect virtual circuit
• Case 5: Single IPSec connection with only a single tunnel

Redundancy Remedy: Case 1

This topic describes one of several redundancy issues that you might be alerted to in the Console.

Summary of the Issue

You have redundant FastConnect virtual circuits that connect your on-premises network to a VCN. However, both of those virtual circuits terminate on the same Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

Depending on your situation, there are two possible ways to fix the problem.

If You Are Using an Oracle Partner

The following diagram illustrates the issue.

Before the fix:

In this case, you have multiple FastConnect virtual circuits, each using a different Oracle partner (called X and Y in the diagram). Each partner has two physical connections to Oracle, and each goes to a different Oracle router (called A and B in the diagram).

The problem is that both virtual circuits happen to terminate on the same Oracle router (router A in the diagram).

After the fix:
To fix the problem, work with one of the partners to establish a new virtual circuit that goes to the *other* Oracle router (router B in the diagram). When that new secondary virtual circuit is up and running, delete the old secondary virtual circuit (in the diagram, the one on physical connection Y-A).

*If You Are Using a Third-Party Provider or Colocated with Oracle*

The following diagram illustrates the issue.

**Before the fix:**
In this case, you have two physical connections (*cross-connect groups*), and both go to the same Oracle router (router A in the diagram).

**After the fix:**
Networking

To fix the problem, one of your physical connections must go to a different router (B in the diagram). To do that, set up a new physical connect (cross-connect group) in the Oracle Console. During setup, specify the proximity of that connection to other FastConnect connections in that location. For example, the following image shows how to request that your secondary cross-connect group is created on a different router than your primary connection in that FastConnect location (called MyConnection-1).

![Image showing how to request a secondary cross-connect group on a different router.]

After you've worked to set up the cabling in the data center, and the new secondary cross-connect group is up and running, you can create a new virtual circuit on that cross-connect group. When the virtual circuit is up and running, confirm that failover works between the primary and new secondary cross-connect group. Then you can terminate the old virtual circuit and old cross-connect group.

**Redundancy Remedy: Case 2**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You have a FastConnect virtual circuit that connects your on-premises network to a VCN. For redundancy you use Site-to-Site VPN, but with only a single active IPSec tunnel. Both the FastConnect virtual circuit and the IPSec tunnel terminate on the same Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

**How to Fix the Issue**

The following diagram illustrates the issue.
Before the fix:

In this case, you have a FastConnect virtual circuit and Site-to-Site VPN as backup. Notice that each VPN Connect consists of two IPSec tunnels, and Oracle automatically provisions each tunnel on a different Oracle router. However, you must configure your CPE so that both tunnels are up/active.

The problem is that:
- Only one of the two IPSec tunnels is up/active.
- The one IPSec tunnel that is up terminates on the same Oracle router as the virtual circuit.

Notice that some CPEs only support one IPSec tunnel being up/active to a given destination.

After the fix:

If your CPE supports having two IPSec tunnels up/active to the same destination, configure the second tunnel to also be up/active. Oracle recommends configuring them both to use BGP dynamic routing for the IPSec tunnels.

If your CPE supports only a single active IPSec tunnel to a given destination, configure the other IPSec tunnel to be up. Then switch the original IPSec tunnel to be down/inactive. The following diagram illustrates that setup. Also, if your CPE supports BGP dynamic routing, configure the tunnel to use it instead of static routing.
Redundancy Remedy: Case 3

This topic describes one of several redundancy issues that you might be alerted to in the Console.

Summary of the Issue

You have redundant Site-to-Site VPN connections that connect your on-premises network to a VCN. Although each connection consists of two IPSec tunnels, only one tunnel per connection is up/active, and both of those tunnels terminate on the same Oracle edge router. Your connection to Oracle is at risk when routine maintenance is performed on that router.

How to Fix the Issue

The following diagram illustrates the issue.

Before the fix:

In this case, you have a primary connection and a secondary connection as backup. Notice that each Site-to-Site VPN consists of two IPSec tunnels, and Oracle provisions each on a different Oracle router. However, you must configure your CPE so that both tunnels are up/active.

The problem has two parts:

- In each connection, only one of the two IPSec tunnels is up/active.
- Both of the tunnels that are up/active terminate on the same Oracle router.
Some CPEs only support one IPSec tunnel being up/active to a given destination.

After the fix:

![Diagram showing two IPSec tunnels configured to be up/active](image)

If your CPE supports having two IPSec tunnels up/active to the same destination, configure the second tunnel to also be up/active. Oracle recommends configuring all tunnels to use BGP dynamic routing.

If your CPE supports only a single active IPSec tunnel to a given destination, then for one of the connections only, switch which of the two IPSec tunnels is configured to be up. The following diagram illustrates that setup. Oracle recommends configuring both tunnels to use BGP dynamic routing.

**Redundancy Remedy: Case 4**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You use FastConnect to connect your on-premises network to a VCN. Although you might have multiple virtual circuits in this connection, only one of them is up (the BGP status is UP). Your connection to Oracle is at risk when routine maintenance is performed on the Oracle router.

You can fix the problem in one of two possible ways.

**Option A: Use a Second Virtual Circuit**

The details of the fix depend on your situation.
If You Are Using an Oracle FastConnect Partner

The following diagram illustrates the issue.

**Before the fix:**

In this case, you have only a single FastConnect virtual circuit that is up.

**After the fix:**

After the fix, you have two FastConnect virtual circuits that are up, each to a different Oracle router. Some partners give you an option to specify which physical location to use for each virtual circuit. Other partners automatically use a different physical connection for the secondary virtual circuit.

If You Are Using a Third-Party Provider or Colocated with Oracle

The following diagram illustrates the issue.

**Before the fix:**
In this case, you have only a single FastConnect virtual circuit that is up.

**After the fix:**

To fix the problem, set up a secondary physical connection to Oracle. It must go to a different router (B in the diagram). To do that, set up a new physical connect (cross-connect group) in the Oracle Console. During setup, specify the proximity of that connection to other FastConnect connections in that location. For example, the following
image shows how to request that your secondary cross-connect group is created on a different router than your primary connection in that FastConnect location (called MyConnection-1).

Option B: Use Site-to-Site VPN with Both Tunnels Up/Active

This option is recommended if your CPE supports having two IPSec tunnels up/active to the same destination. The details of the fix depend on your situation.

If You Are Using an Oracle Partner

The following diagram illustrates the issue.

Before the fix:

In this case, you have only a single FastConnect virtual circuit that is up.

After the fix:
Here you set up Site-to-Site VPN as backup. You must configure your CPE so that both IPSec tunnels are up/active. Oracle automatically provisions each tunnel on a different Oracle router. Therefore, the secondary tunnel (to router B in the diagram) will be available when Oracle performs maintenance on the virtual circuit's router (router A in the diagram). Oracle recommends configuring both tunnels to use BGP dynamic routing.

**If You Are Using a Third-Party Provider or Colocated with Oracle**

The following diagram illustrates the issue.

**Before the fix:**

In this case, you have only a single FastConnect virtual circuit that is up.
After the fix:

![Network Diagram](image)

Here you set up Site-to-Site VPN as backup. You must configure your CPE so that both IPSec tunnels are up/active. Oracle automatically provisions each tunnel on a different Oracle router. Therefore, the secondary tunnel (to router B in the diagram) will be available when Oracle performs maintenance on the virtual circuit's router (router A in the diagram). Oracle recommends configuring both tunnels to use BGP dynamic routing.

**Redundancy Remedy: Case 5**

This topic describes one of several redundancy issues that you might be alerted to in the Console.

**Summary of the Issue**

You use Site-to-Site VPN to connect your on-premises network to a VCN. Although Oracle provisions two IPSec tunnels for the connection, *only one* of them is up/active. Your connection to Oracle is at risk when routine maintenance is performed on the Oracle router.

**How to Fix the Issue**

The following diagram illustrates the issue.

**Before the fix:**

![Network Diagram](image)

Notice that a Site-to-Site VPN consists of two IPSec tunnels, and Oracle automatically provisions each on a different Oracle router.

**After the fix:**
Networking

If your CPE supports having two IPSec tunnels up-active to the same destination, configure the second tunnel to also be up-active. Oracle recommends configuring both tunnels to use BGP dynamic routing.

**Network Visualizer**

**Overview**

Your Oracle virtual network is composed of VCNs, subnets, gateways, and other resources. These entities are related and connected through routing that is often complex. These resources can also have complex relationships with other Oracle Cloud Infrastructure services. The ability to have a concise picture of these entities and their relationships is essential for understanding the design and operation of a virtual network.

The Network Visualizer provides a diagram of the implemented topology of all VCNs in a selected region and tenancy. It can provide two levels of granularity:

- **Regional Network Topology**: You can see a high-level layout and routing topology of your entire virtual network configuration within a region. This topology includes DRGs, VCNs, CPEs, and various types of gateway.
- **Virtual Cloud Network Topology**: You can see the organization of a single VCN including its subnets and routing configuration. This topology includes subnets, VLANs, and gateways to other resources.

**Working with Regional Network Topologies**

The Network Visualizer tool diagram helps you view a high-level structure of your network configuration and facilitates quick navigation between its core components. It provides a view of all resources in a given combination of region and compartment.

You can view and understand the following from this diagram:

- How VCNs are inter-connected
- How on-premises networks are connected (using FastConnect or Site-to-Site VPN)
- Which routing entities (DRGs and so on) control traffic routing
- How your transit routing is configured

When you open a diagram for a compartment, it shows resources for all compartments nested underneath. You are also able to filter out objects from the compartments that you don't want to see.

You can see cross-region connections between network resources and you can also quickly change regions in the console and see the VCNs in another region.

The **Regional Map** view uses the following symbols and conventions:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="cpe.png" alt="CPE" /></td>
<td>Customer-Premises Equipment (CPE)</td>
</tr>
</tbody>
</table>

External resources | External devices like a CPE are shown in the left side of the canvas, which is shaded and separated by a dashed line.

Oracle cloud resources | Oracle cloud resources are shown in the main area of the canvas.
Working with Virtual Cloud Network Topologies

The Cloud Network Topology diagram visualizes the internal organization of a VCN at the subnet level, focusing on cross-AD deployment and network security.

You can view and understand the following from this diagram and the accompanying information panel:

- Which subnets and VLANs belong to the VCN
- How subnets and VLANs are organized across availability domains
- Security applied within the VCN
- Whether subnets in a VCN are public or private
- How subnets and VLANs are organized across compartments
- Which gateways (RPG, LPG, NGW, SGW, IGW) are part of the VCN
- Which routes are defined between subnets and gateways

The Virtual Network Map uses the following symbols and conventions:

| Regional resources | Routable resources not internal to the VCN but routable from the VCN are shown in the left side of the canvas, which is shaded and separated by a dashed line. |
Networking

VCN resources like subnets and VLANs are shown in the main area of the canvas. Gateways connecting the VCN to other resources in the region are shown on the dashed line defining the border of the VCN.

Note:
Load balancers and compute instances in a subnet are not shown in this view.

Using the Console

View the Network Topology regional map

1. In the Console, confirm you're viewing the region and compartment that you want to see represented in a diagram.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Network Visualizer.
   
   Wait briefly for the network map to generate.
3. If you need to change compartment, click CHANGE COMPARTMENT and select a different compartment.
4. If you want to see resources in all compartments nested within the selected compartment, click INCLUDE CHILD COMPARTMENTS.
5. Elements in the control bar include, from left to right:
   - **Map**: Displays the currently selected region.
   - **To find a resource by name, enter the name in the search window. When a match is found and selected, the view will zoom in to that resource.**
   - **Refresh**: updates the view in the main map window. The view is refreshed every three minutes, but if a change was made since the last refresh you can choose to manually trigger a refresh of the diagram.
   - **Filter**: Allows you to turn on and off the filters used in the current view.
   - **Legend**: Displays the symbols used in the map and their meaning.

   Resources in your external on-premises network are shown on the left side of the canvas and are separated from elements in the Oracle Cloud by a dashed line.

   The zoom controls are in the lower right corner of the diagram canvas, and you can click the canvas and hold as you move to pan up, down, left, or right. You can also double-click to zoom in.

   Routes that are enabled between resources are shown on the lines connecting the resources. Routes can be one way, but are most often two-way connections.

   You can dynamically rearrange resources on the map by dragging them. Be aware these changes are temporary and do not persist if the map is refreshed.

   Some resources are displayed with both a name and an associated CIDR block. When more than one CIDR block is associated with a resource, a +1 or +2 is added as appropriate. The additional CIDR blocks are listed in the details screen for the resource.

   Any connected elements you do not have the needed permissions to view are shown with a tag: Only the OCID is visible for that resource.

6. Click any resource on the map (the resource changes color to indicate the selection) to view basic information for that item in the right-hand column. The details presented vary depending on the component you selected.

   For some components, you can also click **Open Additional Details** to open a details screen for that component.
   These details are read-only summaries of the basic components for that resource. Links to that resource's details page are provided in case you want to make edits.

**View the Virtual Cloud Network map**

While viewing a regional map:

1. Click a VCN.
2. Click the **Go to VCN Map** button in the Resource Information panel.
   Wait briefly for the network map to generate.
3. If you need to change compartment, click **CHANGE COMPARTMENT** and select a different compartment.
4. If you want to see resources in all compartments nested within the selected compartment, click **INCLUDE CHILD COMPARTMENTS**.
5. Elements in the control bar include, from left to right:
   - **Map:** Displays the currently selected region.
   - **To** find a resource by name, enter the name in the search window. When a match is found and selected, the view will zoom in to that resource.
   - ![Refresh](image) **Refresh:** updates the view in the main map window. The view is refreshed every three minutes, but if a change was made since the last refresh you can choose to manually trigger a refresh of the diagram.
   - ![Filter](image) **Filter:** Allows you to turn on and off the filters used in the current view.
   - ![Legend](image) **Legend:** Displays the symbols used in the map and their meaning.

Routable resources in the region but not within the specified VCN are shown on the left side of the canvas, separated with a dashed line from the resources (like subnets and VLANs) inside the chosen VCN. Gateways and DRG attachments are placed on this dashed line, and you can drag them on the line to make the relationships clearer. Resources that are not routable from the VCN are not shown.

The zoom controls are in the lower right corner of the diagram canvas, and you can click the canvas and hold as you move to pan up, down, left, or right. You can also double-click to zoom in.

Some resources are displayed with both a name and an associated CIDR block. When more than one CIDR block is associated with a resource, a +1 or +2 is added as appropriate.

Any connected elements you do not have the needed permissions to view are shown with a tag: ![tag](image). Only the OCID is visible for that resource.

6. Click any resource on the map (the resource changes color to indicate the selection) to view basic information for that item in the right-hand column. The details presented vary depending on the component you selected.

For some components, you can also click **Open Additional Details** to open a details screen for that component. These details are read-only summaries of the basic components for that resource. Links to that resource's details page are provided in case you want to make edits.

You can **Enable Routing Information** for subnets and VLANs, which maintains the display of the routing information for connections to and from the resource. Using this control you can display as many or as few routes as you choose.

You can navigate back to the Network Topology regional map by clicking on the name of the region in the control bar, or by selecting one of the connected VCNs and clicking **Go to Region Map** in the resource information.

**Using the API**

For information about using the API and signing requests, see [REST APIs](page 5528) and [Security Credentials](page 207). For information about SDKs, see [Software Development Kits and Command Line Interface](page 5351).

Network visualization uses these operations and references:

- **Topology**
- **NetworkingTopology**
- **GetNetworkingTopology**
- **VcnTopology**
- **GetVcnTopology**
- **TopologyEntityRelationship**
- **TopologyContainsEntityRelationship**
- **TopologyAssociatedWithEntityRelationship**
- **TopologyRoutesToEntityRelationship**
- **TopologyRoutesToRelationshipDetails**
Chapter 35

Notifications

This chapter explains how to use the Notifications service.

Notifications Overview

The Oracle Cloud Infrastructure Notifications service broadcasts messages to distributed components through a publish-subscribe pattern, delivering secure, highly reliable, low latency and durable messages for applications hosted on Oracle Cloud Infrastructure and externally. Use Notifications to get notified when event rules are triggered or alarms are breached, or to directly publish a message.

How Notifications Works

The Notifications service enables you to set up communication channels for publishing messages using topics and subscriptions. When a message is published to a topic, the Notifications service sends the message to all of the topic's subscriptions.

When a subscriber’s endpoint does not acknowledge receipt of the message, the Notifications service retries delivery. This situation can occur when the endpoint is offline. For example, the email server for an email address may be down.

Delivery retry details

Notifications retries delivery following these steps until either (a) acknowledgement is received or (b) the subscription's retry duration is over. By default, the retry duration is two hours.

1. Immediate retry.
2. Exponential backoff retry for the period of the subscription's retry duration, using the following timing:
   a. 1 minute
   b. 2 minutes
   c. 4 minutes
   d. 8 minutes
   e. 16 minutes
   f. 32 minutes
3. Discarding of the message at the end of the retry duration.

You can change the retry duration for a subscription. For instructions using the Console, see To update the retry duration for a subscription on page 4261. For the API, use the following operation: UpdateSubscription.

Notifications Concepts

The following concepts are essential to working with Notifications.

message

The content that is published to a topic. Each message is delivered at least once per subscription. Every message sent out as email contains a link to unsubscribe from the related topic.
Notifications

**Friendly formatting**: Select friendly formatting to increase human readability of messages.

Supported subscription protocols:

- **Email**

Supported message types:

- Service connector messages (when Notifications is the target service)
  
  See service connector message examples and steps to select friendly formatting for existing service connectors.

**subscription**

An endpoint for a *topic*. Published *messages* are sent to each subscription for a *topic*.

Supported subscription protocols:

- **Email**:
  
  Sends an email message when you publish a *message* to the subscription’s parent *topic*.
  
  Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
  
  Some message types allow *friendly formatting*.

- **Function**:
  
  Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

- **HTTPS (Custom URL)**:
  
  Sends specified information when you publish a *message* to the subscription's parent *topic*.

- **PagerDuty**:
  
  Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

- **Slack**:
  
  Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.
  
  Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

- **SMS**:
  
  Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

  **Note:**

  International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

  SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>
</tr>
<tr>
<td>Chile</td>
<td>CL</td>
</tr>
<tr>
<td>China</td>
<td>CN</td>
</tr>
<tr>
<td>Costa Rica</td>
<td>CR</td>
</tr>
<tr>
<td>Croatia</td>
<td>HR</td>
</tr>
<tr>
<td>Czechia</td>
<td>CZ</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
<tr>
<td>Germany</td>
<td>DE</td>
</tr>
<tr>
<td>Hungary</td>
<td>HU</td>
</tr>
<tr>
<td>India</td>
<td>IN</td>
</tr>
<tr>
<td>Ireland</td>
<td>IE</td>
</tr>
<tr>
<td>Israel</td>
<td>IL</td>
</tr>
<tr>
<td>Japan</td>
<td>JP</td>
</tr>
<tr>

</tr>
</tbody>
</table>
## Notifications

### Country or region

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spain</td>
<td>ES</td>
</tr>
<tr>
<td>Sweden</td>
<td>SE</td>
</tr>
<tr>
<td>Switzerland</td>
<td>CH</td>
</tr>
<tr>
<td>Ukraine</td>
<td>UA</td>
</tr>
<tr>
<td>United Arab Emirates</td>
<td>AE</td>
</tr>
<tr>
<td>United Kingdom</td>
<td>GB</td>
</tr>
<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

### Topic

A communication channel for sending messages to the subscriptions in the topic. Each topic name is unique across the tenancy.

**Note:**

Messages sent out as email by the Oracle Cloud Infrastructure Notifications service are processed and delivered through Oracle resources in U.S.-based regions.

### Flow of Message Publication

Notifications publishes messages when event rules are triggered, alarms are breached, service connectors run, or someone directly publishes a message.

#### Event rules

Notifications sends event messages when rules are triggered. The event message is sent to the topic specified in the rule. For example, a message might be configured for new databases. See Managing Rules for Events on page 2399.

#### Alarms

Notifications sends alarm messages when alarms are breached. The alarm message is sent to the topic specified in the alarm. For example, an alarm message might be configured for high CPU usage. See Managing Alarms on page 3523.
Notifications sends service connector messages when service connectors are running. The service connector message is sent to the topic specified in the service connector. For example, a service connector might be configured to send usage logs. See Managing Service Connectors on page 4757.

Direct publication

Notifications sends messages when you (or a service or app) publish the messages directly. The message is sent to the topic you specify. See Publishing Messages on page 4262.

Availability

The Notifications service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.
Service Comparison for Sending Email Messages

Consider the following service features when deciding whether to use the Notifications service or the Email Delivery service to send your email messages. For more information about Email Delivery, see Overview of the Email Delivery Service on page 2326.

<table>
<thead>
<tr>
<th>Service Feature</th>
<th>Notifications service</th>
<th>Email Delivery service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires confirmation before sending email.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Allows email decorations, such as signatures.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Allows raw email messages.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Supports MIME attachments.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Supports special handling for failed email delivery.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Priced for small messages (less than 32 KB, with a 64-KB limit).</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Priced for large messages (greater than 32 KB, with a 2-MB limit).</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Moving Topics and Subscriptions to a Different Compartment

You can move topics and subscriptions from one compartment to another. When you move a topic to a new compartment, its associated subscriptions remain in their existing compartment. The same consideration applies when moving a subscription: its associated topic remains in its existing compartment.

After you move the topic or subscription to the new compartment, inherent policies apply immediately and affect access to the moved topic or subscription through the Console. For more information, see To move a resource to a different compartment on page 3139.

Important:

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service on page 3016.

Ways to Access Notifications

You can access the Notifications service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

Console: To access Notifications using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.

API: To access Notifications through API, use Notifications API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to Notifications, see Allow a group to manage topics on page 2822, Allow a group to manage topic subscriptions on page 2822, and Allow a group to publish messages to topics on page 2822.

Limits on Notifications

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Limits for publishing messages (PublishMessage operation)

All limits are per tenancy.

<table>
<thead>
<tr>
<th>Limit type</th>
<th>Limit amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message size per request</td>
<td>64KB</td>
</tr>
<tr>
<td>Message delivery rate per endpoint for HTTP-based protocols (endpoints that begin with &quot;http:&quot; or &quot;https:&quot; )</td>
<td>60 messages per minute</td>
</tr>
<tr>
<td>Message delivery rate per endpoint for Email protocol</td>
<td>10 messages per minute</td>
</tr>
<tr>
<td>Messages per minute (also known as Transactions Per Minute, or TPM)</td>
<td>60 per topic</td>
</tr>
</tbody>
</table>

Best Practices for Your Subscriptions and Topics

This topic covers best practices related to subscriptions and topics.

Prevent Processing of Duplicate Items

As depicted at Flow of Message Publication on page 4251, an event, alarm, or direct publication can trigger a message. The Notifications service then sends the message to many types of subscriptions, including email, HTTPS endpoints, and functions.

Depending on your goals, you may want to prevent your system from processing duplicate messages from a given message trigger. This situation is especially relevant when messages are sent to function subscriptions, which can
result in double invocations. (For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 4264.)

To prevent your system from processing duplicate messages, write code that de-duplicates received messages by using identifiers specific to the trigger:

- For any message, consider using a custom de-dupe key entered in the body of the message.
- For alarm-triggered messages, use a combination of dedupekey and timestampEpochMillis from the alarm message.
- For event-triggered messages, use eventID from the event message.
- For directly published messages, use x-oci-ns-messageid in the header (provided by Notifications).

For handling duplicate requests sent to Oracle Cloud Infrastructure API endpoints, see Retry Token on page 5532.

For related troubleshooting information, see Troubleshooting Notifications on page 4283.

Managing Topics and Subscriptions

This section describes how to manage topics and their subscriptions.

A topic is a communication channel for sending messages to its subscriptions. A topic can have zero, one, or multiple subscriptions that are notified whenever a message is published to a topic.

Prerequisites

IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. For Functions, you must have FN_INVOKE permission against the function to be able to add the function as a subscription to a topic.

To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2701.

If you get a response that you don't have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview on page 4248.

Creating Automation with Functions and Events

You can create automation by publishing messages to function subscriptions. For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 4264.

You can create also automation based on state changes of your topics and subscriptions (Notifications resources) by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Using the Console

To create a topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click Create Topic at the top of the topic list.
3. In the Create Topic dialog box, configure your topic.
   - Name: Required. Specify a friendly name for the topic. It must be unique across the tenancy; validation is case-sensitive. Avoid entering confidential information.
   - Description: Optional. Enter a description for the topic. Avoid entering confidential information.
4. Click Create.

To delete a topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. For the topic you want to delete, click the Actions icon (three dots), and then click Delete.
3. Confirm when prompted.
To update the description for a topic

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click the name of the topic you want to update.
3. On the topic detail page, next to **Description**, click the edit icon.
4. Edit the description.
5. Click the save icon.

To move a topic to a different compartment

Associated subscriptions remain in their current compartments. For more information, see Moving Topics and Subscriptions to a Different Compartment on page 4253.

**Note:**

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service on page 3016.

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. In the **Scope** section, select a compartment.
3. Find the topic in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To create a subscription

**Note:**

While new subscriptions must be created in the same compartment as the topic, you can move them to different compartments after creating them.

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, configure your subscription for the protocol you want:

**Email subscription**

Sends an email message when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Some message types allow friendly formatting.

- **Protocol**: Select **Email**.
- **Email**: Type an email address.

**Function subscription**

Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

**Note:**

You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.

The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 4284.
Notifications

Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select **Function**.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a `message` to the subscription's parent `topic`.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and
password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Protocol**: Select HTTPS (Custom URL).
- **URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```plaintext
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Protocol**: Select PagerDuty.
- **URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```plaintext
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Protocol**: Select Slack.
- **URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>
</tr>
<tr>
<td>Chile</td>
<td>CL</td>
</tr>
<tr>
<td>China</td>
<td>CN</td>
</tr>
<tr>
<td>Costa Rica</td>
<td>CR</td>
</tr>
<tr>
<td>Croatia</td>
<td>HR</td>
</tr>
<tr>
<td>Czechia</td>
<td>CZ</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
<tr>
<td>Germany</td>
<td>DE</td>
</tr>
<tr>
<td>Hungary</td>
<td>HU</td>
</tr>
<tr>
<td>India</td>
<td>IN</td>
</tr>
<tr>
<td>Ireland</td>
<td>IE</td>
</tr>
<tr>
<td>Israel</td>
<td>IL</td>
</tr>
<tr>
<td>Japan</td>
<td>JP</td>
</tr>
<tr>
<td>Lithuania</td>
<td>LT</td>
</tr>
<tr>
<td>Mexico</td>
<td>MX</td>
</tr>
<tr>
<td>Netherlands</td>
<td>NL</td>
</tr>
<tr>
<td>New Zealand</td>
<td>NZ</td>
</tr>
<tr>
<td>Norway</td>
<td>NO</td>
</tr>
<tr>
<td>Philippines</td>
<td>PH</td>
</tr>
<tr>
<td>Poland</td>
<td>PL</td>
</tr>
<tr>
<td>Portugal</td>
<td>PT</td>
</tr>
<tr>
<td>Romania</td>
<td>RO</td>
</tr>
<tr>
<td>Saudi Arabia</td>
<td>SA</td>
</tr>
<tr>
<td>Singapore</td>
<td>SG</td>
</tr>
<tr>
<td>South Africa</td>
<td>ZA</td>
</tr>
<tr>
<td>South Korea</td>
<td>KR</td>
</tr>
</tbody>
</table>
Notifications

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spain</td>
<td>ES</td>
</tr>
<tr>
<td>Sweden</td>
<td>SE</td>
</tr>
<tr>
<td>Switzerland</td>
<td>CH</td>
</tr>
<tr>
<td>Ukraine</td>
<td>UA</td>

<tr>
<td>United Arab Emirates</td>
<td>AE</td>
</tr>
<tr>
<td>United Kingdom</td>
<td>GB</td>
</tr>
<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

- **Protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using [E.164 format](https://en.wikipedia.org/wiki/E.164). Example SMS endpoints:
  - Phone Number *(E.164 format)*: +14255550100

5. Click **Create**.

The subscription has been created.

Subscriptions using protocols that require confirmation, such as Email, remain in "Pending" status until confirmation is received. For these subscriptions, a subscription confirmation URL is sent. For detailed steps, see [To confirm a subscription](#) on page 4260.

**To confirm a subscription**

Confirmation is not required for function subscriptions.

Navigate to the confirmation URL that is sent to the subscription's endpoint and follow the provided instructions.

Some protocols provide confirmation URLs in unique ways:

- **HTTPS (Custom URL)**: You can find the confirmation URL in the request header or body of the subscription confirmation message (request of content-type: "application/json") that is sent to the endpoint.
  
  - In the request header, see the value of the `X-OCI-NS-ConfirmationURL` field.
  
  **Example request header**:

```
"X-OCI-NS-SignatureVersion":"1.0"
"X-OCI-NS-Signature":"<example-signature>"
"X-OCI-NS-SigningCertURL":"<example-url>"
"X-OCI-NS-TopicOcid":"ocid.compartment.oc1..<unique_ID>"
"X-OCI-NS-Timestamp":"2019-04-19T21:26:00.310+0000"
"X-OCI-NS-MessageId":"<unique_ID>"
"X-OCI-NS-TopicName":"mytopic"
"X-OCI-NS-MessageType":"SubscriptionConfirmation"
"X-OCI-NS-ConfirmationURL":"<exampleConfirmationURL>"
"X-OCI-NS-SubscriptionId":"ocid1.onssubscription.oc1.phx..<unique_ID>"
"X-OCI-NS-State":"Pending"
```

  - In the request body, see the value of the `ConfirmationURL` key.

  **Example ConfirmationURL key and value (request body)**:

```
"ConfirmationURL":"<exampleConfirmationURL>"
```

- **PagerDuty**: Incident titled "Oracle Notification Service Subscription Confirmation". For more information, see [the PagerDuty documentation for Oracle Cloud Infrastructure](https://pdr.dynatrace.com/docs/).
Notifications

- **Slack**: Message sent to Slack channel containing the text "To confirm the subscription".
- **SMS**: Message sent to phone number containing the text "REPLY 'CONFIRM <short-topic-id>' to confirm subscription."

<short-topic-id> is the short code of the topic that the SMS subscription was added to. The short code is used to identify the topic in messages sent to SMS subscriptions. Each short code contains six case-insensitive alphanumeric characters.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missing an SMS confirmation message? See International SMS capabilities.</td>
</tr>
</tbody>
</table>

To resend a subscription confirmation

The ability to resend subscription confirmations is only applicable for pending subscriptions.

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. For the subscription you want to resend the confirmation for, click the Actions icon (three dots), and then click Resend Confirmation.

To update the retry duration for a subscription

The retry duration is part of the delivery policy for the subscription. By default, Notifications retries delivery of a message for up to two hours.

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. For the subscription you want to update, click the Actions icon (three dots), and then click Update Delivery Policy.
3. In the Update Delivery Policy dialog box, click the edit icon for Max Retry Duration in Minutes, type the new value, and then click the save icon.

To move a subscription to a different compartment

The associated topic remains in its current compartment. For more information, see Moving Topics and Subscriptions to a Different Compartment on page 4253.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service on page 3016.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. In the Scope section, select a compartment.
3. Find the subscription in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To delete a subscription (unsubscribe)

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Every message sent out as email contains a link to unsubscribe from the related topic.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. For the subscription you want to delete, click the Actions icon (three dots), and then click Delete.
3. Confirm when prompted.
Managing Tags for a Topic or Subscription

You can apply tags to your resources, such as topics and subscriptions, to help you organize them according to your business needs. You can apply tags at the time you create a topic or subscription, or you can update the topic or subscription later with the tags you want. For general information about applying tags, see Resource Tags on page 239.

To manage tags for a topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Choose the Compartment that contains the topic you want to tag, and then click the topic’s name.
3. Click the Tags tab to view or edit existing tags, or click Add Tags to add new ones.

For more information, see Resource Tags on page 239.

To manage tags for a subscription

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Choose the Compartment that contains the subscription you want to tag, and then click the name of the topic that has the subscription.
3. For the subscription you want to tag, click the Actions icon (three dots), and then click Add Tags.

   To view or edit existing tags, click the Actions icon (three dots), and then click View Tags.

For more information, see Resource Tags on page 239.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage topics:

- CreateTopic
- GetTopic
- ListTopics
- UpdateTopic
- ChangeTopicCompartment
- DeleteTopic

Use these API operations to manage subscriptions:

- CreateSubscription
- GetSubscription
- ListSubscriptions
- UpdateSubscription
- ChangeSubscriptionCompartment
- GetConfirmSubscription
- ResendSubscriptionConfirmation
- GetUnsubscription
- DeleteSubscription

Publishing Messages

This topic describes how to publish messages directly using the Notifications service. You can manually enter the message content or allow a service or app to programmatically define the message content.

Each message is broadcast to all subscriptions in the specified topic. Every message sent out as email contains a link to unsubscribe from the related topic.
Notifications

Message delivery rate limits per endpoint: 60 messages per minute for HTTP-based protocols. (HTTP-based protocols use URL endpoints that begin with "http:" or "https:".) 10 messages per minute for Email protocol.

Prerequisites

• IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview on page 4248.

• Before you can publish a message, you need a topic with at least one subscription. See Managing Topics and Subscriptions on page 4255.

Creating Automation with Functions and Events

You can create automation by publishing messages to function subscriptions. For an example of a function subscription, see Scenario A: Automatically Resize VMs on page 4264.

You can create also automation based on state changes of your topics and subscriptions (Notifications resources) by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Using the Console

To publish a message

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.

2. On the Topics page, for the topic you want, click the Actions icon (three dots), and then click Publish Message.

3. In the Publish Message dialog box, fill in the fields:

   • Title: Enter the title you want to send.

   Rendering of the title by protocol

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

   • Message: Enter the content you want to send.

   Note:

   Message size limit per request: 64KB.

4. Click Publish.

   For troubleshooting information related to published messages, see Message not received on page 4283.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to publish messages:

   PublishMessage
Scenarios

Here are a few basic scenarios to help you understand the Notifications service and generally how the components work together.

Scenario A: Automatically Resize VMs on page 4264
Scenario B: Send Alarm Messages to Slack and SMS on page 4271

Scenario A: Automatically Resize VMs

This topic explains how to set up automatic resizing for virtual machines (VMs) that exceed memory.

This scenario involves writing a function to resize VMs and creating an alarm that sends a message to that function. When the alarm fires, the Notifications service sends the alarm message to the destination topic, which then fans out to the topic’s subscriptions. In this scenario, the topic’s subscriptions include the function as well as your email address and an SMS phone number. The function is invoked on receipt of the alarm message.

Note:
The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 4284.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring, Notifications, and Functions. You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic. To resize VMs, the function must be authorized to update Compute instances. To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2701.

Task 1: Create and Authorize Your Function

Once you create your function to resize VMs using your preferred SDK and authorize your function to access VMs (include the function in a dynamic group and grant that dynamic group access), all other scenario steps can be completed in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.
Notifications

For more information about authorizing functions to access other Oracle Cloud Infrastructure resources, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2701.

Function code sample

Note:

For this code sample, we recommend handling idempotency via a database.

The following code sample is for a function to resize VMs. For instructions on creating and deploying functions, see Creating and Deploying Functions on page 2684.

```python
import io
import json
import oci
from fdk import response

def increase_compute_shape(instance_id, alarm_msg_shape):
    signer = oci.auth.signers.get_resource_principals_signer()
    compute_client = oci.core.ComputeClient(config={}, signer=signer)
    current_shape = compute_client.get_instance(instance_id).data.shape
    print("INFO: current shape for Instance {}:
    {1}".format(instance_id,current_shape), flush=True)
    if current_shape != alarm_msg_shape:
        return "The shape of Instance {} differs from the Alarm
        message".format(instance_id)
    # improve the logic below to handle more scenarios, make sure the shapes
    you select are available in the region and AD
    if  current_shape == "VM.Standard1.1":
        new_shape = "VM.Standard2.1"
    elif current_shape == "VM.Standard2.1":
        new_shape = "VM.Standard2.2"
    else:
        return "Instance {} cannot get a bigger shape than its current
        shape {}").format(instance_id,current_shape)
    print("INFO: new shape for Instance {}:
    {1}".format(instance_id,new_shape), flush=True)
    try:
        update_instance_details =
        oci.core.models.UpdateInstanceDetails(shape=new_shape)
        resp = compute_client.update_instance(instance_id=instance_id,
        update_instance_details=update_instance_details)
        print(resp, flush=True)
    except Exception as ex:
        print('ERROR: cannot update instance {}'.format(instance_id),
        flush=True)
        raise
    return "The shape of Instance {} is updated, the instance is
    rebooting...").format(instance_id)

def handler(ctx, data: io.BytesIO=None):
    alarm_msg = {}
    message_id = func_response = ""
    try:
        headers = ctx.Headers()
        message_id = headers["x-oci-ns-messageid"]
    except Exception as ex:
        print('ERROR: Missing Message ID in the header', ex, flush=True)
        raise
    print("INFO: Message ID = ", message_id, flush=True)
    # the Message Id can be stored in a database and be used to check for
duplicate messages
    try:
alarm_msg = json.loads(data.getvalue())
print("INFO: Alarm message: ")
print(alarm_msg, flush=True)
except (Exception, ValueError) as ex:
print(str(ex), flush=True)
if alarm_msg["type"] == "OK_TO_FIRING":
    if alarm_msg["alarmMetaData"][0]["dimensions"]["dimensions"][0] == alarm_msg["alarmMetaData"][0]["dimensions"][0][0]  # assuming the first dimension matches the instance to resize
        print("INFO: Instance to resize: ", alarm_metric_dimension["resourceId"], flush=True)
        func_response = increase_compute_shape(alarm_metric_dimension["resourceId"], alarm_metric_dimension["shape"],
    )
    print("INFO: ", func_response, flush=True)
    else:
        print('ERROR: There is no metric dimension in this alarm message", flush=True)
        func_response = "There is no metric dimension in this alarm message"
    else:
        print('INFO: Nothing to do, alarm is not FIRING", flush=True)
        func_response = "Nothing to do, alarm is not FIRING"
return response.Response(
    ctx,
    response_data=func_response,
    headers={"Content-Type": "application/json"}
)

Include your function in a dynamic group

Find and note your function OCID (format is ocid1.fnfunc.oocl.iad.exampleuniqueID), then specify the following rule in the relevant dynamic group:

resource.id = '<function-ocid>'

Create a policy to grant the dynamic group access to VMs (Compute instances)

Add the following policy:

allow dynamic-group <dynamic-group-name> to use instances in tenancy

Task 2: Create the alarm, topic, and subscriptions

You can create the alarm, topic, and subscriptions in the Console, CLI, or API.

Using the Console

This section walks through creating the alarm, topic, and subscriptions using the Console. Your function must be deployed.

Note:

Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

Create the alarm, topic, and function subscription
This example walks through using the Console to create an alarm that sends a message to run the function when high memory usage is detected. During this process, you'll create a topic that references your function. You can add the SMS and email subscriptions later.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.
2. Click **Create alarm**.
3. On the **Create Alarm** page, under **Define alarm**, set up your threshold:
   
   - **Metric description**:
     - **Compartment**: (select the compartment that contains your VM)
     - **Metric Namespace**: oci_computeagent
     - **Metric Name**: MemoryUtilization
     - **Interval**: 1m
     - **Statistic**: Max
   
   - **Trigger rule**:
     - **Operator**: greater than
     - **Value**: 90
     - **Trigger Delay Minutes**: 1

4. Select your function under **Notifications, Destinations**:
   
   - **Destination Service**: Notifications Service
   - **Compartment**: (select the compartment where you want to create the topic and associated subscriptions)
   - **Topic**: Click **Create a topic**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you already created your topic and function subscription, you can select that topic here instead of creating a new one.</td>
</tr>
</tbody>
</table>

   - **Topic Name**: Alarm Topic. Avoid entering confidential information.
   - **Subscription Protocol**: Function
   - **Function Compartment**: (select the compartment that contains your function)
   - **Function Application**: (select the application that contains your function)
   - **Function**: (select your function)

5. Click **Save alarm**.

Add an SMS subscription

This example walks through using the Console to add an SMS subscription to the topic you created when you set up the alarm.

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, set up your SMS subscription:
   
   - **Protocol**: Select SMS.
   - **Country**: Select the country for the phone number.
   - **Phone Number**: Enter the phone number, using E.164 format.

   Example SMS endpoints:
   
   - Phone Number (E.164 format): +14255550100
5. Click **Create**.

The SMS subscription has been created and a subscription confirmation message is sent to the specified phone number. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new SMS subscription, follow the instructions in the received confirmation message. (Look for the message containing the phrase "REPLY 'CONFIRM" followed by your topic name.)

Add an email subscription (optional)

This example walks through using the Console to add an optional email subscription to the topic you created when you set up the alarm.

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, set up your email subscription:
   - **Protocol**: Select **Email**.
   - **Email**: Type an email address.
5. Click **Create**.

The email subscription has been created and a subscription confirmation URL is sent to the specified email address. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new email subscription, open your email and navigate to the confirmation URL.

**Using the CLI**

This section walks through creating the topic, subscriptions, and alarm using the CLI. Your function must be deployed.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

1. **Create the topic**

Open a command prompt and run the `oci ons topic create` command:

```
oci ons topic create --name "Alarm Topic" --compartment-id "$<compartment-ocid>"
```
2. Add the subscriptions

To this topic, add subscriptions referencing your function OCID, an SMS phone number, and an optional email address.

- Create a function subscription: Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "ORACLE_FUNCTIONS" --subscription-endpoint "<function-ocid>"
  ```

- Create an SMS subscription: Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SMS" --subscription-endpoint "<sms-endpoint>"
  ```

- Create an email subscription (optional): Open a command prompt and run the `oci ons subscription create` command:

  ```bash
  oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
  ```

3. Create the alarm

Create an alarm that defines the memory threshold and references this topic as the destination: Open a command prompt and run the `oci monitoring alarm create` command:

```bash
oci monitoring alarm create --display-name "VM Memory Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --namespace "oci_computeagent" --query-text "MemoryUtilization[1m].max() > 90" --severity "CRITICAL" --destinations "<topic-ocid>" --is-enabled true
```

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

Using the API

This section walks through creating the topic, subscriptions, and alarm using the API. Your function must be deployed.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

1. **CreateTopic**: Create a topic.

   **Example CreateTopic request**

   ```bash
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "name": "Alarm Topic",
     "compartmentId": "<compartment_OCID>"
   }
   ```
2. **CreateSubscription**: To this topic, add subscriptions referencing your function OCID, SMS phone number, and an optional email address.

**Example CreateSubscription request: Function**

```
POST /20181201/subscriptions
Host: cp.notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "ORACLE_FUNCTIONS",
  "endpoint": "<function_OCID>"
}
```

**Example CreateSubscription request: SMS**

```
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "SMS",
  "endpoint": "<sms-endpoint>"
}
```

**Example CreateSubscription request: Email**

```
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "topicId": "<topic_OCID>",
  "compartmentId": "<compartment_OCID>",
  "protocol": "EMAIL",
  "endpoint": "john.smith@example.com"
}
```

3. **CreateAlarm**: Create an alarm that defines the memory threshold and references this topic.

**Example CreateAlarm request**

```
POST /20180401/alarms
Host: telemetry.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "displayName": "VM Memory Alarm",
  "compartmentId": "<compartment_OCID>",
  "metricCompartmentId": "<compartment_OCID>",
  "namespace": "oci_computeagent",
  "query": "MemoryUtilization[1m].max() > 90",
  "severity": "CRITICAL",
  "destinations": [
    "<topic_OCID>"
  ],
  "isEnabled": true
}
```

For help with troubleshooting, see the [Troubleshooting Notifications](#) on page 4283.
Scenario B: Send Alarm Messages to Slack and SMS

This topic explains how to set up automatic notifications to a Slack channel and an SMS phone number when alarms are triggered.

This scenario involves setting up a Slack endpoint for a channel and creating an alarm that sends a message to both that channel and an SMS phone number. When the alarm fires, the Notifications service sends the alarm message to the destination topic, which then fans out to the topic's subscriptions. In this scenario, the topic's subscriptions include the Slack channel and SMS phone number as well as your email address.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring and Notifications.

Task 1: Set up your Slack endpoint

Create an incoming webhook to your Slack app.

Example of an incoming webhook to a Slack app (equivalent to the Slack endpoint for your subscription): https://hooks.slack.com/services/T00000000/B00000000/xxxxxxxxxxxxxxxxxxxx

Once you set up your Slack endpoint, you can complete all other scenario steps in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Task 2: Create the alarm, topic, and subscriptions

You can create the alarm, topic, and subscriptions in the Console, CLI, or API.

Using the Console

This section walks through creating the alarm, topic, and subscriptions using the Console.

Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

Create the alarm, topic, and Slack subscription

This example walks through using the Console to create an alarm that sends a message to Slack when a high CPU usage is detected. During this process, you'll create a topic that references your Slack channel (Slack endpoint, including the webhook token). You can add the SMS and email subscriptions later.

2. Click Create alarm.
3. On the Create Alarm page, under Define alarm, set up your threshold:
   • Metric description:
     • Compartment: (select the compartment that contains your VM)
     • Metric Namespace: oci_computeagent
     • Metric Name: CpuUtilization
     • Interval: 1m
     • Statistic: Count
   • Trigger rule:
     • Operator: greater than
     • Value: 90
     • Trigger Delay Minutes: 1

4. Add your Slack endpoint under Notifications, Destinations:
   • Destination Service: Notifications Service
   • Compartment: (select the compartment where you want to create the topic and associated subscriptions)
   • Topic: Click Create a topic

   Note:
   If you already created your topic and Slack subscription, you can select that topic here instead of creating a new one.

   • Topic Name: Alarm Topic. Avoid entering confidential information.
   • Subscription Protocol: Slack
   • URL: Your Slack endpoint, including the webhook token.

5. Click Save alarm.

6. Confirm your new Slack subscription: Navigate to the confirmation URL that is sent to the Slack channel. (Look for the message containing the phrase "To confirm the subscription".)

Add an SMS subscription

This example walks through using the Console to add an SMS subscription to the topic you created when you set up the alarm.

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.

2. Click the name of the topic that you want to add the subscription to.

   Example: "Alarm Topic" (assuming you used the suggested topic name when creating the topic in the alarm).

3. On the topic detail page, click Create Subscription.

4. In the Create Subscription dialog box, set up your SMS subscription:
   • Protocol: Select SMS.
   • Country: Select the country for the phone number.
   • Phone Number: Enter the phone number, using E.164 format.

   Example SMS endpoints:
   • Phone Number (E.164 format): +14255550100

5. Click Create.

   The SMS subscription has been created and a subscription confirmation message is sent to the specified phone number. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new SMS subscription, follow the instructions in the received confirmation message. (Look for the message containing the phrase "REPLY 'CONFIRM" followed by your topic name.)

Add an email subscription (optional)

This example walks through using the Console to add an optional email subscription to the topic you created when you set up the alarm.
1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.

2. Click the name of the topic that you want to add the subscription to. Example: "Alarm Topic" (assuming you used the suggested topic name when creating the topic in the alarm).

3. On the topic detail page, click **Create Subscription**.

4. In the **Create Subscription** dialog box, set up your email subscription:
   - **Protocol**: Select **Email**.
   - **Email**: Type an email address.

5. Click **Create**.

   The email subscription has been created and a subscription confirmation URL is sent to the specified email address. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new email subscription, open your email and navigate to the confirmation URL.

---

**Using the CLI**

This section walks through creating the topic, subscriptions, and alarm using the CLI.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

1. **Create the topic**

   Open a command prompt and run the `oci ons topic create` command:

   ```bash
   oci ons topic create --name "Alarm Topic" --compartment-id "<compartment-ocid>"
   ```

2. **Add the subscriptions**

   To the topic you just created in the previous step, add subscriptions referencing your Slack endpoint (including the webhook token) and an optional email address and SMS phone number.

   - Create a Slack subscription: Open a command prompt and run the `oci ons subscription create` command:
     ```bash
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SLACK" --subscription-endpoint "<slack-endpoint>"
     ```

   - Create an SMS subscription: Open a command prompt and run the `oci ons subscription create` command:
     ```bash
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "SMS" --subscription-endpoint "<sms-endpoint>"
     ```

   - Create an email subscription (optional): Open a command prompt and run the `oci ons subscription create` command:
     ```bash
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
     ```

3. **Create the alarm**

   Create an alarm that defines the CPU threshold and references this topic as the destination: Open a command prompt and run the `oci monitoring alarm create` command:

   ```bash
   oci monitoring alarm create --display-name "VM Memory Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --namespace "oci_computeagent" --query-text
   ```
For help with troubleshooting, see Troubleshooting Notifications on page 4283.

**Using the API**

This section walks through creating the topic, subscriptions, and alarm using the API.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

1. **CreateTopic**: Create a topic.

   **Example CreateTopic request**

   ```
   POST /20181201/topics
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "name": "Alarm Topic",
   "compartmentId": "<compartment_OCID>"
   }
   ```

2. **CreateSubscription**: To this topic, add subscriptions referencing your Slack channel and optionally your email address and SMS phone number.

   **Example CreateSubscription request: Slack**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "topicId": "<topic_OCID>",
   "compartmentId": "<compartment_OCID>",
   "protocol": "SLACK",
   "endpoint": "<slack-endpoint>"
   }
   ```

   **Example CreateSubscription request: SMS**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "topicId": "<topic_OCID>",
   "compartmentId": "<compartment_OCID>",
   "protocol": "SMS",
   "endpoint": "<sms-endpoint>"
   }
   ```

   **Example CreateSubscription request: Email**

   ```
   POST /20181201/subscriptions
   Host: notification.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
   "topicId": "<topic_OCID>",
   "compartmentId": "<compartment_OCID>",
   "protocol": "EMAIL",
   "endpoint": "john.smith@example.com"
   }
3. **CreateAlarm**: Create an alarm that defines the CPU threshold and references this topic.

**Example CreateAlarm request**

```
POST /20180401/alarms
Host: telemetry.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "displayName": "CPU Alarm",
    "compartmentId": "<compartment_OCID>",
    "metricCompartmentId": "<compartment_OCID>",
    "namespace": "oci_computeagent",
    "query": "CPUUtilization[1m].count() > 90",
    "severity": "CRITICAL",
    "destinations": [
        "<topic_OCID>",
    ],
    "isEnabled": true
}
```

For help with troubleshooting, see [Troubleshooting Notifications](#) on page 4283.

**Scenario C: File Jira Tickets for Reminders**

This topic explains how to file automatic Jira tickets whenever maintenance reminder events occur. In this scenario, whenever a reminder for upcoming database maintenance comes from Oracle Cloud Infrastructure, a Jira ticket is created for your on-call engineer.

This scenario involves writing a function to file Jira tickets (and creating a secret to store your Jira credentials), adding that function and optional email as subscriptions to a topic, and creating a rule that sends messages to that topic when maintenance reminder events occur (see [Database Service: Autonomous Container Database Event Types](#) on page 2460). The message fans out to the topic's subscriptions, which includes a group email address in addition to the function. The function is invoked on receipt of the message.

Everything but the function can be set up in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

**Note:**

The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at [Function not invoked or run](#) on page 4284.
For more information about this scenario, see Automated Jira Ticketing using OCI Events, Notifications, and Functions and the associated GitHub repository.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Events, Notifications, and Functions. You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic. To access your Jira credentials, the function must be authorized to read secrets. This scenario walks through steps to provide this authorization.

**Task 1: Store your Jira credentials in a secret**

You can create a secret in the Console, CLI, or API. You'll reference this secret later, when creating your function.

**Using the Console**

To create the secret for your Jira credentials

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a secret.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create a secret.
   - Create a new vault for the secret by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Secrets, and then click Create Secret.
5. In the Create Secret dialog box, choose a compartment from the Create in Compartment list. (Secrets can exist outside the compartment the vault is in.)
6. Click Name, and then enter a name to identify the secret. Avoid entering confidential information.
   - Example name: jira_auth_plain_text
7. Click Description, and then enter a brief description of the secret to help identify it. Avoid entering any confidential information in this field.
   - Example description: jira_auth_plain_text
8. Choose the master encryption key that you want to use to encrypt the secret contents while they're imported to the vault. (The key must belong to the same vault.)

9. For Secret Type Template, select Plain-Text.

10. Click Secret Contents, and then enter your Jira credentials in the following format, with a colon separating your login email from your auth token:

<your-jira-cloud-login-email>:<your-jira-cloud-auth-token>

11. Click Create Secret.

12. Note the secret OCID for use in your function code to securely fetch the secret.

For more information about creating secrets using the Vault service, see To create a new secret on page 5068.

Using the CLI

To create the secret using the CLI

Create a secret storing your Jira credentials: Open a command prompt and run the

oci vault secret create-base64 command:

oci vault secret create-base64 --compartment-id <compartment_OCID> --secret-name <secret_name> --vault-id <vault_OCID> --description <secret_description_text> --key-id <encryption_key_OCID> --secret-content-content <base64_encoded_secret_content> --secret-content-name <unique_content_name>

Avoid entering confidential information.

For more information about managing secrets using the CLI, see Using the Command Line Interface (CLI) on page 5073.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the CreateSecret operation.

Example CreateSecret request

POST /20180608/secrets
Host: <managementEndpoint>
<authorization and other headers>

{"vaultId": "<vault_OCID>",
 "compartmentId": "<compartment_OCID>",
 "secretName": "jira_auth_plain_text",
 "description": "jira_auth_plain_text",
 "keyId": "<key_OCID>",
 "secretContent":{
  "content": "<base64_encoded_secret_contents>",
  "contentType": "BASE64"
 })

For more information about managing secrets using the API, see Using the API on page 5078.

Task 2: Create the function

This section provides the code sample for creating your function and covers steps to authorize the function to access your Jira credentials in the secret created using the Vault service.

Function code sample

The following code sample is for a function to file Jira tickets.
Add your secret OCID in the line that includes getSecretForOcid.

For instructions on creating and deploying functions, see Creating and Deploying Functions on page 2684.

```java
public String handleRequest(CloudEvent cloudEvent) {
    // Json body of Cloud event from Oracle Event Service in serialized into
    // cloudEvent object by Fn SDK implicitly
    System.err.println("Inside Java jira function with input as "+
    cloudEvent.getEventType() + " "+ cloudEvent.getData().getResourceName());

    String response = jiraCreateTicket(cloudEvent);
    if (response != null) return response;
    return null;
}

private String jiraCreateTicket(CloudEvent cloudEvent) {
    try {
        //create jira ticket body as per CloudEvent
        String jsonBodyJira = getJiraApiBody(cloudEvent);

        String jiraCloudEndpoint = System.getenv().get("JIRA_CLOUD_URL");
        String ocidForSecretForJiraAuthToken = System.getenv().get("JIRA_CLOUD_SECRET_OCID");
        String jiraAuthToken = getSecretForOcid(ocidForSecretForJiraAuthToken); // base64 encoded form of
        // actual REST call to JIRA cloud
        OkHttpClient client = new OkHttpClient().newBuilder()
            .build();
        MediaType mediaType = MediaType.parse("application/json");
        RequestBody body = RequestBody.create(mediaType, jsonBodyJira);
        Request request = new Request.Builder()
            .url(jiraCloudEndpoint)
            .method("POST", body)
            .addHeader("Accept", "application/json")
            .addHeader("Content-Type", "application/json")
            .addHeader("Authorization", "Basic " + jiraAuthToken)
            .build();
        Response response = client.newCall(request).execute();
        return response.body().string();
    } catch (JsonProcessingException e) {
        e.printStackTrace();
    } catch (IOException e) {
        e.printStackTrace();
    }
    return null;
}
```

**Authorize your function to access secrets**

Use a *dynamic group* to grant your function the ability to read secrets. Your function must have this authorization to access your Jira credentials, which are stored in the secret you created earlier.

**To authorize your function to access secrets (Console)**

1. Find and note your function **OCID** (format is ocid1.fnfunc.o1.iad.exampleuniqueID).
2. Include your function in a dynamic group: In the relevant dynamic group, specify the following rule:

   \[
   \text{resource.id = '<function-ocid>'}
   \]

Alternatively, you can create a dynamic group that includes all functions:

\[
\text{ALL{resource.type='fnfunc', resource.compartment.id='<compartment_OCID>'}}
\]

3. Grant the dynamic group access to secrets: Add the following policy:

   \[
   \text{allow dynamic-group <dynamic-group-name> to read secret-family in tenancy}
   \]

To authorize your function for access to other Oracle Cloud Infrastructure resources, such as Compute instances, include the function in a dynamic group and create a policy to grant the dynamic group access to those resources. For more information, see Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2701.

For more information about dynamic groups, see Managing Dynamic Groups on page 3118.

**Task 3: Create the topic, subscriptions, and rule**

This section walks through creating a topic, adding your function and optional email as subscriptions, and creating the rule that sends a message whenever the Database service emits an event for a database maintenance reminder. Your function must be deployed.

Everything can be set up in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

For more information about managing topics and subscriptions, see Managing Topics and Subscriptions on page 4255. For more information about managing rules, see Managing Rules for Events on page 2399.

**Using the Console**

To create the topic

This section walks through creating the topic you'll use for the subscriptions and rule.

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click Create Topic at the top of the topic list.
3. In the Create Topic dialog box, configure your topic.
   - **Name**: Required. Specify a friendly name for the topic. It must be unique across the tenancy; validation is case-sensitive. Avoid entering confidential information.
     
     Example: Maintenance Topic
   - **Description**: Optional. Enter a description for the topic. Avoid entering confidential information.
4. Click Create.

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

To create the function subscription

This section walks through adding your function as a subscription to the topic. Your function must be deployed.

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click the name of the topic that you want to add the subscription to.

Example: "Maintenance Topic" (assuming you used the suggested topic name when creating the topic).
3. On the topic detail page, click Create Subscription.
4. In the Create Subscription dialog box, configure your function subscription:

   **Note:**
   
   The function must be deployed. You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.
The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 4284.

Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select Function.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

5. Click **Create**.

The subscription has been created.

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

To create an email subscription

This section walks through adding an optional email subscription to your topic.

1. Open the navigation menu and click **Developer Services**. Under Application Integration, click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.
   
   Example: "Maintenance Topic" (assuming you used the suggested topic name when creating the topic).

3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, set up your email subscription:
   - **Protocol**: Select **Email**.
   - **Email**: Type an email address.

5. Click **Create**.

The email subscription has been created and a subscription confirmation URL is sent to the specified email address. The subscription remains in "Pending" status until it has been confirmed.

6. To confirm your new email subscription, open your email and navigate to the confirmation URL.

For more information, see To confirm a subscription on page 4260.

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

To create the rule

This section walks through creating the rule that sends a message to the topic whenever the Database service emits an event for a database maintenance reminder.

1. Open the navigation menu and click **Observability & Management**. Under Events Service, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.

Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.

3. Enter the following.
   - **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
     
     Example: Maintenance Reminder
   - **Description**: Specify a description of what the rule does. You can change this description later. Avoid entering confidential information.
     
     Example: Sends messages to Maintenance Topic

4. In **Rule Conditions**, create a filter for database reminder events:
   - For **Service Name**, select **Database**.
   - In **Event type**, select Autonomos Container Database – Maintenance Reminder.
5. In **Actions**, select the topic you previously created:
   a. Select **Notifications**.
   b. Select the **Notifications Compartment**.
   c. Select the **Topic** that you previously created.

6. Click **Create Rule**.

**Using the CLI**

This section walks through creating the topic, subscriptions, and rule using the CLI. Your function must be deployed.

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

1. **Create the topic**

   Open a command prompt and run the `oci ons topic create` command:

   ```
   oci ons topic create --name "Maintenance Topic" --compartment-id "<compartment-ocid>"
   ```

2. **Add the subscriptions**

   To the topic you just created in the previous step, add subscriptions referencing your function OCID and an optional email address.

   • Create a function subscription: Open a command prompt and run the `oci ons subscription create` command:

     ```
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "ORACLE_FUNCTIONS" --subscription-endpoint "<function-ocid>"
     ```

   • Create an email subscription: Open a command prompt and run the `oci ons subscription create` command:

     ```
     oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "maintenance.team@example.com"
     ```

3. **Create the rule**

   Create a rule that is triggered by maintenance reminders and references this topic as the destination:

   a. Create a file, `action.json`, that contains the following, referencing your topic created previously:

   ```
   {
   "actions": [
   {
   "actionType": "ONS",
   "description": "string",
   "isEnabled": true,
   "topicId": "<topic_OCID>"
   }
   ]
   }
   ```

   b. Open a command prompt and run the `oci events rule create` command:

   ```
   oci events rule create --display-name <friendly_name> --is-enabled true --condition "{"eventType": ["com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder"]}" --compartment-id <compartment_OCID> --actions file://action.json
   ```

   For more information about creating rules using the CLI, see **To create a rule** on page 2409.
Notifications

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

Using the API

This section walks through creating the topic, subscriptions, and rule using the API. Your function must be deployed.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

1. CreateTopic: Create a topic.

Example CreateTopic request

```plaintext
POST /20181201/topics
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "name": "Maintenance Topic",
    "compartmentId": "<compartment_OCID>"
}
```

2. CreateSubscription: To this topic, add subscriptions referencing your function OCID and an optional email address.

Example CreateSubscription request: Function

```plaintext
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "topicId": "<topic_OCID>",
    "compartmentId": "<compartment_OCID>",
    "protocol": "ORACLE_FUNCTIONS",
    "endpoint": "<function_OCID>"
}
```

Example CreateSubscription request: Email

```plaintext
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "topicId": "<topic_OCID>",
    "compartmentId": "<compartment_OCID>",
    "protocol": "EMAIL",
    "endpoint": "maintenance.team@example.com"
}
```

3. CreateRule: Create a rule that is triggered by maintenance reminders and references this topic as the destination.

Example CreateRule request

```plaintext
POST /20181201/rules
Host: events.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "displayName": "Maintenance Reminder",
    "condition": "{
        "eventType": "com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder"
    }",
```

Oracle Cloud Infrastructure User Guide 4282
Notifications

```
"compartmentId": "<compartment_OCID>",
"isEnabled": true,
"actions": {
  "actions": [
    {
      "actionType": "ONS",
      "topicId": "<topic_OCID>",
      "isEnabled": true
    }
  ]
}
```

For help with troubleshooting, see Troubleshooting Notifications on page 4283.

### Troubleshooting Notifications

This topic covers troubleshooting techniques for Notifications.

#### Message not received

**Tip:**

Assess alarms and messages using their unique identifiers. See Prevent Processing of Duplicate Items on page 4254. To view the format used by alarm messages, see Message format and examples on page 3460.

Check these items:

- **Alarm firing transition:** If the message is a result of a firing alarm, then view the history of the alarm. Note times for any transition to a firing state. You'll use noted times for comparison to metrics for your topic ("Publication and delivery").

  **To view history for your alarm**
  2. On the Alarm Definitions page, click the alarm that you want to view history for.
  3. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.

- **Publication and delivery:** Note times for messages published to your topic as well as messages delivered to your topic. Compare to times of the firing alarm or other inciting incident.

  **To view timing of published and delivered messages for your topic**
  1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
  2. Choose the Compartment that contains your topic, and then click the topic's name.
  3. In the Resources menu, click Metrics.

    The Metrics page displays a chart for each metric that is emitted by the metric namespace for Notifications. For more information about the emitted metrics, see Available Metrics: oci_notification on page 4286.
  4. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.
  5. Review the following metric charts:

    - Published Messages Total Count
    - Delivered Messages Count

- **Service permissions (alarm messages):** If your topic is in an Oracle Platform Services managed compartments (named "ManagedCompartmentForPaas"), then the Monitoring service may not have permissions to use it, and alarm messages sent to that topic may not be received. For more details, including steps for resolution, see Alarm Messages are not Received in Oracle Platform Services Managed Compartments.
• **Unsupported method used to send messages:** Confirm that the method you used to send messages is supported for the **subscription protocols** used by the topic. Messages sent by unsupported methods are dropped, as indicated by data points in the **Failed Messages Count** metric chart.

The value of the metric dimension **endpointType** corresponds to the subscription protocol. For example, if you attempt to send an SMS message through an unsupported method, then the message is dropped and the counter of this metric chart is increased, with the corresponding data point showing an **endpointType** value of SMS.

**To view dropped messages for your topic**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Choose the **Compartment** that contains your topic, and then click the topic’s name.
3. In the **Resources** menu, click **Metrics**.

   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Notifications. For more information about the emitted metrics, see Available Metrics: oci_notification on page 4286.

4. Adjust the time range by selecting from **Quick Selects** or changing the **Start Time** and **End Time**.
5. Review the **Failed Messages Count** metric chart.

• **International SMS capabilities:** For missing SMS messages, confirm that you have the ability to send and receive SMS messages to and from other countries. International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

**Function not invoked or run**

This section provides troubleshooting information for function subscriptions. For an example function subscription, see Scenario A: Automatically Resize VMs on page 4264.

**Note:**

The Notifications service has no information about a function after it's invoked.

**Tip:**

Assess alarms and messages using their unique identifiers. See Prevent Processing of Duplicate Items on page 4254. To view the format used by alarm messages, see Message format and examples on page 3460.

Check these items:

• **Message receipt:** See Message not received on page 4283.
• **Function invocation:** Note times for invocations of your function. Compare to times of the firing alarm or other inciting incident.

  **Note:**

  If this is the first invocation, response may be delayed.

  **To view timing of invocations for your function**

  1. Open the detail page for your function by doing one of the following.

     • Find your function on the related subscription page:

       a. Open the navigation menu and click **Developer Services.** Under **Application Integration**, click **Notifications**.

       b. Choose the **Compartment** that contains your function subscription.

       c. Click **Subscriptions**.

       d. Under **Endpoint**, in the row for your function subscription, click the name of your function.

     • Find your function on a Functions page:

       a. In the Console, open the navigation menu and click **Developer Services.** Under **Functions**, click **Applications**.

       b. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see [Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure](#) on page 2770).

       c. Select the compartment containing the application that contains your function.

          The **Applications** page shows all the applications in the compartment you selected.

       d. Click the name of the application containing your function.

       e. Click the name of your function.

        The function detail page is displayed.

  2. Under **Resources**, click **Metrics**.

    The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see [Available Metrics: oci_faas](#) on page 2748.

  3. Adjust the time range by selecting from **Quick Selects** or changing the **Start Time** and **End Time**.

  4. Review the **Invocations** chart.

• **Function run:** Note times for runs of your function. Compare to times of the firing alarm or other inciting incident.

  **To view timing of runs of your function (logs)**

  See [Storing and Viewing Function Logs](#) on page 2724.

  **To view timing of runs of your function (metrics)**

  1. Open the detail page for your function by doing one of the following.

     • Find your function on a subscription page:

       a. Open the navigation menu and click **Developer Services.** Under **Application Integration**, click **Notifications**.

       b. Choose the **Compartment** that contains your function subscription.

       c. Click **Subscriptions**.

       d. Under **Endpoint**, in the row for your function subscription, click the name of your function.

     • Find your function on a Functions page:

       a. In the Console, open the navigation menu and click **Developer Services.** Under **Functions**, click **Applications**.
b. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

c. Select the compartment containing the application that contains your function.

The Applications page shows all the applications in the compartment you selected.

d. Click the name of the application containing your function.

e. Click the name of your function.

The function detail page is displayed.

2. Under Resources, click Metrics.

The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas on page 2748.

3. Adjust the time range by selecting from Quick Selects or changing the Start Time and End Time.

4. Review the Duration chart.

Notifications Metrics

You can monitor the health, capacity, and performance of your messages by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_notification (the Notifications service).

Resources: Not applicable. Measures data for messages, which are not resources.

Overview of the Notifications Service Metrics

The Notifications service metrics help you measure the number and size of messages that are in initial requests, are delivered, and are not delivered.

Prerequisites

• IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_notification

The metrics listed in the following table are automatically available for messages you publish to topics. You do not need to enable monitoring on any resources to get these metrics.

Each metric includes a subset of the following dimensions:

AVAILABLEBILITYDOMAIN

The availability domain in which the associated topic resides.

ENDPOINTTYPE

The subscription protocol of the endpoint used for the delivery attempt.

REGION

The region in which the associated topic resides.

RESOURCEID

The OCID of the resource to which the metric applies.
TOPICDISPLAYNAME

The friendly name of the associated *topic*.

Using the Console

To view default metric charts for a single topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Choose the Compartment that contains the topic you want to view, and then click the topic's name.
3. In the Resources menu, click Metrics (if necessary).

The Metrics page displays a default set of charts for the current topic.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for multiple topics

2. For Metric Namespace, select oci_notification.

The Service Metrics page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

Tip:

- Filter metrics by dimension, such as a selected topic, by clicking Add above the charts (to the right of Dimensions).
• **Aggregate data** across all topics (show a single line in the chart) by selecting the check box for **Aggregate Metric Streams** on the right.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 36

Object Storage

This chapter explains how to upload, manage, and access data using Object Storage.

### Object Storage

Object Storage is a fully programmable, scalable, and durable cloud storage service. Use this service to store and easily access an unlimited amount of data at low cost.

#### Get Started
- Overview of Object Storage on page 4290
- Object Storage characteristics
- Ways to access Object Storage
- Use Object Storage

#### Storage Tiers
- Understand storage tiers
- Manage object lifecycles

#### Troubleshooting

- Cloud infrastructure community forum

#### Overview of Object Storage

The Oracle Cloud Infrastructure Object Storage service is an internet-scale, high-performance storage platform that offers reliable and cost-efficient data durability. The Object Storage service can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos.

With Object Storage, you can safely and securely store or retrieve data directly from the internet or from within the cloud platform. Object Storage offers multiple management interfaces that let you easily manage storage at scale.
The elasticity of the platform lets you start small and scale seamlessly, without experiencing any degradation in performance or service reliability.

Object Storage is a regional service and is not tied to any specific compute instance. You can access data from anywhere inside or outside the context of the Oracle Cloud Infrastructure, as long you have internet connectivity and can access one of the Object Storage endpoints. Authorization and resource limits are discussed later in this topic.

Oracle Cloud Infrastructure supports multiple storage tiers that offer cost and performance flexibility. Standard is the default storage tier for Object Storage buckets.

Object Storage also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Object Storage public endpoints from private IP addresses in private subnets. For example, you can back up DB systems to an Object Storage bucket over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Object Storage. See Access to Oracle Services: Service Gateway on page 4127 for details.

Object Storage is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 166.

Object Storage Resources

Use the following Object Storage resources to store and manage data. Authorization and resource limits are discussed later in this topic.

Buckets

Buckets are logical containers for storing objects. Users or systems create buckets as needed within a region. A bucket is associated with a single compartment that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

Objects

Any type of data, regardless of content type, is stored as an object. An object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

Namespace

Namespace serves as the top-level container for all buckets and objects. At account creation time, each tenant is assigned one unique system-generated and immutable namespace name. The namespace spans all compartments within a region. You control bucket names, but those bucket names must be unique within a namespace. While the namespace is region-specific, the namespace name itself is the same in all regions. See Understanding Object Storage Namespaces on page 4294 for more details, including information about older tenancy names, illustrative examples of namespaces, and how to obtain your namespace string.

Compartment

A compartment is the primary building block used to organize your cloud resources. When your tenancy is provisioned, a root compartment is created for you. You can then create compartments under your root compartment to organize your resources. You control access by creating policies that specify what actions groups of users can take on the resources in those compartments. An Object Storage bucket can only exist in one compartment.

Object Storage Characteristics

Object Storage provides the following features:

STRONG CONSISTENCY

When a read request is made, Object Storage always serves the most recent copy of the data that was written to the system.

DURABILITY

Object Storage is a regional service. Data is stored redundantly across multiple storage servers. Object Storage actively monitors data integrity using checksums and automatically detects and repairs corrupt data.
Object Storage actively monitors and ensures data redundancy. If a redundancy loss is detected, Object Storage automatically creates more data copies. For more details about Object Storage durability, see the Object Storage FAQ.

custom metadata

You can define your own extensive metadata as key-value pairs for any purpose. For example, you can create descriptive tags for objects, retrieve those tags, and sort through the data. You can assign custom metadata to objects and buckets using the Oracle Cloud Infrastructure CLI or SDK. See Software Development Kits and Command Line Interface on page 5351 for details.

ENCRYPTION

Object Storage employs 256-bit Advanced Encryption Standard (AES-256) to encrypt object data on the server. Each object is encrypted with its own data encryption key. Data encryption keys are always encrypted with a master encryption key that is assigned to the bucket. Encryption is enabled by default and cannot be turned off. By default, Oracle manages the master encryption key.

In addition to this default encryption, you can employ these other strategies to encrypt data:

- You can optionally configure a bucket so that it's assigned an Oracle Cloud Infrastructure Vault master encryption key that you control and rotate on your own schedule. See Overview of Vault on page 5006 for details.
- You can optionally encrypt each Object Storage object using your own encryption key. See Using Your Own Keys for Server-Side Encryption on page 4406 for details.

Ways to Access Object Storage

You can access Object Storage using any of the following options, based on your preference and its suitability for the task you want to complete:

- The Console is an easy-to-use, browser-based interface.

  To access the Console, you must use a supported browser.

  Oracle Cloud Infrastructure supports the following browsers and versions:

  - Google Chrome 69 or later
  - Safari 12.1 or later
  - Firefox 62 or later

  You are prompted to enter your cloud tenant, your user name, and your password.

- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Using the CLI on page 5333.

- The REST API provides the most functionality, but requires programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs on page 5528. Object Storage is accessible with the following APIs:

  - Object Storage Service
  - Amazon S3 Compatibility API
  - Swift API (for use with Oracle RMAN)

  Oracle Cloud Infrastructure provides SDKs that interact with Object Storage without you having to create a framework. For general information about using the SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using Object Storage

If you are ready to use Object Storage, you can find more information in the following topics:

- For instructions on how to create a bucket and store an object in the bucket, see "Putting Data into Object Storage" in the Oracle Cloud Infrastructure Getting Started Guide.
• For task documentation related to buckets, see Managing Buckets on page 4298, Using Replication on page 4343, and Using Retention Rules to Preserve Data on page 4362.

• For task documentation related to objects, see Managing Objects on page 4322, Using Object Versioning on page 4350, and Copying Objects on page 4401.

• For task documentation related to lifecycle management, see Using Object Lifecycle Management on page 4370.

• For API reference documentation, see Object Storage Service API.

• For SDK and CLI information, see Software Development Kits and Command Line Interface on page 5351.

• For more information about using Archive Storage, see Overview of Archive Storage on page 566.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API). IAM also manages user credentials for things like API signing keys, auth tokens, and customer secret keys for Amazon S3 Compatibility API. See User Credentials on page 3056 for details.

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create users and groups, create buckets, download objects, and manage Object Storage-related policies and rules. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see the Policy Reference on page 2837. For specific details about writing policies for Object Storage, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Blocking Access to Object Storage Resources from Unauthorized IP Addresses

You can enhance the security of your Object Storage policies by restricting access only to requests that originate from an allowed IP address. First, you create a network source to specify the allowed IP addresses, then you add a condition to your policy to restrict access to the IP addresses in the network source. An example of a policy that restricts access to only IP addresses in a network source is:

```plaintext
allow group CorporateUsers to manage object-family in tenancy where request.networkSource.name='corpnet'
```

For information on creating network sources and using them in a policy, see Managing Network Sources on page 3123.

Object Storage IP Addresses

The Oracle Cloud Infrastructure Object Storage service uses the CIDR block IP range 134.70.0.0/16 for all regions.

Limits on Object Storage Resources

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

To set tenancy or compartment-specific storage limits, administrators can use Object Storage Quotas on page 297.

Other limits include:

• Number of Object Storage namespaces per root compartment: 1
• Maximum object size: 10 TiB
• Maximum object part size in a multipart upload: 50 GiB
• Maximum number of parts in a multipart upload: 10,000
• Maximum object size allowed by PutObject API: 50 GiB
• Maximum size of object metadata: 2 K
Understanding Object Storage Namespaces

Object Storage

namespace serves as the top-level container for all buckets and objects. At account creation time, each tenant is assigned one unique system-generated and immutable namespace name. The namespace spans all compartments within a region. You control bucket names, but those bucket names must be unique within a namespace. While the namespace is region-specific, the namespace name itself is the same in all regions.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot customize, change, or request a namespace name change.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For some older tenancies, the namespace name string might be based on your tenancy name instead of being machine generated. If your namespace was created based on your tenancy name, your namespace uses all lower-case letters (regardless of the presence of capital letters in your tenancy name). When using the API, CLI, or SDKs, do not use capital letters in your namespace name string.</td>
</tr>
</tbody>
</table>

If your tenancy is assigned a namespace name of axaxnprrorw5, that is your namespace name in all regions. You can create a bucket named MyBucket in US West (Phoenix). You cannot create another bucket named MyBucket in US West (Phoenix). You can, however, create a bucket named MyBucket in Germany Central (Frankfurt). Because the namespace name is unique to a tenant, other customers can create buckets named MyBucket in their own namespaces.

Within a namespace, buckets and objects exist in flat hierarchy, but you can simulate a directory structure to help navigate a large set of objects. See Object Naming Using Prefixes and Hierarchies on page 4323 for details.

The namespace metadata stores the default compartment assignments for the Amazon S3 Compatibility API and the Swift API. For more information, see Viewing and Specifying Designated Compartments.

Using the Console

To view your Object Storage namespace string:

Open the Profile menu and click Tenancy: <your_tenancy_name>.

Your namespace string is listed under Object Storage Settings.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>While the Object Storage namespace string is displayed under Object Storage Settings, you cannot edit the namespace string. The namespace string appears here for information only.</td>
</tr>
</tbody>
</table>

Using the Command Line Interface (CLI)

Run the following command get your Object Storage namespace:

oci os ns get

Your Object Storage namespace is returned:

```json
{
  "data": "MyNamespace"
}
```
Tip:

You can use `-ns`, `--namespace`, or `--namespace-name` for CLI commands that require you to specify the Object Storage namespace string.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the `GetNamespace` operation to get your Object Storage namespace. If you have the `OBJECTSTORAGE_NAMESPACE_READ` permission and supply the compartment or tenancy OCID in the optional `compartmentId` parameter, you can also get the namespace of a different tenancy's Object Storage namespace.

**Understanding Storage Tiers**

Oracle Cloud Infrastructure offers distinct storage class tiers to address the need for both performant, frequently accessed "hot" storage, less frequently accessed "cool" storage, and rarely accessed "cold" storage. Storage tiers help you maximize access performance where appropriate and minimize storage costs where possible.

Every object uploaded to Object Storage is assigned to a storage tier. The storage tier property of the object determines its storage costs and any associated retrieval fees. The storage tier property is assigned to an object in one of two ways:

- The object is automatically assigned the default storage tier of the bucket (Standard or Archive) that you are uploading the object to.
- If you are uploading an object to a Standard default storage tier bucket, you can explicitly assign any permitted storage tier (Standard, Infrequent Access, or Archive) to the object.

**Important:**

- Standard storage tier buckets can contain a mix of objects with different storage tier assignments. An object remains in the Standard bucket, even if the object is archived, restored, or if tier assignment is changed.
- Archive storage tier buckets can only contain objects with an Archive storage tier assignment. Archive buckets do not contain a mix of objects with different storage tier assignments. An object remains in the Archive bucket, even if the object is restored.

You interact with the data stored in any of the storage tiers using the same Object Storage resources and management interfaces. In addition, each storage tier supports the full range of Object Storage features. Specific storage tier details or interactions that you need to be aware of are covered in the Scope and Constraints section for the feature.

**Standard Tier**

The Standard tier is the primary, default storage tier used for Object Storage service data. The Standard storage tier is "hot" storage used for data that you need to access quickly, immediately, and frequently. Data accessibility and performance justifies a higher price to store data in the Standard tier.

You choose a default storage tier (Standard or Archive) when you create a bucket. When set at bucket creation, you cannot change the default storage tier for a bucket. When you upload objects to a bucket, the objects are automatically assigned the default storage tier of the bucket (Standard). You can, however, change the storage tier of an object to either Infrequent Access or Archive.

Standard storage tier buckets can contain a mix of objects with different storage tier assignments. An object remains in the Standard bucket, even if the object is archived, restored, or its tier assignment is changed.
When you choose a Standard default storage tier during bucket creation, you can also enable **Auto-Tiering**. Auto-Tiering helps you reduce storage costs by automatically moving objects between the Standard and Infrequent Access storage tiers based on data access patterns. See [Enabling Auto-Tiering](#) on page 4297 for details.

Some primary use cases for the Standard storage tier include the following:

- Content repository for accessible scalable data, images, logs, and video
- Repository for accessible backups
- Data repository for Hadoop/big data. Provides a scalable storage platform to store large datasets and operate seamlessly on those datasets. The [HDFS Connector for Object Storage](#) on page 5505 provides connectivity to various big data analytic engines like Apache Spark and MapReduce. This connectivity enables the analytics engines to work directly with data stored in Object Storage. For more information, see [Hadoop Support](#) on page 4422.

**Infrequent Access**

The **Infrequent Access** tier is "cool" storage used for data that you access infrequently, but that must be available immediately when needed. Storage costs are lower than **Standard**.

If you are uploading an object to a Standard default storage tier bucket, you can explicitly assign the object to the lower-cost Infrequent Access storage tier.

The Infrequent Access tier has a minimum storage retention period and data retrieval fees:

- The minimum storage retention period for the Infrequent Access tier is 31 days. If you delete or overwrite objects in the Infrequent Access tier before the retention requirements are met, you are charged the prorated cost of storing the data for the full 31 days.
- When you need to access objects stored in this tier, you are charged a per GiB data retrieval fee.

**Note:**

Minimum retention penalties are charged only when deletes and overwrites result in data removal. Deletes and overwrites in a version-enabled bucket that creates a previous version rather than removing data, does not result in a penalty.

Some primary use cases for the Infrequent Access storage tier include the following:

- Backups of on-premises data
- Repository for rarely accessed backups
- Storage for data replicated or copied from another region

**Archive**

The **Archive** tier is the primary, default storage tier used for **Archive Storage** service data. The Archive storage tier is "cold" storage used for data seldom or rarely access, but that must be retained and preserved for long periods of time.

You choose a default storage tier (Standard or Archive) when you create a bucket. When set at bucket creation, you cannot change the default storage tier for a bucket. When you upload objects to a bucket in an Archive tier, the objects are automatically assigned the default storage tier of the bucket (Archive).

Archive storage tier buckets can only contain objects with an Archive storage tier assignment. Archive buckets do **not** contain a mix of objects with different storage tier assignments. An object remains in the Archive bucket, even if the object is restored.

Objects in the Archive tier must be restored before they are available for access. The cost efficiency of the Archive tier offsets the lead time required to access the data. However, the Archive tier has a minimum storage retention period and some additional storage fees:

- The minimum storage retention period for the Archive tier is 90 days. If you delete or overwrite objects in the Archive tier before the retention requirements are met, you are charged the prorated cost of storing the data for the full 90 days.
When you restore objects, you are returning those objects to the Standard tier for access. You are billed for the Standard class tier while the restored objects reside in that tier.

**Note:**
Minimum retention penalties are charged only when deletes and overwrites result in data removal. Deletes and overwrites in a version-enabled bucket that creates a previous version rather than removing data, does not result in a penalty.

Some primary use cases for the Archive storage tier include the following:

- Compliance and audit mandates
- Retroactive log data analysis to determine usage pattern or to debug problems
- Historical or rarely accessed content repository data
- Application-generated data requiring archival for future analysis or legal purposes

**Enabling Auto-Tiering**

Auto-Tiering monitors data access patterns and helps you reduce storage costs by automatically moving objects larger than 1 MiB out of the Standard tier into the more cost-effective Infrequent Access tier. Auto-Tiering is enabled at the bucket-level and monitors the data access patterns of all objects in the bucket. You can enable Auto-Tiering for any Standard storage tier bucket at creation time. You can also enable Auto-Tiering at any time after bucket creation.

**Note:**
You cannot enable Auto-Tiering if you have a lifecycle policy rule that moves objects, object versions, or previous object versions to the Infrequent Access tier. If appropriate, delete the rule and try to enable Auto-Tiering again.

After you enable Auto-Tiering, objects remain in the Standard tier until they meet the minimum access and storage requirements required for movement eligibility to Infrequent Access. If Object Storage moved objects to Infrequent Access that are later accessed more frequently, we automatically move the objects back to the Standard tier without incurring any retrieval and prorated storage fees.

Because you incur no retrieval or prorated storage fees, enabling Auto-Tiering is particularly cost-effective for the following use cases:

- New application data storage that has no established access patterns
- Data storage that has changing access patterns

**Next Steps**

Now that you have some understanding of storage tiers and how they work, here are some links to the tasks related to storage tiers:

- Creating a bucket, specifying the default storage tier, and optionally enabling Auto-Tiering
  - Using the Console
  - Using the CLI
  - Using the API
- Uploading and specifying the storage tier for an object
  - Using the Console
  - Using the CLI
  - Using the API
Managing Buckets

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment. The compartment has policies that indicate what actions you can perform on a bucket and all the objects in the bucket.

You cannot nest buckets—a bucket cannot contain other buckets.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you are new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators:

• The policy Let Object Storage admins manage buckets and objects on page 2813 lets the specified group do everything with buckets and the associated objects.
• If you must write more restrictive policies for buckets, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to manage buckets:

• You can't move a bucket from a security zone to a standard compartment because it might be less secure. For details, see Restrict Resource Movement.
• Buckets in a security zone must be private.
• Buckets in a security zone must use customer-managed master encryption keys in the Vault service.

Pre-Authenticated Requests

Pre-authenticated requests provide a way to let you access a bucket or an object without having your own credentials. For example, you can create a request that lets you upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests on page 4387 for details.

Object Versioning

You can enable object versioning to retain previous versions of objects. Object versioning lets you view, retrieve, and recover previous versions of objects and provides protection against accidental or malicious object overwrite or deletion. For information about this feature, see Using Object Versioning on page 4350.

Object Lifecycle Policies

Using object lifecycle policies applied at the bucket level, you can automatically manage the archiving and deletion of objects according to a pre-defined schedule. For information about this feature, see Using Object Lifecycle Management on page 4370.

Retention Rules

You can apply retention rules at the bucket level to provide immutable object storage options for data written to Object Storage for governance, regulatory compliance, and legal requirements. For information about this feature, see Using Retention Rules to Preserve Data on page 4362.
Replication Policy
Using a replication policy for a bucket, you can automatically replicate the objects in one Object Storage bucket to another bucket in the same region or a different region. For information about this feature, see Using Replication on page 4343.

Tagging Resources
You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 239.

Object Storage currently supports adding tags to buckets.

Monitoring Resources
You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring buckets, see Object Storage Metrics on page 4416.

Usage Reports
A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation. A usage report is generated daily and stored in an Object Storage bucket. For more information, see Cost and Usage Reports Overview on page 323 and Accessing Cost and Usage Reports on page 325.

Creating Automation for Buckets and Objects Using the Events Service
You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Buckets emit events for bucket state changes by default. Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Bucket Names
Bucket names are system generated by default, but you can overwrite the default with a name you specify.

System-Generated Bucket Names
When a bucket is created, the system generates a default name for that bucket, for example bucket-20190306-1359. This bucket name identifies the current year, month, and day that the bucket was created. You can use that system-generated name for your new bucket or you can specify a different name.

User-Specified Bucket Names
If you change this default bucket name or the name of any bucket, observe the following:

- Make the name unique within your tenancy’s Object Storage namespace.
- Use from 1 to 256 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

| Important: |
| Bucket names and object names are case-sensitive. Object Storage handles accounts-payable and Accounts-Payable as separate buckets. |

- Avoid entering confidential information.
Default Storage Tiers

When you create a bucket, you decide which default storage tier is appropriate for storing the objects:

- Use the Standard tier for data to which you need fast, immediate, and frequent access.
- Use the Archive tier for data to which you seldom or rarely access, but that must be retained and preserved for long periods of time.

The storage tier property is then assigned to each object that you upload to a bucket.

For more information, see Understanding Storage Tiers on page 4295. To automate the movement of data to the most cost effective tier, see Enabling Auto-Tiering on page 4297.

**Important:**

You cannot change the default storage tier of a bucket after creation.

Public Buckets

When you create a bucket, the bucket is considered a private bucket and the access to the bucket and bucket contents requires authentication and authorization. However, Object Storage supports anonymous, unauthenticated access to a bucket that is not in a security zone. You make a bucket **public** by enabling read access to the bucket.

**Important:**

Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, any user can obtain object metadata, download bucket objects, and optionally list bucket contents. We recommend using pre-authenticated requests instead of public buckets. Pre-authenticated requests support more authorization, expiry, and scoping capabilities not possible with public buckets. See Using Pre-Authenticated Requests on page 4387 for details.

**Required Permissions**

The following permissions are required to configure a public bucket:

- To enable public access when creating a bucket, use permission BUCKET_CREATE.
- To enable public access for an existing bucket, use permission BUCKET_UPDATE.

**Options**

When creating a public bucket, you have the following options:

- You can configure the access to allow listing and downloading objects. List and download access is the default.
- You can configure the access to allow downloading objects only. A user would not be able to list bucket contents.

**Scope and Constraints**

Understand the following scope and constraints regarding public access:

- Buckets in a security zone can't be public.
- Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
- Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

You can enable anonymous public access for new or existing buckets using the Console, CLI, or an SDK to access the API.
Using the Console
To get a list of buckets

Open the navigation menu and click Storage. Under Object Storage, click Buckets.

A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

To create a bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Select a compartment from the Compartment list on the left side of the page.
3. Click Create Bucket.
4. In the Create Bucket dialog box, specify the attributes of the bucket:
   - **Bucket Name**: The system generates a default bucket name that reflects the current year, month, day, and time, for example **bucket-20190306-1359**. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Default Storage Tier**: Select the default tier in which you want to store your data. When you upload objects, the objects are automatically assigned to and uploaded to this tier by default. Available default storage tiers include:
     - **Standard** is the primary, default storage tier used for Object Storage service data. Use the Standard tier for storing data that requires fast and immediate access. Standard buckets do, however, provide an option to assign and upload objects to different storage tiers (Infrequent Access and Archive), while remaining in the Standard bucket.
     - **Archive** is the default storage tier used for Archive Storage service data. Use the Archive tier for storing data that does not require immediate access, but requires long retention periods. Access to data in the Archive tier is not immediate. Archived data must be restored before the data is accessible.
   - **Encryption**: Buckets are encrypted with keys managed by Oracle by default, but you can optionally encrypt the data in this bucket using your own Vault encryption key. To use Vault for your encryption needs, select Encrypt Using Customer-Managed Keys. Then, select the Vault Compartment and Vault that contain the master encryption key you want to use. Also select the Master Encryption Key Compartment and Master Encryption Key. For more information about encryption, see Overview of Vault on page 5006. For details on how to create a vault, see Managing Vaults on page 5011.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create Bucket.

The bucket is created immediately and you can start uploading objects. Objects added to archive buckets are immediately archived and must be restored before they are available for download.

To view bucket details

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains your buckets.
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.

**To change the visibility of a bucket**

A bucket is either private (the default) or public. See Public Buckets on page 4300 for more information.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can't change the visibility of a bucket from private to public if that bucket is in a security zone.</td>
</tr>
<tr>
<td>We recommend using pre-authenticated requests instead of public buckets. Pre-authenticated requests support more authorization, expiry, and scoping capabilities not possible with public buckets. See Using Pre-Authenticated Requests on page 4387 for details.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name to see the bucket details.
3. Click Edit Visibility.
4. In the Edit Visibility dialog box, edit the visibility settings:
   - Visibility
     - Public
     - Private
   - If you select Public to enable public access, decide whether you want to let users list the bucket contents. To set the visibility of bucket object lists, click Allow users to list objects from this bucket.
5. Click Save Changes.

**To move a bucket to a different compartment**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can't move a bucket from a security zone to a standard compartment. You also need to ensure that the resource users have sufficient access permissions for the compartment to which the resource is being moved.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. In the Scope section, select a compartment.
3. Find the bucket in the list, click the Actions icon (three dots), and then click Move Resource.
   Alternatively, you can choose a bucket, and then click Move Resource on the bucket details page.
4. Choose the destination compartment from the list.
5. Click Move Resource.

**To manage tags for a bucket**

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name.
3. You can manage tags in the following ways:
   - To view the tags associated with the bucket, click the **Tags** tab, located to the right of the **Bucket Information** tab.
   - To add one or more tags, click **Add Tags**.
   - To rename a tag, click the pencil icon to the left of a tag name, edit the name, and save.
   - To delete a tag, click the pencil icon to the left of a tag name and click **Remove Tag**.

For more information, see **Resource Tags** on page 239.

### To delete a bucket

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot recover a deleted bucket.</td>
</tr>
</tbody>
</table>

You cannot delete a bucket that contains any of the following resources:

- Objects and object versions
- Pre-authenticated requests
- Replication policy
- Uncommitted multipart uploads

The Console collects and provides a count of each resource that would prevent bucket deletion. Upon your confirmation, the resources are deleted and the bucket is deleted in a single action.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can also cancel a deletion in progress. Understand, however, resources deleted before the cancellation cannot be recovered.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Find the bucket that you want to delete.

3. Click the Actions icon (three dots), and then click **Delete**.

   Alternatively, you can choose a bucket and click **Delete** on the bucket details page.

4. Review the summary of resources that will be deleted.

5. Type the name of the bucket to confirm resource and bucket deletion and click **Delete**.

   The deletion stops if you navigate away from the page or you close the browser. When possible, guidance is provided to help you investigate and resolve any errors before attempting the bucket deletion again.

### To assign a Vault master encryption key to a bucket

Buckets are encrypted with keys managed by Oracle by default. Optionally, you can encrypt the data encryption keys that encrypt the objects in a bucket using your own Vault master encryption key.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buckets in a security zone can't use the default encryption key managed by Oracle. You must use your own Vault master encryption key.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket that you want to encrypt.

3. Next to **Encryption Key**, do one of the following:
   - If the bucket is encrypted with a key managed by Oracle, click the **Assign** link.
   - If the bucket already has a Vault master encryption key assigned, to assign a different key, click the **Edit** link.
4. In the dialog box, provide or edit the following information:
   - **Vault Compartment** and **Vault** that contain the master encryption key you want to use. The current compartment is displayed by default.
   - **Master Encryption Key Compartment** and **Master Encryption Key**. The current compartment is displayed by default.

5. When you are finished, click **Assign** or **Edit**.

See **Overview of Vault** on page 5006 for more details.

**To remove a Vault master encryption key from a bucket**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
   
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket for which you want to remove a Vault key assignment.

3. Next to **Encryption Key**, click the **Unassign** link.

4. In the **Confirm** dialog box, click **OK** to remove the key assignment from the bucket.

**To re-encrypt a bucket's data encryption keys**

If you've rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same, most recent version of the assigned master encryption key, re-encrypt the bucket.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
   
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket for which you want to re-encrypt all data encryption keys.

3. Click **Re-encrypt**. (If the button is not enabled, that's because the bucket is using a master encryption key managed by Oracle rather than a Vault master encryption. Or, the bucket does not contain any objects.)

4. In the confirmation dialog box, click **Re-encrypt** to generate a work request to re-encrypt all data encryption keys associated with the bucket.

The **Work Requests Details** dialog box that displays tells you about the work request, including the percentage completed and the work request ID. You can copy the work request ID to monitor the request status later.

**To enable or disable Auto-Tiering**

You can enable or disable Auto-Tiering for any Standard storage tier bucket.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

   A list of buckets is displayed.

2. Choose the compartment that contains your buckets.

3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.

4. Next to **Auto-Tiering**, click **Edit**.

5. In the dialog box, select (to enable) or deselect (to disable) **Enable Auto-Tiering**.

6. Click **Save Changes**.

**To view the approximate bucket size and number of objects in the bucket**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

2. Choose the compartment that contains your buckets.

   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.

- **Approximate Count** is the approximate number of objects in the bucket. Count statistics are reported periodically. A lag can occur between what is displayed and the actual object count.

- **Approximate Size** is the approximate total size of all objects in the bucket. Size statistics are reported periodically. A lag can occur between what is displayed and the actual size of the bucket.

**To enable or disable emitting events for object state changes**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains your buckets.
   
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.
4. Next to **Emit Object Events**, click **Edit**.
5. In the dialog box, select (to enable) or deselect (to disable) **Emit Object Events**.
6. Click **Save Changes**.

**To enable or suspend object versioning**

You can enable or suspend object versioning on any bucket.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains your buckets.
   
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.
4. Next to **Object Versioning**, click **Edit**.
5. In the dialog box, select **Enable Versioning** (if not yet enabled) or **Suspend Versioning** (if previously enabled).

**To enable or disable virtual folders**

Virtual folders is enabled by default. You can disable or re-enable virtual folders on any bucket.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains your buckets.
   
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.
4. Next to **Virtual Folders**, click **Edit**.
5. In the dialog box, select **Enabled** or **Disabled**.
6. Click **Save Changes**.

**To view or copy the Oracle Cloud Identifier (OCID) for a bucket**

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains your buckets.
   
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click View Bucket Details.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

---

**Note:**

The examples in this section use the full syntax for all parameters, for example --namespace and --compartment-id. For some parameters,
there are shortened versions that you can use instead, like -ns and -c. See the CLI online help for instances of a shortened parameter associated with a command.

To get a list of buckets

```bash
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id>
```

For example:

```bash
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```
{
   "data": [
   {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5",
      "freeform-tags": null,
      "name": "MyStandardBucket",
      "namespace": "MyNamespace",
      "time-created": "2020-05-22T19:22:25.032000+00:00"
   },
   {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
      "freeform-tags": null,
      "name": "MyArchiveBucket",
      "namespace": "MyNamespace",
      "time-created": "2020-06-22T13:04:05.879000+00:00"
   }
   ]
}
```

By default, getting a list of buckets returns up to the first 1,000 buckets in the compartment.

Note:

If you do not specify the --fields tags option when listing buckets, null is returned as the value for both free form and defined tags.

For example:

To include resource tag data, use the --fields tags option:

```bash
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id> --fields tags
```

For example:

```bash
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID --fields tags
```

```
{
   "data": [
   {
```
To create a bucket

Creating a Standard default storage tier bucket

By default, a bucket is created in the Standard Object Storage tier. You do not need to explicitly set `--storage-tier`. Standard is the primary, default storage tier used for Object Storage service data. Use the Standard tier for storing data that requires fast and immediate access. Standard buckets do, however, provide an option to assign and upload objects to different storage tiers (Infrequent Access and Archive), while remaining in the Standard bucket.

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id>
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
```

You can also enable Auto-Tiering on a Standard bucket at creation time by specifying the optional `--auto-tiering InfrequentAccess` parameter. See Enabling Auto-Tiering on page 4297 for details. For example:

```
oci os bucket create --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --auto-tiering Infrequent Access
```

A Standard tier bucket is created immediately and you can start uploading objects.

**Creating an Archive default storage tier bucket**

To create an Archive tier bucket, you must explicitly set `--storage-tier Archive`. Archive is the default storage tier used for Archive Storage service data. Use the Archive tier for storing data that does not require immediate access, but requires long retention periods. Access to data in the Archive tier is not immediate. Archived data must be restored before the data is accessible.

```
oci os bucket create --namespace <object_storage_namespace> --name <archivebucket_name> --compartment-id <target_compartment_id> --storage-tier Archive
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyArchiveBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```
An Archive Storage bucket is created and you can start uploading objects. Objects uploaded to Archive Storage buckets are immediately archived and must be restored before they are available for download.

To enable or disable Auto-Tiering

You can enable Auto-Tiering on a Standard during bucket creation or at a later time using the update action. See Enabling Auto-Tiering on page 4297 for details. For example:

```bash
oci os bucket update --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --auto-tiering InfrequentAccess
```

You can also disable Auto-Tiering at any time using the update action. For example:

```bash
oci os bucket update --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --auto-tiering Disabled
```
To create a public bucket that allows listing and downloading bucket objects

To create a public bucket that allows listing and downloading bucket objects, you must explicitly set `--public-access-type ObjectRead`.

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --public-access-type ObjectRead
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```json
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "auto-tiering": "Disabled",
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyPublicObjectReadBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-level-audit-mode": "Disabled",
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-22T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e"
}
```
To create a public bucket that allows downloading bucket objects only

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --public-access-type ObjectReadWithoutList
```

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyPublicObjectReadBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --public-access-type ObjectReadWithoutList{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "ec20c59a-f5ba-4a6d-8a7e-b69bb9bb76ad",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
        "kms-key-id": null,
        "metadata": {},
        "name": "MyPublicObjectReadWithoutListBucket",
        "namespace": "MyNamespace",
        "object-events-enabled": false,
        "object-lifecycle-policy-etag": null,
        "public-access-type": "ObjectReadWithoutList",
        "replication-enabled": false,
        "storage-tier": "Standard",
        "time-created": "2020-06-22T20:18:29.203000+00:00",
        "versioning": "Disabled"
    },
    "etag": "ec20c59a-f5ba-4a6d-8a7e-b69bb9bb76ad"
}
```

To create a bucket with resource tags

You can create standard Object Storage tier or Archive tier buckets with resource tags.

To add resource tags when creating a bucket, set one or both of the `--defined-tags` and `--freeform-tags` options.

**Tip:**

The `--defined-tags` and `--freeform-tags` options require that the input to be a complex type formatted in valid JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

The following example syntax creates a standard Object Storage tier bucket with a defined tag:

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --defined-tags '<JSON_formatted_defined_tag>'
```
Examples of defined tag formatting:

```
{"Operations": {"CostCenter": "42"}}
```

```
{"Logistics": {"Procurement": "Madrid Center"}, "Financials": {"Production": "Unit 5"}}
```

**Note:**

If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single defined tag is formatted

```
{"Logistics": {"Procurement": "Madrid Center\"}}
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyBucketDefined --compartment-id ocid.compartment.oc1..exampleuniqueID --defined-tags "{"Operations": {"CostCenter": "42"}}"
```

The following example syntax creates a Standard tier bucket with a free-form tag:

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --freeform-tags <JSON_formatted_free-form_tag>
```

Examples of free-form tag formatting:

```
{"Chicago_Team": "marketing_videos"}
```

```
{"Project": "prototype 3", "Manager": "Meadows"}
```
Note:
If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single free-form tag is formatted as '{"Chicago_Team": "marketing_videos"}'

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyBucketFreeform --compartment-id ocid.compartment.oc1..exampleuniqueID --freeform-tags "{"Chicago_Team": "marketing_videos"}
```

```
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "6f4bda10-fc8b-462e-8563-875639fd7294",
        "freeform-tags": {
            "Chicago_Team": "marketing_videos"
        },
        "is-read-only": false,
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "kms-key-id": null,
        "metadata": {},
        "name": "MyBucketFreeform",
        "namespace": "MyNamespace",
        "object-events-enabled": false,
        "object-lifecycle-policy-etag": null,
        "public-access-type": "NoPublicAccess",
        "storage-tier": "Standard",
        "time-created": "2020-06-23T20:51:16.260000+00:00"
    },
    "etag": "6f4bda10-fc8b-462e-8563-875639fd7294"
}
```

To view bucket details

```bash
oci os bucket get --name <bucket_name>
```

For example:

```bash
oci os bucket get --name MyBucket
```

```
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
        "kms-key-id": null,
        "metadata": {},
        "name": "MyBucket",
        "namespace": "MyNamespace",
        "object-events-enabled": false,
```
To add custom key-value metadata pairs to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --metadata <JSON-formatted_key-value_pair>
```

<JSON-formatted_key-value_pair> is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --metadata '{"Department": "Finance"}"
```

To make a bucket private or public

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --public-access-type [NoPublicAccess|ObjectReadWithoutList|ObjectRead]
```

- **NoPublicAccess**: Allows only an authenticated caller to access the bucket and bucket contents. NoPublicAccess is the default value.
- **ObjectReadWithoutList**: Allows public access for the GetObject, HeadObject, and ListObjects operations.
- **ObjectRead**: Allows public access for the GetObject and HeadObject operations.
For example:

```sh
oci os bucket update --namespace MyNamespace --name MyBucket --public-access-type ObjectRead
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
        "kms-key-id": null,
        "metadata": {
            "department": "Finance"
        },
        "name": "MyBucket",
        "namespace": "MyNamespace",
        "object-events-enabled": false,
        "object-lifecycle-policy-etag": null,
        "public-access-type": "ObjectRead",
        "replication-enabled": false,
        "storage-tier": "Standard",
        "time-created": "2020-06-22T19:04:05.879000+00:00",
        "versioning": "Disabled"
    },
    "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60"
}
```

To move a bucket to a different compartment

```sh
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <new_target_compartment_id>
```

<new_target_compartment_id> is the compartment ID associated with the compartment to which you are moving the bucket.

For example:

```sh
oci os bucket update --namespace MyNamespace --name MyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "new_ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "fe4fb648-8ddd-42eb-9732-d431aafac354",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
        "kms-key-id": null,
        "metadata": {
            "department": "Finance"
        },
        "name": "MyBucket",
        "namespace": "MyNamespace",
```
To add resource tags to a bucket

To add defined resource tags to a bucket:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --defined-tags <JSON_formatted_defined_tag>
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --defined-tags '{"Operations": {"CostCenter": "42"}}'
```

To add free-form resource tags to a bucket:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --freeform-tags <JSON_formatted_free-form_tag>
```
Object Storage

For example:

```shell
oci os bucket update --namespace MyNamespace --name MyBucket --freeform-tags '{"Chicago_Team": "marketing_videos"}'
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "auto-tiering": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-22T19:04:05.879000+00:00",
    "versioning": "Disabled"
  },
  "etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48"
}
```

**Tip:**

Provide key-value pair input for `--defined-tags` and `--freeform-tags` as valid formatted JSON. For examples of JSON-formatted resource tags, see To create a Standard or Archive tier bucket with resource tags. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

**To delete a bucket**

**Caution:**

You cannot recover a deleted bucket.

You cannot delete a bucket that contains any of the following resources:

- Objects and object versions
- Pre-authenticated requests
- Replication policy
- Uncommitted multipart uploads
Tip:
If you are deleting a bucket that contains one or more of these resources, consider using the Console to accomplish this task. The Console summarizes the count of each resource, deletes the resources that you have permission to delete, and then deletes the empty bucket in a single action. For details, To delete a bucket on page 4303 in Using the Console on page 4301.

```bash
oci os bucket delete --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```bash
oci os bucket delete --namespace MyNamespace --name MyDeletedBucket
```

Are you sure you want to delete this resource? [y/N]:

Select `y` and press `Enter`. The bucket is deleted with no further prompting.

**To assign a Vault key to a bucket**

```bash
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
```

`<target_key_id>` is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where the data is stored.

For example:

```bash
oci os bucket create --namespace MyNamespace --name MyKeyBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --kms-key-id ocid1.key.region1.sea..exampleuniqueID
```

```json
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "auto-tiering": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1..exampleuniqueID",
    "is-read-only": false,
    "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID",
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess"
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-06-29T23:00:35.490000+00:00",
    "versioning": "Disabled"
  },
  "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

See Overview of Vault on page 5006 for more details.
To update the Vault key assigned to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id <target_key_id>
```

<target_key_id> is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where the data is stored.

For example:

```
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id ocid1.key.region1.sea.exampleuniqueID_updated
```

```json
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
        "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID_updated",
        "metadata": {},
        "name": "MyKeyBucket",
        "namespace": "MyNamespace",
        "object-events-enabled": false,
        "object-lifecycle-policy-etag": null,
        "public-access-type": "NoPublicAccess",
        "replication-enabled": false,
        "storage-tier": "Standard",
        "time-created": "2020-06-29T23:00:35.490000+00:00",
        "versioning": "Disabled"
    },
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

To remove the Vault key assigned to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id ""
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id ""
```

```json
{
    "data": {
        "approximate-count": null,
        "approximate-size": null,
        "auto-tiering": null,
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "created-by": "ocid1.user.oc1..exampleuniqueID",
        "defined-tags": {},
        "etag": "10a50818-e495-45a9-b1ce-cc815f7b39ad",
        "freeform-tags": {},
        "id": "ocid1.bucket.oc1..exampleuniqueID",
        "is-read-only": false,
```
To re-encrypt a bucket's data encryption keys

If you've rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same, most recent version of the assigned master encryption key, re-encrypt the bucket.

```
oci os bucket reencrypt --name <bucket_name>
```

For example:

```
oci os bucket reencrypt --name MyBucket
```

To view the approximate bucket size and number of objects in the bucket

```
oci os bucket get --name <bucket_name> --fields approximateCount --fields approximateSize
```

- approximateCount is the approximate number of objects in the bucket. Count statistics are reported periodically. You might see a lag between what is displayed and the actual object count.
- approximateSize is the approximate total size of all objects in the bucket. Size statistics are reported periodically. You might see a lag between what is displayed and the actual size of the bucket.

For example:

```
oci os bucket get --name MyBucket --fields approximateCount --fields approximateSize
```
To enable or disable emitting events for object state changes

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --object-events-enabled [true|false]

For example, to enable emitting events for all objects in the bucket named MyBucket:

oci os bucket update --namespace MyNamespace --name MyBucket --object-events-enabled true

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
When accessing the Object Storage API, the bucket name is used with the Object Storage namespace name to form the request URL:

```
{n/<object_storage_namespace>/b/<bucket>}
```

Use the following API operations to manage buckets:

- CreateBucket
- DeleteBucket
- GetBucket
- HeadBucket
- ListBuckets
- ReencryptBucket
- UpdateBucket

**Note:**
Two key properties are worthy of mention in the payload for CreateBucket and UpdateBucket APIs:

- `publicAccessType` property controls whether the bucket is private or public and limits the capability to list public bucket contents.
- `objectEventsEnabled` property controls if events are emitted for the objects in this bucket.

### Managing Objects

In the Oracle Cloud Infrastructure Object Storage service, an object is a file or unstructured data you upload to a bucket within a `compartment` within an Object Storage `namespace`. The object can be any type of data, for example, multimedia files, data backups, static web content, or logs. You can store objects that are up to 10 TiB. Objects are processed as a single entity. You can't edit or append data to an object, but you can replace the entire object.

This topic describes how to manage objects within a single bucket. For information on copying an object to another bucket, see Copying Objects.

You might also be interested in exploring an Object Storage feature that retains previous versions of objects. Among other things, object versioning protects objects from accidental or malicious overwrite or deletion. For more information, see Using Object Versioning on page 4350.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a `policy` by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which `compartment` to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators:

- The policy Let Object Storage admins manage buckets and objects on page 2813 lets the specified group do everything with buckets and objects. Objects always reside in the same compartment as the bucket.
- If you need to write a more restrictive policy for objects, the inspect objects lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, read objects lets you download the object itself.
- If you create more restrictive policies that grant individual permissions:
  - `OBJECT_VERSION_DELETE` is required to delete previous object versions on your behalf using lifecycle policies.
  - `OBJECT_UPDATE_TIER` is required to change the storage tier of an object.
See Details for Object Storage, Archive Storage, and Data Transfer on page 3017 for more information on Object Storage user permissions.

**Pre-Authenticated Requests**

Pre-authenticated requests provide a way to let users access a bucket or object without having their own credentials. For example, you can create a request that lets a user upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests on page 4387 for details.

**Object Names**

Unlike other resources, objects do not have Oracle Cloud Identifiers (OCIDs). Instead, users define an object name when they upload an object.

Use the following guidelines when naming an object:

- Use from 1 to 1024 characters.
- Valid characters are letters (upper or lower case), numbers, and characters other than line feed, carriage return, and NULL.

**Important:**

Bucket names and object names are case-sensitive. Object Storage handles q3-field-assets.xlsx and Q3-Field-Assets.XSLX as separate objects.

- Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
- Avoid entering confidential information.
- Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

**Tip:**

Object names can include one or more forward slash (/) characters in the name. See Object Naming Using Prefixes and Hierarchies for more information on using the forward slash in object names to create hierarchies.

**Object Naming Using Prefixes and Hierarchies**

Within an Object Storage namespace, buckets and objects exist in a flat structure. However, you can simulate a directory structure by adding a prefix string that includes one or more forward slashes (/) to an object name. Doing so lets you list one directory at a time, which is helpful when navigating a large set of objects.

For example:

```
marathon/finish_line.jpg
marathon/participants/p_21.jpg
```

If you added prefixes to object names, you can:

- Use the CLI or API to perform bulk downloads and bulk deletes of all objects at a specified level of the hierarchy.
- Use the Console to display a hierarchical view of your objects in virtual folders. In the previous example, marathon would be displayed as a folder containing an object named finish_line.jpg and
participants would be a subfolder of marathon, containing an object named p_21.jpg. You can bulk upload objects to any level of the hierarchy and perform bulk deletes of all the objects in a bucket or folder.

Bulk operations at a specified level of the hierarchy do not affect objects in any level above.

When naming objects, you can also use prefix strings without a delimiter. No delimiters would allow search operations in the Console and certain bulk operations in the CL or API to match on the prefix portion of the object name. For example, in the object names below, the string gloves_27_ can serve as a prefix for matching purposes when performing bulk operations:

<table>
<thead>
<tr>
<th>gloves_27_dark_green.jpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>gloves_27_light_blue.jpg</td>
</tr>
</tbody>
</table>

When you perform bulk uploads with the Console, CLI, or API, you can prepend a prefix string to the names of the files you are uploading.

For hierarchy and prefix string details for a particular management interface, see the individual tasks in Using the Console on page 4301, Using the Command Line Interface (CLI) on page 4305, and Using the API on page 4343.

Optional Response Headers and Metadata

When you upload objects, you can provide optional response headers and user-defined metadata. Response headers are HTTP headers sent from Object Storage to Object Storage clients when objects are downloaded. User-defined metadata are name-value pairs stored with an object. You can use the Console, REST API, or CLI to provide these optional attributes.

Important:
No validation is performed on the response headers or metadata you provide.

You can specify values for the following response headers:

- Content-Disposition
  Defines presentation only information for the object. Specifying values for this header has no effect on Object Storage behavior. Programs that read the object determine what to do based on the value provided. For example, you could use this header to let users download objects with custom file names in a browser:

  attachment; filename="fname.ext"

  See https://tools.ietf.org/html/rfc2616#section-19.5.1 for more information.

- Cache-Control
  Defines the caching behavior for the object. Specifying values for this header has no effect on Object Storage behavior. Programs that read the object determine what to do based on the value provided. For example, you could use this header to identify objects that require caching restrictions:

  no-cache, no-store

You specify user-defined metadata in the form of name-value pairs. User-defined metadata names are stored and returned to Object Storage clients with the mandatory prefix of `opc-meta-`.

**Object Lifecycle Management**

Object Lifecycle Management lets you automatically manage the deletion of uncommitted multipart uploads, the movement of objects to a different storage tier, and the deletion of supported resources on your behalf within a given bucket. These automated actions are based on rules that you define and manage. See Using Object Lifecycle Management on page 4370 for more information about this feature.

**Multipart Uploading and Downloading**

The Oracle Cloud Infrastructure Object Storage service supports multipart uploading and downloading for objects.

- For information about the API and CLI multipart uploading functionality, see Using Multipart Uploads on page 4382.
- For CLI information on multipart downloading, see downloading an object using multipart download.
- For API documentation related to multipart downloading, see the GetObject API call and its `range` parameter.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For more information about monitoring objects, see Object Storage Metrics on page 4416.

**Creating Automation for Objects Using the Events Service**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

**Using Storage Gateway to Upload and Download Objects**

Storage Gateway is another way you can upload objects to and download objects from Oracle Cloud Infrastructure Object Storage.

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through file systems that you create in Storage Gateway. Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket to upload and download objects.

See Overview of Storage Gateway on page 4796 for details.

**Using the Console**

**To upload objects to a bucket or folder**

The Console uses multipart uploads to upload objects larger than 64 MiB.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your objects are larger than 64 MiB and will be uploaded using multipart uploads, you need OBJECT_CREATE and OBJECT_OVERWRITE permissions.</td>
</tr>
</tbody>
</table>
Object Storage

See Using Multipart Uploads on page 4382 and Details for Object Storage, Archive Storage, and Data Transfer on page 3017 for details.

1. From the Object Storage Buckets screen, click the bucket name to view its details.
2. Click Objects under Resources.
3. To upload objects to the bucket, click Upload. To upload objects to a folder in the bucket, click the Actions icon (three dots) to the right of the folder that you want to upload objects to, then click Upload.
4. Optionally, specify an Object Name Prefix. If provided, this prefix is prepended to each one of the files you upload. You can specify the following prefix strings:
   - Prefix strings with a forward slash (/) delimiter to simulate hierarchy and create folders or subfolders
   - Prefix strings without a delimiter for matching purposes to perform allowed bulk operations

See Object Naming Using Prefixes and Hierarchies on page 4323 for more details.
5. The object is automatically assigned the default storage tier of the bucket (Standard or Archive) that you are uploading the object to. If the Storage Tier field displays Standard, you can optionally change the storage tier to upload objects to:
   - Infrequent Access
   - Archive

   **Note:**
   Standard storage tier buckets can contain a mix of objects with different storage tier assignments. An object remains in the Standard bucket, even if the object is archived, restored, or if tier assignment is changed.
6. Select the object or objects that you want to upload in one of two ways:
   - Drag and drop one or more files from your computer.
   - Click the select files link to display a file selection dialog box.

   The files you select to upload are displayed in a list. If you decide that you do not want to upload a particular file, click the X to the right of the file name.

   If the files you select to upload are already stored in the bucket or folder with the same name, the Console displays messages warning you of an overwrite.
7. To specify values for optional response headers and metadata to be displayed in Object Details, click Show Optional Response Headers and Metadata.
   a. Select the attribute Type that you are adding.
   b. To add a Response Header, select the Name and enter a Value.
   c. To add Metadata, enter the Name and Value.
   d. To add attributes, click + Add More Headers or Metadata.
8. Click Upload.

   The selected objects are uploaded and displayed in the list of objects in the bucket or folder.

**To download an object from a bucket or folder**

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to download.
6. For the object you want to download, click the Actions icon (three dots), and then click Download.
To create a folder or subfolder

If the Virtual Folders view is enabled, you can create a folder in a bucket or you can create a subfolder in an existing folder or subfolder.

1. From the Object Storage Details screen, click the bucket name to view its details.
2. Click Objects under Resources.
3. To create a folder in a bucket, click More Actions above the Objects table, then click Create New Folder. To create a subfolder in a folder or subfolder, click the Actions icon (three dots) to the right of the folder that you want to create a folder or subfolder, then click Create New Folder.
4. Enter a Name for the folder or subfolder. Avoid entering confidential information.
5. Click Create.

The folder or subfolder is created and displayed in the Objects table.

To view object details

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want details.
6. Choose the object for which you want details.
7. Click the Actions icon (three dots), and then click View Object Details. Object details include:
   - Basic Information
   - Response Headers
   - Metadata
8. Optionally, click Download to download the selected object.

To rename an object

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to rename.
6. For the object you want to rename, click the Actions icon (three dots), and then click Rename.
7. In the Rename Object dialog box, provide the new name for the object and an optional delimited directory structure prefix. For example, p_94.jpg or /marathon/participants/p_94.jpg.
   Avoid entering confidential information.

Caution: Buckets cannot store two objects that use identical names (case-sensitive). If you choose to rename an object using the name of another object in the same bucket, the object that originally used the name is overwritten.

8. Click Save Changes.

To determine which storage tier an object resides

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want details.
6. The Storage Tier column identifies the storage tier in which each object resides.

**To update the storage tier of an object**

You can only update the storage tier for objects that reside in the Standard and Infrequent Access tiers. You cannot update the storage tier for objects that reside in the Archive tier. That means if you update the storage tier of an object to Archive, you can't change it back to a different tier.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You also need to understand the ramifications of updating the storage tier for an object. Objects in the Archive and Infrequent Access tiers have a minimum storage retention period and data retrieval fees. For more information, see Understanding Storage Tiers on page 4295.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_UPDATE_TIER permissions to update the storage tier of an object.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object for which you want to update the storage tier.
6. Choose the object for which you want to update the storage tier.
7. Click the Actions icon (three dots), and then click Update Storage Tier.
8. In the Update Storage Tier dialog, select from the available storage tiers.
9. Click Save Changes.

**To restore objects from Archive Storage**

Depending on the size of the object, it can take at most an hour to restore an object from Archive Storage. You cannot download an item until the item is fully restored.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_RESTORE permissions to restore Archive Storage objects.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click Objects under Resources.
   A list of folders (if enabled) and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to restore.
6. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.

7. Optionally, specify the **Time Available for Download in Hours**.

   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object **Details** or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.

   After the allotted download time expires, the object returns to Archive Storage.

8. Click **Restore Objects**.

   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option**.

**To check the status of an Archive Storage object restoration**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

2. Choose the compartment your bucket is in.

   A list of buckets is displayed.

3. Click the bucket name that contains your object.

4. Click **Objects** under **Resources**.

   A list of folders and objects in the bucket are displayed.

5. Expand any folders and subfolders as needed to locate the object for which you want to check the restoration status.

6. Check the **Status** field in the **Object** table.

   **Status** displays one of the following:

   - Archived
   - Restoring
   - Restored

**To re-encrypt an object**

**Tip:**

You need **OBJECT_READ** and **OBJECT_OVERWRITE** permissions to re-encrypt an object.

To encrypt and decrypt an object's data encryption keys with a different master encryption key, you can re-encrypt the object. When re-encrypting an object, you can choose either a different key from the one assigned to the bucket or the most recent version of the key assigned to the bucket. Until you explicitly re-encrypt an object, the key version associated with the bucket (when the object was inserted into the bucket) continues to decrypt all the object's data encryption keys.

You can re-encrypt an object's data encryption keys with a key managed by Oracle, a key that you created and control through a vault that you manage, or a customer-provided encryption key (SSE-C).

**Note:**

If you use server-side encryption with customer-provided keys (SSE-C), you must use the CLI to provide the SSE-C key during the encryption or re-encryption process. Using the CLI, you can re-encrypt an object with a different SSE-C key, a key managed by Oracle, or a key that you manage through the Vault service. In the Console, you can only re-encrypt an object to use the latest version of the Oracle-managed key assigned to the bucket or the latest version of a Vault key. It does not matter whether the chosen key version is the one assigned to the bucket.
1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the name of the bucket that has the object for which you want to re-encrypt data encryption keys.

3. Under **Objects**, find the object that you want to re-encrypt. Click the Actions icon (three dots), and then click **Re-encrypt**.

4. Do one of the following, depending on whether the key assigned to the bucket is an Oracle-managed key or a key in a vault that you manage:

   - For buckets encrypted with an Oracle-managed key, you can re-encrypt the object with the latest version of that key by clicking **Use the key assigned to the bucket**. Or, you can re-encrypt the object with a key in a vault by clicking **Use a customer-managed key** and then choosing a key from a compartment and vault that you have access to.
   - For buckets encrypted with a customer-managed key, you can re-encrypt the object with the latest version of that key by clicking **Use the key assigned to the bucket**. Or, you can re-encrypt the object with a different Vault key by clicking **Use a different customer-managed key** and then choosing another key from a compartment and vault that you have access to.

5. When you are ready, click **Re-encrypt** to re-encrypt all data encryption keys associated with the object.

   If you receive an error, verify that you have the correct permissions. If you have access to the object, confirm that the object exists and has not recently been deleted. If you have permissions and the object exists, also confirm whether the object is encrypted with an SSE-C key. To re-encrypt an object that you encrypted with an SSE-C key, you need to use the CLI to provide the SSE-C key to the Object Storage service for use during decryption and subsequent re-encryption, as appropriate. For more information, see the **To re-encrypt an object** on page 4340 CLI topic.

**To delete objects from a bucket or a folder**

You can permanently delete an object from a bucket or folder. You cannot, however, recover a deleted object unless you have object versioning enabled. See **Using Object Versioning** on page 4350 for details.

**Note:**

You cannot delete an object that has an active retention rule.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.

2. Choose the compartment that contains the bucket that contains the object or objects you want to delete.

   A list of buckets is displayed.

3. Click the bucket name that contains your object.

4. Click **Objects** under **Resources**.

   A list of folders and objects in the bucket are displayed.

5. Expand the folders and subfolders as needed to locate the object or objects that you want to delete.

6. To delete a single object, click the Actions icon (three dots) to the right of the object you want to delete, and then click **Delete**. To delete multiple objects, select the check boxes to the left of each object you want to delete, and then click **Delete**.

7. Confirm when prompted.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**Note:**

The examples in this section use the full syntax for parameters, for example `--namespace` and `--bucket-name`. Sometimes, there are shortened parameter terms that you can use instead of the full ones, for example `-ns` for `--namespace` and `-bn` for `--bucket-name`. The CLI online --
help for a particular command displays the shortened parameters that you can use.

To list the objects in a bucket

`oci os object list --namespace <object_storage_namespace> --bucket-name <bucket_name>`

By default, a minimal number of fields are returned for each object. For example:

```
oci os object list --namespace MyNamespace --bucket-name MyBucket
{
  "data": [ 
    {
      "etag": "7588e71f-433f-4518-ba2d-90082208bd5d",
      "md5": "As+3syAEbvmHpm86M+D3A==",
      "name": "eventlogreference.htm",
      "size": 13515,
      "storage-tier": "InfrequentAccess",
      "time-created": "2021-01-11T15:47:44.427000+00:00",
      "time-modified": "2021-01-11T15:47:44.441000+00:00"
    },
    {
      "etag": "833c709g-f74e-4ce5-a7c8-ffa29a112d88",
      "md5": "J19YwOG5hspS4NKTVy8g==",
      "name": "flowlogreference.htm",
      "size": 16601,
      "storage-tier": "Archive",
      "time-created": "2021-01-11T15:47:44.617000+00:00",
      "time-modified": "2021-01-11T15:47:44.638000+00:00"
    },
    {
      "etag": "3b833478-87c5-49f1-8bb4-f33b66c2758a",
      "md5": "skstBGw3YChBoo16Y/YwEA==",
      "name": "objectstoragelogreference.htm",
      "size": 18631,
      "storage-tier": "Standard",
      "time-created": "2021-01-11T20:50:48.996000+00:00",
      "time-modified": "2021-01-11T20:50:49.019000+00:00"
    }
  ]
},
"prefixes": []
}
```

To get object details

`oci os object head --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>`

For example:

```
oci os object head --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
{
  "accept-ranges": "bytes",
  "access-control-allow-credentials": "true",
  "access-control-allow-methods": "POST,PUT,GET,HEAD,DELETE,OPTIONS",
  "access-control-allow-origin": "*",
  "access-control-expose-headers": "accept-ranges,access-control-allow-credentials,access-control-allow-methods,access-control-allow-
```
If the object resides in an Archive tier bucket, the output also includes archival-state.

**To upload an object to a bucket**

```
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> [--name <object_name>] [--storage-tier <object_storage_tier>] --no-multipart
```

<file_location> is the source directory path of the object being uploaded, such as C:\workspace\Uploads \MyFile.txt or /home/user/Documents/Uploads/MyFile.txt.

<object_name> is the name of the uploaded object excluding the path. This parameter is required if the object is being read from STDIN. If you want to use the filename as the uploaded object's name (if not being read from STDIN), omit the --name option. The resulting object name does not include the path information (for example, C: \workspace\Uploads\), just the actual file name by itself (MyFile.txt).

For example, to upload an object using the original filename, omit the --name option:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\Uploads\MyFile.txt --no-multipart
```

If you do not specify --storage-tier, the object is automatically assigned and uploaded to the default storage tier of the bucket (Standard or Archive).

If you are uploading to a Standard tier bucket, you can specify --storage-tier <object_storage_tier> to upload the object to a different storage tier:

- InfrequentAccess
- Archive

For example, to upload an object to the default storage tier of the bucket, omit --storage-tier:

```
oci os object put --namespace MyNamespace --bucket-name MyStandardBucket --file C:\workspace\Uploads\MyFile.txt --name MyFile.txt --no-multipart
```

```
Object Storage

Or:

```bash
oci os object put --namespace MyNamespace --bucket-name MyArchiveBucket --file C:\workspace\Uploads\MyFile.txt --name MyFile.txt --no-multipart
{
  "etag": "cadb9f8a-3292-45e6-ale8-f075699fb619",
  "last-modified": "Fri, 11 Dec 2020 14:04:19 GMT",
  "opc-content-md5": "9P610SaYe4fXxaek8s1uDw=="
}
```

For example, to upload an object to the Infrequent Access tier, specify --storage-tier:

```bash
oci os object put --namespace MyNamespace --bucket-name MyStandardBucket --file C:\workspace\Uploads\MyDocument.txt --storage-tier InfrequentAccess --no-multipart
{
  "etag": "6b292c1a-b01b-4f36-97c8-4567fb43d071",
  "last-modified": "Sat, 12 Dec 2020 12:58:01 GMT",
  "opc-content-md5": "9P610SaYe4fXxeK8s1uDw=="
}
```

For example, to upload an object to the Archive tier, specify --storage-tier:

```bash
oci os object put --namespace MyNamespace --bucket-name MyStandardBucket --file C:\workspace\Uploads\MyDocument.txt --storage-tier Archive --no-multipart
{
  "etag": "6b292c1a-b01b-4f36-97c8-4567fb43d071",
  "last-modified": "Sat, 12 Dec 2020 12:58:01 GMT",
  "opc-content-md5": "9P610SaYe4fXxeK8s1uDw=="
}
```

An object can be uploaded as a single part or as multiple parts. Use the --no-multipart option to upload as a single part. For detailed information on multipart uploads, see Using Multipart Uploads on page 4382.

To add optional response headers, use one or more of the following options:

- --cache-control
- --content-disposition
- --content-encoding
- --content-language
- --content-disposition
- --content-type

For more information about attributes that you can add when you upload an object, see Optional Response Headers and Metadata on page 4324. For more details about these headers, see the Command Line Reference.

For example:

```bash
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\MyFile --cache-control no-cache --no-multipart
```

To add custom metadata key-value pairs, use the --metadata option:

```bash
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> --name <object_name> --metadata <json_formated_key-value_pairs> --no-multipart
```

<JSON-formatted_key-value_pair> is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.
Object Storage

For example:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file C:\workspace\MyFile.txt --metadata '{"Department": "Finance"}' --no-multipart
```

```
{  "etag": "3504606b-8412-db5d-924a-aaeacfd1df6",  "last-modified": "Wed, 20 Nov 2019 04:37:29 GMT",  "opc-content-md5": "1B2M2r8AsgTpgAmY7PhCflg=="
}
```

To bulk upload objects to a bucket

```
oci os object bulk-upload --namespace <object_storage_namespace> --bucket-name <bucket_name> --src-dir <source_directory_location>
```

`<source_directory_location>` is the upload directory path, such as `C:\workspace\Upload\` or `/home/user/Documents/Upload`. If your source directory has subdirectories, the subdirectory names are prepended to the names of the files stored in those subdirectories, delimited with a forward slash (/) character. For example, if a file named `maple.jpg` is stored in the subdirectory `trees`, when the file is uploaded, Object Storage assigns the name `trees/maple.jpg` to the resulting object.

If you are uploading to a Standard tier bucket, you can optionally specify the `<object_storage_tier>` to upload the object to:

- `InfrequentAccess`
- `Archive`

If you do not specify the `--storage-tier` option, the object is uploaded to the default storage tier of the bucket.

For example, to upload objects to the default storage tier of the bucket:

```
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files
```

Uploaded logFile.log [###########################] 100%
Uploaded MyFile.txt [###########################] 100%

```
{  "skipped-objects": [],  "upload-failures": {},  "uploaded-objects": {    "MyFile.txt": {      "etag": "e25f95e6-a2bd-435c-83d6-785f838134d5",      "last-modified": "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",      "opc-content-md5": "opc-content-md5": "vqglL/ToD0FxnqE83wBycw=="
    },    "logFile.log": {      "etag": "bbcf33dd-a177-4406-bed1-a4f7125da800",      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",      "opc-content-md5": "opc-content-md5": "K8vB8NVASlvtL2BE5ksUjw=="
    }
  }
```

For example, to upload objects to the Infrequent Access storage tier:

```
oci os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --storage-tier InfrequentAccess
```

Uploaded logFile.log [###########################] 100%
Uploaded MyFile.txt [###########################] 100%

```
{  "skipped-objects": [],
```
For example, to upload objects to the Archive tier:

```bash
csi os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --storage-tier Archive
```

Uploaded logFile.log [####################################] 100%
Uploaded MyFile.txt [####################################] 100%

```json
{  
  "skipped-objects": [],
  "upload-failures": {},
  "uploaded-objects": {
    "MyFile.txt": {
      "etag": "e25f95e6-a2bd-435c-83d6-785f838134d5",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "vqglL/ToD0FxnxqE83wBycw=="
    },
    "logFile.log": {
      "etag": "bbcf33dd-a177-4406-bed1-a4f7125da800",
      "last-modified": "Sat, 12 Dec 2020 11:31:36 GMT",
      "opc-content-md5": "K8vB8NVASIvtL2BE5ksUjw=="
    }
  }
}
```

To append a prefix string to the object names created by your uploads, use the `--object-prefix` option. For example:

```bash
csi os object bulk-upload --namespace MyNamespace --bucket-name MyBucket --src-dir C:\workspace\Files --object-prefix /bicycling/gloves/
```

Uploaded /bicycling/gloves/gloves_27_A.jpg
[####################################] 100%
Uploaded /bicycling/gloves/gloves_31_A.jpg
[####################################] 100%

```json
{  
  "skipped-objects": [],
  "upload-failures": {},
  "uploaded-objects": {
    "/bicycling/gloves/gloves_27_A.jpg": {
      "etag": "7ba793ce-a341-4c56-9baf-61ca2c56ad50",
      "last-modified": "Sat, 12 Dec 2020 18:35:09 GMT",
      "opc-content-md5": "1B2M2Y8AsgTpgAm17PhCfge="
    },
    "/bicycling/gloves/gloves_31_A.jpg": {
      "etag": "6efa58a6-a723-4696-a31f-3c5099adbec4",
      "last-modified": "Sat, 12 Dec 2020 18:35:09 GMT",
      "opc-content-md5": "6GxlLP9fa71HvlpL9N4DQ=="
    }
  }
}
```
To add custom metadata key-value pairs, use the `--metadata <JSON_formatted_key-value_pairs>` option.

<JSON-formatted_key-value_pair> is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

**To download an object from a bucket**

```bash
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location>
```

<file_location> is the destination path for the file being downloaded, such as C:\workspace\Downloads\MyFile.txt or /home/user/Documents/Downloads/MyFile.txt.

The `--name <object_name>` parameter is required.

For example:

```bash
oci os object get --namespace MyNamespace --bucket-name MyBucket --file c:\workspace\Downloads\MyFile.txt --name MyFile.txt
```

No information is returned when you run the command. The file is downloaded to the specified destination.

**To download an object using multipart download**

Multipart object downloading is available using the byte-range request standard defined in RFC 7233, section 2.1.

```bash
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location> --range bytes=<byte_range>
```

For example:

```bash
oci os object get --namespace MyNamespace --bucket-name MyBucket --name MyObject.mp4 --file c:\workspace\Downloads\MyObject.mp4 --range bytes=0-499
```

**To bulk download all objects within a bucket**

```bash
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location>
```

<download_directory_location> is the destination path for the objects being downloaded, such as C:\workspace\Downloads\ or /home/user/Documents/Downloads/. If the directory does not exist, Object Storage creates the directory when the command is run.

For example:

```bash
oci os object bulk-download --namespace MyNamespace --bucket-name MyBucket --download-dir c:\workspace\Downloads
```

Downloaded MyFile.txt [####################################] 100%
Downloaded logFile.log [####################################] 100%

```json
{
  "download-failures": {},
  "skipped-objects": []
}
```
For a complete list of object bulk download options, see the Command Line Reference.

**To bulk download objects by object name prefix string**

If you have named your objects with prefix strings, you can bulk download objects in a bucket that match a specified prefix string.

```bash
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <prefix_string>
```

`<download_directory_location>` is the destination path for the objects being downloaded, such as `C:\workspace\Downloads` or `/home/user/Documents/Downloads/`. If the directory does not exist, Object Storage creates the directory when the command is run.

For example:

```bash
oci os object bulk-download --namespace MyNamespace --bucket-name MyBucket --download-dir c:\workspace\Downloads --prefix gloves_27
```

In the example above, an object named `gloves_27_A.jpg` is downloaded, while an object named `gloves_31_A.jpg` is not downloaded.

If you named your objects so that they exist in Object Storage in a hierarchy, you can download objects at a specified level and below. Specify the prefix that matches the level of your choosing:

```bash
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <level_1/level_2/>
```

The preceding command downloads the following objects:

- `<level_1/level_2/object_name>`
- `<level_1/level_2/level_3/object_name>`
- `<level_1/level_2/level_3/level_4/object_name>`

To download only those objects at a given hierarchy level (and not objects in levels above or below), see **To bulk download objects at a specified hierarchy level**.

**To bulk download objects at a specified hierarchy level**

If you named your objects so that they exist in Object Storage in a hierarchy, you can bulk download all objects at a specified hierarchy level.

```bash
oci os object bulk-download --namespace <object_storage_namespace> --bucket-name <bucket_name> --download-dir <download_directory_location> --prefix <level_1/level_2/> --delimiter /
```

`<download_directory_location>` is the destination path for the objects being downloaded, such as `C:\workspace\Downloads` or `/home/user/Documents/Downloads/`. If the directory does not exist, Object Storage creates the directory when the command is run.

**Note:**

Currently, only the forward slash (/) is the supported delimiter for the `--delimiter` option.

The preceding command downloads objects only at `<level_2>` of the hierarchy. For example, the following object is downloaded:

`<level_1/level_2/object_name>`
The preceding command does not download objects in levels above or below <level_2>. For example, the preceding command does not download the following objects:

- <level_1/object_name>
- <level_1/level_2/level_3/object_name>
- <level_1/level_2/level_3/level_4/object_name>

To download objects at a given hierarchy level along with all objects in the hierarchy sublevels, see To bulk download objects by object name prefix string.

**To rename an object**

```
oci os object rename --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_original_name> --new-name <object_new_name>
```

For example:

```
oci os object rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt

{
  "etag": "3504606b-8412-4b5d-924a-aeeac1df1dfe"
}
```

To make the rename operation dependent on the object having a specific entity tag, use the `--src-obj-if-match-e-tag` option.

For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --src-obj-if-match-e-tag 6672BECB67CFFBCE0530292F202BACE
```

For rename operations where you intend to overwrite one object in a bucket with another, you can make the renaming dependent on having a specific entity tag. To do so, use the `--new-obj-if-match-e-tag` option.

For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --new-obj-if-match-e-tag 6672BECB67CFFBCE0530292F202BACE
```

When renaming an object, you can prevent the system from overwriting another object in the same bucket by using the `--new-obj-if-none-match-e-tag *` option. This option prevents the renaming operation from completing if an object exists with the `--new-name` value specified and the same entity tag of the source object.

For example:

```
oci os object rename rename --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --new-name MyRenamedFile.txt --new-obj-if-none-match-e-tag *
```

**To determine which storage tier an object resides**

```
oci os object head --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```
For example:

```bash
oci os object head --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
{
  "accept-ranges": "bytes",
  "access-control-allow-credentials": "true",
  "access-control-allow-methods": "POST,PUT,GET,HEAD,DELETE,OPTIONS",
  "access-control-allow-origin": "*",
  "access-control-expose-headers": "accept-ranges,access-control-allow-credentials,access-control-allow-methods,access-control-allow-origin,content-length,content-md5,content-type,etag,last-modified,opc-client-info,opc-client-request-id,opc-request-id,x-api-id",
  "content-length": "823",
  "content-md5": "9P610SaYe4fXxaeK8siuDw==",
  "content-type": "application/octet-stream",
  "date": "Fri, 11 Dec 2020 14:22:51 GMT",
  "etag": "cadb9f8a-3292-45e6-a1e8-f075699fb619",
  "last-modified": "Fri, 11 Dec 2020 14:04:19 GMT",
  "opc-client-request-id": "C732DB8E25BC406FBD359740D18C78D4",
  "opc-request-id": "phx-1:EzxtLDJJxPWDLUQ30AEYBRRX__EYrrKK2rEYq23k8Qd749g2YtKO1hx4jDwVh3",
  "storage-tier": "InfrequentAccess",
  "version-id": "82d3a264-08c4-4732-a9b1-e246ee0e4fa1",
  "x-api-id": "native"
}
```

If the object resides in an Archive tier bucket, the output also includes `archival-state`.

You can also determine which storage tier an object resides by listing the objects or object versions for a bucket. See To list the objects in a bucket.

**To update the storage tier of an object**

If an object resides in a Standard default storage tier bucket, you can change the storage tier of the object. Valid storage tiers for an object are:

- Standard
- InfrequentAccess
- Archive

```bash
oci os object update-storage-tier --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --storage-tier <object_storage_tier>
```

For example:

```bash
oci os object update-storage-tier --namespace MyNamespace --bucket-name MyStandardBucket --name MyFile.txt --storage-tier Archive
```

**To restore an Archive Storage tier object**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need OBJECT_RESTORE permissions to restore Archive Storage objects.</td>
</tr>
</tbody>
</table>

```bash
oci os object restore --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]```
By default, you have 24 hours to download an object after restoration. However, you can optionally specify --hours with an integer value of download time of from 1 to 240 hours.

To check the status of an Archive Storage object restoration

```
oci os object restore-status --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name>
```

To re-encrypt an object

**Tip:**

You need OBJECT_READ and OBJECT_OVERWRITE permissions to re-encrypt an object.

You can re-encrypt the data encryption keys that encrypt an object. You can do so by re-encrypting the object's data encryption keys with the latest version of the master encryption key assigned to the bucket, whether it's an Oracle managed key or a key in a vault that you manage. You can also re-encrypt the object's data encryption keys with a different key in a vault or a different SSE-C key. If you use SSE-C keys, you must provide the SSE-C key during the object decryption and subsequent re-encryption process, as appropriate.

You can re-encrypt an object's data encryption keys with the latest key version of the key assigned to the bucket.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```

For example:

```
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
```

The object's data encryption keys are re-encrypted with no further information returned.

If the object's data encryption keys are currently encrypted with an SSE-C key, you must also provide the name of the file that contains the base64-encoded string of the AES-256 source encryption key to first decrypt the object.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key>
```

For example:

```
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey
```

You can re-encrypt an object's data encryption keys with a specific Vault key.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --kms-key-id <key_OCID>
```

For example:

```
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplepsuqmoys4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq
```

Again, if the key is currently encrypted with an SSE-C key, you must also provide the name of the file that contains the base64-encoded string of the AES-256 source encryption key to first decrypt the object.

```
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-
```

Oracle Cloud Infrastructure User Guide 4340
For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey --kms-key-id ocid1.key.region1.sea.exampleaaacu2.exmplesmtpsuqmo4v4m3s8uqgo2z6f3zfaux21mqz2
```

You can re-encrypt an object's data encryption keys with an SSE-C key.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --encryption-key-file MySSE-CKey
```

If the object is currently encrypted with an SSE-C key, and you want to encrypt the object's data encryption keys with a different SSE-C key, provide the file name of each key.

```bash
oci os object reencrypt --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --source-encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key_currently_assigned> --encryption-key-file <name_of_file_containing_base64-encoded_AES-256_key_desired>
```

For example:

```bash
oci os object reencrypt --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt --source-encryption-key-file MySSE-CKey --encryption-key-file MyNewSSE-CKey
```

**To delete an object**

If object versioning is disabled or suspended, you can permanently delete an object.

```bash
oci os object delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name>
```

For example:

```bash
oci os object delete --namespace MyNamespace --bucket-name MyBucket --name MyFile.txt
```

Are you sure you want to delete this resource? [y/N]: y

The object is deleted with no further information returned.

**To bulk delete all objects within a bucket**

```bash
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```bash
oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket
```
WARNING: This command will delete 2 objects. Are you sure you wish to continue? [y/N]:

Deleted MyRenamedFile.txt [####################################] 100%
Deleted logFile.log [####################################] 100%

{  
  "delete-failures": {},  
  "deleted-objects": [  
    "MyRenamedFile.txt",  
    "logFile.log"  
  ]
}

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the --dry-run option.

For example:

oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket --dry-run

{  
  "delete-failures": {},  
  "deleted-objects": [  
    "MyFile.txt",  
    "logFile.log"  
  ]
}

**To bulk delete objects by object name prefix string**

If you named your objects with prefix strings, you can bulk delete objects in a given bucket by providing a prefix to match.

oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <prefix_string>

For example:

oci os object bulk-delete --namespace MyNamespace --bucket-name MyBucket --prefix gloves_A

The preceding command deletes the objects gloves_27_A.jpg and gloves_31_A.jpg, but does not delete the object shoes_1.jpg.

If you named your objects so that they exist in a hierarchy, specify a prefix to match to bulk delete objects at a given level and below.

oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <level_1/level_2/>

The preceding command deletes the following files:

- <level_1/level_2/object_name>
- <level_1/level_2/level_3/object_name>
- <level_1/level_2/level_3/level_4/object_name>

To delete only those objects at a given hierarchy level (and not objects in levels above or below), see To bulk delete objects at a specified hierarchy level.

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the --dry-run option.
To bulk delete objects at a specified hierarchy level

If you named your objects so that they exist in a hierarchy, you can bulk delete only those objects at a given hierarchy level (and not objects in levels above or below).

```
oci os object bulk-delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --prefix <level_1/level_2/> --delimiter /
```

**Note:**
Currently, only the forward slash (/) is the supported delimiter for the `--delimiter` option.

The preceding bulk delete command deletes the following object:

```
<level_1/level_2/>object_name
```

The preceding command does not bulk delete objects in levels above or below `<level_2>`. For example, the command would not delete the following objects:

- `<level_2/object_name>`
- `<level_1/level_2/level_3/object_name>`
- `<level_1/level_2/level_3/level_4/object_name>`

To delete objects at a given hierarchy level along with all objects in the hierarchy sublevels, see To bulk delete objects by object name prefix string.

To see a list of the files impacted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Object Storage prepends the Object Storage namespace string and bucket name to the object name when constructing a URL for use with the API:

```
/n/<object_storage_namespace>/b/<bucket>/o/<object_name>
```

The object name is everything after the `/o/`, which could include hierarchy levels and prefix strings.

Use the following API operations to manage objects:

- **DeleteObject**
- **GetObject**
- **HeadObject**
- **ListObjects**
- **PutObject** (see Special Instructions for Object Storage PUT for signing request requirements)
- **RenameObject**
- **ReencryptObject**
- **RestoreObjects**

**Using Replication**

Replication provides protection from regional outages, aids in disaster recovery efforts, and addresses data redundancy compliance requirements. Maintaining multiple copies of data in regional locations closer to user access can also reduce latency.

This topic describes Object Storage replication and provides details on how to replicate the objects in one bucket to another bucket in the same region or a different region.
About Object Storage Replication

Enabling Object Storage replication is as simple as creating a replication policy on the source bucket that identifies the region and the bucket to replicate to. After the replication policy is created, the destination bucket is read-only and updated only by replication from the source bucket. Objects uploaded to a source bucket after policy creation are asynchronously replicated to the destination bucket. Objects deleted from the source bucket after policy creation are automatically deleted from the destination bucket. Objects uploaded to a source bucket before policy creation are not replicated.

Replication overwrites any object in the destination bucket that has the same name as an object in the source bucket. A replicated object has the same name, metadata, ETag, and MD5 value as the object in the source bucket. The creation timestamp, modified timestamp, and archival state can be different, so these attributes are not replicated from the source.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Important:

Replication does not work if you do not authorize the Object Storage service to replicate objects on your behalf. See Service Permissions on page 4344 for more information.

User Permissions

You must have the required access to both the source and destination buckets when configuring replication. You must also have permissions to manage objects in the source and destination buckets.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, here is a simple user access policy that lets a StorageAdmins group do anything with the Object Storage service resources in the tenancy:

  Allow group StorageAdmins to manage object-family in tenancy

- Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage buckets and objects in a compartment called ObjectStore in the tenancy:

  Allow group StorageAdmins to manage buckets in compartment ObjectStore
  Allow group StorageAdmins to manage objects in compartment ObjectStore

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

Service Permissions

Because Object Storage is a regional service, you must authorize the Object Storage service for each region carrying out replication on your behalf. For example, you might authorize the Object Storage service in region US East (Ashburn) to manage objects on your behalf. After you authorize the Object Storage service, you can replicate the objects in a bucket in US East (Ashburn) to a bucket in another region.

To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 208.

For administrators:

To enable replication, you must authorize the service to manage objects on your behalf:
• For example, here is a service access policy that lets the Object Storage service do anything with the resources in the tenancy in the US West (Phoenix) region:

```
Allow service objectstorage-us-phoenix-1 to manage object-family in tenancy
```

• Alternatively, you can create policies that reduce the scope of access. For example, you can create a policy that lets the Object Storage service do anything with the resources in a compartment called ObjectStore in the US West (Phoenix) region:

```
Allow service objectstorage-us-phoenix-1 to manage object-family in compartment ObjectStore
```

• You can also create more restrictive policies that grant the individual permissions required for replication. For example:

```
Allow service objectstorage-us-phoenix-1 to manage object-family in compartment ObjectStore where any {request.permission='BUCKET_READ', request.permission='BUCKET_UPDATE', request.permission='OBJECT_READ', request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE', request.permission='OBJECT_OVERWRITE', request.permission='OBJECT_RESTORE', request.permission='OBJECT_DELETE'}
```

### Scope and Constraints

- Replication policy creation does not automatically create a destination bucket. Create the destination bucket before creating the replication policy on the source bucket.
- A source or destination bucket can be in the Standard (Object Storage) or Archive Storage tier.
- Maximum of one replication policy per source bucket.
- Maximum of one source for each replication destination bucket.
- Maximum of one destination for each replication source bucket.
- A destination bucket cannot also be a replication source. Chained replication is not supported.
- After the replication policy is created, the destination bucket is read-only and updated only by replication from the source bucket. Objects uploaded to the source bucket are automatically replicated to the destination bucket. Objects deleted from the source bucket are automatically deleted from the destination bucket.
- You cannot delete a replication destination bucket unless you stop replication and make the bucket writable again.

### Interaction Between Replication and Other Object Storage Features

This section describes some key things you need to know about the interaction between replication and other Object Storage features.

**Lifecycle Management**

You can combine replication with Lifecycle Management policies that manage the archiving and deletion of objects. Lifecycle policies must, however, honor the read-only properties of the replication destination bucket. A lifecycle policy that deletes objects from the replication destination bucket does not work. Carefully review and test any combination replication and lifecycle policies that you implement.

Here are examples of combination policies that might benefit you:

- You can create a lifecycle policy on the source that deletes objects with certain file extensions after a specified number of days. The result of that deletion would also be reflected in the replication destination.
- You can create a lifecycle policy on the destination that archives objects after a specified number of days. If you do not need immediate access to those objects, you could benefit from reduced storage costs.
Server-Side Encryption Using Your Own Keys

Replication cannot replicate objects that have been encrypted with an SSE-C key. For more information, see Using Your Own Keys for Server-Side Encryption on page 4406.

Stopping Replication

Stopping replication can be initiated from either the replication source or the destination.

- To stop replication from the source, delete the replication policy. Deleting a replication policy is permanent. You cannot recover a deleted policy. If you want to replicate to that target destination again, create a new policy.
- To stop replication from the destination, make the destination bucket writable again. When you make the bucket writable, the destination bucket no longer accepts replication requests from the source. Replication status on the source changes from active to a client error state. If you want this destination to again be the target replication destination, delete the policy on the source bucket and create a new policy.

Troubleshooting Replication

This topic provides troubleshooting solutions for issues you might encounter using replication.

Unable to create a replication policy on the source bucket

Here are the common causes for replication policy creation failures:

- The destination bucket cannot have versioning enabled.
- The destination bucket cannot have retention rules.
- Your IAM permissions are missing or incomplete. Policy creation requires:
  - User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
  - Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

  Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 4344.

Policy is in error on the source bucket

If the policy status changes from active to error, check these items:

- You intentionally or unintentionally stopped replication on the destination bucket. To once again replicate to this target bucket, delete the existing policy on the source bucket and create a new policy.
- Ensure that your user permissions are still in place.
- Ensure that the policies that authorize Object Storage access to the source and destination buckets and their objects are still in place.
- You might have exceeded your storage limits on the destination bucket. If you are a Free Trial or Always Free customer, your storage is limited. Upgrade to paid account or delete your replication policy.

Unable to stop replication on the destination bucket and make the bucket writable

If stopping a replication policy fails, the most likely cause is missing or incomplete IAM permissions. Policy creation requires:

- User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
- Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

  Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 4344.
Using the Console
To create a replication policy
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. Choose the compartment that contains the bucket you want to replicate from.
4. Click the bucket name.
5. Click Replication Policy under Resources to access the replication policy list.
6. Click Create Policy.
   The Console checks the IAM policies that are in place to ensure replication policy creation success. If you see a policy missing warning, you can let the Console try to create any missing policies or copy the missing policy details to the clipboard to email your administrator. If you think you have the required policies in place, go ahead and try to create the replication policy.
7. In the Create Policy dialog, enter the following:
   • Name: Required. The system generates a default policy name that reflects the current year, month, day, and time, for example replication-policy-20200129-2230. If you change this default to a different policy name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   • Destination Region: Required. The Oracle Cloud Infrastructure region containing the destination bucket that you want to replicate to. Your tenancy must be subscribed to a region for you to replicate to that region.
   • Destination Bucket: The name of the destination bucket for replication. Specify an existing target bucket. Replication cannot automatically create the bucket.
8. Click Create.
   After the policy is created, Replication: Source is added to Bucket Information. Objects uploaded to the source bucket after policy creation are asynchronously replicated to the destination bucket.

To view the source replication policy details
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the source replication bucket.
4. Click the source replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

To view the destination replication policy details
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the destination replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

To stop replication on the destination bucket and make the bucket writable
If you stop replication, the policy is removed from this destination bucket and cannot be recovered. The bucket reverts to a standard read/write bucket and is no longer a replication target.
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct replication destination region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the destination replication bucket name.
5. Click Replication Policy under Resources to access the replication policy list.
6. Click Stop Replication.

To delete the replication policy on the source bucket
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the destination replication bucket.
4. Click the replication destination bucket name.
5. Click Replication Policy under Resources to access the replication policy list.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create a replication policy

```bash
oci os replication create-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --destination-region <destination_region_identifier> --destination-bucket <destination_bucket_name>
```

For example:

```bash
oci os replication create-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --destination-region us-ashburn-1 --destination-bucket MyDestinationBucket --name MyReplicationPolicy
```

```
{   "data": {     "destination-bucket": "MyDestinationBucket",     "destination-region": "us-ashburn-1",     "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",     "name": "MyReplicationPolicy",     "status": "ACTIVE",     "status-message": "The policy is active.",     "time-created": "2020-02-06T16:44:10+00:00",     "time-last-sync": "2020-02-06T16:44:20+00:00"   }
}
```

Objects uploaded to the source bucket after policy creation are asynchronously replicated to the destination bucket.

To view the replication policy details

```bash
oci os replication get-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --replication-id <replication_policy_identifier>
```

For example:

```bash
oci os replication get-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --replication-id bacb8334-b191-4026-aa65-5e4f5165ae3e
```

```
{   "data": {     "destination-bucket": "MyDestinationBucket",     "destination-region": "us-ashburn-1",     "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",     "name": "MyReplicationPolicy",     "status": "ACTIVE",     "status-message": "The policy is active.",     "time-created": "2020-02-06T16:44:10+00:00",     "time-last-sync": "2020-02-06T16:49:40+00:00"
   }
}````
To list replication policies

Note:

There is currently a maximum of one replication policy per bucket.

```
oci os replication list-replication-policies --namespace <object_storage_namespace> --bucket-name <destination_bucket_name>
```

For example:

```
oci os replication list-replication-policies --namespace MyNamespace --bucket-name MySourceBucket
```

```
{
  "data": [
    {
      "destination-bucket": "MyDestinationBucket",
      "destination-region": "us-ashburn-1",
      "id": "bacb8334-b191-4026-aa65-5e4f5165ae3e",
      "name": "MyReplicationPolicy",
      "status": "ACTIVE",
      "status-message": "The policy is active.",
      "time-created": "2020-02-06T16:44:10+00:00",
      "time-last-sync": "2020-02-06T16:53:42+00:00"
    }
  ]
}
```

To list the replication source for a destination bucket

```
oci os replication list-replication-sources --namespace <object_storage_namespace> --bucket-name <destination_bucket_name> --region <destination_region_identifier>
```

For example:

```
oci os replication list-replication-sources --namespace MyNamespace --bucket-name MyDestinationBucket --region us-ashburn-1
```

```
{
  "data": [
    {
      "policy-name": "MyReplicationPolicy",
      "source-bucket": "MySourceBucket",
      "source-region": "us-phoenix-1"
    }
  ]
}
```

To stop replication on the destination bucket and make the bucket writable

```
oci os replication make-bucket-writable --namespace <object_storage_namespace> --bucket-name <destination_bucket_name> --region <destination_region_identifier>
```
For example:

```
oci os replication make-bucket-writable --namespace MyNamespace --bucket-name MyDestinationBucket --region us-ashburn-1
```

If the command is successful, you are returned to the prompt.

**To delete the replication policy on the source bucket**

```
oci os replication delete-replication-policy --namespace <object_storage_namespace> --bucket-name <source_bucket_name> --replication-id <replication_policy_identifier>
```

For example:

```
oci os replication delete-replication-policy --namespace MyNamespace --bucket-name MySourceBucket --replication-id bacb8334-b191-4026-aa65-5e4f5165ae3e
```

Are you sure you want to delete this resource? [y/N]: y

If the command is successful, you are returned to the prompt.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to use and manage replication:

- CreateReplicationPolicy
- GetReplicationPolicy
- ListReplicationPolicies
- ListReplicationSources
- MakeBucketWritable (Stops replication)

**Using Object Versioning**

Object versioning provides data protection against accidental or malicious object update, overwrite, or deletion.

**Important:**

Standard Oracle Cloud Infrastructure pricing applies to each bucket that is enabled for versioning. You are charged for all latest object versions and previous object versions (including deleted versions) stored in the bucket. Previous object versions are retained until you explicitly delete them.

Object versioning does increase your storage costs. Consider using Object Lifecycle Management to help you manage object versions automatically.

This topic describes Object Storage versioning and provides details on how to create and manage object versions.

**About Object Versioning**

Object versioning is enabled at the bucket level. Versioning directs Object Storage to automatically create an object version each time a new object is uploaded, an existing object is overwritten, or when an object is deleted. You can enable object versioning at bucket creation time or later.

A bucket that is versioning-enabled can have many versions of an object. There is always one latest version of the object and zero or more previous versions.
Understanding Object Versioning Status

Each Object Storage bucket has object versioning status of disabled, enabled, or suspended. By default, object versioning is disabled on a bucket. It's important to understand the behavior associated with each object versioning status.

Disabled
If object versioning is disabled on a bucket:

- Object versioning has never been enabled on the bucket.
- When you upload an object with the same name as an existing object, the object is overwritten and the overwritten object is not retained or recoverable.
- When you delete an object, the deletion is permanent and objects are not recoverable.

Enabled
If object versioning is enabled on a bucket:

- When you upload an object with the same name as an existing object, the existing object becomes a previous version and the newly uploaded object becomes the latest version.
- Each uploaded object is assigned a unique version identifier. The identifier lets you direct Object Storage actions to a specific version.
- When you delete an object, Object Storage retains a version of the deleted object. For more information about object deletion, see Understanding Object Version Deletion on page 4351.
- You cannot disable object versioning. You can, however, suspend versioning.

Suspended
If object versioning is suspended on a bucket:

- Upload and delete behavior is the same as a bucket that has versioning disabled.
- Object versions created before versioning suspension are retained, unless you take explicit action to delete them.
- You can re-enable object versioning at any time.

Understanding Object Version Deletion

No object is physically deleted from a bucket that has versioning enabled until you take explicit action to do so. When you delete an object without targeting a specific version, the latest object version becomes a previous object version and a special delete marker is created that marks the deletion point. A delete marker contains only minimal metadata. If you delete a folder, a delete marker is created for each object in the folder. You can simply delete the delete marker to make that deleted version become the latest object version.

When you upload an object with the same name as the delete marker, the uploaded object becomes the latest version of the object. The delete marker remains. There can be multiple delete markers for an object and you can recover any of the previous object versions.

Object version deletion is different. When you delete an object version, the version is permanently deleted. Permanent deletion also happens if you explicitly delete the latest version by version ID. All delete operations that target a specific object version ID permanently deletes the data.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators:
• You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, to let the IAM group StorageAdmins do everything in the tenancy:

| Allow group StorageAdmins to manage object-family in tenancy |

• Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage only buckets and objects in a compartment called ObjectStore in the tenancy:

| Allow group StorageAdmins to manage buckets in compartment ObjectStore |
| Allow group StorageAdmins to manage objects in compartment ObjectStore |

• If you create more restrictive policies that grant individual permissions, BUCKET_UPDATE is required to enable versioning. Uploading objects, overwriting existing objects, or deleting objects require the regular permissions necessary for those operations. OBJECT_VERSION_DELETE is required to delete object versions. For example, to allow a group called StorageSupport to manage Object Storage resources, but prevent that group from permanently removing object versions:

| Allow group StorageSupport to manage object-family in tenancy where request.operation != 'DeleteObjectVersion' |

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

Scope and Constraints

• Versioning can be enabled on a bucket in the Standard (Object Storage) or Archive Storage tier.
• Restoring an archived object is an in-place operation and does not create an object version.
• You can rename the latest version of an object, but you cannot rename a previous object version. Renaming an object creates a new object.

Interaction Between Versioning and Other Object Storage Features

This section describes some key things you need to know about the interaction between object versioning and other Object Storage features.

Bucket Re-Encryption

Bucket re-encryption (using either Oracle or your own master encryption key) also re-encrypts any existing object versions.

Lifecycle Management

Lifecycle policies can archive the latest version or previous versions of an object. When Lifecycle policies delete the latest version of an object, that object becomes a previous version and a delete marker is created. When Lifecycle policies delete a previous version of an object, that deletion is permanent.

Copying Objects

If you copy the latest version of an object to a different bucket, only the object is copied. None of the object's previous versions are copied. You can copy a previous version of an object to another bucket, but that action creates either the latest version of a new object or a new object version in the destination bucket.

Replication

• Replication cannot replicate previous object versions.
• You cannot enable versioning on a replication destination bucket. A destination bucket is read-only.
Retention Rules

- You cannot add retention rules to a bucket that has versioning enabled.
- You cannot enable versioning on a bucket with active retention rules.
- You can add retention rules to a bucket that has versioning suspended. However, you cannot resume versioning with active retention rules.

Troubleshooting Versioning

This topic provides troubleshooting solutions for issues you might encounter using versioning.

Unable to enable versioning

If enabling versioning fails, the most likely cause is missing or incomplete IAM permissions. Enabling versioning requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, BUCKET_UPDATE permissions.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4351.

Unable to delete a bucket

If deleting a bucket fails, the most likely cause is that the bucket is not empty.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot recover a deleted bucket.</td>
</tr>
</tbody>
</table>

You cannot delete a bucket that contains any of the following resources:

- Objects and object versions
- Pre-authenticated requests
- Replication policy
- Uncommitted multipart uploads

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you delete an object in a version-enabled bucket, a previous version of that object is created. Select Show Deleted Objects to display the object versions that might prevent you from deleting the bucket.</td>
</tr>
</tbody>
</table>

Unable to delete a previous object version

If deleting a previous object version fails, the most likely cause is missing or incomplete IAM permissions. Object version deletion requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, OBJECT_VERSION_DELETE permissions.

Using the Console

To enable versioning during bucket creation

1. Follow the steps for creating a bucket.
2. Select Enable Object Versioning to direct Object Storage to create an object version each time the content changes or the object is deleted.

To enable object versioning after bucket creation

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that you want to enable object versioning.
4. Click the bucket name.
5. In **Bucket Information**, locate **Object Versioning**.
   
   **Object Versioning** indicates the current versioning status. Versioning is disabled by default. If you did not enable object versioning during bucket creation, **Object Versioning** is Disabled.
6. Click **Edit**.
7. Click **Enable Versioning**.

**To suspend object versioning**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that you want to suspend object versioning.
4. Click the bucket name.
5. In **Bucket Information**, locate **Object Versioning**.
   
   **Object Versioning** indicates the current versioning status. Versioning is **Enabled**.
6. Click **Edit**.
7. Click **Suspend Versioning**.

**To re-enable object versioning from suspension**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that you want to re-enable object versioning.
4. Click the bucket name.
5. In **Bucket Information**, locate **Object Versioning**.
   
   **Object Versioning** indicates the current versioning status. Versioning is **Suspended**.
6. Click **Edit**.
7. Click **Enable Versioning**.

**To view the latest version of an object**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that you want to see the list of object versions.
4. Click the bucket name.
5. Click **Objects** under **Resources**.
6. Expand any folders and subfolders as needed to find the object for which you want to display previous versions.
   
   The latest version of each object is displayed.

**To view the previous versions of an object**

**Tip:**

When you delete an object in a version-enabled bucket, a previous version of that object is automatically created. Select **Show Deleted Objects** to display these object versions.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that you want to see the list of object versions.
4. Click the bucket name.
5. Click **Objects** under **Resources**.
6. Expand any folders and subfolders as needed to find the object for which you want to display previous versions.
   The latest version of each object is displayed.
7. Locate the object for which you want to display previous versions.
8. Click the file expander, located to the left of the the Actions icon (three dots).

The list of all previous versions of the object is displayed.

To view the details of an object version
1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the **List Scope** section, select the compartment that contains the bucket that has the object version that you want to delete.
4. Click the bucket name.
5. Click **Objects** under **Resources**.
   A list of folders and the latest versions of objects in the bucket are displayed.
6. Expand any folders and subfolders as needed to locate the object for which you want to view details.
7. To display the details for the latest version of an object, click the Actions icon (three dots) to the right of the object, and then click **View Object Details**.
8. To display the details for a previous version of an object, click the file expander, located to the left of the the Actions icon (three dots).

The list of all previous versions of the object is displayed.

9. Click the Actions icon (three dots) to the right of the object version, and then click View Object Details.

**To delete an object**

When versioning is enabled, deleting an object without targeting a specific version creates a delete marker and a previous version of the object that can be recovered.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that has the object that you want to delete.
4. Click the bucket name.
5. Click Objects under Resources.

   A list of folders and objects in the bucket are displayed.
6. Expand any folders and subfolders as needed to locate the object that you want to delete.
7. Click the Actions icon (three dots) to the right of the object, and then click Delete.
8. Confirm the deletion when prompted.

**To delete the previous version of an object**

When versioning is enabled, deleting an object without targeting a specific version creates a delete marker and previous version of the object that can be recovered. However, deleting a previous version of an object is a permanent deletion.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that has the object version that you want to delete.
4. Click the bucket name.
5. Click Objects under Resources.

   A list of folders and objects in the bucket are displayed.
6. Expand any folders and subfolders as needed to locate the object for which you want to delete a previous version.
7. Click the file expander, located to the left of the Actions icon (three dots).

The list of all previous versions of the object is displayed.

8. Locate the previous version of the object that you want to delete.
9. Click the Actions icon (three dots) to the right of the object version, and then click Delete.
10. Confirm the deletion when prompted.

**To recover a deleted object version**

Recovering a deleted object version is as simple as deleting the delete marker that was created when you deleted the latest version of an object. The previous version of the object listed just below the delete marker is recovered and becomes the latest version of the object.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket that has the object version that you want to recover.
4. Click the bucket name.
5. Click Objects under Resources.
   A list of folders and objects in the bucket are displayed.
6. Select Show Deleted Objects.
7. Expand any folders and subfolders as needed to locate the object that you want to recover.
8. Click the file expander, located to the located to the left of the the Actions icon (three dots) of the deleted object to display the versions that you can recover.
9. Click the Actions icon (three dots) to the right of the delete marker of the object, and then click Delete.
10. Confirm deletion when prompted.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.
To determine the object versioning status for a bucket

```
oci os bucket get --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```
oci os bucket get --namespace MyNamespace --name MyBucket
{
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid1.compartment.oc1..aaaaaaaamnk2ilreg5fkgu7rarfbhbdv3a5ji4eixxgk14uprbqk6aefv5sq",
    "created-by": "ocid1.user.oc1..aaaaaaah46lg3ueurftovn3urjgstl94laxnre3djeu5jxy5uaqhy7acgq",
    "defined-tags": {
        "Financials": {
            "key1": "nondefault"
        }
    },
    "etag": "79833b3f-89bd-41ac-bf86-0fbe331f3071",
    "freeform-tags": {},
    "id": "ocid1.bucket.oc1.phx.aaaaaaaa4feuzkcag77lxjndnujoiza7rh2unbpwytinhwxyymy5zk6uq",
    "is-read-only": false,
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-level-audit-mode": "Disabled",
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "replication-enabled": false,
    "storage-tier": "Standard",
    "time-created": "2020-04-14T14:25:32.465000+00:00",
    "versioning": "Disabled"
},
"etag": "79833b3f-89bd-41ac-bf86-0fbe331f3071"
}
```

To enable versioning during bucket creation

To enable versioning in a Standard tier bucket, you do not need to explicitly set `--storage-tier` because a bucket is created in the standard Object Storage tier by default:

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --versioning enabled
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyStandardBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --versioning enabled
```
To enable versioning in an Archive tier bucket, you must explicitly set --storage-tier Archive:

oci os bucket create --namespace <object_storage_namespace> --name <archivebucket_name> --compartment-id <target_compartment_id> --storage-tier Archive

For example:

oci os bucket create --namespace MyNamespace --name MyArchiveBucket --compartment-id ocid.compartment.oc1..exampleuniqueID --storage-tier Archive --versioning enabled

{"data": {
  "approximate-count": null,
  "approximate-size": null,
  "compartment-id": "ocid1.compartment.oc1..aaaaaaamnk2ilreg5fkgu7rarfbdhvdv3a5ji4eixxgk14uprbqk6aefv5sq",
  "created-by": "ocid1.user.oc1..aaaaaaah46lg3ueuptovn3urjgst1g4laxnre3djelu5jxy5uaqhgy7acgq",
  "defined-tags": {
    "Financials": {
      "key1": "nondefault"
    }
  },
  "etag": "5f19e314-68ad-4abf-9aa5-ae326bf83092",
  "freeform-tags": {},
  "id": "ocid1.bucket.oc1.phx.aaaaaaaozijn7ktq42wmyyrsxacy5z7biosoevlkmqv5w5z5cv56urg5ca",
  "is-read-only": false,
  "kms-key-id": null,
  "metadata": {},
  "name": "MyArchiveBucket",
  "namespace": "MyNamespace",
  "object-events-enabled": false,
  "object-level-audit-mode": "Disabled",
  "object-lifecycle-policy-etag": null,
  "public-access-type": "NoPublicAccess",
  "replication-enabled": false,
  "storage-tier": "Standard",
  "time-created": "2020-04-14T14:08.421000+00:00",
  "versioning": "Enabled"
},
"etag": "a91fd091-e112-483e-8e23-2b5d11e3dc2d"}
To enable object versioning after bucket creation

```
ooci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --compartment-id <target_compartment_id> --versioning Enabled
```

For example:

```
ooci os bucket update --namespace MyNamespace --name MyBucket --versioning Enabled
```

To list object versions

```
ooci os object list-object-versions --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:
oci os object list-object-versions --namespace MyNamespace --bucket-name MyStandardBucket
{
    "data": {
        "items": [
            {
                "etag": null,
                "is-delete-marker": false,
                "md5": null,
                "name": "MyTextDocument.txt",
                "size": null,
                "time-created": null,
                "time-modified": "2020-04-14T22:18:08.777000+00:00",
                "version-id": "2d528a44-5b15-40dc-b303-20993d1ade66"
            },
            {
                "etag": null,
                "is-delete-marker": false,
                "md5": null,
                "name": "MyTextDocument.txt",
                "size": null,
                "time-created": null,
                "time-modified": "2020-04-14T22:17:10.371000+00:00",
                "version-id": "a175ddc0-cc86-425f-bc2e-9b9bcb9b9f92"
            },
            {
                "etag": null,
                "is-delete-marker": false,
                "md5": null,
                "name": "MyTextDocument.txt",
                "size": null,
                "time-created": null,
                "time-modified": "2020-04-14T22:14:47.675000+00:00",
                "version-id": "8d8f06ef-e0c2-4435-bea6-f7c3ec80a444"
            }
        ],
        "prefixes": null
    }
}

To get the contents of an object version

oci os object get --name <object_name> --file path/to/file/name --version-id <version_identifier> --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example, to retrieve the contents of an object version into a file called TextDocument.txt:

To delete an object version

oci os object delete --name <object_name> --version-id <version_identifier> --namespace <object_storage_namespace> --bucket-name <bucket_name>

For example:

oci os object delete --name MyTextDocument.txt delete --version-id 8d8f06ef-e0c2-4435-bea6-f7c3ec80a444 --namespace MyNamespace --bucket-name MyStandardBucket
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations to enable object versioning:

- CreateBucket (enable versioning during bucket creation)
- UpdateBucket (enable versioning after bucket creation)

Use the following API operation to list object versions:

- ListObjectVersions

To perform version-specific operations, use the following APIs with a version identifier query parameter:

- CopyObject
- DeleteObject
- GetObject
- HeadObject
- RestoreObjects

Object-related APIs that do not take a version identifier query parameter operate only on an object, not object versions.

Using Retention Rules to Preserve Data

Retention rules provide immutable, WORM-compliant storage options for data written to Object Storage and Archive Storage for data governance, regulatory compliance, and legal hold requirements. Retention rules can also protect your data from accidental or malicious update, overwrite, or deletion. Retention rules can be locked to prevent rule modification and data deletion or modification even by administrators.

This topic describes Object Storage rule-based retention and provides details on how to create and manage these rules.

About Object Storage Data Retention

Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. Object Storage provides a flexible approach to data retention that supports the following use cases.

REGULATORY COMPLIANCE

Your industry might require you to retain a certain class of data for a defined length of time. Your data retention regulations might also require that you lock the retention settings. If you lock the settings, the only change you can make is to increase the retention duration.

For Object Storage regulatory compliance, you create a time-bound retention rule and specify a duration. Object modification and deletion are prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp. Lock the rule as required.

DATA GOVERNANCE

You might need to protect certain data sets as a part of internal business process requirements. While retaining the data for a defined length of time is necessary, that time period could change.

For Object Storage data governance, you create a time-bound retention rule and specify a duration. Object modification and deletion are prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp. To be able to delete the rule and allow changes to the duration as required, do not lock the rule.
LEGAL HOLD

You might need to preserve certain business data in response to potential or on-going lawsuits. A legal hold does not have a defined retention period and remains in effect until removed.

For Object Storage legal holds, you create an indefinite retention rule. Object modification and deletion are prevented until you delete the rule. You cannot lock an indefinite retention rule because the rule has no duration.

It's important to understand retention duration for time-bound rules. Even though you are creating retention rules for a bucket, the duration of a rule is applied to each object in the bucket individually, and is based on the object's Last Modified timestamp. Let's say you have two objects in the bucket, ObjectX and ObjectY. ObjectX was last modified 14 months ago and ObjectY was last modified 3 months ago. You create a retention rule with a duration of 1 year. This rule prevents the modification or deletion of ObjectY for the next 9 months. The rule allows the modification or deletion of ObjectX because the retention rule duration (1 year) is less that the object's Last Modified timestamp (14 months). If ObjectX is overwritten some time in the coming year, modification and deletion would be prevented for the rule duration time remaining.

Locking a retention rule is an irreversible operation. Not even a tenancy administrator can delete a locked rule. There is a mandatory 14-day delay before a rule is locked. This delay lets you thoroughly test, modify, or delete the rule or the rule lock before the rule is permanently locked. A rule is active at the time of creation. The lock only controls whether the rule itself can be modified. After a rule is locked, only increases in the duration are allowed. Object modification is prevented and the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

For an independent assessment of the Object Storage retention rules feature's ability to meet regulatory requirements for record management and retention, see Cohasset Associate's SEC 17a-4(f), FINRA 4511(c), CFTC 1.31(c)-(d) and MiFID II Compliance Assessment.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators:

• You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy. For example, to let the IAM group StorageAdmins do everything in the tenancy:

  Allow group StorageAdmins to manage object-family in tenancy

• Alternatively, you can create policies that reduce the scope of access. For example, you can create the policies to let the StorageAdmins group manage only buckets and objects in a compartment called ObjectStore in the tenancy:

  Allow group StorageAdmins to manage buckets in compartment ObjectStore
  Allow group StorageAdmins to manage objects in compartment ObjectStore

• If you create more restrictive policies that grant individual permissions, BUCKET_UPDATE and RETENTION_RULE_MANAGE is required to create, edit, and delete retention rules. BUCKET_UPDATE, RETENTION_RULE_MANAGE, and RETENTION_RULE_LOCK is required to lock retention rules.

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

Scope and Constraints

• Retention rules can be applied to a bucket in the Standard (Object Storage) or Archive Storage tier.
• The actions that you can perform on a bucket with active retention rules are limited. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules). The duration for time-bound rules is applied to each object individually, and is based on the object's Last Modified timestamp.

• You can create multiple retention rules for a bucket. Indefinite retention rule is applied before any time-bound rule is considered.

• When a retention rule is locked, the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

Interaction Between Retention and Other Object Storage Features

Carefully review the policies and rules that you have in place for the other Object Storage features that you are using. Some of these policies and rules may no longer make sense with retention rules. This section describes some key things you need to know about the interaction between retention rules and other Object Storage features.

Bucket Re-Encryption

Retention rules do not block bucket re-encryption using either Oracle or your own Vault master encryption keys.

Multipart Uploads

Uncommitted (unfinished or failed) multipart uploads are not protected by retention rules and can be deleted at any time.

Lifecycle Management

• Lifecycle policies can archive objects with retention rules.

• Lifecycle Management cannot remove objects protected by active retention rules.

Replication

• You can create retention rules on a replication source bucket.

• You cannot create retention rules on a replication destination bucket.

• You cannot enable replication on a destination bucket that has retention rules.

Versioning

• You cannot add retention rules to a bucket that has versioning enabled.

• You cannot enable versioning on a bucket with active retention rules.

• You can add retention rules to bucket that has versioning suspended. However, you cannot resume versioning with active retention rules.

Troubleshooting Retention Rules

This topic provides troubleshooting solutions for issues you might encounter using retention rules.

Unable to create a retention rule

If creating a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule creation requires:

• User permissions that let you access the bucket and manage the objects in those buckets.

• Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4363.
Unable to lock a retention rule

If locking a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Minimally, BUCKET_UPDATE, RETENTION_RULE_MANAGE, and RETENTION_RULE_LOCK permissions are required to lock retention rules.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4363.

Unable to delete a retention rule

You cannot delete a time-bound retention rule that is locked. When a retention rule is locked, the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

If deleting an indefinite retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule deletion requires:

- User permissions that let you access the bucket and manage the objects in those buckets.
- Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

Using the Console

To create a retention rule

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. Choose the compartment that contains the bucket where you want to create a retention rule.
4. Click the bucket name.
5. Click Retention Rules under Resources to access the retention rule list.
6. Click Create Rule.
7. In the Create Retention Rule dialog, enter the required rule Name. The system generates a default rule name that reflects the current year, month, day, and time, for example retention-rule-20200229-1002. If you change this default to a different rule name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
8. Choose the retention rule type that you want to create:
   - Time-Bound rules have a user-defined duration. Object modification is prevented for the duration specified. Duration is applied to each object individually, and is based on the object's Last Modified timestamp.
   - Indefinite rules have no duration or expiration. Object modification is prevented until an indefinite rule is deleted.
9. If you are creating a time Time-Bound rule, enter the retention rule duration attributes:
   - Retention Time Amount
   - Retention Time Unit
10. Optionally, select Enable Retention Rule Lock if you want to lock the rule.
11. Click Create.

   The rule is displayed in the Retention Rules list.

To lock a time-bound retention rule

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click Retention Rule under Resources to access the rule list.
   - If you are creating a retention rule, click Create Retention Rule. Specify the duration amount and unit, then select Enable Retention Rule Lock. Click Create.
   - If you are editing a retention rule, click the Actions icon (three dots) to the right of the rule name, and then click Edit. Select Enable Retention Rule Lock. Click Save Changes.
To view retention rule details

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click Retention Rule under Resources to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click View Details.

To edit a retention rule

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the retention rule.
4. Click the bucket name.
5. Click Retention Rule under Resources to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click Edit.
   - If you are editing an indefinite retention rule, you can only edit the name of the rule.
   - If you are editing a time-bound retention rule, you can edit multiple attributes. You can edit the name, the duration time amount and time unit, and optionally select whether to lock the rule.
   - If you are removing a retention rule lock during the delay period, deselect Enable Retention Rule Lock. For more information about retention rule locking, see About Object Storage Data Retention on page 4362.
7. If you are enabling a retention rule lock, confirm the rule lock details by selecting Update the Retention Rule with a Scheduled Lock Time of <date and time>.
8. Click Save Changes.

To delete a retention rule

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Ensure that the correct region is selected from the regions menu (shown at the top of the Console).
3. In the List Scope section, select the compartment that contains the bucket.
4. Click the bucket name.
5. Click Retention Rule under Resources to access the rule list.
6. Click the Actions icon (three dots) to the right of the rule name, and then click Delete.
7. Confirm deletion when prompted.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create an indefinite retention rule

```
oci os retention-rule create --namespace <object_storage_namespace> --bucket-name <bucket_name> --display-name <display_name>
```

For example:
```
oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket --display-name LegalHold
```
"time-rule-locked": null,
"etag": "7f51ef6c-3fca-48f7-9060-c129911c1a50"
}

To create a time-bound, unlocked retention rule

oci os retention-rule create --namespace <object_storage_namespace>
--bucket-name <bucket_name> --display-name <display_name> --time-
amount <time_integer> --time-unit <days|years>

For example:

oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket
--display-name DataGovernance --time-amount 5 --time-unit days
{
  "data": {
    "display-name": "DataGovernance",
    "duration": {
      "time-amount": 5,
      "time-unit": "DAYS"
    },
    "etag": "efb9178f-4213-49f7-878d-7bbe57decc0b",
    "id": "89f4ca0c-4ad9-4fa5-8005-95e7741c531c",
    "time-created": "2020-03-25T15:08:01.601000+00:00",
    "time-modified": "2020-03-25T15:08:01.601000+00:00",
    "time-rule-locked": null
  },
  "etag": "efb9178f-4213-49f7-878d-7bbe57decc0b"
}

To create a time-bound, locked retention rule

See the Command Line Interface (CLI) on page 5316 or the Command Line Reference for supported date and time
formats for --time-rule-locked.

oci os retention-rule create --namespace <object_storage_namespace>
--bucket-name <bucket_name> --display-name <display_name> --time-
amount <time_integer> --time-unit <days|years> --time-rule-locked <date and
time>

For example:

oci os retention-rule create --namespace MyNamespace --bucket-name MyBucket
--display-name RegulatoryCompliance --time-amount 5 --time-unit years --
time-rule-locked "2020-04-28 00:00"
{
  "data": {
    "display-name": "RegulatoryCompliance",
    "duration": {
      "time-amount": 5,
      "time-unit": "YEARS"
    },
    "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f",
    "id": "b1a6c84c-57c4-416c-b006-f864b0904c9e",
    "time-created": "2020-03-25T15:11:44.423000+00:00",
    "time-modified": "2020-03-25T15:11:44.423000+00:00",
    "time-rule-locked": "2020-04-28T00:00:00+00:00"
  },
  "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f"
}
**To list retention rules**

`oci os retention-rule list --namespace <object_storage_namespace> --bucket-name <bucket_name>`

For example:

```
oci os retention-rule list --namespace MyNamespace --bucket-name MyBucket
{
  "data": {
    "items": [
      {
        "display-name": "RegulatoryCompliance",
        "duration": { "time-amount": 5, "time-unit": "YEARS" },
        "etag": "c05f02d3-d2b5-4378-9fcb-3a92ba0e018f",
        "id": "b1a6c84c-57c4-416c-b006-f864b0904c9e",
        "time-created": "2020-03-25T15:11:44.423000+00:00",
        "time-modified": "2020-03-25T15:11:44.423000+00:00",
        "time-rule-locked": "2020-04-28T00:00:00+00:00"
      },
      {
        "display-name": "DataGovernance",
        "duration": { "time-amount": 5, "time-unit": "DAYS" },
        "etag": "efb9178f-4213-49f7-878d-7bbe57decc0b",
        "id": "89f4ca0c-4ad9-4fa5-8005-9e7741c531c",
        "time-created": "2020-03-25T15:08:01.601000+00:00",
        "time-modified": "2020-03-25T15:08:01.601000+00:00",
        "time-rule-locked": null
      },
      {
        "display-name": "LegalHold",
        "duration": null,
        "etag": "7f51ef6c-3fca-48f7-9060-c129911c1a50",
        "id": "5772c87f-6723-4ecc-b44c-bef86643be92",
        "time-created": "2020-03-25T14:53:20.792000+00:00",
        "time-modified": "2020-03-25T14:53:20.792000+00:00",
        "time-rule-locked": null
      }
    ]
  }
}
```

**To view retention rule details**

`oci os retention-rule get --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id <retention_rule_identifier>`

For example:

```
oci os retention-rule get --namespace MyNamespace --bucket-name MyBucket --retention-rule-id bla6c84c-57c4-416c-b006-f864b0904c9e
{
  "data": {
    "display-name": "RegulatoryCompliance",
  }
}
```
To update a time-bound retention rule after creation

oci os retention-rule update --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id --display-name <display_name> --time-amount <time_integer> --time-unit <days|years> --time-rule-locked <date and time>

For example, to increase the duration of and change the date a retention rule is locked:

oci os retention-rule update --namespace MyNamespace --bucket-name MyBucket --retention-rule-id bla6c84c-57c4-416c-b006-f864b0904c9e --time-amount 6 --time-unit years --time-rule-locked "2020-04-30 00:00"

To remove a retention rule lock during the delay period

oci os retention-rule update --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id --display-name <display_name> --time-rule-locked ""
To delete a retention rule

```
oci os retention-rule delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --retention-rule-id <retention_rule_identifier>
```

For example:

```
oci os retention-rule delete --namespace MyNamespace --bucket-name MyBucket --retention-rule-id 4ed833b1-fb27-4a40-a8ab-14e09636a724
```

Are you sure you want to delete this resource? [y/N]: y

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to use and manage retention rules:

- CreateRetentionRule
- GetRetentionRule
- ListRetentionRules
- UpdateRetentionRule
- DeleteRetentionRule

Using Object Lifecycle Management

By using Object Lifecycle Management to manage your Object Storage and Archive Storage data, you can reduce your storage costs and the amount of time you spend manually managing data.

Object Lifecycle Management works by taking automated action based on rules that you define. These rules instruct Object Storage to delete uncommitted multipart uploads, move objects to a different storage tier, and delete supported resources on your behalf within a given bucket. A bucket's lifecycle rules are collectively known as an object lifecycle policy. The resources that Object Lifecycle Management supports include objects, object versions, and uncommitted or failed multipart uploads.

For example, you can define rules that automatically do things like the following:

- Move Standard tier objects with a .doc extension to either the Infrequent Access or Archive tier 60 days after creation or last update.
- Move Standard tier objects to the Archive tier 30 days after creation or last update, and then automatically delete those archived objects after 180 days.
- Move Standard tier objects to the Infrequent Access tier 90 days after creation or last update.
- Delete any previous object versions 120 days after the object version transitions from the latest version to a previous version.
- Delete uncommitted or failed multipart uploads after 5 days.
- Delete all objects and object versions in a bucket in preparation for bucket deletion.

Each Object Storage or Archive Storage bucket can have a single lifecycle policy consisting of up to 1,000 rules. Object-related rules can have object name prefix and pattern matching conditions. Uncommitted multipart upload rules do not support prefix and pattern matching conditions.
You can create, edit, delete, enable, and disable individual rules in the Console as needed. To update a lifecycle policy using the CLI or API, overwrite an existing policy with a new policy. Ensure that the new policy is inclusive of all the policy rules that you want to apply to the bucket.

**Required IAM Policies**

Important:

You cannot use Object Lifecycle Management until you authorize the Object Storage service to archive and delete objects on your behalf. See Service Permissions on page 4371 for more information.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**User Permissions**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators:

- The policy Let Object Storage admins manage buckets and objects on page 2813 lets the specified group do everything with buckets and objects, including adding and managing lifecycle policies.
- If you create more restrictive policies that grant individual permissions:
  - OBJECT_VERSION_DELETE is required to delete previous object versions on your behalf using lifecycle policies.
  - OBJECT_UPDATE_TIER is required to change the storage tier of an object.

See Details for Object Storage, Archive Storage, and Data Transfer on page 3017 for more information on Object Storage user permissions.

**Service Permissions**

To execute object lifecycle policies, you must authorize the service to archive and delete objects on your behalf. To do so, create the following policy in the root compartment of your tenancy:

```
Allow service objectstorage-<region_identifier> to manage object-family in compartment <compartment_name>
```

Because Object Storage is a regional service, you must authorize the Object Storage service in each region you use lifecycle policies. Object Storage ensures that your data is not read from any unauthorized region.

If you don't have permissions to write policies for the root compartment of your tenancy, contact your Oracle Cloud Infrastructure administrator. To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 208.

Instead of using the policy verb manage, you can grant individual permissions to the service. For example:

```
Allow service objectstorage-<region_identifier> to
  manage object-family in compartment <compartment_name>
  where any {request.permission='BUCKET_INSPECT',
  request.permission='BUCKET_READ', request.permission='OBJECT_INSPECT',
  request.permission='OBJECT_CREATE', request.permission='OBJECT_DELETE',
  request.permission='OBJECT_VERSION_DELETE')
```

**Options**

When creating object lifecycle policy rules, you have the following options:
• When a lifecycle rule is created, the system generates a default name for that rule, for example lifecycle-rule-20190321-1559. This rule name identifies the current year, month, day, and time that the rule was created. You can use that system-generated name for your new rule or you can specify a different name for it.

• You can create lifecycle rules that do the following:
  • Move or delete all objects in the bucket.
  • Move or delete objects in the bucket that match the object name filters you specify. You can select objects using both object name prefixes and pattern matching. See Using Object Name Filters on page 4372 for details.
  • Delete uncommitted or failed multipart uploads. For more information, see Using Multipart Uploads on page 4382.

If object versioning is enabled or suspended on a bucket, you can also create lifecycle rules that do the following:
  • Move or delete the previous versions of all objects in the bucket.
  • Move or delete the previous versions of objects in the bucket that match the name filters you specify. You can select objects using both object name prefixes and pattern matching. See Using Object Name Filters on page 4372 for details.
  • You specify the number of days until the specified action is taken.
  • You decide whether a new rule is enabled or disabled upon creation.

Using Object Name Filters

Use object name filters to specify a subset of objects, object versions, or previous object versions that a lifecycle rule applies to. Create a separate object name filter rule for each rule target (objects, object versions, or previous object versions).

Important: Do not specify object name filters if you want a rule to apply to the all objects, all object versions, or all previous object versions target.

Two types of object name filters are supported:

• Prefix matching is an exact matching of the left-most characters of an object name. Prefix matching does not support wildcard characters. While Object Storage buckets and objects exist in a flat structure, prefixes let you simulate a directory structure when used with a slash (/). See Object Naming Using Prefixes and Hierarchies on page 4323 for details.

• Pattern matching matches on the entire object name, but supports using wildcard characters and other pattern matching constructs as needed to match zero or more characters within the object name.

Important: Object name filters operate on the entire object name. Prefixes (displayed as virtual folders and subfolders in the Console) are part of the object name.

In this illustration, /marathon/participants/p_21.jpg is the name of the object, not p_21.jpg.

You can add object name filters in any order. Object Lifecycle Management evaluates the precedence of the rules as follows:
1. Pattern exclusions
2. Pattern inclusions
3. Prefix inclusions

Using Prefix Matching to Filter Objects

You can use prefix strings for matching purposes when performing lifecycle management-related operations. Certain bulk operations can also be performed by matching on the prefix portions of the object name.

- In the following object name examples, prefixes include one or more forward slashes (/) to simulate a directory structure. The string marathon/ or marathon/participants/ can serve as a prefix for matching purposes in lifecycle rules:

```
marathon/finish_line.jpg
marathon/podium.jpg
marathon/participants/p_21.jpg
marathon/participants/p_29.jpg
```

- In the following object name examples, the string gloves_27_ can serve as a prefix for matching purposes in lifecycle rules:

```
gloves_27_dark_green.jpg
gloves_27_light_blue.jpg
gloves_27_deep_purple.jpg
gloves_27_bright_orange.jpg
```

Using Pattern Matching to Filter Objects

Object Storage supports the following pattern matching characters to either include or exclude objects:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
<th>Pattern Examples</th>
<th>Matches</th>
<th>Doesn’t Match</th>
</tr>
</thead>
</table>
| *         | Matches 0 or more characters | *.tmp | foo.tmp  
foo/bar/baz.tmp | tmp  
Atmp |
|           |             | *.xls | .xls  
/home/user/file.xls | xls  
.xl |
|           |             | /archive/* | /archive/sub/dir/  
/archive/1/2/3/4/  
foo.txt | /src/archive/a  
archive/b |
| ?         | Matches any one character | X?Z | XyZ  
X_Z | XZ  
XYYZ |
| \         | Escapes the next character | \dir\sub\* | \dir\sub\ABC  
\dir\sub\ | dir\sub\abc  
dirs\sub |
<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
<th>Pattern Examples</th>
<th>Matches</th>
<th>Doesn’t Match</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-ab3]</td>
<td>-a</td>
<td>-a</td>
<td></td>
<td>-ab</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td></td>
<td></td>
<td>3b</td>
</tr>
<tr>
<td>backup.tar.gz.[0-9]</td>
<td>backup.tar.gz.0</td>
<td>backup.tar.gz.5</td>
<td>backup.tar.gz10</td>
<td>backup.tar.gz.9</td>
</tr>
<tr>
<td>page-[0-9]*</td>
<td>page-0</td>
<td>page-2</td>
<td>page-22</td>
<td>page-2X</td>
</tr>
<tr>
<td>[a-z]</td>
<td>[a-z]</td>
<td>a</td>
<td>z</td>
<td>[a-z]</td>
</tr>
</tbody>
</table>

Patterns are limited to 1024 characters. The following are examples of invalid patterns:

- \ 
- [^a-z] 
- [z-a] 
- [z-a] 

### Scope and Constraints

Understand the following scope and constraints regarding object lifecycle policy rules:
• When you create a lifecycle policy rule, that rule applies to all objects, all object versions, or all previous object versions that exist in the bucket unless you add object name filters for that target.
• Prefix and pattern matching filtering applies only to rules for objects, object versions, or previous object versions. Object filtering does not apply to uncommitted multipart uploads.
• A rule that deletes an object always takes priority over a rule that would move that same object to another storage tier.
• When you create a rule that moves or deletes previous object versions, you specify the number of days until the move or deletion occurs. The “number of days” countdown is based on when the object version transitioned from being the latest object version to being a previous object version. This time can be determined by looking at the “last modified” time of the preceding most recent version of the object. The following screenshot illustrates the time used to start the countdown for archival or deletion in the .

![Objects](image)

• If Auto-Tiering is enabled, you cannot create a rule that moves objects, object versions, or previous object versions to Infrequent Access.
• Be aware of minimum retention periods when you create rules that move or delete the latest version or previous versions of objects.
  • The Archive tier has a minimum retention requirement of 90 days. Objects moved or deleted from the Archive tier that have not met the 90-day retention minimum are billed for 90 days of storage.
  • Infrequent Access tier has a minimum retention requirement of 31 days. Objects moved or deleted from the Infrequent Access tier that have not met the 31-day retention minimum are billed for 31 days of storage.
• You can create up to 1,000 lifecycle rules per bucket.

**Working with Object Lifecycle Management Policies**

You can create, delete, edit, or disable lifecycle policy rules using the Console, the Command Line Interface (CLI), an SDK, or the API.

**Caution:**

Objects deleted on your behalf by lifecycle policies cannot be recovered. Be sure when creating and editing your lifecycle policies that you are not unintentionally deleting data you want to retain. Oracle recommends that you test your lifecycle policy on development data before using the policy in production.

**Using the Console**

**To create a lifecycle policy rule**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Choose the compartment containing the bucket for which you want to create a lifecycle rule.
3. Click the bucket name.
4. Click **Lifecycle Policy Rules** under **Resources** to access the lifecycle policy rule list.
5. Click **Create Rule**.

The Console checks the IAM policies that are in place to ensure policy rule creation success. If you see a policy missing warning, you can let the Console try to create any missing policies or copy the missing policy details to the clipboard to email your administrator. If you think you have the required policies in place, go ahead and try to create the lifecycle policy rule.

6. Provide the following information:

- **Name**: Required. The system generates a default rule name that reflects the current year, month, day, and time, for example `lifecycle-rule-20190321-1559`. If you change this default to any other rule name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.

- **Target**: Required. Select the target to which the lifecycle rule applies.
  
  - If object versioning is **Disabled**, select the rule target **Objects** or **Uncommitted Multipart Uploads**.
  
  - If object versioning is **Enabled** or , **Suspended** select the rule target **Latest Version of Objects**, **Previous Versions of Objects**, or **Uncommitted Multipart Uploads**.

- **Lifecycle Action**:
  
  - If the rule target is **Objects**, **Latest Version of Objects**, or **Previous Versions of Objects**, select **Move to Archive**, **Move to Infrequent Access**, or **Delete**.
  
  - If **Auto-Tiering** is enabled on the bucket, **Move to Infrequent Access** is not available for selection.

  - If the rule target is **Uncommitted Multipart Uploads**, **Delete** is the only option and is selected by default.

- **Number of Days**: The number of days until the specified action is taken.

### Note:

If the rule archives or deletes a previous object version, the "number of days" countdown is based on when the object version transitioned from being the latest object version to being a previous object version. This time can be determined by looking at the "last modified" time of the preceding most recent version of the object. The following screenshot illustrates the time used to start the countdown for archival or deletion in the .

7. If the rule target is **Objects**, **Latest Version of Objects**, or **Previous Versions of Objects**, you can optionally add one or more **Object Name Filters** to specify which objects the lifecycle rule applies to. You can choose objects or object versions using **prefixes** and **pattern matching**. If no object name filters are specified, the rule applies to all objects in the bucket.

To create an object name filter:

- **Click Add Filter**.
- **Select the Filter Type**.
- **Enter the Filter Value**.
- **Click Add Another Filter** to add as many filters as you need for this rule.
8. Select whether the rule is enabled or disabled upon creation using the State selector.
9. Click Create.

To edit a lifecycle policy rule
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment containing the bucket for which you want to edit a lifecycle rule.
3. Click the bucket name.
4. Click Lifecycle Policy Rules under Resources to access the rule list.
5. Click the Actions icon (three dots) to the right of the rule that you want to edit, and then click Edit.
6. In the Edit Lifecycle Rule dialog box, edit the following as needed for each rule you want to change.
   - Name: A user-friendly name for the rule. Avoid entering confidential information.
   - Lifecycle Action:
     - If the rule target is Objects, Latest Version of Objects, or Previous Versions of Objects, select Move to Archive, Move to Infrequent Access, or Delete.
     - If the rule target is Uncommitted Multipart Uploads, Delete is the only option and is selected by default.
   - Number of Days: The number of days until the specified action is taken.
   - If the rule pertains to objects or object versions, you can edit, delete, or add prefix or pattern Object Name Filters.
     - Enable or disable the rule using the State selector.
7. Click Save Changes.

To enable, disable, or delete a lifecycle policy rule
You can enable, disable, or delete a rule using the Console. The system stops the execution of disabled or deleted rules immediately.
1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment containing the bucket for which you want to enable, disable, or delete a lifecycle rule.
3. Click the bucket name.
4. Click Lifecycle Policy Rules under Resources to access the rule list.
5. Click the Actions icon (three dots) to the right of the rule that you want to manage, and then click one of the following:
   - Enable (only displays if the rule is disabled)
   - Disable (only displays if the rule is enabled)
   - Delete

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create or replace a lifecycle policy for a bucket

Note:
To edit an existing lifecycle policy using the CLI, you need to replace the policy with a new complete version that includes all changed rules.

oci os object-lifecycle-policy put --namespace <object_storage_namespace> --bucket-name <bucket_name> --items <json_formatted_lifecycle_policy>
Tip:

The `--items` option requires that you provide key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

The `--items` key-value pair input must specify the following:

```json
[
    {
        "action": "string",
        "isEnabled": true,
        "name": "string",
        "objectNameFilter": {
            "exclusionPatterns": [
                "string",
                "string"
            ],
            "inclusionPatterns": [
                "string",
                "string"
            ],
            "inclusionPrefixes": [
                "string",
                "string"
            ]
        },
        "target": "string",
        "timeAmount": 0,
        "timeUnit": "string"
    }
]
```

Specify one of the following values for `action`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHIVE</td>
<td>Specify this action to move objects, object versions, or previous object versions to the Archive tier.</td>
</tr>
<tr>
<td>INFREQUENT_ACCESS</td>
<td>Specify this action to move objects, object versions, or previous object versions to the Infrequent Access tier. If Auto-Tiering is enabled on the bucket, you cannot specify INFREQUENT_ACCESS.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Specify this action to delete objects, object versions, or object versions.</td>
</tr>
<tr>
<td>ABORT</td>
<td>Use this action to delete failed or incomplete multipart uploads.</td>
</tr>
</tbody>
</table>

Specify one of the following values for `target`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objects</td>
<td>Use this action to move objects, object versions, or previous object versions to the Archive tier.</td>
</tr>
<tr>
<td>object-versions</td>
<td>Use this action to move objects, object versions, or previous object versions to the Infrequent Access tier.</td>
</tr>
<tr>
<td>multipart-uploads</td>
<td>Use this action to delete objects, object versions, or previous object versions.</td>
</tr>
</tbody>
</table>

Specify `timeUnit` in days.
The following example creates or replaces a lifecycle policy that includes a rule for moving previous object versions with names that include the pattern ".doc" from the Standard tier to the Archive tier after 60 days. The policy also includes a rule that deletes previous object versions after 180 days.

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardBucket --items
  '[
    {
      "action": "ARCHIVE",
      "is-enabled": true,
      "name": "Move-to-Archive-Rule",
      "object-name-filter": {
        "exclusion-patterns": null,
        "inclusion-patterns": [
          "*.doc"
        ],
        "inclusion-prefixes": null
      },
      "target": "previous-object-versions",
      "time-amount": 60,
      "time-unit": "DAYS"
    },
    {
      "action": "DELETE",
      "is-enabled": true,
      "name": "Delete-Rule",
      "object-name-filter": {
        "exclusion-patterns": null,
        "inclusion-patterns": [
          "*.doc"
        ],
        "inclusion-prefixes": null
      },
      "target": "previous-object-versions",
      "time-amount": 180,
      "time-unit": "DAYS"
    }
  ]'
```

The following example creates or replaces a lifecycle policy that includes a rule for moving all objects from the Standard tier to the Infrequent Access tier after 45 days. The policy also includes a rule that moves all objects to the Archive tier after 90 days.

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --items
  '[
    {
      "action": "INFREQUENT_ACCESS",
      "is-enabled": true,
      "name": "Move-to-Infrequent-Access-Rule",
      "object-name-filter": null,
      "target": "objects",
      "time-amount": 45,
      "time-unit": "DAYS"
    },
    {
      "action": "ARCHIVE",
      "is-enabled": true,
      "name": "Move-to-Archive-Rule",
      "object-name-filter": null,
      "target": "objects",
      "time-amount": 90,
    }
  ]'
```
The following example creates or replaces a lifecycle policy rule that deletes previous object versions from the Archive tier after 240 days:

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyArchiveTierBucket --items
'[
  {
    "action": "DELETE",
    "is-enabled": true,
    "name": "Delete-from-Archive-Rule",
    "object-name-filter": null,
    "target": "previous-object-versions",
    "time-amount": 240,
    "time-unit": "DAYS"
  }
]
```

The following example creates or replaces a lifecycle policy rule that deletes all uncommitted or failed multipart uploads after 5 days:

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyBucket --items
'[
  {
    "action": "ABORT",
    "is-enabled": true,
    "name": "Delete-Failed-Multipart-Uploads-Rule",
    "object-name-filter": null,
    "target": "multipart-uploads",
    "time-amount": 5,
    "time-unit": "DAYS"
  }
]
```

Instead of using the --items option, you can pass the JSON key-value pairs in a file. For example:

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --file /path/to/file/filename
```

On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

For example:

```
oci os object-lifecycle-policy put --namespace MyNamespace --bucket-name MyStandardTierBucket --items "[{{"action":"ARCHIVE","is-enabled":true,"name":"move-to-Archive-rule","target":"previous-object-versions","timeAmount":180,"timeUnit":"DAYS"}}]"
```

To delete a bucket's lifecycle policy

Deletes all of the lifecycle policy rules that you have defined for the specified bucket.

```
oci os object-lifecycle-policy delete --namespace <object_storage_namespace> --bucket-name <bucket_name>
```
For example:

```bash
oci os object-lifecycle-policy delete --namespace MyNamespace --bucket-name MyStandardTierBucket
```

When prompted, confirm the deletion.

**To get a bucket's lifecycle policy**

Gets all of the lifecycle policy rules that you have defined for the specified bucket.

```bash
oci os object-lifecycle-policy get --namespace <object_storage_namespace> --bucket-name <bucket_name>
```

For example:

```json
oci os object-lifecycle-policy get --namespace MyNamespace --bucket-name MyStandardTierBucket
{
  "data": {
    "items": [
      {
        "action": "ABORT",
        "is-enabled": true,
        "name": "Delete-Failed-Multipart-Uploads-Rule",
        "object-name-filter": null,
        "target": "multipart-uploads",
        "time-amount": 5,
        "time-unit": "DAYS"
      },
      {
        "action": "DELETE",
        "is-enabled": true,
        "name": "Delete-from-Archive-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "target": "objects",
        "time-amount": 240,
        "time-unit": "DAYS"
      },
      {
        "action": "INFREQUENT_ACCESS",
        "is-enabled": true,
        "name": "Move-to-Infrequent-Access-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "target": "objects",
        "time-amount": 45,
        "time-unit": "DAYS"
      },
      {
        "action": "ARCHIVE",
        "is-enabled": true,
        "name": "Move-to-Archive-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        }
      }
    ]
  }
}```
For example, to get the lifecycle policy that archives objects after 30 days:

```bash
oci os object-lifecycle-policy get --namespace MyNamespace --bucket-name MyBucketWithoutVersioning
```

```json
{
  "data": {
    "items": [
      {
        "action": "ARCHIVE",
        "is-enabled": true,
        "name": "Archive-After-30-Days-Rule",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "target": "objects",
        "time-amount": 30,
        "time-unit": "DAYS"
      }
    ],
    "time-created": "2020-10-27T17:56:27.085000+00:00"
  },
  "etag": "lifecycle-policy-a3f5d4a6-ca25-4a28-9ee6-7d073f51e754"
}
```

### Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage object lifecycle policies:

- **PutObjectLifecyclePolicy**
- **GetObjectLifecyclePolicy**
- **DeleteObjectLifecyclePolicy**

### Using Multipart Uploads

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. You can perform multipart uploads using the API, the Software Development Kits and Command Line Interface on page 5351, or the Command Line Interface (CLI) on page 5316. The Console uses multipart uploads to upload objects larger than 64 MiB.

With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads performed through the API can also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload.

Multipart uploads accommodate objects that are too large for a single upload operation. We recommend that you use multipart uploads to upload objects larger than 100 MiB. The maximum size for an uploaded object is 10 TiB. Object
parts must be no larger than 50 GiB. Using multipart uploads, you have the flexibility of pausing between the uploads of individual parts, and resuming the upload when your schedule and resources allow.

You can use object lifecycle policy rules to automatically delete any uncommitted or failed multipart uploads after a specified number of days. See Using Object Lifecycle Management on page 4370 for details.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you are new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  Allow group <IAM_group_name> to manage object-family in tenancy

- Alternatively, you can create policies that reduce the scope of access. For example, to let the specified group manage only buckets and objects in a particular compartment in the tenancy:

  Allow group <IAM_group_name> to manage buckets in compartment <compartment_name>

  **Important:**
  
  If you write more restrictive policies, ensure that you include the permissions required for multipart uploads. The user needs a policy that grants both OBJECT_CREATE and OBJECT_OVERWRITE permissions.

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For more information about monitoring multipart uploads, see Object Storage Metrics on page 4416.

**Using the Multipart Upload API**

A multipart upload performed using the API consists of the following steps:

1. Initiating an upload
2. Uploading object parts
3. Committing the upload

Before you use the multipart upload API, you are responsible for creating the parts to upload. Object Storage provides API operations for the remaining steps. The service also provides API operations for listing in-progress multipart uploads, listing the object parts in an in-progress multipart upload, and aborting in-progress multipart uploads initiated through the API. Here we provide a high-level overview of the API steps, but you can refer to the API Reference for specifics about supported API calls.
Creating Object Parts

With multipart upload, you split the object you want to upload into individual parts. Individual parts can be as large as 50 GiB. Decide what part number you want to use for each part. Part numbers can range from 1 to 10,000. You do not need to assign contiguous numbers, but Object Storage constructs the object by ordering part numbers in ascending order.

Initiating an Upload

After you finish creating object parts, initiate a multipart upload by making a CreateMultipartUpload REST API call. Provide the object name and any object metadata. Object Storage responds with a unique upload ID that you must include in any requests related to this multipart upload. Object Storage also marks the upload as active. The upload remains active until you explicitly commit it or abort it.

Uploading Object Parts

Make an UploadPart request for each object part upload. In the request parameters, provide the Object Storage namespace, bucket name, upload ID, and part number. In the request body, include the object part. Object parts can be uploaded in parallel and in any order. When you commit the upload, Object Storage uses the part numbers to sequence object parts. Part numbers do not have to be contiguous. If multiple object parts are uploaded using the same upload ID and part number, the CommitMultipartUpload API commits the last part uploaded.

Object Storage returns an ETag (entity tag) value for each part uploaded. You need both the part number and corresponding ETag value for each part when you commit the upload.

If you have network issues, you can restart a failed upload for an individual part. You do not need to restart the entire upload. If for some reason, you cannot perform an upload all at once, multipart upload lets you continue uploading parts at your own pace. While a multipart upload is still active, you can keep adding parts as long as the total number is less than 10,000.

You can check on an active multipart upload by listing all parts that have been uploaded. (You cannot list information for an individual object part in an active multipart upload.) The ListMultipartUploadParts operation requires the Object Storage namespace, bucket name, and upload ID. Object Storage responds with information about the parts associated with the specified upload ID. Parts information includes the part number, ETag value, MD5 checksum, and part size (in bytes).

Similarly, if you have multiple multipart uploads occurring simultaneously, you can see what uploads are in-progress. Make an ListMultipartUploads API call to list active multipart uploads in the specified Object Storage namespace and bucket.

Charges for parts storage begin accruing when you upload data.

Committing the Upload

When you have uploaded all object parts, commit the upload. Use the CommitMultipartUpload request parameters to specify the Object Storage namespace, bucket name, and upload ID. Include the part number and corresponding ETag value for each part in the body of the request. When you commit the upload, Object Storage constructs the object from its constituent parts. The object is stored in the specified bucket and Object Storage namespace. You can treat it like you would any other object. Garbage collection releases storage space occupied by any part numbers you uploaded, but did not include in the CommitMultipartUpload request.

You cannot list or retrieve parts from a completed upload. You cannot append or remove parts from the completed upload either. If you want, you can replace the object by initiating a new upload.

If you decide to abort a multipart upload instead of committing it, wait for in-progress part uploads to complete and then use the AbortMultipartUpload operation. If you abort an upload while part uploads are still in progress anyway, Object Storage cleans up both completed and in-progress parts. Upload IDs from aborted multipart uploads cannot be reused.
API Documentation

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage multipart uploads:

- AbortMultipartUpload
- CommitMultipartUpload
- CreateMultipartUpload
- ListMultipartUploadParts
- ListMultipartUploads
- UploadPart (see Special Instructions for Object Storage PUT for signing request requirements)

Using the CLI

When you perform a multipart upload using the CLI, you do not need to split the object into parts as you are required to do by the API. Instead, you specify the part size of your choice, and Object Storage splits the object into parts and performs the upload of all parts automatically. You can choose to set the maximum number of parts that can be uploaded in parallel. By default, the CLI limits the number of parts that can be uploaded in parallel to three. When using the CLI, you do not have to perform a commit when the upload is complete.

You can also use the CLI to list in-progress multipart uploads, and to abort multipart uploads initiated through the API.

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To perform a multipart upload using the CLI

To upload an object, run `oci os object put` with the `--part-size` flag. The `--part-size` value represents the size of each part in mebibytes (MiBs). Object Storage waives the minimum part size restriction for the last uploaded part. The `--part-size` value must be an integer.

Optionally, you can use the `--parallel-upload-count` flag to set the maximum number of parallel uploads allowed.

```
oci os object put --namespace <object_storage_namespace> --bucket-name <bucket_name> --file <file_location> --name <object_name> --part-size <upload_part_size_in_MB> --parallel-upload-count <maximum_number_parallel_uploads>
```

For example:

```
oci os object put --namespace MyNamespace --bucket-name MyBucket --file ~/path/to/file --name MyObject --parallel-upload-count 10 --part-size 500
```

Upload ID: 277fffff5-e1b5-e81d-5f81-c374a8f33998
Split file into 12 parts for upload.
Uploading object ################################### 100%
{ "etag": "861c8341-74d8-4142-8da4-28e1ce7783ba", "last-modified": "Wed, 25 Sep 2019 19:59:15 GMT", "opc-multipart-md5": "9Qnleyou2yMiy009Bc7o1A==--12" }

For more information on the `oci os object put` command, see To upload an object to a bucket.

To list the parts of an unfinished or failed multipart upload

```
oci os multipart list --namespace <object_storage_namespace> --bucket-name <bucket_name>
```
For example:

```bash
oci os multipart list --namespace MyNamespace --bucket-name MyBucket{
  "data": [
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
      "object": "MyObject",
      "time-created": "2019-07-25T21:55:21.973000+00:00",
      "upload-id": "0b7ab4d8-9ff2-9d5f-2034-63a02fdd7afa"
    },
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
      "object": "MyObject",
      "time-created": "2019-07-25T21:53:09.246000+00:00",
      "upload-id": "1293ac9d-83f8-e055-a5a7-d1e13277b5c0"
    },
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
      "object": "MyObject",
      "time-created": "2019-07-25T21:46:34.981000+00:00",
      "upload-id": "33e7a875-9e94-c3bc-6577-2ee5d8226b53"
  ]
...
```

Tip:
See the Command Line Reference for command options to control the pagination of the list output.

To delete a part of an uncommitted or failed multipart upload

```bash
oci os multipart abort --namespace <object_storage_namespace> --bucket-name <bucket_name> --object-name <object_name> --upload-id <upload_ID>
```

For example:

```bash
oci os multipart abort --namespace MyNamespace --bucket-name MyBucket --object-name MyObject --upload-id 0b7ab4d8-9ff2-9d5f-2034-63a02fdd7afa
```

WARNING: Are you sure you want to permanently remove this incomplete upload? [y/N]: y

Tip:
The CLI interface asks you to confirm the deletion request. To delete without the confirmation prompt, use the --force flag.

You can also create a lifecycle policy that automatically deletes uncommitted or failed multipart uploads. See Using Object Lifecycle Management on page 4370 for details.

To delete all parts of an uncommitted or failed multipart upload

```bash
#!/bin/bash

BUCKET=$1

oci os multipart list --bucket-name $BUCKET | \
  jq -c '.data | map({"o": .object, "i": ."upload-id"}) | .[]' | \
while read JSON; do
    OBJECTNAME=$(echo $JSON | jq '.o' | sed -e 's/"//g')
```
UPLOADID=$(echo $JSON | jq '.i' | sed -e 's/"//g;')
echo Removing Object name $OBJECTNAME, ID $UPLOADID
oci os multipart abort --bucket-name $BUCKET \
   --object-name $OBJECTNAME \
   --upload-id $UPLOADID \
   --force

done

You can also create a lifecycle policy that automatically deletes uncommitted or failed multipart uploads. See Using Object Lifecycle Management on page 4370 for details.

Using Pre-Authenticated Requests

Pre-authenticated requests provide a way to let users access a bucket or an object without having their own credentials. Users continue to have access to the bucket or object as long as the creator of the request has permissions to access those resources. For example, you can create a request that lets an operations support user upload backups to a bucket without owning API keys. Or, you can create a request that lets a business partner access all your quarterly financial reports in a bucket without owning API keys.

When you create a pre-authenticated request, a unique URL is generated. Anyone you provide this URL to can access the Object Storage resources identified in the pre-authenticated request, using standard HTTP tools like curl and wget.

Important:
Assess the business requirement for pre-authenticated access to a bucket or objects. A pre-authenticated request URL gives anyone who has the URL access to the targets identified in the request. Carefully manage the distribution of the URL.

Required Permissions

To Create a Pre-Authenticated Request

To create or manage pre-authenticated requests, you need PAR_MANAGE permission to the target bucket.

While you only need PAR_MANAGE permission to create a pre-authenticated request, you must also have the appropriate permissions for the access type that you are granting. For example:

- If you are creating a pre-authenticated request for uploading objects to a bucket, you need OBJECT_CREATE and OBJECT_OVERWRITE permissions in addition to PAR_MANAGE.
- If you are creating a pre-authenticated request for read/write access to objects in a bucket, you need OBJECT_READ, OBJECT_CREATE, and OBJECT_OVERWRITE permissions in addition to PAR_MANAGE.

Important:
If the creator of a pre-authenticated request is deleted or loses the required permissions after they created the request, the request will no longer work.

To Use a Pre-Authenticated Request

Permissions of the pre-authenticated request creator are checked each time you use a pre-authenticated request. The pre-authenticated request no longer works when any of the following occurs:

- Permissions of the pre-authenticated request creator have changed.
- User who created the pre-authenticated request is deleted.
- Federated user who created the pre-authenticated request has lost the user capabilities that they had when they created the request.
- Pre-authenticated request has expired or has been deleted.
Options

You can create a pre-authenticated request that grants read, write, or read/write access to one of the following:

- All objects in the bucket.
- A specific object in the bucket.
- All objects in the bucket that have a specified prefix.

For requests that apply to multiple objects, you can also decide whether you want to let users list those objects.

Scope and Constraints

Understand the following scope and constraints regarding pre-authenticated requests:

- You can create an unlimited number of pre-authenticated requests.
- A pre-authenticated request created for all objects in a bucket lets request users upload any number of objects to the bucket.
- Expiration date is required, but has no limits. You can set them as far out in the future as you want.
- You can't edit a pre-authenticated request. If you want to change user access options or enable object listing in response to changing requirements, you must create a new pre-authenticated request.
- By default, pre-authenticated requests for a bucket or objects with prefix cannot be used to list objects. You can explicitly enable object listing when you create a pre-authenticated request.
- When you create a pre-authenticated request that limits scope to objects with a specific prefix, request users can only GET and PUT objects with the prefix name specified in the request. Trying to GET or PUT an object without the specified prefix or with a different prefix fails.
- The target and actions for a pre-authenticated request are based on the creator's permissions. The request is not, however, bound to the creator's account login credentials. If the creator's login credentials change, a pre-authenticated request is not affected.
- Deleting a pre-authenticated request revokes user access to the associated bucket or object.
- Pre-authenticated requests cannot be used to delete buckets or objects.
- You cannot delete a bucket that has a pre-authenticated request associated with that bucket or with an object in that bucket.

Working with Pre-Authenticated Requests

You can create, list, or delete pre-authenticated requests using the Console, CLI, or by using an SDK to access the API.

Important:

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation, is not stored in Object Storage, and cannot be retrieved later.

Using the unique request URL, you can use a tool like curl to read and write data using the pre-authenticated request. Object Storage now supports writing large files using multipart uploads with pre-authenticated requests.

To put an object

$ curl -X PUT --data-binary '@<local-filename>' <unique-PAR-URL>

For example:

$ curl -X PUT --data-binary '@using-dita-guide.pdf'
https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvQHbUaw6ADzKhDnaqMuXWef_lhTxCiS9ngCw/n/MyNamespace/b/MyParBucket/o/using-dita-guide.pdf
To put an object with custom metadata

You can also provide custom metadata for any object using opc-meta-<name>:<value> headers.

```
$ curl -X PUT -H "opc-meta-<name>:<value>" --data-binary '@<local-filename>' <unique-PAR-URL>
```

For example:

```
$ curl -X PUT -H "opc-meta-version:2020May" PUT --data-binary '@CorporateTerminologyUsageGuide.pdf' https://objectstorage.us-phoenix-1.oraclecloud.com/p/71LzRt_v81vT7BVLbeQOB5KAX67AxzeKXwJ8m1A5dN0WHeYH39a7KiY2UXnUBhaX/n/MyNamespace/b/MyParBucket/o/CorporateTerminologyUsageGuide.pdf
```

To put a large object

Multipart uploads accommodate objects that are too large for a single upload operation. We recommend that you use multipart uploads to upload objects larger than 100 MiB. The maximum size for an uploaded object is 10 TiB. Object parts must be no larger than 50 GiB. Using multipart uploads, you have the flexibility of pausing between the uploads of individual parts, and resuming the upload when your schedule and resources allow.

**Step 1:** To direct Object Storage to create a multipart upload, you simply include the header opc-multipart: true in the PUT command.

```
$ curl -X PUT -H "opc-multipart:true" <unique-PAR-URL>
```

For example:

```
$ curl -X PUT -H "opc-multipart:true" https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvQhBua6A6ZhK1naqMuXWef_lhTxCiS9ngCw/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf
```

The PUT with the opc-multipart: true header returns an access URI to use to upload parts and commit the multipart upload, for example:

```
{"namespace":"MyNamespace","bucket":"MyParBucket","object":"OCI_User_Guide.pdf","uploadId":"b5bb4079-9d50-ac59-182e-4d133a962382","timeCreated":"2021-03-05T14:48:53.738Z","storageTier":"Standard"}
```

**Step 2:** Use the access URI together with the Object Storage hostname for the target region to upload parts, specifying the part number at the end of the URI. For example, to upload an object in three parts, issue the following PUT commands:

```
$ curl -X PUT --data-binary '@data.1' https://objectstorage.us-phoenix-1.oraclecloud.com/p/8dF1nPzKO12s9R6EGCxtdRKr-zSG45X2BA1k63dim_SMrgg_HMz99FblpOWEs5Lh/n/MyNamespace/b/MyParBucket/u/OCI_User_Guide.pdf/id/b5bb4079-9d50-ac59-182e-4d133a962382/1
$ curl -X PUT --data-binary '@data.2' https://objectstorage.us-phoenix-1.oraclecloud.com/p/8dF1nPzKO12s9R6EGCxtdRKr-zSG45X2BA1k63dim_SMrgg_HMz99FblpOWEs5Lh/n/MyNamespace/b/MyParBucket/u/OCI_User_Guide.pdf/id/b5bb4079-9d50-ac59-182e-4d133a962382/2
$ curl -X PUT --data-binary '@data.3' https://objectstorage.us-phoenix-1.oraclecloud.com/p/8dF1nPzKO12s9R6EGCxtdRKr-zSG45X2BA1k63dim_SMrgg_HMz99FblpOWEs5Lh/n/MyNamespace/b/MyParBucket/u/OCI_User_Guide.pdf/id/b5bb4079-9d50-ac59-182e-4d133a962382/3
```
Step 3: To commit the multipart upload, use the POST command with the access URI. For example:

```
$ curl -X POST https://objectstorage.us-phoenix-1.oraclecloud.com/
p/8dF1NpzKOl2zs9r6EGxtdRKr-zSG45X2BA1k63dIM_SMrgg_HMzg9FblpOWEsS5Lh/
n/MyNamespace/b/MyParBucket/u/OCI_User_Guide.pdf/id/b5bb4079-9d50-ac59-182e-4d133a962382/
```

You can delete all parts of an uncommitted or failed multipart upload using the DELETE command with the access URI. For example:

```
$ curl -X DELETE https://objectstorage.us-phoenix-1.oraclecloud.com/
p/8dF1NpzKOl2zs9r6EGxtdRKr-zSG45X2BA1k63dIM_SMrgg_HMzg9FblpOWEsS5Lh/
n/MyNamespace/b/MyParBucket/u/OCI_User_Guide.pdf/id/b5bb4079-9d50-ac59-182e-4d133a962382/
```

You can also provide custom metadata for any object using opc-meta- headers. The "-H opc-meta-<name>:<value>" is only needed on the first pre-authenticated request that creates the multipart upload, not on each individual part. See To put an object with custom metadata on page 4389 for more information.

To get an object

```
$ curl -X GET <unique-PAR-URL>
```

For example:

```
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/p/ MR7rGASetBbu4L1R5ZH91meUZjvKOGmd4rtnjHzazF9o6sJZLyFUXiLQzSamEp/n/ MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf 'data.1' 'data.2' 'data.3'
```

To get a list of objects

For pre-authenticated requests that apply to multiple objects, the request creator can optionally let you list objects.

```
$ curl -X GET <unique-PAR-URL>
```

For example:

```
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/
p/2W0shPVWv9uqy6abokChGEXYdCZ8175CoO26YkSARiRevW1DWDQUtFPUCn/n/ MyNamespace/b/MyParBucket/o/
"objects": [{"name":"InfoWorld DeepDive - Tips for Git and GitHub Users.pdf"}, {"name":"OCI_User_Guide.pdf"}, {"name":"OracleCorporateTerminologyUsageGuideRedwood.pdf"}, {"name":"VPN.png"}, {"name":"eventslogreference.htm"}, {"name":"functionslogreference.htm"}, {"name":"glob.txt"}, {"name":"loadbalancerreference.htm"}, {"name":"objectstORAGElogreference.htm"}, {"name":"servicechanges.html"}, {"name":"servicediscovery.dita"}, {"name":"serviceessentials.html"}, {"name":"servicelogreference.htm"}, {"name":"services.html"}, {"name":"udx-1494-lifecycle-rule-glob.pdf"}]
```

By default, the object list returns only the names of the objects. Optionally, you can use the fields query parameter to also include the size (object size in bytes), etag, md5, timeCreated (object creation date and time), timeModified (object modification date and time), storageTier, and archivalState fields. Specify the value of this parameter as a comma-separated, case-insensitive list of those field names that you want to include in the object list. For example:

```
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/
p/2W0shPVWv9uqy6abokChGEXYdCZ8175CoO26YkSARiRevW1DWDQUtFPUCn/n/
```
In addition to fields, pre-authenticated requests support all other ListObjects query parameters and list pagination.

### To get metadata from an object

```bash
$ curl --head <unique-PAR-URL>
```

For example:

```bash
$ curl --head https://objectstorage.us-phoenix-1.oraclecloud.com/p/MR7rGASetBbu4L1R5ZH91meU2JvKOGmd4rtnjDhazP906s2KzLYFUxILQzSamEp/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf
```

HTTP/1.1 200 OK

Using the Console

To create a pre-authenticated request for all objects in a bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click Pre-Authenticated Requests under Resources to display the list of existing pre-authenticated requests.
5. Click Create Pre-Authenticated Request.
6. Provide the following information:
   - **Name:** Required. The system automatically generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example par-bucket-20210330-1643. If you change this default name, use only letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Pre-Authenticated Request Target:** Required. Bucket is selected by default, however, you can select a different target.
   - **Access Type:** Select one of the following types:
     - Permit object reads (the default)
     - Permit object writes
     - Permit object reads and writes
   - **Enable Object Listing:** Select this option if you want to also let pre-authenticated request users list the objects in the bucket.
   - **Expiration:** Accept the one week, system-generated expiration date or use the date and time editor to use a different expiration date and time.
7. Click Create Pre-Authenticated Request.
   After a request is created, the Pre-Authenticated Request Details dialog box displays the URL used to access the bucket.
8. Click the copy icon to the right of the URL and paste the URL somewhere in durable storage for future reference.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation, is not stored in Object Storage, and cannot be retrieved later.</td>
</tr>
</tbody>
</table>

9. Click Close.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alternatively, you can create a pre-authenticated request for all objects in a bucket from the Console bucket list page.</td>
</tr>
<tr>
<td>1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.</td>
</tr>
</tbody>
</table>
2. On the bucket list page, click the Actions icon (three dots) to the right of the bucket, and then click **Create Pre-Authenticated Request**.

3. Provide the information to complete the dialog.

**To create a pre-authenticated request for a specific object**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Objects** under **Resources** to display the list of objects.
5. For the object that you want to create a pre-authenticated request, click the Actions icon (three dots), and then click **Create Pre-Authenticated Request**.
6. Provide the following information:
   - **Name**: Required. The system automatically generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example **par-object-20210330-1654**. If you change this default name, use only letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Pre-Authenticated Request Target**: Required. **Object** is selected by default, however, you can select a different target.
   - **Object Name**: The name of the object that you are creating the pre-authenticated request for is displayed. You cannot change the name of the object.
   - **Access Type**: Select one of the following types:
     - Permit read on the object
     - Permit writes to the object
     - Permit reads on and writes to the object
   - **Expiration**: Accept the one week, system-generated expiration date or use the date and time editor to a different expiration date and time.

7. Click **Create Pre-Authenticated Request**.

   After a request is created, the **Pre-Authenticated Request Details** dialog box displays the URL used to access the bucket.

8. Click the copy icon to the right of the URL and paste the URL somewhere in durable storage for future reference.

**Important:**

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation, is not stored in Object Storage, and cannot be retrieved later.

9. Click **Close**.

**To create a pre-authenticated request for objects with a specific prefix**

When you create a pre-authenticated request with a prefix, you are limiting the scope of the request to only those objects with that prefix.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Pre-Authenticated Requests** under **Resources** to display the list of existing pre-authenticated requests.
5. Click **Create Pre-Authenticated Request**.
6. Select the required **Pre-Authenticated Request Target** of **Objects with prefix** to properly set the context for the other fields in the dialog.
7. Provide the following information:

- **Name**: Required. The system automatically generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example `par-object-prefix-20210330-1723`. If you change this default name, use only letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.

- **Prefix**: Required. Prefix string to match on to specify the objects that the pre-authenticated request applies to:
  - You can specify a prefix that includes one or more forward slashes (/) to match on object names that simulate a hierarchy or a directory structure.
  - You can specify a prefix string without a delimiter to match on the left-most characters of the object name.
  See [Object Naming Using Prefixes and Hierarchies](#) on page 4323 for details.

- **Access Type**: Select one of the following types:
  - Permit object reads (the default)
  - Permit object writes
  - Permit object reads and writes

- **Enable Object Listing**: Select this option if you want to also let pre-authenticated request users list the prefixed objects.

- **Expiration**: Accept the one week, system-generated expiration date or use the date and time editor to use a different expiration date and time.

8. Click **Create Pre-Authenticated Request**.

After a request is created, the **Pre-Authenticated Request Details** dialog box displays the URL used to access the bucket.

9. Click the copy icon to the right of the URL and paste the URL somewhere in durable storage for future reference.

---

**Important:**

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation, is not stored in Object Storage, and cannot be retrieved later.

---

10. Click **Close**.

**Tip:**

Alternatively, you can create a pre-authenticated request for objects with a specific prefix from the Console bucket list page.

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. On the bucket list page, click the Actions icon (three dots) to the right of the bucket that you want to specify prefixed objects, and then click **Create Pre-Authenticated Request**.
3. Change the required **Pre-Authenticated Request Target** to **Objects with prefix**.
4. Provide the information to complete the dialog.

**To copy a pre-authenticated request ID**

To copy the ID for a pre-authenticated request to the clipboard, do the following:

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Pre-Authenticated Requests** under **Resources** to display the list of pre-authenticated requests.
5. For the pre-authenticated request ID that you want to copy, click the Actions icon (three dots), and then click Copy Pre-Authenticated Request ID.

The ID for the selected pre-authentication request is copied to the clipboard.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create a pre-authenticated request for all objects in a bucket

```
oci os preauth-request create --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <preauthenticated_request_name> --access-type <enum_value> --time-expires <timestamp> [--bucket-listing-action ListObjects]
```

Avoid entering confidential information in the `<preauthenticated_request_name>`.

The `<enum_value>` for --access-type is one of the following when creating a pre-authenticated request for all objects in a bucket:

- **AnyObjectRead** permits reads on all objects in the bucket
- **AnyObjectWrite** permits writes to all objects in the bucket
- **AnyObjectReadWrite** permits reads and writes to all objects in the bucket

`<timestamp>` is required and must be an RFC 3339 timestamp. For example: 2017-09-01T00:09:51.000+02:00.

Listing objects is denied by default. If the --access-type is AnyObjectRead or AnyObjectReadWrite, you can specify the optional --bucket-listing-action ListObjects parameter when creating the pre-authenticated request that lets users list the objects in the bucket.

For example, to create a pre-authenticated request that allows reads and writes to all objects in the bucket named MyParBucket:

```
oci os preauth-request create --namespace MyNamespace --bucket-name MyParBucket --name MyAllObjectsReadWritePAR --access-type AnyObjectReadWrite --time-expires="2022-11-21T23:00:00+00:00" --bucket-listing-action ListObjects
```

```{json}
{  "data": {
    "access-type": "AnyObjectReadWrite",
    "access-uri": "/p/2WOshPVWw9uqIqy6abokChGEXYdCZ8175CoO26YkSARiRevW1DWJQUvtFPoecn/n/MyNamespace/b/MyParBucket/o/",
    "bucket-listing-action": "ListObjects",
    "id": "QgT6f1skUMbXDhpRX9u7ci8AJ7f9GzdEKnNJ3XQmHzE/N/kDhLEbN2HvPN",
    "name": "MyAllObjectsReadWritePAR",
    "object-name": null,
    "time-created": "2021-04-02T22:25:27.322000+00:00",
    "time-expires": "2022-11-21T23:00:00+00:00"
  }
}
```

**Important:**

The access-uri provided by the system when you create a pre-authenticated request is the key element of the URL you need to construct to provide user access to the target bucket. Copy the access-uri to durable storage. The access-uri is displayed only at the time of creation and cannot be retrieved later.
The unique pre-authenticated request URL provided to users for the previous example is constructed as follows:

```
https://objectstorage.<region_identifier>.oraclecloud.com<access-uri>
```

See About Regions and Availability Domains on page 208 for the list of valid region identifiers.

For example, here is the complete URL for the request that allows reads and writes to all objects in the bucket named MyParBucket:

```
https://objectstorage.us-phoenix-1.oraclecloud.com/p/ZWOhPvVW9uqIqy6aokChGEVydcZ8175CoO26YksARlRevWlDWJp_QUvtFPUocn/n/MyNamespace/b/MyParBucket/o/
```

Here is an example of using curl to PUT an object using the pre-authenticated request that allows reads and writes to all objects in the bucket named MyParBucket and has listing objects enabled:

```
$ curl -X PUT --data-binary '@edit-lifecycle-rules.pdf'
https://objectstorage.us-phoenix-1.oraclecloud.com/p/104eqVvX05HcnrKkWS8Kdf4m8S812KLDyGdbArxa8hDdHssXTKiUD0w2HNCEDS4W/n/MyNamespace/b/MyParBucket/o/edit-lifecycle-rules.pdf
```

Here is an example of using curl to GET objects using the same pre-authenticated request:

```
```

Notice the GET lists the recent PUT for edit-lifecycle-rules.pdf and all other objects in the bucket. Optionally, you can use the fields query parameter to also include the size (object size in bytes), etag, md5, timeCreated (object creation date and time), timeModified (object modification date and time), storageTier, and archivalState fields. See To get a list of objects on page 4390 for more details.

### To create a pre-authenticated request for an object

```
oci os preauth-request create --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <preauthenticated_request_name> --access-type <enum_value> --time-expires <timestamp> --object-name <object_name>
```

Avoid entering confidential information in the pre-authenticated request name.

The `<enum_value>` for --access-type is one of the following when creating a pre-authenticated request for an object:

- **ObjectRead** permits object reads
- **ObjectWrite** permits object writes
- **ObjectReadWrite** permits both object reads and writes

The `<timestamp>` is required and must be an RFC 3339 timestamp. For example:

```
2017-09-01T00:09:51.000+02:00
```
For example, to create a pre-authenticated request that allows reads and writes to an object named `OCI_User_Guide.pdf` in the bucket named `MyParBucket`:

```bash
oci os preauth-request create --namespace <object_storage_namespace> --bucket-name MyParBucket --name MyObjectReadWritePAR --access-type ObjectReadWrite --object-name OCI_User_Guide.pdf --time-expires="2022-11-21T23:00:00+00:00"
```

```json
{  "data": {      "access-type": "ObjectReadWrite",      "access-uri": "/p/v0YC_6i3NamyrK1Ids0SKnWUMQLw_PFolSyGCpjVUJ6h_A1tnkXJ9VRcuQZTgjRa/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf",      "bucket-listing-action": null,      "id": "vNObHudqwf7pfCq9pup/LMLTLxBt2N2OCKkrGwimLFOoJ1Vfxj/dlESbxyd54vpf:OCI_User_Guide.pdf",      "name": "MyObjectReadWritePAR",      "object-name": "OCI_User_Guide.pdf",      "time-created": "2021-04-01T14:37:26.869000+00:00",      "time-expires": "2022-11-21T23:00:00+00:00"  }
}
```

**Important:**

The `access-uri` provided by the system when you create a pre-authenticated request is the key element of the URL you need to construct to provide user access to the target object. Copy the `access-uri` to durable storage. The `access-uri` is displayed only at the time of creation and cannot be retrieved later.

The unique pre-authenticated request URL provided to users for the previous example is constructed as follows:

```bash
https://objectstorage.<region_ID>.oraclecloud.com<access-uri>
```

For example, here is the complete URL for the request that allows reads and writes to an object named `OCI_User_Guide.pdf` in the bucket named `MyParBucket`:

```bash
https://objectstorage.us-phoenix-1.oraclecloud.com/p/v0YC_6i3NamyrK1Ids0SKnWUMQLw_PFolSyGCpjVUJ6h_A1tnkXJ9VRcuQZTgjRa/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf
```

Here is an example of using curl to **PUT** an object using the pre-authenticated request that allows reads and writes to the target object named `OCI_User_Guide.pdf` in the bucket named `MyParBucket`:

```bash
$ curl -X PUT --data-binary '@OCI_User_Guide.pdf'
 https://objectstorage.us-phoenix-1.oraclecloud.com/p/v0YC_6i3NamyrK1Ids0SKnWUMQLw_PFolSyGCpjVUJ6h_A1tnkXJ9VRcuQZTgjRa/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf
```

Here is an example of using curl to **GET** the target object using the same pre-authenticated request:

```bash
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/p/v0YC_6i3NamyrK1Ids0SKnWUMQLw_PFolSyGCpjVUJ6h_A1tnkXJ9VRcuQZTgjRa/n/MyNamespace/b/MyParBucket/o/OCI_User_Guide.pdf
'@OCI_User_Guide.pdf'
```
To create a pre-authenticated request for objects with a specific prefix

When you create a pre-authenticated request with a prefix, you are limiting the scope of the request to only those objects with that prefix.

```
oci os preauth-request create --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <preauthenticated_request_name> --access-type <enum_value> --object-name="<prefix>" --time-expires <timestamp> [--bucket-listing-action ListObjects]
```

Avoid entering confidential information in the `<preauthenticated_request_name>`.

The `<enum_value>` for --access-type is one of the following when creating a pre-authenticated request for all objects in a bucket:

- **AnyObjectRead** permits reads on objects with the specified prefix
- **AnyObjectWrite** permits writes to objects with the specified prefix
- **AnyObjectReadWrite** permits both reads and writes to objects with the specified prefix

The `<timestamp>` is required and must be an RFC 3339 timestamp. For example: 2017-09-01T00:09:51.000+02:00.

Specify the prefix to match on in the --object-name parameter:

- You can specify a prefix that includes one or more forward slashes (/) to match on object names that simulate a hierarchy or a directory structure.
- You can specify a prefix string without a delimiter to match on the left-most characters of the object name.

Listing objects is denied by default. If the --access-type is **AnyObjectRead** or **AnyObjectReadWrite**, you can specify the optional --bucket-listing-action ListObjects parameter when creating the pre-authenticated request that lets users list the objects in the bucket.

For example, to create a pre-authenticated request that allows reads and writes to objects with the prefix service in the bucket named MyParBucket:

```
oci os preauth-request create --namespace MyNamespace --bucket-name MyParBucket --name PrefixedObjectsReadWritePAR --access-type AnyObjectReadWrite --object-name service --time-expires "2022-11-21T23:00:00+00:00" --bucket-listing-action ListObjects
```

{  "data": {
    "access-type": "AnyObjectReadWrite",
    "access-uri": "/p/104eqXvxQ5HcnrZK8d4mS812KLDyG_dbArxa8hDdHsXTK1UD0w2HNCEDS4W/n/MyNamespace/b/MyParBucket/o/",
    "bucket-listing-action": "ListObjects",
    "id": "YOExD1FsN6BNeW8Uo4aK8WHiz59enVQmlaID+4cxFobgcaofVbZkrg371rxK+6Vb",
    "name": "PrefixedObjectsReadWritePAR",
    "object-name": "service",
    "time-created": "2021-04-01T15:35:40.609000+00:00",
    "time-expires": "2022-11-21T23:00:00+00:00"
  }
}

**Important:**

The access-uri provided by the system when you create a pre-authenticated request is the key element of the URL you need to construct to provide user access to the target objects. Copy the access-uri to durable storage. The access-uri is displayed only at the time of creation and cannot be retrieved later.
Object Storage

The unique pre-authenticated request URL provided to users for the previous example is constructed as follows:
https://objectstorage.<region_identifier>.oraclecloud.com<access-uri>
See About Regions and Availability Domains on page 208 for the list of valid region identifiers.
For example, here is the complete URL for the request that allows reads and writes to objects with the prefix
service in the bucket named MyParBucket:
https://objectstorage.us-phoenix-1.oraclecloud.com/p/
l04eqXvxQ5HcnrXkWS8Kdf4mS812KLDyG_dbArXa8hDdHssXTKiUD0w2HNCEDS4W/n/
MyNamespace/b/MyParBucket/o/
When you create a pre-authenticated request that limits the scope to objects with a specific prefix, request users can
only GET and PUT objects with the prefix name specified in the request. Trying to GET or PUT an object without or
with a different prefix fails.
Here is an example of using curl to PUT an object using the pre-authenticated request that allows reads and writes to
objects with the prefix service in the bucket named MyParBucket:
$ curl -X PUT --data-binary '@servicediscovery.dita'
https://objectstorage.us-phoenix-1.oraclecloud.com/p/
l04eqXvxQ5HcnrXkWS8Kdf4mS812KLDyG_dbArXa8hDdHssXTKiUD0w2HNCEDS4W/n/
MyNamespace/b/MyParBucket/o/servicediscovery.dita
Here is an example of using curl to GET objects using the same pre-authenticated request:
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/p/
l04eqXvxQ5HcnrXkWS8Kdf4mS812KLDyG_dbArXa8hDdHssXTKiUD0w2HNCEDS4W/n/
MyNamespace/b/MyParBucket/o/
{"objects":[{"name":"servicechanges.html"},{"name":"servicediscovery.dita"},
{"name":"serviceessentials.html"},{"name":"servicelogreference.htm"},
{"name":"services.html"}]}
Notice the GET lists the recent PUT for servicediscovery.dita and all other objects with a service
prefix. Optionally, you can use the fields query parameter to also include the size (object size in bytes), etag,
md5, timeCreated (object creation date and time), timeModified (object modification date and time),
storageTier, and archivalState fields. See To get a list of objects on page 4390 for more details.
Here is another example of using curl to PUT an object using the same pre-authenticated request. The request fails
because the object does not have a service prefix:
$ curl -X PUT --data-binary '@objectstoragelogreference.htm'
https://objectstorage.us-phoenix-1.oraclecloud.com/p/
l04eqXvxQ5HcnrXkWS8Kdf4mS812KLDyG_dbArXa8hDdHssXTKiUD0w2HNCEDS4W/n/
MyNamespace/b/MyParBucket/o/objectstoragelogreference.htm
{"code":"NotAuthenticated","message":"PAR does not exist"}
To list pre-authenticated requests
You can list all the pre-authenticated requests that are associated with a particular bucket and the objects in that
bucket.
oci os preauth-request list --namespace <object_storage_namespace> --bucketname <bucket_name>
For example:
oci os preauth-request list --namespace MyNamespace --bucket-name
MyParBucket
{

Oracle Cloud Infrastructure User Guide

4399


To get a pre-authenticated request

```bash
oci os preauth-request get --namespace <object_storage_namespace> --bucket-name <bucket_name> --par-id <preauthenticated_request_id>
```

For example:

```bash
oci os preauth-request get --namespace MyNamespace --bucket-name MyParBucket --par-id YOExD1FspNYBNEwF8Uo4aK8WHi59enVQmlaID+4cxFobgcaofVbZkg371rxK+6Vb
```

```

    "time-expires": "2022-11-21T23:00:00+00:00"
  }]
```
To delete a pre-authenticated request

```
oci os preauth-request delete --namespace <object_storage_namespace> --bucket-name <bucket_name> --par-id <preauthenticated_request_id>
```

For example:

```
oci os preauth-request delete --namespace MyNamespace --bucket-name MyParBucket --par-id YOExD1FsNYBNEwF8Uo4aK8WHiz59enVQm1aID+4cxPobgcaofVb2kg371rxK+6Vb
Are you sure you want to delete this resource? [y/N]: y
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to work with pre-authenticated requests:

- CreatePreauthenticatedRequest
- DeletePreauthenticatedRequest
- GetPreauthenticatedRequest
- ListPreauthenticatedRequests

Copying Objects

This topic describes how to copy objects in Object Storage. You can copy objects to other buckets in the same region and to buckets in other regions.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Caution:

Object copy does not work if you do not authorize the Object Storage service to copy objects on your behalf. See Service Permissions on page 4402 for more information.

User Permissions

You must have the required access to both the source and destination buckets when performing an object copy. You must also have permissions to manage objects in the source and destination buckets.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

```
Allow group <IAM_group_name> to manage object-family in tenancy
```
• Alternatively, you can create policies that reduce the scope of access. For example, to let the specified group manage only buckets and objects in a particular compartment in the tenancy:

```
Allow group <IAM_group_name> to manage buckets in compartment <compartment_name>
```

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

**Service Permissions**

Because Object Storage is a regional service, you must authorize the Object Storage service for each region carrying out copy operations on your behalf. For example, you might authorize the Object Storage service in region US East (Ashburn) to manage objects on your behalf. After you authorize the Object Storage service, you can copy an object stored in a US East (Ashburn) bucket to a bucket in another region.

To determine the region identifier value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 208.

For administrators:

To enable object copy, you must authorize the service to manage objects on your behalf:

• You can create a policy that authorizes the service in the specified region to manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

```
Allow service objectstorage-<region_identifier> to manage object-family in tenancy
```

• Instead of using the policy verb `manage`, you can create a policy that reduces the scope of access by instead using one of the following statements:

```
Allow service objectstorage-<region_identifier> to manage object-family in tenancy
where any {request.permission='OBJECT_READ',
          request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE',
          request.permission='OBJECT_OVERWRITE',
          request.permission='OBJECT_DELETE'}
```

```
Allow service objectstorage-<region_identifier> to manage object-family in compartment <compartment_name>
where any {request.permission='OBJECT_READ',
          request.permission='OBJECT_INSPECT', request.permission='OBJECT_CREATE',
          request.permission='OBJECT_OVERWRITE',
          request.permission='OBJECT_DELETE'}
```

**Copy Object Work Requests**

The Object Storage service handles copy requests asynchronously. The service creates a queue for copy requests, and then processes the requests when system resources become available. To provide visibility for in-progress copy operations, Object Storage creates a work request. You can track the progress of the copy operation by monitoring the status of the work request.

The work request statuses are:

**ACCEPTED**

The copy request is in the work request queue to be processed.

**IN_PROGRESS**

The object copy is in progress.
COMPLETED
The copy operation has successfully completed.

CANCELING
The copy request is in the process of being canceled.

CANCELED
The copy request has been canceled.

FAILED
The copy operation has failed. Work requests that do not complete because of overwrite rules or insufficient user authorizations are assigned the failed status.

You can determine the reason a copy failed in the following ways:

• To use the CLI, see To obtain the details of a failed copy work request on page 4405.
• To use the API, see ListWorkRequestErrors.

Copy Object Overwrite Rules
Use overwrite rules to control the copying of objects based on their entity tag (ETag) values.

• **Overwrite destination object**: Use this option when you do not want to limit a copy operation by an ETag value. This option is the default. This option can be used for any copy operation, regardless of whether it involves overwriting an existing object.

• **Do not overwrite any destination object**: Use this option to prevent the overwriting an existing copy of an object in the destination location, regardless of the destination object's ETag value.

• **Overwrite destination object only if it matches the specified ETag**: Use this option to prevent the accidental overwriting of an object in the destination location that does not have the specified ETag. When you use this option, the copy operation only succeeds if the ETag you supply when initiating the copy request matches the ETag of the destination object.

• **Copy object only if the source matches the specified ETag**: Use this option if you want the copy operation successful only if the ETag you supply when initiating the copy request matches the ETag of the source object. For objects that are intentionally updated and overwritten as part of data management activity, this option ensures that only the specified version of the object (as indicated by the ETag) is allowed to be copied. If the object's ETag value changes after the copy work request is created, but before the copy operation is run, the copy operation will not complete.

  | Caution: |
  | If you overwrite an object, the operation cannot be undone. |

Scope and Constraints

• Objects cannot be copied directly from Archive Storage. To copy objects that are currently in Archive Storage, you must first restore the object to the Standard Object Storage tier. Objects can be copied directly to Archive tier buckets from the Standard or Infrequent Access tiers. When you copy objects into an Archive Storage bucket, the copy of the object is immediately archived.

• Specify an existing target bucket for the copy request. The copy operation does not automatically create buckets.

• When an object is copied, the destination object receives a new ETag value.

• If you rename, overwrite, or delete a source object during a copy operation, the copy operation fails and the destination object is not created or overwritten.

• Bulk copying is not supported. Identify a single object in the copy request.

Using the Console
The Console consumes the REST API and is subject to the same considerations as any Oracle Cloud Infrastructure client.
To make a copy of an object

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment that contains the bucket that contains your object.
3. Select the bucket containing the object that you want to copy.
4. Click Objects under Resources to display a list of objects in the bucket.
5. For the object you want to copy (the source object), click the Actions icon (three dots), and then click Copy.

The Console checks the IAM policies that are in place to object copy success. If you see a policy missing warning, you can let the Console try to create any missing policies or copy the missing policy details to the clipboard to email your administrator. If you think you have the required policies in place, go ahead and try the copy operation.
6. In the Copy Object dialog, enter the following:
   - **Destination Namespace**: The Object Storage Namespace of the destination bucket for your copied object. The namespace string of your tenancy is supplied as the default value.
   - **Destination Region**: The Oracle Cloud Infrastructure region containing the destination bucket for your copied object. Your tenancy must be subscribed to a region for you to copy an object to a bucket in that region.
   - **Destination Bucket**: The name of the destination bucket for your copied object. Specify an existing target bucket. The copy operation does not automatically create buckets.
   - **Destination Object Name**: Optionally, you can specify a different destination object name. By default, the Destination Object Name is the same name as the object you are copying.
   - **Destination Storage Tier**: If you are uploading to a Standard tier bucket, you can optionally specify the storage tier to upload the object to:
     - Infrequent Access
     - Archive
   - **Overwrite Rule**: Select the overwrite rule appropriate for your copy request. See Copy Object Overwrite Rules for information on the overwrite rule options.
7. Click Copy Object.

A dialog confirms that your copy request was submitted successfully.

To monitor the status of an object copy work request

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment containing your bucket.
3. Click the bucket name of the bucket containing the object being copied.
4. Click Work Requests under Resources.

A list of work requests is displayed. The status of the request and details including object name, request ID, and the destination bucket's name, region, and namespace is also displayed.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To make a copy of an object

oci os object copy --namespace-name <object_storage_namespace> --bucket-name <source_bucket_name> --source-object-name <source_object> --destination-namespace <destination_namespace_string> --destination-region <destination_region> --destination-bucket <destination_bucket_name> --destination-object-name <destination_object_name>

For example:

oci os object copy --namespace-name ansh8lvru1zp --bucket-name photos --source-object-name hummingbird.jpg --destination-namespace ansh8lvru1zp --
If you are uploading to a Standard tier bucket, you can optionally specify the storage tier to upload the object to:

- Infrequent Access
- Archive

For example:

```
oci os object copy --namespace-name <object_storage_namespace> --bucket-name <source_bucket_name> --source-object-name <source_object> --destination-namespace <destination_namespace_string> --destination-object-storage-tier <destination_object_storage_tier> --destination-region <destination_region> --destination-bucket <destination_bucket_name> --destination-object-name <destination_object_name>
```

To get the status of an object copy work request

```
oci os work-request get --work-request-id <request_id>
```

If you do not have the work request ID, you can get a list of work requests, including the request IDs, for a specified compartment, see To get a list of work requests for a compartment on page 4405.

To obtain the details of a failed copy work request

```
oci os work-request-errors list --work-request-id <request_id>
```

If you do not have the work request ID, you can get a list of work requests, including the request IDs, for a specified compartment, see To get a list of work requests for a compartment on page 4405.

To get a list of work requests for a compartment

```
oci os work-request list --compartment-id <compartment_id>
```

To cancel a copy object work request

```
oci os work-request cancel --work-request-id <request_id>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to view and manage work requests for copy object operations:

- CopyObject
- ListWorkRequests
- GetWorkRequest
- CancelWorkRequest
- ListWorkRequestErrors
Using Your Own Keys for Server-Side Encryption

The Oracle Cloud Infrastructure Object Storage service encrypts and decrypts all objects using 256-bit AES encryption. By default, Object Storage service manages the master encryption key used to encrypt each object's encryption keys.

You can alternatively employ one of these encryption strategies:

- You can assign a key that you created and control through the Oracle Cloud Infrastructure Vault service. See Overview of Vault on page 5006 for details.
- You can encrypt objects using your own encryption key. The key you supply is known as a customer-provided encryption key.

This topic provides the details for implementing and using server-side encryption with customer-provided keys (SSE-C).

About SSE-C

Using optional API headers, you can provide your own 256-bit AES encryption key that is used to encrypt and decrypt objects uploaded to and downloaded from Object Storage:

- When you upload an object, you supply the encryption key. Object Storage encrypts the object using that key and immediately deletes the key.
- When you want to download an object, you supply the same key that was used to encrypt the object and Object Storage decrypts and returns the object to you.

You manage the encryption keys and Object Storage manages the encryption and decryption.

**Important:**

Object Storage does not store your encryption keys. You are responsible for tracking the key that is associated with each object and rotating the key as necessary. If you lose your encryption key, you cannot retrieve your object.

Scope and Constraints

Understand the following scope and constraints regarding SSE-C:

- An SSE-C key cannot be associated with a bucket and can only be used to encrypt individual objects.
- You can encrypt objects using your own encryption key using pre-authenticated requests. To retrieve an SSE-C encrypted object using a pre-authenticated request, you need to specify your encryption key.
- To delete or rename an SSE-C encrypted object, you do not need to specify your encryption key.
- You can only specify either a kmsKeyId or an sseCustomerKey in the ReencryptObject request payload, not both. If the request payload is empty, the object is encrypted using the encryption key assigned to the bucket. The bucket encryption mechanism can either be a master encryption key managed by Oracle or the Vault service.
- You can only use the Object Storage APIs and the CLI to provide SSE-C keys. You can't use the Console to upload or retrieve objects using a customer-provided key.
- The Amazon S3 Compatibility API also supports SSE-C.

Using SSE-C

If you want to use your own keys for server-side encryption, specify the following three request headers with the encryption key information:
<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>opc-sse-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm.</td>
<td>CopyObject, GetObject, HeadObject, PutObject, CreateMultipartUpload, UploadPart</td>
</tr>
<tr>
<td>opc-sse-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to encrypt or decrypt the data.</td>
<td></td>
</tr>
<tr>
<td>opc-sse-customer-key-sha256</td>
<td>Specifies the base64-encoded SHA256 hash of the encryption key.</td>
<td></td>
</tr>
</tbody>
</table>

For **CopyObject**:

If the source object is encrypted with an SSE-C key, you must also specify the following three headers so that Object Storage can decrypt the object.

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>opc-source-sse-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm to use to decrypt the source object.</td>
<td>CopyObject</td>
</tr>
<tr>
<td>opc-source-sse-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to decrypt the source object.</td>
<td></td>
</tr>
<tr>
<td>opc-source-sse-customer-key-sha256</td>
<td>Specifies the base64-encoded SHA256 hash of the encryption key used to decrypt the source object.</td>
<td></td>
</tr>
</tbody>
</table>

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

If you are new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For more information about Object Storage-specific policies, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.

**Using the CLI**

You can also use your own encryption keys to encrypt objects using the CLI.

You can supply the optional parameter --encryption-key-file `<filename>` for the following commands:

- oci os object put
- oci os object get
- oci os object head
- oci os object resume-put
- oci os object bulk-upload
- oci os object bulk-download
- oci os object copy
- oci os object reencrypt

`<filename>` points to a file containing the base64-encoded string of the AES-256 encryption key. No other parameters are required. Object Storage decodes the key to compute the SHA256 hash of the encryption key.
If the source object is encrypted with an SSE-C key, you must also specify the optional parameter `--source-encryption-key-file <filename>` for the following commands:

- `oci os object copy`
- `oci os object reencrypt`

`<filename>` points to a file containing the base64-encoded string of the AES-256 source encryption key. No other parameters are required. Object Storage decodes the key to compute the SHA256 hash of the source encryption key.

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Amazon S3 Compatibility API

Using the Amazon S3 Compatibility API, customers can continue to use their existing Amazon S3 tools (for example, SDK clients) and make minimal changes to their applications to work with Object Storage. The Amazon S3 Compatibility API and Object Storage datasets are congruent. If data is written to the Object Storage using the Amazon S3 Compatibility API, the data can be read back using the native Object Storage API and conversely.

Differences between the Object Storage API and the Amazon S3 Compatibility API

The Object Storage Service provided by Oracle Cloud Infrastructure and Amazon S3 use similar concepts and terminology. In both cases, data is stored as objects in buckets. The differences are in the implementation of features and tools for working with objects.

The following highlights the differences between the two storage technologies:

- **Compartments**
  Amazon S3 doesn't use compartments. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.

- **Global bucket namespace**
  Object Storage doesn't use a global bucket namespace. Instead, namespace serves as the top-level container for all buckets and objects. At account creation time, each tenant is assigned one unique system-generated and immutable namespace name. The namespace spans all compartments within a region. You control bucket names, but those bucket names must be unique within a namespace. While the namespace is region-specific, the namespace name itself is the same in all regions. You can have a bucket named `MyBucket` in US West (Phoenix) and a bucket named `MyBucket` in Germany Central (Frankfurt).

- **Encryption**
  The Oracle Cloud Infrastructure Object Storage service encrypts all data at rest by default. Encryption can't be turned on or off using the API.

- **Object Level Access Control Lists (ACLs)**
  Oracle Cloud Infrastructure does not use ACLs for objects. Instead, an administrator needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create users and groups, create buckets, download objects, and manage Object Storage-related policies and rules.

For more information, see Overview of the Object Storage service.

Amazon S3 Compatibility API Prerequisites

To enable application access from Amazon S3 to Object Storage, you need to set up access to Oracle Cloud Infrastructure and modify your application.

**Setting up access to Oracle Cloud Infrastructure**

1. Sign Up for Oracle Cloud Infrastructure and obtain a unique namespace.
2. Any user of the Amazon S3 Compatibility API with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For basic information about policies, see How Policies Work. For policies that enable use of Object Storage, see Common Policies and the Policy Reference on page 2837.

3. Use an existing or create a Customer Secret Key. A Customer Secret Key consists of an Access Key/Secret Key pair. See Working with Customer Secret Keys on page 3151 for details. To use or create the key pair:
   - To use an existing Customer Secret Key, you must already know the Secret Key. For security reasons, you cannot retrieve a Secret Key after generation. To show or copy the Access Key, open the Profile menu and click User Settings. On the left side of the page, click Customer Secret Keys. Hover over the Access Key associated with the Name of a particular Customer Secret key, then click Copy.
   - To create a Customer Secret Key using the Console, see To create a Customer Secret key on page 3158.
   - To create a Customer Secret Key using the Command Line Interface (CLI), see https://docs.oracle.com/iaas/tools/oci-cli/2.12.11/oci_cli_docs/cmdref/iam/customer-secret-key/create.html.

Modifying your application

1. Configure a new endpoint for the application that includes the namespace name and the region identifier. For example: mynamespace.compat.objectstorage.us-phoenix-1.oraclecloud.com.

2. Set the target region as one of the Oracle Cloud Infrastructure regions.

   **Important:**

   If your application does not support setting the region identifier to the correct Oracle Cloud Infrastructure identifier, you must either set the region to us-east-1 or leave it blank. Using this configuration, you can only use the Amazon S3 Compatibility API in your Oracle Cloud Infrastructure home region. If you can manually set the region, you can use the application against any Oracle Cloud Infrastructure region.

3. Configure the application to use the Customer Secret key. The Customer Secret Key consists of an Access Key and Secret Key. Both of these keys must be supplied to the application.

4. Use path-based access in your application. Virtual host-style access (accessing a bucket as bucketname.namespace.compat.objectstorage.region.oraclecloud.com) is not supported.

You can now use the Amazon S3 Compatibility API to access Object Storage in Oracle Cloud Infrastructure.

Amazon S3 Compatibility API Support

Amazon S3 Compatibility API support is provided at the bucket level and object level.

**Bucket APIs**

The following bucket APIs are supported:

- DeleteBucket
- GetLocation
- HeadBucket
- GetService (list all my buckets)
- ListObjects
- PutBucket

**Object APIs**

The following object APIs are supported:

- BulkDelete
- DeleteObject
- GetObject
- HeadObject
Multipart Upload APIs

The following multipart upload APIs are supported:

- AbortMultipartUpload
- CompleteMultipartUpload
- InitiateMultipartUpload
- ListParts
- ListUploads
- UploadPart

Tagging APIs

The following tagging APIs are supported:

- DeleteBucketTagging
- GetBucketTagging
- PutBucketTagging

SSE-C Support

Using optional API headers, you can provide your own 256-bit AES encryption key that is used to encrypt and decrypt objects uploaded to and downloaded from Object Storage.

If you want to use your own keys for server-side encryption, specify the following three request headers with the encryption key information:

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-server-side-encryption-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm.</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HeadObject</td>
</tr>
<tr>
<td>x-amz-server-side-encryption-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to encrypt or decrypt the data.</td>
<td>PutObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UploadPart</td>
</tr>
<tr>
<td>x-amz-server-side-encryption-customer-key-md5</td>
<td>Specifies the base64-encoded 128-bit MD5 digest of the encryption key. This value is used to check the integrity of the encryption key.</td>
<td></td>
</tr>
</tbody>
</table>

Object Storage has distinct APIs for copying objects and copying parts. Amazon S3 uses the presence of the following headers in PutObject and UploadPart to determine copy operations. To copy a source object that is encrypted with an SSE-C key, you must specify these three headers so that Object Storage can decrypt the object.

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-algorithm</td>
<td>Specifies &quot;AES256&quot; as the encryption algorithm to use to decrypt the source object.</td>
<td>PutObject</td>
</tr>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-key</td>
<td>Specifies the base64-encoded 256-bit encryption key to use to decrypt the source object.</td>
<td></td>
</tr>
</tbody>
</table>
Object Storage

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>APIs Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-copy-source-server-side-encryption-customer-key-md5</td>
<td>Specifies the base64-encoded 128-bit MD5 digest of the encryption key used to decrypt the source object.</td>
<td></td>
</tr>
</tbody>
</table>

**Supported Amazon S3 Clients**

You can configure various client applications to talk to Object Storage's Amazon S3-compatible endpoints. This topic provides some configuration examples for supported Amazon S3 Clients. Review the prerequisites in [Amazon S3 Compatibility API Prerequisites](#) on page 4408.

**AWS SDK for Java**

The AWS SDK for Java repository, file download, and documentation links are available on GitHub: [https://github.com/aws/aws-sdk-java](https://github.com/aws/aws-sdk-java).

Here is an example of configuring AWS SDK for Java to use Object Storage

```java
// Put the Access Key and Secret Key here
AWSCredentialsProvider credentials = new AWSStaticCredentialsProvider(new BasicAWSCredentials("gQ4+YC530sBa8qZI6WcbUbtH8oar0exampleuniqueID", "7fa22331eb62bf4605dc9a42aaexampleuniqueID"));

// Your namespace
String namespace = "namespace";

// The region to connect to
String region = "us-ashburn-1";

// Create an S3 client pointing at the region
String endpoint = String.format("%s.compatibility.objectstorage.%s.oraclecloud.com", namespace, region);
AwsClientBuilder.EndpointConfiguration endpointConfiguration = new AwsClientBuilder.EndpointConfiguration(endpoint, region);
AmazonS3 client = AmazonS3Client.builder()
    .withCredentials(credentials)
    .withEndpointConfiguration(endpointConfiguration)
    .disableChunkedEncoding()
    .enablePathStyleAccess()
    .build();
```

**AWS SDK for Javascript**

The AWS SDK for Javascript repository, documentation links, and installation instructions are available on GitHub: [https://github.com/aws/aws-sdk-js](https://github.com/aws/aws-sdk-js).

Here is an example of configuring AWS SDK for Javascript to use Object Storage

```javascript
s3 = new AWS.S3({
    region: 'us-ashburn-1',
    endpoint: 'https://' + mynamespace + '.compat.objectstorage.us-ashburn-1.oraclecloud.com',
    accessKeyId: 'gQ4+YC530sBa8qZI6WcbUbtH8oar0exampleuniqueID',
    secretAccessKey: '7fa22331eb62bf4605dc9a42aaexampleuniqueID',
    s3ForcePathStyle: true,
    signatureVersion: 'v4',
});
```
AWS SDK for Python (Boto3)

The AWS SDK for Python (Boto3) repository, documentation links, and installation instructions are available on GitHub: https://github.com/boto/boto3.

Here is an example of configuring AWS SDK for Python to use Object Storage

```python
import boto3
s3 = boto3.resource(
    's3',
    aws_access_key_id="gQ4+YC530sBa8qZI6WcbUbtH8oar0exampleuniqueID",
    aws_secret_access_key="7fa22331ebe62bf4605dc9a42aaexampleuniqueID",
    region_name="us-phoenix-1", # Region name here that matches the endpoint
    endpoint_url="https://mynamespace.compat.objectstorage.us-phoenix-1.oraclecloud.com" # Include your namespace in the URL
)

# Print out the bucket names
for bucket in s3.buckets.all():
    print bucket.name
```

Mounting Object Storage buckets using s3fs

s3fs lets Linux and macOS mount Object Storage as a file system. The s3fs repository, documentation links, installation instructions, and examples are available on GitHub: https://github.com/s3fs-fuse/s3fs-fuse.

s3fs is not suitable for all applications. Understand the following limitations:

- Object storage services have high latency compared to local file systems for time to first-byte and lack random write access. s3fs achieves the best throughput on workloads that only read large files.
- You cannot partially update a file, so changing a single byte requires uploading the entire file.
- Random writes or appends to files require rewriting the entire file.
- s3fs does not support partial downloads, so even if you only want to read one byte of a file, you need to download the entire file.
- s3fs does not support server-side file copies. Copied files must first be downloaded to the client and then uploaded to the new location.
- Metadata operations, such as listing directories, have poor performance because of network latency.
- s3fs does not support hard links or the atomic renames of files or directories.
- s3fs provides no coordination between multiple clients mounting the same bucket.

To mount an Object Storage bucket as a file system

1. Follow the installation instructions provided on GitHub: https://github.com/s3fs-fuse/s3fs-fuse.

   If you are unable to install using a pre-built package, follow the compilation instructions here: https://github.com/s3fs-fuse/s3fs-fuse/blob/master/COMPILATION.md.

2. Review and perform the prerequisites in Amazon S3 Compatibility API Prerequisites on page 4408. You need an Access Key/Secret Key pair and a proper IAM policy that lets you mount a bucket as a file system. For example:

   ```
   Allow group s3fsAdmins to manage object-family in compartment MyCompartment
   ```

3. Enter your Access Key/Secret Key pair credentials in a ${HOME}/.passwd-s3fs credential file:

   ```
   cat ${HOME}/.passwd-s3fs
   ```
For example:

cat ${HOME}/.passwd-s3fs
gQ4+YC530sBa8qZI6WcbUbthH8oor0exampleuniqueID:7fa22331be62bf4605dc9a42aaexampleuniqueID

Then, set owner-only permissions for the credential file:

chmod 600 ${HOME}/.passwd-s3fs

4. Create a mount point to mount an Object Storage bucket:

```bash
mkdir /path/to/<local_directory_name>
s3fs <bucket_name> <local_directory_name> -o passwd_file=${HOME}/.passwd-s3fs -o url=https://<namespace_name>.compat.objectstorage.<region_ID>.oraclecloud.com -o use_path_request_style -o kernel_cache -o multipart_size=128 -o parallel_count=50 -o multireq_max=100 -o max_background=1000 [-o endpoint=<region_ID>]
```

Where:

- `<bucket_name>` is the name of the bucket that you want to mount.
- `<local_directory_name>` is the name of the local directory where you want to mount the bucket.
- `<namespace_name>` is the unique system-generated assigned to your tenancy at account creation time. You can use the CLI or the Console to obtain your namespace name. See Understanding Object Storage Namespaces on page 4294 for details.
- `<region_ID>` is the region identifier where the bucket resides. See Regions and Availability Domains on page 208 for details.
- `endpoint`: If you want to mount a bucket that was created in your home region, you do not need to specify the `endpoint` parameter. If you want to mount a bucket that was created in a different region, you need to specify the `endpoint` parameter.

5. If you want to automatically mount the bucket as a file system on system startup using s3fs, add following to the `/etc/fstab` file:

```bash
<bucket_name> /path/to/<local_directory_name> fuse.s3fs
use_path_request_style,password_file=/root/.s3fs-password,url=https://<namespace_name>.compat.objectstorage.<region_ID>.oraclecloud.com kernel_cache,multipart_size=128,parallel_count=50, multireq_max=100, max_background=1000
```

6. To verify the s3fs bucket mount, run the `df -h` command. The output shows the new mount point for the bucket. Navigate to the new mount point and run the `ls` command to list all objects in the bucket.

### To troubleshoot mounting an Object Storage bucket

- If you get authorization errors, review your IAM policies and ensure you have one that lets you mount a bucket as a file system. For example:

  ```bash
  Allow group s3fsAdmins to manage object-family in compartment MyCompartment
  ```

- Ensure that you are using the correct namespace name in the URL in the s3fs command. To verify your namespace name, see Understanding Object Storage Namespaces on page 4294.

- Ensure that the named bucket that you are trying to mount exists and is in a compartment that you have access to. Use one of the following ways to verify the bucket name:
  
  - Log into the Console and find the named bucket is in the compartment that you have access to.
  - Use the CLI command `oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id>.`
• If you are trying to mount a bucket that was created in a region other than your home region, you need to specify that other region in both the url and endpoint parameters.

• If you mount a bucket as the root user, other users are not able to list or access objects in the bucket unless you add `-o allow_other` to the `s3fs` command or `allow_other` to the `/etc/fstab` mount options. You can also supply specific UID and GID parameters to specify user access details.

• If you reviewed and verified the troubleshooting solutions and need to contact Support, run the mount command again in DEBUG mode to get more failure details. Add the following to the end of the command and save the output:

```
-o dbglevel=info -f -o curldbg
```

To unmount an Object Storage bucket from a file system

Run the following command, specifying the mount point:

```
umount /path/to/<local_directory_name>
```

### Designating Compartments for the Amazon S3 Compatibility and Swift APIs

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment and data is stored as objects in buckets.

In addition to the native Object Storage APIs, Object Storage provides API support for both Amazon S3 Compatibility API and Swift API. However these APIs do not understand the Oracle Cloud Infrastructure concept of a compartment. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.

When you designate a different compartment to use for the Amazon S3 Compatibility API or Swift API, any new buckets you create using the Amazon S3 Compatibility API or the Swift API are created in this newly designated compartment. Buckets previously created in a different compartment are not automatically moved to the newly designated compartment. See Managing Buckets on page 4298 if you want to move previously created buckets to this newly designated compartment.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

Compartments have policies that indicate what actions a user can perform on a bucket and all the objects in the bucket.

For administrators:

• To change the default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with `OBJECTSTORAGE_NAMESPACE_UPDATE` permissions.

• To see the current default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with `OBJECTSTORAGE_NAMESPACE_READ` permissions.

• To move a bucket to a different compartment, a user must belong to a group with `BUCKET_UPDATE` and `BUCKET_CREATE` permissions in the source compartment, and `BUCKET_CREATE` permissions in the target compartment.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for buckets and objects, see Details for Object Storage, Archive Storage, and Data Transfer on page 3017.
**Viewing and Specifying Designated Compartments**

You can view the current default compartment designations for Amazon S3 Compatibility API and Swift API data. If your permissions allow, you can also change the Amazon S3 Compatibility API and Swift API compartment designations.

Designated compartment names:

- Must be unique across all the compartments in your tenancy.
- Can be from 1 to 100 characters in length.
- Must not contain confidential information.
- Valid are letters (upper or lower case), numbers, hyphens, and underscore.

**Using the Console**

To view your Amazon S3 Compatibility API and Swift API compartment designations

Open the **Profile** menu ( ) and click **Tenancy: <your_tenancy_name>**.

Your default compartment designations for the APIs are listed under **Object Storage Settings**.

To edit your tenancy's Amazon S3 Compatibility API and Swift API compartment designations

1. Open the **Profile** menu ( ) and click **Tenancy: <your_tenancy_name>**.
2. Click **Edit Object Storage Settings**.
3. In the **Edit Object Storage Settings** dialog:
   - Select the compartment that you want for the **Amazon S3 Compatibility API Designated Compartment**.
   - Select the compartment that you want for the **Swift API Designated Compartment**.
4. Click **Save**.

The new **Object Storage Settings** are displayed.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

To get your tenancy's Amazon S3 Compatibility API and Swift API compartment designations

Use this CLI command to display metadata associated with the Amazon S3 and Swift compartments for the specified namespace in your tenancy.

```
oci os ns get-metadata --namespace <object_storage_namespace>
```

For example:

```
oci os ns get-metadata --namespace MyNamespace
{
  "data": {
    "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "namespace": "MyNamespace"
  }
}
```

To update your tenancy's Amazon S3 Compatibility API compartment designation

Use this CLI command to specify the default Amazon S3 compartment for the specified namespace in your tenancy.

```
oci os ns update-metadata --namespace <object_storage_namespace> --default-s3-compartment-id <your_oci_compartment_id>
```
<your oci compartment id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```
ooci os ns update-metadata --namespace MyNamespace --default-s3-compartment-id ocid.compartment.oc1..exampleuniqueID
{
    "data": {
        "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "default-swift-compartment-id": null,
        "namespace": null
    }
}
```

To update your tenancy's Swift API compartment designations

Use this CLI command to specify the default Swift compartment for the specified namespace in your tenancy.

```
ooci os ns update-metadata --namespace <object storage namespace> --default-swift-compartment-id <your oci compartment id>
```

<your oci compartment id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```
ooci os ns update-metadata --namespace MyNamespace --default-swift-compartment-id ocid.compartment.oc1..exampleuniqueID
{
    "data": {
        "default-s3-compartment-id": null,
        "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "namespace": null
    }
}
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operation to get your default Amazon S3Compatibility API and Swift API compartment designations, and change those compartment designations:

- GetNamespaceMetadata
- UpdateNamespaceMetadata

Object Storage Metrics

You can monitor the health, capacity, and performance of your buckets and objects by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_objectstorage (the Object Storage service).

Resources include buckets and objects.

Overview of the Object Storage Service Metrics

Object Storage can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos. The Object Storage service metrics help you measure the amount of storage you're using. You can also use these metrics to monitor the performance of requests in terms of latency and utilization as measured by counts of requests made per bucket.
Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_objectstorage

The metrics listed in the following tables are automatically available for any buckets you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have an object stored in a bucket to get any metrics. Buckets with no objects emit no metric data.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjectCount</td>
<td>Number of Objects</td>
<td>count</td>
<td>The count of objects in the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
<td>resourceID</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>resourceDisplayName</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>tier</td>
</tr>
</tbody>
</table>

Note:
Valid alarm intervals depend on the frequency at which the metric is emitted. Be sure to set alarm intervals equal to or greater than the frequency at which the metrics are emitted. You can find the emit frequency for each metric in the Default Metrics on page 4417 and Custom Query Metrics on page 4418 tables.

Each metric includes the following dimensions:

RESOURCEID
The OCID of the bucket to which the metric applies.

RESOURCEDISPLAYNAME
The name of the bucket.

TIER
The storage tier (standard or archive) where the object resides.

Default Metrics

The following default metric charts are available for each Object Storage bucket from the bucket details page. See To view default metric charts for a bucket.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>StoredBytes</td>
<td>Bucket Size</td>
<td>bytes</td>
<td>The size of the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
</tr>
</tbody>
</table>

**Custom Query Metrics**

The following custom query metric charts are available using **Metrics Explorer**. See [To view custom query metric charts using Metrics Explorer](#) on page 4420.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description/ Emit Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllRequests</td>
<td>All Requests Count</td>
<td>count</td>
<td>The total number of all HTTP requests made in a bucket. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td>ClientErrors</td>
<td>Client-Side Error Count</td>
<td>count</td>
<td>The total number of 4xx errors for requests made in a bucket. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td>EnabledOLM</td>
<td>Enabled Object Lifecycle Management</td>
<td>count</td>
<td>Indicates whether a bucket has any executable Object Lifecycle Management policies configured. EnabledOML emits: • 1 if policies are configured • 0 if no policies are configured Emit frequency: every 3 hours</td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description/ Emit Frequency</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------</td>
<td>------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>FirstByteLatency</strong></td>
<td>First Byte Latency Time</td>
<td>time (ms)</td>
<td>The per-request time measured from the time Object Storage receives the complete request to when Object Storage returns the first byte of the response. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td><strong>PostRequests</strong></td>
<td>PostObject Request Count</td>
<td>count</td>
<td>The total number of HTTP Post requests made in a bucket. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td><strong>PutRequests</strong></td>
<td>PutObject Request Count</td>
<td>count</td>
<td>The total number of PutObject requests made in a bucket. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td><strong>TotalRequestLatency</strong></td>
<td>Overall Latency Time</td>
<td>time (ms)</td>
<td>The per-request time from the first byte received by Object Storage to the last byte sent from Object Storage. Emit frequency: every 100 ms</td>
</tr>
<tr>
<td><strong>UncommittedParts</strong></td>
<td>Incomplete MultiPart Upload Size</td>
<td>bytes</td>
<td>The size of any multipart upload parts that have not been discarded (aborted) or committed. Emit frequency: every hour</td>
</tr>
</tbody>
</table>
Using the Console

To view default metric charts for a bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the Compartment that contains the bucket you want to view, and then click the bucket's name.
3. In the Resources menu, click Metrics.

The Metrics page displays a default set of charts for the current bucket.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts by dimension

2. For Metric Namespace, select oci_objectstorage.
3. For Dimensions, click Add.
4. For Dimension Name, select a dimension and then select a Dimension Value.

Add more dimensions as needed.
5. Click Done.

The Service Metrics page displays a default set of charts for the selected metric namespace and dimension. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view custom query metric charts using Metrics Explorer

The Metrics Explorer page displays an empty chart with fields to build a query.

2. Select a compartment.
3. From Metric Namespace, select oci_objectstorage.
4. From Metric Name, select a metric.
5. (Optional) Refine your query.

For instructions, see To create a query on page 3504.
6. Click Update Chart.

The chart shows the results of your new query. You can optionally add more queries by clicking Add Query below the chart.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

• Monitoring API for metrics and alarms
• Notifications API for notifications (used with alarms)

Accessing Object Storage Resources Across Tenancies

This topic describes how to write policies that let your tenancy access Object Storage resources in other tenancies.
Cross-Tenancy Policies

Your organization might also want to share resources with another organization that has its own tenancy. It could be another business unit in your company, a customer of your company, a company that provides services to your company, and so on. In cases like these, you need cross-tenancy policies in addition to the required user and service policies described previously.

To access and share resources, the administrators of both tenancies need to create special policy statements that explicitly state the resources that can be accessed and shared. These special statements use the words Define, Endorse, and Admit.

Endorse, Admit, and Define Statements

Here's an overview of the special verbs used in cross-tenancy statements:

- **Endorse**: States the general set of abilities that a group in your own tenancy can perform in other tenancies. The Endorse statement always belongs in the tenancy with the group of users crossing the boundaries into the other tenancy to work with that tenancy's resources. In the examples, we refer to this tenancy as the source.

- **Admit**: States the kind of ability in your own tenancy that you want to grant a group from the other tenancy. The Admit statement belongs in the tenancy who is granting "admittance" to the tenancy. The Admit statement identifies the group of users that requires resource access from the source tenancy and identified with a corresponding Endorse statement. In the examples, we refer to this tenancy as the destination.

- **Define**: Assigns an alias to a tenancy OCID for Endorse and Admit policy statements. A Define statement is also required in the destination tenancy to assign an alias to the source IAM group OCID for Admit statements. Define statements must be included in the same policy entity as the endorse or the admit statement.

The Endorse and Admit statements work together, but they reside in separate policies, one in each tenancy. Without a corresponding statement that specifies access, a particular Endorse or Admit statement grants no access. Agreement is required from both tenancies.

**Important:**

In addition to policy statements, you must also be subscribed to a region to share resources across regions.

Source tenancy policy statements

The source administrator creates policy statements that endorse a source IAM group allowed to manage resources in the destination tenancy.

Here is an example of a broad policy statement that endorses the IAM group StorageAdmins group to do anything with all Object Storage resources in any tenancy:

```plaintext
Endorse group StorageAdmins to manage object-family in any-tenancy
```

To write a policy that reduces the scope of tenancy access, the destination administrator must provide the destination tenancy OCID. Here is an example of policy statements that endorse the IAM group StorageAdmins group to manage Object Storage resources in the DestinationTenancy only:

```plaintext
Define tenancy DestinationTenancy as ocid1.tenancy.oc1..<unique_ID>
Endorse group StorageAdmins to manage object-family in tenancy DestinationTenancy
```

Destination tenancy policy statements

The destination administrator creates policy statements that:
• Defines the source tenancy and IAM group that is allowed to access resources in your tenancy. The source
administrator must provide this information.
• Admits those defined sources to access Object Storage resources that you want to allow access to in your tenancy.

Here is an example of policy statements that endorse the IAM group StorageAdmins in the source tenancy to do anything with all Object Storage resources in your tenancy:

```plaintext
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StorageAdmins as ocid1.group.oc1..<unique_ID>
Admit group StorageAdmins of tenancy SourceTenancy to manage object-family in tenancy
```

Here is an example of policy statements that endorse the IAM group StorageAdmins in the source tenancy to manage Object Storage resources only the SharedBuckets compartment:

```plaintext
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StorageAdmins as ocid1.group.oc1..<unique_ID>
Admit group StorageAdmins of tenancy SourceTenancy to manage object-family in compartment SharedBuckets
```

**Hadoop Support**

Using the HDFS connector, you can run Hadoop or Spark jobs against data in the Oracle Cloud Infrastructure Object Storage service. The connector has the following features:

• Supports read and write data stored in Object Storage
• Is compatible with existing buckets of data
• Is compatible with Hadoop 2.7.2

For information about downloading, configuring, and using the HDFS connector, see HDFS Connector for Object Storage on page 5505.

**Object Storage Troubleshooting**

These troubleshooting topics can help you understand and resolve common Object Storage issues without the need to contact Support.

**Troubleshooting Console Connections**

When the Console displays error messages that begin with "Error retrieving" followed by a resource name, it means that the Console cannot connect to the Object Storage APIs to retrieve and display the requested resources. There are multiple reasons why this can happen. Walk through these steps to determine why the Console cannot connect to the APIs.

**Step 1: Try to connect to the Object Storage API endpoint in the region containing the buckets you are trying to access using the Console.**

1. Open a browser.
   
   See https://docs.oracle.com/iaas/api/#/en/objectstorage/latest/ for the list of API endpoints. If you are able to connect to the API endpoint, a JSON object is returned. For example:

   ```json
   {"code":"NotFound","message":"Not Found"}
   ```

3. If you **can** connect to the API endpoint, **create a support ticket**. If you **cannot** connect to the API endpoint, continue to **Step 2**.
Step 2: Make sure your VPN is not blocking Console access to the Object Storage APIs.

1. Disconnect from any connected VPNs.
2. Open a browser.
3. Go to the API endpoint that contains the buckets you are trying to access in the Console: https://objectstorage.<region_identifier>.oraclecloud.com.

See https://docs.oracle.com/iaas/api/#/en/objectstorage/latest/ for the list of API endpoints. If you are able to connect to the API endpoint, a JSON object is returned. For example:

```
{"code":"NotFound","message":"Not Found"}
```

4. If you can connect to the API endpoint, contact your security team about your VPN blocking URL access to the Object Storage APIs. If you cannot connect to the API endpoint, continue to Step 3.

Step 3: Make sure your Web proxy servers are not blocking Console access to the Object Storage APIs.

1. Disable any configured proxies.
2. Open a browser.
3. Go to the API endpoint that contains the buckets you are trying to access in the Console: https://objectstorage.<region_identifier>.oraclecloud.com.

See https://docs.oracle.com/iaas/api/#/en/objectstorage/latest/ for the list of API endpoints. If you are able to connect to the API endpoint, a JSON object is returned. For example:

```
{"code":"NotFound","message":"Not Found"}
```

4. If you can connect to the API endpoint, contact your security team about your proxies blocking URL access to the Object Storage APIs. If you cannot connect to the API endpoint, continue to Step 4.

Step 4: Make sure DNS filtering is not blocking Console access to the Object Storage APIs.

1. Open a terminal window.
2. Run the following command to test DNS resolution to the API region:

```
host objectstorage.<region_identifier>.oraclecloud.com
```

3. If the hostname resolves successfully, create a support ticket. If the hostname does not resolve successfully, contact your security team about your DNS-based security filtering blocking access to the Object Storage APIs.

Troubleshooting Replication

This topic provides troubleshooting solutions for issues you might encounter using replication.

Unable to create a replication policy on the source bucket

Here are the common causes for replication policy creation failures:

- The destination bucket cannot have versioning enabled.
- The destination bucket cannot have retention rules.
- Your IAM permissions are missing or incomplete. Policy creation requires:
  - User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
  - Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 4344.
Policy is in error on the source bucket

If the policy status changes from active to error, check these items:

- You intentionally or unintentionally stopped replication on the destination bucket. To once again replicate to this target bucket, delete the existing policy on the source bucket and create a new policy.
- Ensure that your user permissions are still in place.
- Ensure that the policies that authorize Object Storage access to the source and destination buckets and their objects are still in place.
- You might have exceeded your storage limits on the destination bucket. If you are a Free Trial or Always Free customer, your storage is limited. Upgrade to paid account or delete your replication policy.

Unable to stop replication on the destination bucket and make the bucket writable

If stopping a replication policy fails, the most likely cause is missing or incomplete IAM permissions. Policy creation requires:

- User permissions that let you access both the source and destination buckets and let you manage the objects in those buckets.
- Service permissions that authorize Object Storage itself to access both the source and destination bucket and their objects.

Review the existing policies that grant user and service permissions. For more information, see Required IAM Policies on page 4344.

Troubleshooting Retention Rules

This topic provides troubleshooting solutions for issues you might encounter using retention rules.

Unable to create a retention rule

If creating a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule creation requires:

- User permissions that let you access the bucket and manage the objects in those buckets.
- Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4363.

Unable to lock a retention rule

If locking a retention rule fails, the most likely cause is missing or incomplete IAM permissions. Minimally, BUCKET_UPDATE, RETENTION_RULE_MANAGE, and RETENTION_RULE_LOCK permissions are required to lock retention rules.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4363.

Unable to delete a retention rule

You cannot delete a time-bound retention rule that is locked. When a retention rule is locked, the rule can only be deleted by deleting the bucket. A bucket must be empty before it can be deleted.

If deleting an indefinite retention rule fails, the most likely cause is missing or incomplete IAM permissions. Rule deletion requires:

- User permissions that let you access the bucket and manage the objects in those buckets.
- Minimally, BUCKET_UPDATE and RETENTION_RULE_MANAGE permissions.

Troubleshooting Versioning

This topic provides troubleshooting solutions for issues you might encounter using versioning.
Unable to enable versioning

If enabling versioning fails, the most likely cause is missing or incomplete IAM permissions. Enabling versioning requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, BUCKET_UPDATE permissions.

Review the existing policies that grant user permissions. For more information, see Required IAM Policies on page 4351.

Unable to delete a bucket

If deleting a bucket fails, the most likely cause is that the bucket is not empty.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot recover a deleted bucket.</td>
</tr>
</tbody>
</table>

You cannot delete a bucket that contains any of the following resources:

- Objects and object versions
- Pre-authenticated requests
- Replication policy
- Uncommitted multipart uploads

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you delete an object in a version-enabled bucket, a previous version of that object is created. Select Show Deleted Objects to display the object versions that might prevent you from deleting the bucket.</td>
</tr>
</tbody>
</table>

Unable to delete a previous object version

If deleting a previous object version fails, the most likely cause is missing or incomplete IAM permissions. Object version deletion requires:

- User permissions that let you use the bucket and manage the objects in that bucket.
- Minimally, OBJECT_VERSION_DELETE permissions.

Get Started with Object Storage

Object Storage provides unlimited, high-performance, durable, and secure data storage. Data is uploaded as objects that are stored in buckets.
Features

Flexible storage for unstructured data

The Object Storage service can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos. Object Storage provides several connectivity options, including a native REST API, along with OpenStack Swift API compatibility, and an HDFS plugin. Object Storage also offers a Java SDK and Python CLI access for management.

Strong encryption

All data stored in Object Storage is encrypted at rest using the AES 256 encryption algorithm.

Deep integration with Identity and Access Management

Tight integration with Oracle Cloud Infrastructure Identity and Access Management policies manages access to buckets and objects.

Chapter 37

Registry

This chapter explains how to store, share, and manage development artifacts like Docker images in an Oracle-managed registry.

Container Registry

Container Registry enables you to store, share, and manage container images (such as Docker images) in an Oracle-managed registry.

Overview of Container Registry

Oracle Cloud Infrastructure Registry (also known as Container Registry) is an Oracle-managed registry that enables you to simplify your development to production workflow. Container Registry makes it easy for you as a developer to store, share, and manage container images (such as Docker images). And the highly available and scalable architecture of Oracle Cloud Infrastructure ensures you can reliably deploy your applications. So you don't have to worry about operational issues, or scaling the underlying infrastructure.
You can use Container Registry as a private Docker registry for internal use, pushing and pulling Docker images to and from the Container Registry using the Docker V2 API and the standard Docker command line interface (CLI). You can also use Container Registry as a public Docker registry, enabling any user with internet access and knowledge of the appropriate URL to pull images from public repositories in Container Registry.

Container Registry is an Open Container Initiative-compliant registry. As a result, you can store container images (such as Docker images) that conform to Open Container Initiative specifications in Container Registry. You can also store manifest lists (sometimes known as multi-architecture images) to support multiple architectures (such as ARM and AMD64). And you can store Helm charts (for more information about the Helm feature that supports chart storage in Open Container Initiative-compliant registries, see Registries in the Helm documentation).

Container Registry supports private access from other Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) in the same region through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as worker nodes in clusters managed by Container Engine for Kubernetes) access Oracle Cloud Infrastructure services such as Container Registry without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway on page 4127.

Container Registry is integrated with IAM, which provides easy authentication with native Oracle Cloud Infrastructure identity.

For an introductory tutorial, see Pushing an Image to Oracle Cloud Infrastructure Registry.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 5528.

Note that Container Registry fully implements a Docker protocol that enables you to use the Docker Registry HTTP API (as well as the Oracle Cloud Infrastructure API) to manage images. See Preparing for Container Registry on page 4430 for the list of regional endpoints, and see the Docker documentation for information about using the Docker Registry HTTP API.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.
If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Container Registry Capabilities and Limits**

In each region that is enabled for your tenancy, you can create up to 500 repositories in Oracle Cloud Infrastructure Registry consuming a maximum of 500 GB in total (if you need more storage, Contact Us). Each repository can hold up to 100,000 images. See Service Limits on page 243.

You are charged for stored images, as shown in the Cloud Price List.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Container Registry, see:

- Policies to Control Repository Access on page 4457
- Details for Container Registry on page 3031

**Preparing for Container Registry**

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry (also known as Container Registry):

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Container Registry is available (see Availability by Region on page 4430).
- You must have access to the Docker CLI (for example, to push and pull images on a local machine, you'll need to have installed Docker on the local machine).
- You must either belong to a group to which a policy grants the appropriate permissions, or belong to the tenancy's Administrators group. See Policies to Control Repository Access on page 4457.
- You must have an Oracle Cloud Infrastructure auth token. If you don't have an auth token already, see Getting an Auth Token on page 4457.

**Availability by Region**

Container Registry is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 208. Refer to that topic to see region identifiers, region keys, and availability domain names.

Note that Container Registry fully implements a Docker protocol that enables you to use the Docker Registry HTTP API (as well as the Oracle Cloud Infrastructure API) to manage images at the regional endpoints below. See the Docker documentation for information about using the Docker Registry HTTP API.

**Container Registry Concepts**

This topic describes key concepts you need to understand when using Oracle Cloud Infrastructure Registry (also known as Container Registry).

**Images**

Container Registry is an Open Container Initiative-compliant registry. As a result, you can store any artifacts that conform to Open Container Initiative specifications, such as Docker images, manifest lists (sometimes known as multi-architecture images), and Helm charts. The instructions in this documentation assume you are storing and retrieving Docker container images using the Docker CLI. Docker container images are commonly referred to as Docker images, or simply as images.

A Docker image is a read-only template with instructions for creating a Docker container. A Docker image holds the application that you want Docker to run as a container, along with any dependencies. To create a Docker image, you first create a Dockerfile to describe that application. You then build the Docker image from the Dockerfile. Having created a Docker image, you store it in a Docker registry such as Container Registry.

Repositories can be private or public. Any user with internet access and knowledge of the appropriate URL can pull images from a public repository in Container Registry.

A repository exists within a particular tenancy, region, and compartment. When referring to the tenancy that owns a repository, you specify the tenancy's namespace. The tenancy namespace is an auto-generated random string of alphanumeric characters. For example, the namespace of the acme-dev tenancy might be ansh81vrulzp. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev). To find out the tenancy namespace of the current tenancy, open the Profile menu and click Tenancy:

You must belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission to:
- create a new public repository
- change an existing repository into a public repository
• change an existing public repository into a private repository

If you make a repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository. You can use identity policies to allow other users to perform other operations on repositories (both public and private) that you create.

Usually, before pushing any images, you'll create an empty repository in a compartment and give the repository a name (for example, `project01/acme-web-app`). If you belong to the tenancy's Administrators group or have been granted the `REPOSITORY_MANAGE` permission, you can also specify whether the repository is to be private or public (see Policies to Control Repository Access on page 4457). Having created the repository, images you subsequently push to Container Registry that include the repository name are pushed to that repository.

For example, for convenience you might want to group together multiple versions of an image in the acme-dev tenancy in the Ashburn region into the repository called `project01/acme-web-app`. First, you create the `project01/acme-web-app` repository. Then, you include the name of the repository when you push the image, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. For example, `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:4.6.3`.

Note that creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the root compartment, creating an empty repository in advance is not strictly necessary. For more information, see Notes about Repository Creation on page 4436.

### Terminology Summary

When working with repositories in Container Registry, you'll find it helpful to have a clear understanding of the following terms and how they relate to each other.

**repository path**

A repository path (sometimes referred to as `<repo-path>` in this documentation) is the fully-qualified path to a repository in Container Registry. It has the following structure:

```
<region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

For example:
- `iad.ocir.io/ansh81vru1zp/project01/acme-web-app`
- `us-phoenix-1.ocir.io/cbuju0t3wa3r/my-hello-app`

**region key**

A region key (sometimes referred to as `<region-key>` in this documentation) identifies the Container Registry region you are using.

For example:
- `iad.ocir.io`
- `us-phoenix-1.ocir.io`

For the list of region keys, see Availability by Region on page 4430.

**tenancy namespace**

A tenancy namespace (sometimes referred to as `<tenancy-namespace>` in this documentation) is an auto-generated, random, and immutable string of alphanumeric characters. For example, the namespace of the `acme-dev` tenancy might be `ansh81vru1zp`.

Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lowercase letters (for example, `acme-dev`). To find out the tenancy namespace of the current tenancy, open the Profile menu ((profile menu icon) and click Tenancy: The tenancy namespace is shown in the Object Storage Namespace field.
repository name

A repository name (sometimes referred to as `<repo-name>` in this documentation) is the name of a repository in Container Registry, to and from which you can push and pull images. Repository names can include one or more slash characters, and are unique across all compartments in the entire tenancy.

For example:

- `project01/acme-web-app`
- `project01/my-test-app`
- `my-hello-app`
- `project01/acme-web-app/component1`
- `project01/acme-web-app/component2`
- `project01/acme-web-app/component1/subcomponent1`

Note that although a repository name can include slash characters, the slash does not represent a hierarchical directory structure. It is simply one character in a string of characters. As a convenience, you might choose to start the names of several different repositories with the same string, perhaps ending in a slash (such as `project01/`). Such a string is sometimes called a 'repository name prefix'. But a repository named `project01/acme-web-app` need not have any relationship with a repository named `project01/my-test-app`. Using the same repository name prefix for some repositories simply makes it easier to organize and control access to them in Container Registry, which can contain many other repositories.

registry identifier

A registry identifier is a Container Registry region key and a tenancy namespace. It has the following structure:

```
<region-key>.ocir.io/<tenancy-namespace>
```

For example:

- `iad.ocir.io/ansh81vru1zp`
- `us-phoenix-1.ocir.io/cbujx0t3wa3r`

image path

An image path is the fully-qualified path to a particular image in a registry. It extends the repository path by adding the tag associated with the image. It has the structure:

```
<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>
```

For example:

- `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`
- `us-phoenix-1.ocir.io/cbujx0t3wa3r/my-hello-app:latest`

tag

A tag or image tag (sometimes referred to as `<tag>` in this documentation) is a string used to refer to a particular image in a known repository. For example:

- `4.6.3`
- `4.6.4`
- `version2.0.test`

image name

The term 'image name' is sometimes used as a short-hand way to refer to a particular image in a particular repository. In this context, an image name has the structure:

```
<repo-name>:<tag>
```
For example:

- project01/acme-web-app:4.6.3
- project01/acme-web-app:4.6.4
- my-hello-app:latest

Creating a Repository

Using Oracle Cloud Infrastructure Registry (also known as Container Registry), you can create an empty repository in a compartment and give it a name that's unique across all compartments in the entire tenancy.

Having created the new repository, you can push an image to the repository using the Docker CLI (see Pushing Images Using the Docker CLI on page 4436). Any images you subsequently push to the registry that include the same repository name are grouped into that repository.

Note that creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the root compartment, creating an empty repository in advance is not strictly necessary. For more information, see Notes about Repository Creation on page 4436.

Using the Console

To create a repository in Container Registry:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the region in which to create the repository.
3. Choose a Compartment you have permission to work in.
4. Click Create Repository.
5. In the Create Repository dialog box, specify details for the new repository:
   - **Compartment**: The compartment in which to create the new repository. The default compartment is the one you selected previously, but you can select any compartment that you have permission to work in.
   - **Repository Name**: A name of your choice for the new repository. The name you enter must be unique across all compartments in the entire tenancy. Avoid entering confidential information.
   - **Public**: Whether the new repository will be a public repository or a private repository. You can only make the new repository public if you belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission. If you make the new repository public, any user with internet access and knowledge of the appropriate URL will be able to pull images from the repository. If you make the repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository.
6. Click Create Repository.
7. (Optional) If you want to automatically create new private repositories in the tenancy's root compartment when docker push commands don't include the name of an existing repository:
   a. Click Settings, and then select General.
   b. Select Create repositories on first push in root compartment to automatically create a new private repository in the tenancy's root compartment if the repository referenced in a docker push command doesn't already exist.

For more information about creating a new repository if the repository referenced in a docker push command doesn't already exist, see Notes about Repository Creation on page 4436.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.
To create a repository

```
oci artifacts container repository create --display-name <repo-name> --compartment-id <compartment_ocid>
```

For example:

```
oci artifacts container repository create --display-name project01/acme-web-app --compartment-id ocid1.compartment.oc1..aaaaaaaarvdfa72n...
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the CreateContainerRepository operation to create a repository.

Notes about Repository Creation

Creating an empty repository in advance of pushing an image is almost certainly going to be your normal workflow. And if you're only authorized to manage repositories in compartments and not in the tenancy's root compartment, you'll always have to create a repository before pushing an image. However, if you're in the unusual position of mostly intending to push images to the tenancy's root compartment, creating an empty repository in advance is not strictly necessary.

When you push an image, you normally use a command in the format `docker push <region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. However, if you select the Create repositories on first push in root compartment option and push an image with a command that includes the name of a repository that doesn't already exist, a new private repository is created automatically in the root compartment.

For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/project02/acme-web-app:7.5.2` and the `project02/acme-web-app` repository doesn't exist, a private repository called `project02/acme-web-app` is created automatically in the root compartment.

Note that you must belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission on the tenancy to create the new private repository in the tenancy's root compartment. See Policies to Control Repository Access on page 4457.

Pushing Images Using the Docker CLI

You use the Docker CLI to push images to Oracle Cloud Infrastructure Registry (also known as Container Registry).

To push an image, you first use the `docker tag` command to create a copy of the local source image as a new image (the new image is actually just a reference to the existing source image). As a name for the new image, you specify the fully qualified path to the target location in Container Registry where you want to push the image, including the name of a repository.

For example, assume you have a local image named `acme-web-app:latest` (the image name comprising the repository name of `acme-web-app`, and the image tag of `latest`). Let's say you want to push this image to Container Registry into a repository called `project01/acme-web-app` with an image tag of `version2.0.test`, in the Ashburn region of the acme-dev tenancy. When you use the `docker tag` command, you'd name the new image with the fully qualified path to its destination, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>`. So in this case, you'd name the new image `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`. Subsequently, when you use the `docker push` command, the image's name ensures it is pushed to the correct destination.

Your permissions control the images you can push to Container Registry (see Policies to Control Repository Access on page 4457). You can push images to repositories you've created (see Creating a Repository on page 4435). You can also push images to repositories that the groups to which you belong have been granted access by appropriate identity policies. If you belong to the Administrators group, you can push images to any repository in the tenancy.
Note that the instructions in this topic assume that the repository to which you want to push images already exists. That will usually be the case, but need not always be so (see Notes about Repository Creation on page 4436).

**Note:**

Container Registry is an Open Container Initiative-compliant registry. As a result, you can store any artifacts that conform to Open Container Initiative specifications, such as Docker images, manifest lists (sometimes known as multi-architecture images), and Helm charts. The instructions in this topic assume you are storing Docker images and using the Docker CLI.

To push images to Container Registry using the Docker CLI:

1. **If you already have an auth token, go to the next step. Otherwise:**
   a. In the top-right corner of the Console, open the **Profile** menu (⋮) and then click **User Settings** to view the details.
   b. On the **Auth Tokens** page, click **Generate Token**.
   c. Enter a friendly description for the auth token. Avoid entering confidential information.
   d. Click **Generate Token**. The new auth token is displayed.
   e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
   f. Close the Generate Token dialog.

2. In a terminal window on the client machine running Docker, log in to Container Registry by entering `docker login <region-key>.ocir.io`, where `<region-key>` corresponds to the key for the Container Registry region you're using. For example, `docker login iad.ocir.io`. See Availability by Region on page 4430.

3. When prompted for a username, enter your username in the format `<tenancy-namespace>/<username>`, where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of your tenancy (as shown on the Tenancy Information page). For example, `ansh81vrulzp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.

4. When prompted for a password, enter the auth token you copied earlier.

5. Locate the image on the client machine that you want to push:
   a. In a terminal window on your client machine, enter `docker images` to list the available images.

For example:

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
<th>CREATED</th>
<th>SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>acme-web-app</td>
<td>latest</td>
<td>8e0506e14874</td>
<td>2 hours ago</td>
<td>162.6 MB</td>
</tr>
<tr>
<td>acme-web-app</td>
<td>version1.0</td>
<td>7d9495d03763</td>
<td>2 hours ago</td>
<td>162.6 MB</td>
</tr>
<tr>
<td>&lt;none&gt;</td>
<td>&lt;none&gt;</td>
<td>6ebd328f833d</td>
<td>5 hours ago</td>
<td>162.6 MB</td>
</tr>
<tr>
<td>hello-world</td>
<td>latest</td>
<td>80b84820d442</td>
<td>5 weeks ago</td>
<td>890 B</td>
</tr>
</tbody>
</table>
b. Find the local image on the client machine that you want to push to Container Registry.

In the output of the `docker images` command, look for the specific image that you want to push. You'll need to uniquely identify this image later, in one of the following ways:

- using its id
- using its image name (its repository name and image tag separated by a colon)

For example, on the client machine you might have an `acme-web-app` image. In the output of the `docker images` command, look for the specific `acme-web-app` image that you want to push. You can uniquely identify that particular image in one of the following ways:

- using its id (for example, `8e0506e14874`)
- using its image name (its repository name and image tag separated by a colon, for example `acme-web-app:latest`)

c. Use the `docker tag` command to create a copy of the original image as a new image (the new image is actually just a reference to the existing original image). As a name (or tag) for the new image, you specify the fully qualified path to the target location in Container Registry where you want to push the image, by entering:

```
docker tag <image-identifier> <target-tag>
```

where:

- `<image-identifier>` uniquely identifies the original image, either using the image's id (for example, `8e0506e14874`), or the image's name (its original repository name and image tag separated by a colon, for example `acme-web-app:latest`).
- `<target-tag>` is the fully qualified path to the target location in Container Registry where you want to push the image, in the format `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>` where:
  - `<region-key>` is the key for the Container Registry region you're using. For example, `iad`. See Availability by Region on page 4430.
  - `ocir.io` is the Container Registry name.
  - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository to which you want to push the image (as shown on the Tenancy Information page). For example, the namespace of the `acme-dev` tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
  - `<repo-name>` is the name of the target repository to which you want to push the image (for example, `project01/acme-web-app`). Note that you'll usually specify a repository that already exists, but that need not always be the case (see Notes about Repository Creation on page 4436).
  - `<tag>` is an image tag you want to give the image in Container Registry (for example, `version2.0.test`).

For example, combining the previous examples, you might enter:

```
docker tag 8e0506e14874 iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

6. Confirm that the Docker image has been correctly tagged on the client machine by entering `docker images` and verifying that the list of images includes an image with the tag you specified.

For example:

```
$ docker images
REPOSITORY                                      TAG                IMAGE ID      CREATED       SIZE
project01/acme-web-app:version2.0.test
```

Oracle Cloud Infrastructure User Guide  4438
### Pulling Images Using the Docker CLI

You use the Docker CLI to pull images from Oracle Cloud Infrastructure Registry (also known as Container Registry).

Your permissions control the images you can pull from Container Registry (see Policies to Control Repository Access on page 4457). You can pull images from repositories you've created, from public repositories, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can pull images from any repository in the tenancy.

*Note:*

Container Registry is an Open Container Initiative-compliant registry. As a result, you can store any artifacts that conform to Open Container Initiative specifications, such as Docker images, manifest lists (sometimes known as multi-architecture images), and Helm charts. The instructions in this topic assume you are storing Docker images and using the Docker CLI.

To pull images from Container Registry using the Docker CLI:
1. If you already have an auth token, go to the next step. Otherwise:
   a. In the top-right corner of the Console, open the Profile menu ( altındaaki gölgesi ) and then click User Settings to view the details.
   b. On the Auth Tokens page, click Generate Token.
   c. Enter a friendly description for the auth token. Avoid entering confidential information.
   d. Click Generate Token. The new auth token is displayed.
   e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won’t see the auth token again in the Console.
   f. Close the Generate Token dialog.
2. In a terminal window on the client machine running Docker, log in to Container Registry by entering `docker login <region-key>.ocir.io`, where `<region-key>` corresponds to the key for the Container Registry region you’re using. For example, `docker login iad.ocir.io`. See Availability by Region on page 4430.
3. When prompted for a username, enter your username in the format `<tenancy-namespace>/<username>`, where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of your tenancy (as shown on the Tenancy Information page). For example, `ansh81vru1zp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.
4. When prompted for a password, enter the auth token you copied earlier.
5. Pull the Docker image from Container Registry to the client machine by entering:
   
   ```bash
   docker pull <region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>
   ```

   where:
   - `<region-key>` is the key for the Container Registry region you're using. For example, iad. See Availability by Region on page 4430.
   - `ocir.io` is the Container Registry name.
   - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository from which you want to pull the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
   - `<repo-name>` is the name of a repository from which you want to pull the image (for example, `project01/acme-web-app`). Note that your user must have access to the repository (see Repositories on page 4432).
   - `<tag>` is the tag of the image that you want to pull from Container Registry (for example, `version2.0.test`).

   For example:
   ```bash
   docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
   ```

   Note that if you don't specify a `<tag>` in the `docker pull` command, Docker pulls the image that has the latest tag.
6. Confirm that the image has been pulled from Container Registry by entering `docker images` and verifying that the list of images on the client machine now includes the image you just pulled.

   For example:
   ```bash
   $ docker images
   ```

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>CREATED</td>
<td>SIZE</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 4440
### Pulling Images from Container Registry during Kubernetes Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry (also known as Container Registry), you have to perform two steps:

- You have to use kubectl to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of kubectl (see the kubectl documentation).
- You have to specify the image to pull from Container Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

**Note:**

Container Registry is an Open Container Initiative-compliant registry. As a result, you can store any artifacts that conform to Open Container Initiative specifications, such as Docker images, manifest lists (sometimes known as multi-architecture images), and Helm charts. The instructions in this topic assume you are storing Docker images and using the Docker CLI.

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.
2. In a terminal window, enter:

   ```
   kubectl create secret docker-registry <secret-name> --docker-server=<region-key>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>'
   ```

   where:

   - `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret. For example, ocirsecret.
   - `<region-key>` is the key for the Container Registry region you're using. For example, iad. See Availability by Region on page 4430.
   - `ocir.io` is the Container Registry name.
   - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be ansh81vru1zp. Note that for some older
tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).

- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-namespace>`. For example, jdoe@acme.com. If your tenancy is federated with Oracle Identity Cloud Service, use the format oracleidentitycloudservice/<oci-username>

- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, kj64r(lasJSSF-;)K8

- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, jdoe@acme.com

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```
kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vrlzp/jdoe@acme.com' --docker-password='kj64r(lasJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.

To specify the image to pull from Container Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Container Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Container Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```
apiVersion: v1
type: Pod
metadata:
  name: nginx-image
spec:
  containers:
    - name: nginx
      image: phx.ocir.io/ansh81vrlzp/project01/nginx-lb:latest
      imagePullPolicy: Always
      ports:
        - name: nginx
          containerPort: 8080
          protocol: TCP
      imagePullSecrets:
        - name: ocirsecret
```

3. Save and close the manifest file.

### Viewing Images and Image Details

To make sure you pull the correct image or to identify images that you no longer need, you can find out detailed information about the images in Oracle Cloud Infrastructure Registry (also known as Container Registry).

Your permissions control the images in Container Registry that you can view information about (see Policies to Control Repository Access on page 4457). You can view information about images in repositories you've created,
Registry and in repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can view information about images in any repository in the tenancy.

**Using the Console**

To view images and image details:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of the repository that contains the image you want to see detailed information about. You see all the different images in the repository, along with the tag of each image and when it was pushed to the registry. You can sort the different images by the date they were pushed or by their tag.
5. Click the image for which you want to see detailed information. The Summary page shows you the size of the image, when it was pushed and by which user, and the number of times the image has been pulled. Use the options on the Summary page as follows:
   - Display the Signatures tab to see details of signature(s) created if the image was signed. For more information, see Signing Images for Security on page 4445.
   - Display the Layers tab to see the SHA message digest of each layer in the selected image.
   - Display the Associated Tags tab to see the full path for the image with the tag you select. Note that if you select a different tag, the summary details change accordingly.
   - Display the Scan Results tab to see a summary of each scan of the image for the last 13 months. For more information, see Scanning Images for Vulnerabilities on page 4453.
6. (Optional) If you want to pull an image, select Copy Pull Command from the Actions menu button. The command you copy includes the fully qualified path to the image's location in Container Registry, in the format <region-key>.ocir.io/<tenancy-namespace>/<repo-name>:<tag>. For example, docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test. See Pulling Images Using the Docker CLI on page 4439.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To view details of an image

```bash
oci artifacts container image get --image-id <image-ocid>
```

For example:

```bash
oci artifacts container image get --image-id ocidi.containerimage.ocl.phx.0.ansh81vrulzp.aaaaaaaaalqzjyks...
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the ListContainerImages and GetContainerImage operations to see image details.

**Deleting and Undeleting an Image**

When you no longer need an old image or you simply want to clean up the list of image tags in a repository, you can delete images from Oracle Cloud Infrastructure Registry (also known as Container Registry).

Your permissions control the images in Container Registry that you can delete (see Policies to Control Repository Access on page 4457). You can delete images from repositories you've created, and from repositories that the
groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete images from any repository in the tenancy.

You can undelete an image you’ve previously deleted, for up to 48 hours after you deleted it. After that time, the image is permanently removed from Container Registry. You use the Oracle Cloud Infrastructure REST API and CLI to undelete images.

In addition to deleting individual images as described below, you can set up image retention policies to delete images automatically based on selection criteria you specify (see Retaining and Deleting Images Using Retention Policies on page 4449).

Note that when you delete an image, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting images to release storage, remember that you can also Contact Us to obtain more storage.

**Using the Console**

To delete an image from Container Registry:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Container Registry**.
2. Choose the registry’s region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository from which to delete the image.
5. Click the name of the image that you want to delete.
6. Select **Delete Image** from the **Actions** menu and confirm that you want to delete the image.

You can undelete an image you’ve previously deleted, for up to 48 hours after you deleted it. After that time, the image is permanently removed from Container Registry.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**To delete an image**

```bash
oci artifacts container image delete --image-id <image-ocid>
```

For example:

```bash
oci artifacts container image delete --image-id
ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaaalqzjyks...
```

**To undelete an image**

```bash
oci artifacts container image restore --image-id <image-ocid>
```

For example:

```bash
oci artifacts container image restore --image-id
ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaaalqzjyks...
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the **DeleteContainerImage** operation to delete an image.

Use the **RestoreContainerImage** operation to undelete an image you’ve previously deleted.
Untagging Images

When you want to clean up the list of images in a repository without actually deleting images, you can remove the tags from images in Oracle Cloud Infrastructure Registry (also known as Container Registry). Removing images is referred to as 'untagging'.

Your permissions control the images in Container Registry that you can untag (see Policies to Control Repository Access on page 4457). You can untag images in repositories you've created, and images in repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can untag images in any repository in the tenancy.

Using the Console

To untag an image in Container Registry:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of the repository containing the image you want to untag.
5. Click the name of the image that you want to untag.
6. Click the tag that you want to remove, select Remove tag from the Actions menu, and confirm that you want to remove the tag.

Tip:
To view the untagged images in a repository, click the name of the repository and then select Unagged under Image Filter.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To untag an image

```
oci artifacts container image remove-version --image-id <image-ocid> --image-version <version>
```

For example:

```
oci artifacts container image remove-version --image-id ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaalqzjyks... --image-version 1.0
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the RemoveContainerVersion operation to untag an image.

Signing Images for Security

For compliance and security reasons, system administrators often want to deploy software into a production system only when they are satisfied that:

- the software comes from a trusted source
- the software has not been modified since it was published, compromising its integrity
To meet these requirements, you can sign images stored in Oracle Cloud Infrastructure Registry (also known as Container Registry). Signed images provide a way to verify both the source of an image and its integrity.

Container Registry enables users or systems to push images to the registry and then sign them using a master encryption key obtained from Oracle Cloud Infrastructure Vault, creating an image signature. An image signature associates a signed image with a particular master encryption key used to sign the image. An image can have multiple signatures, each created using a different master encryption key.

Users or systems pulling a signed image from Container Registry can be confident both that the source of the image is trusted, and that the image's integrity has not been compromised. To further enhance compliance and security, clients can be configured to only pull signed images from the registry.

At a high level, these are the steps to follow to store signed images in Container Registry:

1. **Build the image on your own machine or in your CI/CD system.**
2. **Tag and push the image to Container Registry.**
3. **Sign the image using the Container Registry CLI, creating an image signature that associates the image with the master encryption key and key version in the Vault service.**

### Signing an Image and Creating an Image Signature

Having built an image and pushed it to Container Registry, you can sign the image using a master encryption key obtained from Oracle Cloud Infrastructure Vault, creating an image signature. Note that an image signature is associated with an image's OCID, making it specific to a particular push of the image.

To sign an image and create an image signature:

1. **Build an image on your own machine or in your CI/CD system (for example, using the `docker build` command).**
2. **Push the image to Container Registry.** Follow the instructions in Pushing Images Using the Docker CLI on page 4436 to:
   a. **Log in to Container Registry using the `docker login` command.**
   b. **Tag the image you want to push using the `docker tag` command.** For example:
      ```
      docker tag 8e0506e14874 phx.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
      ```
   c. **Push the image to Container Registry using the `docker push` command.** For example:
      ```
      docker push phx.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
      ```
3. **Obtain the OCID of the image, either using the Console (see Viewing Images and Image Details on page 4442), or using the CLI (use the `oci artifacts container image list --compartment-id <compartment_ocid> --repository-name <repository-name>` command).**
4. **If you don't already have access to an RSA or ECDSA asymmetric key in Oracle Cloud Infrastructure Vault, either obtain access to an existing RSA or ECDSA asymmetric key or create a new master encryption key as an RSA or ECDSA asymmetric key (see To create a new master encryption key on page 5018).**

   Note that the use of AES symmetric keys to sign images is not supported. For more information about different key types, see Overview of Vault on page 5006.

5. **Make a note of both the OCID of the master encryption key and the OCID of the key version stored in Oracle Cloud Infrastructure Vault.** See To view key details on page 5018.
6. **Sign the image you pushed to Container Registry using the master key and key version in the Vault service, creating an image signature, by entering:**
   ```
   oci artifacts container image-signature sign-upload --compartment-id <compartment-ocid> --kms-key-id <key-ocid> --kms-key-version-id <key-version-ocid>
   ```
version-ocid> --signing-algorithm <signing-algorithm> --image-id <image-ocid> --description <signature-description> --metadata <image-metadata-json>

where:

- **--compartment-id <compartment-ocid>** is the OCID of the compartment to which the image's repository belongs. For example, `--compartment-id ocid1.compartment.oc1..aaaaaaa23______smwa`
- **--kms-key-id <key-ocid>** is the OCID of the master encryption key to use to sign the image. For example, `--kms-key-id ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj`
- **--kms-key-version-id <key-version-ocid>** is the OCID of the key version to use to sign the image. For example, `--kms-key-version-id ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb`
- **--signing-algorithm <signing-algorithm>** is one of the following algorithms to use to sign the image:
  - `SHA_224_RSA_PKCS_PSS`
  - `SHA_256_RSA_PKCS_PSS`
  - `SHA_384_RSA_PKCS_PSS`
  - `SHA_512_RSA_PKCS_PSS`
  - `SHA_224_RSA_PKCS1_V1_5`
  - `SHA_256_RSA_PKCS1_V1_5`
  - `SHA_384_RSA_PKCS1_V1_5`
  - `SHA_512_RSA_PKCS1_V1_5`
  - `ECDSA_SHA_256`
  - `ECDSA_SHA_384`
  - `ECDSA_SHA_512`

The algorithm to choose depends on the type of the master encryption key. For RSA keys, supported signature schemes include PKCS #1 and RSASSA-PSS, along with different hashing algorithms. For ECDSA keys, ECDSA is the supported signature scheme with different hashing algorithms. For the latest list of supported algorithms, see Sign and the SignDataDetails resource in the Vault API documentation.

For example, `--signing-algorithm SHA_224_RSA_PKCS_PSS`

- **--image-id <image-ocid>** is the OCID of the image to sign. For example, `--image-id ocid1.containerimage.oc1.phx.0.ansh81vrulzp.aaaaaaaalqzj______yks`
- **--description <signature-description>** is optional text of your choice to describe the image. The description is included as part of the signature, and is shown in the Console. For example, `--description "Image for UAT testing"`
- **--metadata <image-metadata-json>** is optional information of your choice about the image, in a valid JSON format (alphanumeric characters only, with no whitespace or escape characters). For example, `--metadata {"buildnumber": "8447"}`

For example:

```bash
oci artifacts container image-signature sign-upload --compartment-id ocid1.compartment.oc1..aaaaaaa23______smwa --kms-key-id ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj --kms-key-version-id ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb --signing-algorithm SHA_224_RSA_PKCS_PSS --image-id ocid1.containerimage.oc1.phx.0.ansh81vrulzp.aaaaaaaalqzj______yks --description "Image for UAT testing" --metadata {"buildnumber": "8447"}
```

The image you specified is now signed. When you view the list of images in a repository in the Console, the text "(Signed)" appears beside the image name.
**Viewing Signed Images**

You can use the Console to view the signed images in a repository.

To view signed images:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of a repository containing signed images.

   The text "(Signed)" appears beside images that have been signed.
5. (Optional) Click the name of a signed image, and display the Signatures tab to view the signature(s) created when the image was signed.

**Working with Image Signatures**

An image signature associates an image with the master key (obtained from the Vault service) that was used to sign the image. An image can have multiple signatures, each created using a different master encryption key.

Having signed an image in Container Registry and created an image signature, you can:

- view details of the signature
- verify the signature with the Vault service to confirm that the master encryption key used to sign the image is still valid and available
- delete the signature to indicate that the image is no longer to be considered as trusted

To view, verify, or delete the signature(s) that was created when an image was signed:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose a Compartment you have permission to work in.
4. Click the name of the repository containing the signed image.

   The text "(Signed)" appears beside images that have been signed.
5. Click the name of a signed image, and display the Signatures tab to view details of the signature(s) created when the image was signed:

   - **Description**: A description of the signature that was specified when the image was signed.
   - **Status**: The result of the last attempt to verify the image signature with the Vault service.
   - **Date**: When the image was signed and the image signature created.
6. (Optional) To see the master key, key version, and signing algorithm for a particular signature, select View Key Details from the Actions menu beside the signature.
7. (Optional) To verify a particular signature with the Vault service, select Verify Signature from the Actions menu beside the signature.

   The Vault service checks that the source of the image had access to a valid private key when they pushed the image, and that the image has not been modified since it was pushed. If both conditions are met, the signature is shown with a Verified status. Users or systems pulling the image from the registry can be confident both that the source of the image is trusted, and that the image's integrity has not been compromised.

   If image verification fails, check that you have access to the master key, and that it has not been deleted.
8. (Optional) To delete a particular signature, select Delete Signature from the Actions menu beside the signature.

   The signature is deleted and no longer shown on the Signatures tab. If the image has no other signatures, the text "(Signed)" no longer appears beside the image name in the list of images in the repository.
Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To sign an image and create an image signature

```
oci artifacts container image-signature sign-upload --compartment-id <compartment-ocid> --kms-key-id <key-ocid> --kms-key-version-id <key-version-ocid> --signing-algorithm <signing-algorithm> --image-id <image-ocid> --description <signature-description> --metadata <image-metadata-json>
```

For example:

```
oci artifacts container image-signature sign-upload --compartment-id ocid1.compartment.oc1..aaaaaaaa23______smwa --kms-key-id ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj --kms-key-version-id ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb --signing-algorithm SHA_224_RSA_PKCS_PSS --image-id ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaalqzj______yks --description "Image for UAT testing" --metadata {"buildnumber": "8447"}
```

To verify a signed image using an image signature

```
oci artifacts container image-signature get-verify --compartment-id <compartment-ocid> --repo-name <repository-name> --image-digest <image-digest> --trusted-keys <key-ocid> --compartment-id-in-subtree true|false
```

For example:

```
oci artifacts container image-signature get-verify --compartment-id ocid1.compartment.oc1..aaaaaaaa23______smwa --repo-name project01/acme-web-app --image-digest sha256:dalf______31fd --trusted-keys ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj --compartment-id-in-subtree false
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the CreateContainerImageSignature operation to sign an image and create an image signature.

Use the GetContainerImageSignature operation to fetch an image signature, and the Verify operation to verify the signature.

Retaining and Deleting Images Using Retention Policies

You can set up image retention policies to automatically delete images that meet particular selection criteria, namely:

- images that have not been pulled for a certain number of days
- images that have not been tagged for a certain number of days
- images that have not been given particular Docker tags specified as exempt from automatic deletion

An hourly process checks images against the selection criteria, and any that meet the selection criteria are automatically deleted.

You'll often find image retention policies are a more convenient way to manage the images in a repository than manually deleting individual images (see Deleting and Undeleting an Image on page 4443).
In each region in a tenancy, there's a global image retention policy. The global image retention policy's default selection criteria retain all images, so that no images are automatically deleted. However, you can change the global image retention policy so that images are deleted if they meet the criteria you specify. A region's global image retention policy applies to all repositories in the region, unless it is explicitly overridden by one or more custom image retention policies.

You can set up custom image retention policies to override the global image retention policy with different criteria for specific repositories in a region. Having created a custom image retention policy, you apply the custom retention policy to a repository by adding the repository to the policy. The global image retention policy no longer applies to repositories that you add to a custom retention policy.

If you have manage permission on the tenancy, you can:

• modify each region's own global image retention policy
• create new custom image retention policies
• modify the criteria of existing custom image retention policies
• delete custom image retention policies

If you have manage permission on a repository, you can:

• add the repository to a custom image retention policy
• remove the repository from a custom image retention policy

Note the following:

• Only one custom image retention policy at a time can apply to a repository. If a repository has already been added to a custom retention policy and you want to add the repository to a different custom retention policy, you have to remove the policy from the first retention policy before adding it to the second.
• When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.
• The global image retention policy (and any custom image retention policies you create) are specific to a particular region. To delete images consistently in different regions in your tenancy, set up image retention policies in each region with identical selection criteria.
• When you delete an image, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting images to release storage, remember that you can also Contact Us to obtain more storage.

Using the Console to Edit the Global Image Retention Policy

Provided you have manage permission on the tenancy, you can edit the region's global image retention policy that applies to all repositories in a region (except for repositories that have been explicitly added to a custom image retention policy).

To edit the global image retention policy:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.
   You see the current selection criteria of the region's global image retention policy, along with any custom image retention policies that override the global image retention policy for specific repositories.
4. Click Edit Global Policy.
5. In the Global Image Retention Policy dialog, specify new criteria for the global retention policy:

- **Delete any images that haven't been pulled in \( n \) days**: Select this option if you want to delete images that have not been pulled for the number of days you specify.
- **Delete any images that haven't been tagged in \( n \) days**: Select this option if you want to delete images that have not been tagged for the number of days you specify.
- **Exempt Tags**: If you want to prevent images from being deleted on the basis of Docker tags they've been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify `latest,prod-*,*-.tail,*-100.*`.

6. Click **Save Settings**.

Going forward, the criteria you entered for the region's global image retention policy will apply to all repositories in the region, except for repositories that have been explicitly added to a custom image retention policy. Images in repositories that have not been added to a custom image retention policy will be deleted from Container Registry if they meet the criteria you specified in the global image retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

**Using the Console to Create a New Custom Image Retention Policy to Override the Global Policy**

Provided you have manage permission on the tenancy, you can create a new custom image retention policy to override the region's global image retention policy for the repositories you specify. A custom image retention policy is specific to the region in which you create it.

To create a new custom image retention policy:

1. In the Console, open the navigation menu and click **Developer Services**. Under Containers, click **Container Registry**.
2. Choose the registry’s region.
3. Click **Settings**, and then select **Image retention policies**.

   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.

4. Click **Create Policy**.
5. In the Create Repository Image Retention Policy dialog, specify criteria for the new retention policy:

   - **Policy Name**: A name of your choice for the policy. Avoid entering confidential information.
   - **Delete any images that haven't been pulled in \( n \) days**: Select this option if you want to delete images that have not been pulled for the number of days you specify.
   - **Delete any images that haven't been tagged in \( n \) days**: Select this option if you want to delete images that have not been tagged for the number of days you specify.
   - **Exempt Tags**: If you want to prevent images from being deleted on the basis of Docker tags they've been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify `latest,prod-*,*-.tail,*-100.*`.

6. Click **Save Settings**.

   You can now add repositories to the new custom retention policy.
Using the Console to Remove a Repository from a Custom Image Retention Policy

Provided you have manage permission on a repository, you can remove a repository from a custom image retention policy to which it was previously added.

You might want to remove the repository from a custom image retention policy:

• if you want the region's global image retention policy to apply to the repository
• if you want a different custom image retention policy to apply to the repository (only one custom image retention policy at a time can apply to a repository)

To remove a repository from a custom image retention policy:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.
   
   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.
4. Locate the custom image retention policy to which the repository has been added.
5. Click the delete icon beside the repository name to remove it from the custom image retention policy.

Going forward, the region's global image retention policy will apply to the repository (unless you add the repository to a different custom image retention policy). The images in the repository will be deleted from Container Registry if they meet the criteria specified in the global image retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

Using the Console to Add a Repository to a Custom Image Retention Policy

Provided you have manage permission on a repository, you can add a repository to an existing custom image retention policy. Note that if a custom image retention policy already applies to the repository, you'll have to remove the repository from the current policy before adding it to a different policy. Note also that a custom image retention policy is specific to the region in which it was created.

To add a repository to an existing custom image retention policy:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Click Settings, and then select Image retention policies.
   
   You see the current selection criteria of the region's global image retention policy, along with the custom image retention policies that have been defined to override the global image retention policy for specific repositories.
4. Locate the custom image retention policy to which you want to add the repository.
5. Click Add Repository and select from the list the repository you want to add to the custom image retention policy.
   
   Note that the repository list includes all repositories in the region, regardless of whether you have permission to add them to a retention policy. You can only add a repository to a retention policy if you have manage permission on that repository.

   If a repository in the list has a policy name beside it, the repository has already been added to a policy. Before you can add the repository to a different policy, you'll have to remove it from the first policy.
Going forward, the custom retention policy to which you added the repository will override the region's global image retention policy. The images in the repository will be deleted from Container Registry if they meet the criteria specified in the custom retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

Scanning Images for Vulnerabilities

It is not uncommon for the operating system packages included in images to have vulnerabilities. Managing these vulnerabilities enables you to strengthen the security posture of your system, and respond quickly when new vulnerabilities are discovered.

You can set up Oracle Cloud Infrastructure Registry (also known as Container Registry) to scan images in a repository for security vulnerabilities published in the publicly available Common Vulnerabilities and Exposures (CVE) database.

You enable image scanning by adding an image scanner to a repository. From then on, any images pushed to the repository are scanned for vulnerabilities by the image scanner. If the repository already contains images, the four most recently pushed images are immediately scanned for vulnerabilities.

Whenever new vulnerabilities are added to the CVE database, Container Registry automatically re-scans images in repositories that have scanning enabled.

For every scanned image, you can view:

- A summary of each scan of the image for the last 13 months, showing the number of vulnerabilities found in each scan, and a single overall risk level for each scan. Image scan results are retained for 13 months to enable you to compare the scan results over time.
- Detailed results of each image scan, to see a description of each vulnerability, along with its risk level, and (where available) a link to the CVE database for more information.

You can disable image scanning on a particular repository by removing the image scanner.

To perform image scanning, Container Registry makes use of the Oracle Cloud Infrastructure Vulnerability Scanning service and Vulnerability Scanning REST API. For more information about the Vulnerability Scanning service, see Scanning Images.

You can integrate image scanning into your existing software development and deployment lifecycle. Having built an image, your CI/CD tool can use the regular docker push command to push the image to a repository in Container Registry that has image scanning enabled. Your CI/CD tool can obtain the results of the image scan using the Vulnerability Scanning REST API. Based on the results of the image scan, your CI/CD tool can then determine whether to move the image to the next stage in the lifecycle.

Required IAM Policy for Scanning Images for Vulnerabilities

If you enable repositories for image scanning, you must give the Vulnerability Scanning service permission to pull images from Container Registry.

To grant this permission for all images in the entire tenancy:

allow service vulnerability-scanning-service to read repos in tenancy
allow service vulnerability-scanning-service to read compartments in tenancy

To grant this permission for all images in a specific compartment:

allow service vulnerability-scanning-service to read repos in compartment <compartment-name>
allow service vulnerability-scanning-service to read compartments in compartment <compartment-name>
Using the Console to Enable and Disable Image Scanning

When you create a new repository, image scanning is disabled by default. You can use the Console to enable image scanning for a repository by creating a new image scanner. If image scanning has already been enabled, you can use the Console to disable it.

To enable image scanning for a repository:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose the repository's compartment in the List Scope - Compartment field.
4. Click the name of the repository from the list of repositories.
5. Select Add Scanner from the Actions menu and either accept the default settings (usually sufficient) or specify:
   - **Name**: Optionally, a name for the new image scanner.
   - **Create in compartment**: The compartment in which to create the image scanner. The compartment to which the repository belongs is selected by default, but you can select an alternative compartment.
   - **Description**: Optionally, a description of the scanner.
6. Select the scan configuration to use. A scan configuration identifies the images to scan, by designating the compartments to which images belong. You will typically select an existing scan configuration, or create a new scan configuration, that designates the compartment to which the repository itself belongs.
   - **Create new scan configuration**: Scan images belonging to the compartment to which the repository itself belongs, by creating a new scan configuration. Either accept the default settings (usually sufficient) or optionally enter a name for the new scan configuration, and select the compartment in which to create the new scan configuration. All the images in the repository will be scanned.
   - **Select existing scan configuration**: Scan images belonging to the compartment(s) specified in an existing scan configuration. By default, you can see and select scan configurations belonging to the same compartment as the repository. Click Change Compartment to see and select scan configurations belonging to other compartments. All the images in the repository will be scanned, provided the repository belongs to one of the designated compartments in the existing scan configuration you choose.
7. Click Add Scanner to create the new image scanner with the scan configuration you specified.

From now on, any images pushed to the repository are scanned for vulnerabilities by the image scanner. If the repository already contains images, the four most recently pushed images are immediately scanned for vulnerabilities.

To disable image scanning for a repository:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. Choose the repository's compartment in the List Scope - Compartment field.
4. Click the name of the repository from the list of repositories.
5. Select Remove Scanner from the Actions menu.

Using the Console to View Results of Image Scans

To view the results of image scans:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
2. Choose the registry's region.
3. To see vulnerabilities detected in a particular image in a repository:
   a. Choose the repository's compartment in the **List Scope - Compartment** field.
   b. Click the name of the repository from the list of repositories to expand it.
   c. Select the name of the image from the list of images in the repository.
4. Display the **Scan Results** tab to see a summary of each scan of the image for the last 13 months, showing:
   - **Risk level**: The risk level posed by the image, derived by aggregating the risk levels of individual vulnerabilities found in the scan into a single overall risk level.
   - **Issues found**: The number of vulnerabilities found in the scan.
   - **Scan started**: and **Scan finished**: When the scan was run.
5. (optional) To see more information about the vulnerabilities found in a particular scan, select **View Details** from the **Action** menu beside the scan on the **Scan Results** tab to display the **Scan Details** dialog showing:
   - **Issue**: The name given to the vulnerability in the CVE database. Click the link to find out more information about it.
   - **Risk Level**: The severity level of the vulnerability. **Critical** is the highest level (for the most serious issues that should be your highest priority to resolve), followed by **High**, then **Medium**, then **Low**, and finally **Minor** (indicating the least serious issues that you still need to resolve, but which can be your lowest priority).
   - **Description**: A description of the vulnerability.
6. Click **Close**.

**Using the CLI**

For information about using the CLI, see [Command Line Interface (CLI)](page 5316). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](page).

Use the Vulnerability Scanning CLI commands to scan images for vulnerabilities (see [Scanning Images](page 5351)).

**Using the API**

For information about using the API and signing requests, see [REST APIs](page 5528) and [Security Credentials](page 207). For information about SDKs, see [Software Development Kits and Command Line Interface](page 5351).

Use the Vulnerability Scanning API to scan images for vulnerabilities (see [Scanning Images](page 5351)).

**Deleting a Repository**

There is a limit to the number of repositories you can have in any given region in a tenancy. So when you no longer need a repository, it makes sense to delete it from Oracle Cloud Infrastructure Registry (also known as Container Registry).

Your permissions control the repositories in Container Registry that you can delete (see [Policies to Control Repository Access](page 4457)). You can delete repositories you've created, and repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete any repository in the tenancy.

Note that when you delete a repository, it can take up to 48 hours for the deletion to take effect and for storage to actually be released. If you are deleting repositories to release storage, remember that you can also [Contact Us](page) to obtain more storage.

**Using the Console**

To delete a repository from Container Registry:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Container Registry**.
2. Choose the registry's region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository that you want to delete.
5. Select **Delete Repository** from the **Actions** menu and confirm that you want to delete the repository.

The repository is permanently removed from Container Registry.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To delete a repository

```
oci artifacts container repository delete --repository-id <repository-ocid>
```

For example:

```
oci artifacts container repository delete --repository-id ocid1.containerrepo.oc1.us-phoenix-1.0.ansh81vru1zp.aaaaaaaaswe83o...
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the **DeleteContainerRepository** operation to delete a repository.

**Moving Repositories Between Compartments**

When you create a new repository in Oracle Cloud Infrastructure Registry (also known as Container Registry), you specify the compartment in which to create it. Having created the repository in one compartment, you can subsequently move it to a different compartment. For example, to change the users who are authorized to use the repository, or to change how billing for a repository is charged.

Only users with appropriate permissions can access the repository in the compartment that you move it to.

Your permissions control the repositories in Container Registry that you can move, and the compartments that you can move them to (see Policies to Control Repository Access on page 4457). You can move repositories you've created (as well as repositories that the groups to which you belong have been granted access by identity policies) to any compartment to which you have access. If you belong to the Administrators group, you can move any repository in the tenancy to any compartment.

**Using the Console**

To move a repository in Container Registry from one compartment to another:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Container Registry**.
2. Choose the registry's region.
3. Choose a **Compartment** you have permission to work in.
4. Click the name of the repository that you want to move.
5. Select **Move Compartment** from the **Actions** menu.
6. Select the compartment to which you want to move the repository.
7. Click **Submit** to move the repository.

The repository is moved to the compartment you selected.

Only users with appropriate permissions can now access the repository in the compartment that you've moved it to.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.
To move a repository

```
oci artifacts container repository change-compartment --compartment-id <compartment_ocid_new> --repository-id <repository_ocid>
```

For example:

```
oci artifacts container repository change-compartment --compartment-id ocid1.compartment.oc1..aaaaaaaaswegb83o... --repository-id ocid1.containerrepo.oc1.us-phoenix-1.0.ansh81vrulzp.aaaaaaaatxfd94p...
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the ChangeContainerRepositoryCompartment operation to move a repository to a different compartment.

Getting an Auth Token

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry (also known as Container Registry), you must already have an Oracle Cloud Infrastructure username and an auth token. If you haven't got an auth token, or you've forgotten it, or you're not sure, you can create a new auth token. You only see the auth token string when you create it, so be sure to copy the auth token to a secure location immediately.

Tip:

Each user can have up to two auth tokens at a time. So if you do lose or forget the auth token, you can always create a second auth token.

To create a new auth token:

1. In the top-right corner of the Console, open the Profile menu ( ) and then click User Settings to view the details.
2. On the Auth Tokens page, click Generate Token.
3. Enter a friendly description for the auth token. Avoid entering confidential information.
4. Click Generate Token. The new auth token is displayed.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

Policies to Control Repository Access

You have fine-grained control over the operations that users are allowed to perform on repositories in Oracle Cloud Infrastructure Registry (also known as Container Registry).

A user's permissions to access repositories comes from the groups to which they belong. The permissions for a group are defined by identity policies. Policies define which actions the members of a group can perform. Users access repositories and perform operations based on the policies set for the groups they are members of. Identity policies to control repository access can be set at the tenancy and at the compartment level. See Details for Container Registry on page 3031.

Before you can control access to repositories, you must have already created users and already placed them in appropriate groups (see Managing Users on page 3110 and Managing Groups on page 3115). You can then create policies and policy statements to control repository access (see Managing Policies on page 3144).

Note that users in the tenancy's Administrators group can perform any operation on any repository in Container Registry that belongs to the tenancy.
Common Policies

Note:
The policies in this section use example group names, as follows:

• acme-viewers: A group that you want to limit to just viewing a list of repositories.
• acme-pullers: A group that you want to limit to pulling images.
• acme-pushers: A group that you want to allow to push and pull images.
• acme-managers: A group that you want to allow to push and pull images, delete repositories, and edit repository metadata (for example, to make a private repository public).

Make sure to replace the example group names with your own group names.

Enable users to view a list of all the repositories belonging to the tenancy or to a compartment

Type of access: Ability to see a list of all repositories in Container Registry belonging to the tenancy (or to a particular compartment). Users will not be able to:

• view the images or layers in a repository
• push or pull images from or to a repository

Where to create the policy:

• In the tenancy. For example:
  
  Allow group acme-viewers to inspect repos in tenancy

• In the tenancy or in a compartment. For example:
  
  Allow group acme-viewers to inspect repos in compartment acme-compartment

Enable users to pull images from any repository belonging to the tenancy or to a compartment

Type of access: Ability to pull images (layers and manifests) from any repository in Container Registry that belongs to the tenancy (or to a particular compartment).

Where to create the policy:

• In the tenancy. For example:
  
  Allow group acme-pullers to read repos in tenancy

• In the tenancy or in a compartment. For example:
  
  Allow group acme-pullers to read repos in compartment acme-compartment

Enable users to pull images from specific repositories in the tenancy or in a compartment

Type of access: Ability to pull images (layers and manifests) from any repository in Container Registry that has a name starting with "acme-web-app" and that belongs to the tenancy (or that belongs to a particular compartment).

Where to create the policy:

• In the tenancy. For example:
  
  Allow group acme-pullers to read repos in tenancy where all
  { target.repo.name=/acme-web-app*/ }
In the tenancy or in a compartment. For example:

```
Allow group acme-pullers to read repos in compartment acme-compartment
where all { target.repo.name=/acme-web-app/* }
```

Enable users to push images to any repositories (and create new repositories if necessary) in the tenancy or in a compartment

**Type of access:** Ability to push images (layers and manifests) to any repository in Container Registry that belongs to the tenancy or to a particular compartment.

If the specified repository doesn't exist yet, the `REPOSITORY_CREATE` permission ensures users are able to create a new repository in the tenancy's root compartment when they push the image. For more information about this unusual scenario, see [Notes about Repository Creation](#) on page 4436.

Where to create the policy:

- In the tenancy. For example:
  
  ```
  Allow group acme-pushers to use repos in tenancy
  ```

  ```
  Allow group acme-pushers to manage repos in tenancy where ANY
  {request.permission = 'REPOSITORY_CREATE', request.permission =
  'REPOSITORY_UPDATE')
  ```

- In the tenancy or in a compartment. For example, in a compartment:

  ```
  Allow group acme-pushers to use repos in compartment acme-compartment
  ```

  Note that if you create the policy in a compartment other than the root compartment as shown above, users cannot push an image to a repository that doesn't exist yet. That's because the above policy does not give users permission to create a new repository in the tenancy's root compartment. For more information about this unusual scenario, see [Notes about Repository Creation](#) on page 4436.

Enable managers to perform any operation on any repository belonging to the tenancy or to a compartment

**Type of access:** Ability to perform any operation on any repository in Container Registry that belongs to the tenancy (or to a particular compartment), including:

- Pull an image from any repository.
- Push an image to any repository.
- Create a new repository. That is, either to create an empty repository in any compartment, or to create a repository in the tenancy's root compartment when pushing an image for which no repository exists yet. Note that if you create the policy in a compartment other than the root compartment, users cannot push an image to a repository that doesn't exist yet. That's because the policy does not give users permission to create a new repository in the root compartment. For more information about this unusual scenario, see [Notes about Repository Creation](#) on page 4436.
- Delete a repository.
- Change a public repository to a private repository, or a private repository to a public repository.

Where to create the policy:

- In the tenancy. For example:

  ```
  Allow group acme-managers to manage repos in tenancy
  ```
• In the tenancy or in a compartment. For example:

```
Allow group acme-managers to manage repos in compartment acme-compartment
```

Note that if you create the above policy in a compartment other than the root compartment, users cannot push an image to a repository that doesn't exist yet. That's because the policy does not give users permission to create a new repository in the root compartment. For more information about this unusual scenario, see Notes about Repository Creation on page 4436.
Chapter 38

Resource Manager

This chapter introduces the Oracle Resource Manager service and describes how to use it.

Resource Manager

Resource Manager automates deployment and operations for all Oracle Cloud Infrastructure resources. Using the infrastructure-as-code (IaC) model, the service is based on Terraform, an open source industry standard that lets DevOps engineers develop and deploy their infrastructure anywhere.

What's new

Get Started
- Features of Resource Manager
- Select a template for your stack
- Walk through provisioning resources with Resource Manager

Discover Resources
- Recreate infrastructure
- Supported resources

Develop Terraform Configurations
- Terraform configurations for Resource Manager
- Extend Console pages using schema documents
- Preinstall the Oracle Cloud Development Kit

Store and Share Configurations
- Create a stack from Git or a bucket (Object Storage)
- CI/CD walkthrough (CLI)
- Use the deploy button
- Create a private template

Manage Terraform State
- Detect drift for a stack
- View the state of a stack
- Import an existing Terraform state file

Create and Update Stacks
- Create a stack
- Browse templates
- Start from the Create Compute Instance page
- Upgrade your stack to 0.12x

Run Terraform Actions
- Plan
- Apply
- Import
- Destroy

Developer Tools
- API for Resource Manager
- CLI for Resource Manager

Community
- Resource Manager page on Oracle.com
- Watch: Test Drive Resource Manager
- Oracle Cloud Infrastructure blog

Support
- Get help and contact Support

Troubleshooting
- GitHub and GitLab issues
- Deploy button errors
Overview of Resource Manager

Resource Manager is an Oracle Cloud Infrastructure service that allows you to automate the process of provisioning your Oracle Cloud Infrastructure resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. Resource Manager allows you to share and manage infrastructure configurations and state files across multiple teams and platforms. This infrastructure management can't be done with local Terraform installations and Oracle Terraform modules alone. For more information about the Oracle Cloud Infrastructure Terraform provider, see Terraform Provider on page 5412. For a general introduction to Terraform and the "infrastructure-as-code" model, see https://www.terraform.io.

Key Concepts

Following are brief descriptions of key concepts and the main components of Resource Manager.

configuration

Information to codify your infrastructure. Use your configuration to specify the Oracle Cloud Infrastructure resources in a given stack. For example, specify resource metadata, data source definitions, and variable declarations. Each Terraform configuration file is either HashiCorp Configuration Language (HCL) format or JSON format, as indicated by the file's extension (either .tf or .tf.json, respectively).

For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

For example configurations, see Terraform provider examples and Templates on page 4552. For more information, see Terraform Configurations for Resource Manager on page 4470 and Authoring Configurations on page 4471; see also Hashicorp: Configuration.

configuration source provider

Connection information to a source code control system where your Terraform configuration files are stored. Use a configuration source provider to create a stack from a remote, versioned Terraform configuration file.

A configuration source provider has the following types:

• GitHub: Supported products
  • GitHub Enterprise
  • GitHub Enterprise Server
  • GitHub Enterprise Cloud
  • GitHub Free for organizations
  • GitHub Free for user accounts
  • GitHub Team

• GitLab: Supported products
  • GitLab Community Edition
  • GitLab Enterprise Edition
  • GitLab.com

A configuration source provider has the following lifecycle states:

• Active: The configuration source provider is available for use.

For more information, see Managing Configuration Source Providers on page 4544 and To create a stack on page 4509.

For a walk-through using CLI for cloud provisioning in a CI/CD pipeline, see IaC in the Cloud: Integrating Terraform and Resource Manager into your CI/CD Pipeline - Building With the OCI CLI.
drift

Difference between the actual, real-world state of your infrastructure, and the stack's last executed configuration. For example, drift occurs when a team member adds a production tag to your resources, or when a resource fails. You can run drift detection reports to determine if provisioned resources have different states than those resources defined in the stack's last executed configuration. You can also view detailed drift status for each resource.

job

Instructions to perform the actions defined in your configuration. Only one job at a time can run on a given stack; further, you can have only one set of Oracle Cloud Infrastructure resources on a given stack. To provision a different set of resources, you must create a separate stack and use a different configuration.

Resource Manager provides the following job types:

- **Plan**: Parses your Terraform configuration and creates an execution plan for the associated stack. The execution plan lists the sequence of specific actions planned to provision your Oracle Cloud Infrastructure resources. The execution plan is handed off to the apply job, which then executes the instructions.
- **Apply**: Applies the execution plan to the associated stack to create (or modify) your Oracle Cloud Infrastructure resources. Depending on the number and type of resources specified, a given apply job can take some time. You can check status while the job runs.
- **Destroy**: Releases resources associated with a stack. Released resources are not deleted. For example, terminates a Compute instance controlled by a stack. The stack's job history and state remain after running a destroy job. You can monitor the status and review the results of a destroy job by inspecting the stack's log files.
- **Import State**: Sets the provided Terraform state file as the current state of the stack. Use this job to migrate local Terraform environments to Resource Manager.

Jobs store history about their associated stack. For example, plan jobs store generated execution plans and apply jobs store configurations (snapshots) and state files. Jobs reside in the same compartment as the stack they are associated with. An OCID is assigned to each job.

A job has the following lifecycle states:

- **Accepted**: The job was accepted for processing.
- **In Progress**: The job is currently executing.
- **Failed**: The job did not complete execution.
- **Succeeded**: The job completed execution.
- **Canceling**: The job is being canceled.
- **Canceled**: The job was canceled.

module

A group of related resources. Use modules to create lightweight and reusable abstractions, so that you can describe your infrastructure in terms of its architecture. For more information, see Creating Modules.

package

Typically a .zip file to a Terraform configuration that is stored in a supported provider, such as GitHub. For more information, see Using the Deploy to Oracle Cloud Button on page 4557.

resource discovery

A feature to capture deployed Oracle Cloud Infrastructure resources as Terraform configuration and state files. For more information, see Resource Discovery on page 4559.

stack

The collection of Oracle Cloud Infrastructure resources corresponding to a given Terraform configuration. Each stack resides in the compartment you specify, in a single region; however, resources on a given stack can be deployed across multiple regions. An OCID is assigned to each stack.
For steps on creating stacks, see To create a stack on page 4509. For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

A stack has the following lifecycle states:

- **Creating**: The stack is being created.
- **Active**: The stack is available for use.
- **Deleting**: The stack is being deleted.
- **Deleted**: The stack was deleted.
- **Failed**: The stack could not be created.

**state**

The state of your resource configuration, stored in JSON format in a state file (.tfstate). For more information, see State Management on page 4466.

**template**

A pre-built Terraform configuration that provisions a set of resources used in a common scenario. The template can be provided by either Oracle or someone in your tenancy, as a private template. To create stacks from templates, see To create a stack on page 4509. For reference, see Templates on page 4552.

To create private templates, see Managing Private Templates on page 4541.

### Features

#### Templates

A template is a Terraform configuration that you can use to manage infrastructure. Templates can help those who are new to infrastructure as code and those who are updating production workflow configurations. Use templates to try out Resource Manager and to apply proven best practices to your production workflow configuration. For information about Oracle-provided templates, see Templates on page 4552.

Create your own private templates to share with others in the tenancy.

#### Start with a Resource Creation Page

Save your configuration from a resource configuration page to a stack. Use the stack to install, configure, and manage the resource through the "infrastructure-as-code" model. Supported resource configuration pages: Create Compute Instance.

#### CI/CD with Resource Manager

Remotely store your Terraform configurations using integrated source code control systems, such as GitHub and GitLab. This integration helps you achieve continuous integration and continuous delivery (CI/CD).

For more information about remotely storing your configurations, see Managing Configuration Source Providers on page 4544.

For a walk-through using CLI for cloud provisioning in a CI/CD pipeline, see IaC in the Cloud: Integrating Terraform and Resource Manager into your CI/CD Pipeline - Building With the OCI CLI.

In addition, we also allow storing Terraform configurations in Object Storage buckets. For more information, see the bucket step in the instructions for creating a stack.

#### Resource Discovery

A feature to capture deployed resources as Terraform configuration and state files. With this feature, you can:

- Move from manually managed infrastructure to Resource Manager-controlled infrastructure.
- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
• Duplicate or rebuild existing infrastructure in another compartment.

For more information, see Resource Discovery on page 4559 and the following instructions:

• To see how Terraform represents your resources on page 4512
• To recreate (clone) existing infrastructure in another compartment on page 4513

State Management

Resource Manager stores Terraform state files for stacks so you don't have to. Multiple people can work on a stack concurrently because stack state is locked, allowing only one job at a time to run on a given stack. Resource Manager automatically generates and updates the stack's state file (.tfstate, in JSON format). This file maps your stack's resources to your configuration and maintains essential configuration metadata, such as resource dependencies.

For related instructions, see:

• To view the state of a stack on page 4520
• To view the state of a job on page 4524
• To import an existing Terraform state file (run an import job) on page 4524

For more information about Terraform state files, see Hashicorp: State.

Drift Detection

Find out if provisioned resources have different states than those resources defined in the stack's last run configuration and view detailed drift status for each resource.

You can optionally limit the drift detection to specified resources. Each resource is identified by a resource address, which is a string derived from the resource type and name specified in the stack's Terraform configuration plus an optional index. For example, the resource address for the fourth Compute instance with the name "test_instance" is oci_core_instance.test_instance[3] (resource type of oci_core_instance, a period as delimiter, resource name of test_instance, and index of 3 in brackets). For more details and examples of resource addresses, see the Terraform documentation at https://www.terraform.io/docs/internals/resource-addressing.html#examples.

For more information about drift detection, see drift and the following instructions:

• To detect drift for a stack or selected resources on page 4515
• To view the latest drift detection report on page 4518
• To view an old drift detection report on page 4519

Deploy to Oracle Cloud Button

The Deploy to Oracle Cloud button allows you to launch your remote Terraform configuration using the Create Stack workflow available in Resource Manager.

For more information, see Using the Deploy to Oracle Cloud Button on page 4557.

Availability

The Resource Manager service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Generalized Workflow

The following image represents a generalized view of the Resource Manager workflow.
1. Create a Terraform configuration.

   **Note:**
   For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

2. Create a stack.
3. Run a plan job, which produces an execution plan.
4. Review the execution plan.
5. If changes are needed in the execution plan, update the configuration and run a plan job again.
6. Run an apply job to provision resources.
7. Review state file and log files, as needed.
8. You can optionally reapply your configuration, with or without making changes, by running an apply job again.
9. Optionally, to release the resources running on a stack, run a destroy job.

For a detailed walkthrough of the Resource Manager workflow, see Getting Started on page 4489.

**Ways to Access Resource Manager**

You can access the Resource Manager service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.
Console: To access Resource Manager using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Open the navigation menu and click Development Services. Under Resource Manager, click Stacks.

API: To access Resource Manager through APIs, use Resource Manager API. To access this API using the Command Line Interface (CLI), use the `oci resource-manager` designation.

**Default Provider**

By default, Resource Manager supports `terraform-provider-oci`, the Terraform provider for Oracle Cloud Infrastructure.

For supported third-party Terraform providers, see Supported Providers on page 4617.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up `groups`, `compartments`, and `policies` that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to resources in Resource Manager (stacks, jobs, private templates, and configuration source providers), see Policies for Managing Resources Used with Resource Manager on page 3170. For a complete list of Resource Manager permissions, see Details for Resource Manager on page 3033. Policies for managing accessed resource types are also required.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2806.</td>
</tr>
</tbody>
</table>

**Limits on Resource Manager Resources**

See Resource Manager Limits on page 266. See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Resource Manager and Terraform**

Resource Manager uses Terraform to help you provision, configure, and manage Oracle Cloud Infrastructure (OCI) resources. Each stack in Resource Manager is associated with a Terraform configuration and a Terraform state file. An understanding of Terraform concepts is critical to manage resources successfully with Resource Manager.
**Terraform Configuration**

Terraform configurations codify your infrastructure in declarative files that contain the steps required to provision your infrastructure and maintain its state. To manage OCI resources, the configuration must specify the `terraform-provider-oci` Terraform provider.

Resource Manager requires Terraform configurations to create stacks for provisioning and managing OCI resources. Pre-defined Terraform configurations are available as templates, and you can also generate Terraform configurations from existing compartments and from the Create Compute Instance page. After the initial provisioning of your OCI resources, Resource Manager uses the stack’s Terraform configuration to detect drift of resources (the difference between resource states and the configuration).

For a walkthrough that includes writing a sample Terraform configuration, see Getting Started on page 4489.

For information about writing our own Terraform configurations, see Terraform Configurations for Resource Manager on page 4470 and Authoring Configurations on page 4471.

**Terraform State**

Terraform state files are automatically generated and updated by Resource Manager. Resource Manager stores Terraform state files for stacks so you don't have to. The stack's state file (.tfstate, in JSON format) maps your stack's resources to your configuration and maintains essential configuration metadata, such as resource dependencies.

Multiple people can work on a stack concurrently because stack state is locked, allowing only one job at a time to run on a given stack.

For related instructions, see:

- To view the state of a stack on page 4520
- To view the state of a job on page 4524
- To import an existing Terraform state file (run an import job) on page 4524

**Jobs**

Resource Manager jobs use Terraform configuration and state files to manage your Oracle Cloud Infrastructure (OCI) resources through the following Terraform actions.

- **Plan**: Parses your Terraform configuration and creates an execution plan for the associated stack. The execution plan lists the sequence of specific actions planned to provision your OCI resources. The execution plan is handed off to the apply job, which then executes the instructions.
- **Apply**: Applies the execution plan to the associated stack to create (or modify) your OCI resources. Depending on the number and type of resources specified, a given apply job can take some time. You can check status while the job runs.
- **Destroy**: Releases resources associated with a stack. Released resources are not deleted. For example, terminates a Compute instance controlled by a stack. The stack's job history and state remain after running a destroy job. You can monitor the status and review the results of a destroy job by inspecting the stack's log files.
- **Import State**: Sets the provided Terraform state file as the current state of the stack. Use this job to migrate local Terraform environments to Resource Manager.

For a walkthrough that includes running jobs for the Terraform actions Plan, Apply, and Destroy, see Getting Started on page 4489.

For instructions related to jobs for Terraform actions, see Managing Jobs (Console) on page 4521.

**What’s Included with Resource Manager Terraform Host**

The Resource Manager Terraform host VM comes with the following tools pre-installed:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Docker</td>
<td>19.03.11</td>
</tr>
</tbody>
</table>
Terraform Configurations for Resource Manager

This topic describes requirements and recommendations for Terraform configurations used with Resource Manager. For basic information about Terraform configurations, see Authoring Configurations on page 4471. For instructions on using configurations with stacks and jobs, see Managing Stacks and Jobs on page 4508.

For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

In addition to writing your own Terraform configuration file, you also have the option to generate a Terraform configuration from either an existing compartment using resource discovery or a sample template.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not provide user credentials or other confidential information in your Terraform configurations.</td>
</tr>
</tbody>
</table>

Requirements

Terraform configuration files used with Resource Manager must meet the following requirements.

**Terraform Provider**

When using Resource Manager, the region field in the provider "oci" block is the only required field. For more information about defining providers, see Configuration File Requirements on page 4472.

**File Structure**

Resource Manager requires the following file structure for the Terraform configuration:

- The working directory must contain at least one .tf file. The working directory cannot contain a .terraform directory.

  The working directory is the path from which to run Terraform. By default, the working directory is the root directory of your configuration (for an uploaded configuration, the root of your .zip file). When using the API, you can specify a different location for the working directory by setting the workingDirectory parameter.

- The configuration must follow guidelines specified in Authoring Configurations on page 4471.

- No Terraform state files (.tfstate) can exist in the configuration.

- If you plan to upload the configuration locally, then bundle all files into a .zip file.

**Modules**

Resource Manager supports the following Terraform module sources:

- Local paths
- Terraform Registry
- GitHub
- Bitbucket
- Generic Git repositories
- HTTP URLs

**Variables**

We recommend using a schema document with your Terraform configuration to facilitate user entry in the Oracle Cloud Infrastructure Console.

Resource Manager does not have requirements for variables in Terraform configurations. Resource Manager supports the native Terraform behavior for handling variables. Terraform sets variables from your variable definitions that use supported type constraints.
Note:

When defined in the Terraform configuration, the following variables automatically prepopulate with values on the Console pages used to create and edit the stack. The stack's values are used when you select the Terraform actions Plan, Apply, and Destroy.

- tenancy_ocid (tenancy OCID)
- compartment_ocid (compartment OCID)
- region (region)
- current_user_ocid (OCID of the current user)

Example Terraform Configuration for Resource Manager

The following example shows a Terraform configuration that is contained in a single file. This basic sample defines just one Terraform provider, one Oracle Cloud Infrastructure resource, and a set of variables.

```terraform
variable "compartment_ocid" {}
variable "region" {}

provider "oci" {
  region = "${var.region}"}

resource "oci_core_virtual_network" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = "${var.compartment_ocid}"
  display_name = "vcn1"
}
```

More often, Terraform configurations consist of two or more files bundled together (for an uploaded configuration, the files would be bundled in a .zip file). To see more complex, multi-file Terraform configurations, explore the examples at the Oracle Cloud Infrastructure GitHub: terraform-provider-oci/docs/examples.

Where to Store Your Terraform Configurations

When creating a stack with Resource Manager, you can select your Terraform configuration from the following sources.

- Local .zip file
- Local folder
- Object Storage bucket
  - The most recent contents of the bucket are automatically used by any job running on the associated stack.
- Source code control system, such as Git
  - The latest version of your configuration is automatically used by any job running on the associated stack.
- Template (pre-built Terraform configuration from Oracle or a private template)
- Existing compartment (Resource Discovery on page 4559)

Schema Documents

Schema documents are recommended for Terraform configurations when using Resource Manager. See Extend Console Pages Using Schema Documents on page 4571.

Authoring Configurations

Using Terraform, you can describe your Oracle Cloud Infrastructure using the HashiCorp Configuration Language format (HCL) in Terraform configuration files (see Configuration Syntax). Terraform configuration files can use
either of two formats: Terraform domain-specific language (HashiCorp Configuration Language format [HCL]),
which is the recommended approach, or JSON format if the files need to be machine-readable. Configuration files
that use the HCL format end with the .tf file extension; those using JSON format end with the .tf.json file
extension. The Terraform format is human-readable, while the JSON format is machine readable.

Use Terraform configurations to define your Oracle Cloud Infrastructure (OCI) resources, variable definitions, data
sources, and a great deal more. Terraform, then, converts your OCI configurations into a set of API calls against OCI
API endpoints. The key to writing Terraform configuration is understanding how to abstract the wanted infrastructure
cursively into Terraform configuration syntax.

Important:
While the Oracle Cloud Infrastructure API uses camelCase extensively,
Terraform does not support camelCase in configuration files. For this reason,
in the configurations you see underscores rather than capitalization as
separators. For example, where the API uses availabilityDomain, the
Terraform configuration uses availability_domain.

Configuration File Requirements
Terraform configuration (.tf) files have specific requirements, depending on the components that are defined in the
file. For example, you might have your Terraform provider defined in one file (provider.tf), your variables defined in
another (variables.tf), your data sources defined in yet another.

Note:
For example configuration files, see Terraform Provider Examples on the
Oracle Cloud Infrastructure GitHub.

Provider Definitions
The following example using Terraform syntax illustrates the requirements for an OCI Terraform provider definition,
and also shows associated variable definitions. The provider definition relies on variables so that the configuration
file itself does not contain sensitive data. Including sensitive data creates a security risk when exchanging or sharing
configuration files.

```terraform
variable "tenancy_ocid" {} 
variable "user_ocid" {} 
variable "fingerprint" {} 
variable "private_key_path" {} 
variable "region" {} 

provider "oci" {
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
  region = "${var.region}"
}
```

The region attribute specifies the geographical region in which your provider resources are created. To target
multiple regions in a single configuration, you simply create a provider definition for each region and then
differentiate by using a provider alias, as shown in the following example. Notice that only one provider, named "oci"
is defined, and yet the oci provider definition is entered twice, once for the us-phoenix-1 region (with the alias
"phx"), and once for the region us-ashburn-1 (with the alias "iad欢")

```terraform
variable "tenancy_ocid" {} 
variable "user_ocid" {} 
variable "fingerprint" {} 
variable "private_key_path" {} 
variable "compartment_ocid" {} 
```
provider "oci" {
  region = "us-phoenix-1"
  alias = "phx"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}

provider "oci" {
  region = "us-ashburn-1"
  alias = "iad"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}

For more information, see Provider Configuration.

**Variable Definitions**

Variables in Terraform represent parameters for Terraform modules. In variable definitions, each block configures a single input variable, and each definition can take any or all of three optional arguments:

- **type** (optional): Defines the variable type as one of three allowed values: string, list, and map. If this argument is not used, the variable type is inferred based on default. If no default is provided, the type is assumed to be string.
- **default** (optional): Sets the default value for the variable. If no default value is provided, the caller must provide a value or Terraform throws an error.
- **description** (optional): A human-readable description of the variable.

Following are examples of several variable definitions. Some definitions include optional parameters.

```terraform
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

variable "AD" {
  default = "1"
  description = "Availability Domain"
}

variable "CPUCoreCount" {
  default = "2"
  type = "string"
}
```

For more information, see Input Variable Configuration. See also Input Variables.

**Output Configuration**

Output variables provide a means to support Terraform end-user queries. This allows users to extract meaningful data from among the potentially massive amount of data associated with a complex infrastructure. For example, you might be interested only in a handful of key values at any given time and defining output variables allows you to extract exactly the information that you need.

Following is a simple example in which only a few output variables (instance IP addresses and boot volume IDs) are defined:

```terraform
# Output the private and public IPs of the instance
```
output "InstancePrivateIPs" {
  value = ["${oci_core_instance.TFInstance.*.private_ip}"]
}

output "InstancePublicIPs" {
  value = ["${oci_core_instance.TFInstance.*.public_ip}"]
}

# Output the boot volume IDs of the instance
output "BootVolumeIDs" {
  value = ["${oci_core_instance.TFInstance.*.boot_volume_id}"]
}

For more information, see Output Variables. See also Output Configuration.

Resources

Resources are components of your Oracle Cloud Infrastructure. These resources include everything from low-level components such as physical and virtual servers, to higher-level components such as email and database providers, your DNS record.

The full reference of the OCI Terraform provider’s supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

Caution:

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Sensitive Data in State for more information.

Declaring Resources

Following is a simple example of a resource definition that illustrates their basic structure.

resource "oci_core_virtual_network" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = "${var.compartment_ocid}"
  display_name = "vcn1"
}

The resource declaration on the first line of the example uses the keyword "resource" and takes two parameters, resource type and resource name ("oci_core_virtual_network" and "vcn1" in the example). Inside the code block, then, is the resource configuration.

For more information, see Resource Configuration.

Resource Dependencies

When a resource references another resource within its resource block, Terraform automatically infers the primary resource’s dependency on the referenced resource. A resource might also depend on resources that are not explicitly referenced within its block. For example, you might need to create policies for a resource before creating the resource itself.

To define hidden dependencies that Terraform cannot automatically infer, you can use the depends_on meta-argument in the resource block.
The following example creates an `oci_datascience_notebook_session` resource and an `oci_identity_policy` resource for related policies. Adding the `depends_on` meta-argument to the `oci_datascience_notebook_session` resource ensures that the policies are created first:

```terraform
resource "oci_datascience_notebook_session" "ods-notebook-session" {
  count = var.enable_ods ? var.ods_number_of_notebooks : 0

  #Required
  compartment_id = var.compartment_ocid
  notebook_session_configuration_details {
    #Required
    shape = var.ods_compute_shape
    subnet_id = local.private_subnet_id

    #Optional
    block_storage_size_in_gbs = var.ods_storage_size
  }
  project_id = oci_datascience_project.ods-project[0].id
  display_name = "${var.ods_notebook_name}-${count.index}"

  depends_on = ["oci_identity_policy.ods-policy"]
}

resource "oci_identity_policy" "ods-policy" {
  provider = oci.home
  compartment_id = var.compartment_ocid
  description = "Data Science Policies"
  name = var.ods_policy_name
  statements = var.enable_vault ? concat(local.ods_policies , local.vault_policies) : local.ods_policies
}
```

### Referencing Resources in Another Stack

You can reference resources that exist in other stacks. The Terraform `remote_state` data source allows you to read output variables from state files.

For example, when writing a Terraform configuration for a new web application, you can make the web application use the subnet previously created from your network stack, as long as the required subnet values were output in the network stack state file. In the Terraform configuration for your new web application, do the following:

- Pull the state file of the existing network stack into the context of your current Terraform configuration.
- Load the pulled state file to a data source for remote state files.
- Populate the subnet data source in your current configuration with values from the relevant output variables of the referenced state file.
- Optionally print the identifying information for the populated data source to confirm expected values.

**Note:**

In addition to permissions required for Resource Manager operations, you'll need appropriate permissions for resource types you're referencing, in the compartment that you're referencing them. In this example, you need read permissions for network resources in the compartment where they're located.

The following Terraform configuration excerpt references a subnet in another stack:

```terraform
# The following example assumes that the source stack (defined by `stack_id`) has output a value named `subnet_id`
# Terraform v0.12 is assumed
```
variable "stack_id" {}

# Pull the state file of the existing Resource Manager stack (the network stack) into this context
data "oci_resourcemanager_stack_tf_state" "stack1_tf_state" {
  stack_id = "${var.stack_id}"
  local_path = "stack1.tfstate"
}

# Load the pulled state file into a remote state data source
data "terraform_remote_state" "external_stack_remote_state" {
  backend = "local"
  config = {
    path = "${data.oci_resourcemanager_stack_tf_state.stack1_tf_state.local_path}"}
}

# Populate a data source in this configuration using a value from the remote state data source
data "oci_core_subnet" "subnet1" {
  subnet_id = "${data.terraform_remote_state.external_stack_remote_state.outputs.subnet_id}"}

# Print the values of the populated data source
output "print-subnet1" {
  value = "${data.oci_core_subnet.subnet1}"}

Data Sources

Data sources represent read-only views of existing infrastructure intended for semantic use in Terraform configurations. Following is a simple example of a data source configuration to illustrate its basic structure:

# Gets a list of Availability Domains
data "oci_identity_availability_domains" "ADs" {
  compartment_id = "${var.tenancy_ocid}"
}

# Get DB node list
data "oci_database_db_nodes" "DBNodeList" {
  compartment_id = "${var.compartment_ocid}"
  db_system_id = "${oci_database_db_system.TFDBNode.id}"}

# Get DB node details
data "oci_database_db_node" "DBNodeDetails" {
  db_node_id = "${lookup(data.oci_database_db_nodes.DBNodeList.db_nodes[0], "id")}"}

# Gets the OCID of the first (default) vNIC
data "oci_core_vnic" "DBNodeVnic" {
  vnic_id = "${data.oci_database_db_node.DBNodeDetails.vnic_id}"}

For more information, see Data Source Configuration.

Filtering Data Sources
Data sources that return lists of resources support filtering semantics. To use a filter, include this block in your data source definition:

```python
filter {
    name = ""
    values = [""]
}
```

The `name` value corresponds to the qualified property name to filter with and the `values` lists can contain one or more values filter with.

Nested properties and map elements can be addressed by qualifying the property name with parent property name. Example `r1` will give all the instances which have `source_type` image. Example `r2` will give all the instances which contain a defined tag with value "42" for key `CostCenter` in the namespace `Operations`.

```python
data "oci_core_instances" "r1" {
    ...
    filter {
        name = "source_details.source_type"
        values = ["image"]
    }
}

data "oci_core_instances" "r2" {
    ...
    filter {
        name = "defined_tags.Operations.CostCenter"
        values = ["42"]
    }
}
```

Multiple values work as an OR type filter. In the shape example below, the resulting data source would contain both VM shapes `Standard 1.1` and `Standard 1.2`:

```python
data "oci_core_shape" "t" {
    ...
    filter {
        name = "name"
        values = ["VM.Standard1.1", "VM.Standard1.2"]
    }
}
```

Multiple filters blocks can be composed to form AND type comparisons. The example below will return a data source containing running instances in the first AD of a region:

```python
data "oci_core_instances" "s" {
    ...
    filter {
        name = "availability_domain"
        values = ["\w*-AD-1"]
        regex = true
    }

    filter {
        name = "state"
        values = ["RUNNING"]
    }
}
```
As shown above, filters can also employ regular expressions. By setting `regex = true`, each item in the `values` list will be treated as a regular expression. Backslashes in strings for regular expression special characters need to be escaped with another slash, shown above as the first `\` before `\w` in "\w*-AD-1".

```
Note:

Drilling into lists of structured objects is not currently supported. If these properties are targeted no results will be returned from the datasource.
```

**Functions**

Terraform offers a number of built-in functions that you can use in your configuration files. These functions allow you to modify strings, perform calculations against numeric values, manage collections, and much more.

For more information, see [Functions](#).

**For More Information**

- Terraform Configurations
- Terraform Configuration Syntax

**Managing Volumes**

This guide details the following scenarios:

1. Preserving boot volumes when performing Compute instance scaling
2. Boot volume troubleshooting and repair
3. Replicating volumes to another availability domain

To read more about boot volumes, see [Boot Volumes](#).

### Preserving Boot Volumes

You may want to change Compute instance shape while using the same boot volume. When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. This approach is useful for scenarios where instance shape cannot be changed while resizing instances.

To achieve this, you need to detach the boot volume from the running instance. This can be performed by either terminating the instance while preserving the boot volume or by stopping the instance and detaching the boot volume.

All Terraform resources of type `oci_core_instance` have the parameter `preserve_boot_volume` set as `true` by default. This parameter ensures that upon termination of the instance, the attached boot volume is not terminated.

```
resource "oci_core_instance" "TFInstance" {
  ...
  state = "STOPPED"                   // set this state to stop the instance
  preserve_boot_volume = true
}
```

Once the boot volume is detached, the OCID of the boot volume can be referred as the source of the new instance, as illustrated below:

```
resource "oci_core_instance" "TFScaleInstance" {
  ...
  source_details {
    source_type = "bootVolume"
    // reference the original boot volume id here
    source_id   = "ocid1.bootvolume.oci.phx.exampleuniqueID"
  }
}
```
Detaching Boot Volumes for Troubleshooting and Repair

If you think a boot volume issue is causing a Compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Once the boot volume has been detached, the OCID of the boot volume can be referred as the block volume parameter for another instance.

```terraform
resource "oci_core_volume_attachment" "TFBlockAttach" {
  attachment_type = "iscsi"
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"
  // new instance
  instance_id = "ocid1.instance.oc1.phx.exampleuniqueID"

  // attach the boot volume as a block volume
  volume_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
}
```

Once you have resolved the issue, detach this volume from the second instance and attach it as a boot volume to the original instance.

```terraform
resource "oci_core_instance" "TFScaleInstance" {
  
  source_details {
    source_type = "bootVolume"

    // attach back as boot volume
    // reference the volume id here
    source_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
  }
}
```

Replicate a Volume to an Availability Domain within the Region

You can use Terraform to replicate existing Compute instance boot and block volumes to another availability domain within the same region.

To replicate a volume:

1. Create a data source for the volume using `oci_core_boot_volume` or `oci_core_volume`.
2. Use the `oci_core_boot_volume_backup` or `oci_core_volume_backup` resource to create a backup of the source volume.
3. Define the target volume resource to be created from the backup.

The following example Terraform configuration replicates both a boot volume and a block volume:

```terraform
provider "oci" {
  region = "us-ashburn-1"
}

locals {
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"
  target_ad = "ilMx:US-ASHBURN-AD-2"
  source_boot_id = "ocid1.bootvolume.oc1.iad.exampleuniqueID"
  source_volume_id = "ocid1.volume.oc1.iad.exampleuniqueID"
```

```terraform
resource "oci_core_volume_backup" "TFBlockSource" {
  compartment_id = local.compartment_id
  source_volume_id = local.source_volume_id
  lifecycle {
    create_before_destroy = true
  }
}
```

```terraform
resource "oci_core_boot_volume_backup" "TFBootSource" {
  compartment_id = local.compartment_id
  source_boot_volume_id = local.source_boot_id
  lifecycle {create_before_destroy = true}
}
```

```terraform
resource "oci_core_instance" "TFReplicatedInstance" {
  
  source_details {
    source_type = "bootVolume"

    // attach back as boot volume
    // reference the volume id here
    source_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
  }
}
```

```terraform
resource "oci_core_volume_attachment" "TFBlockAttach" {
  attachment_type = "iscsi"
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"
  // new instance
  instance_id = "ocid1.instance.oc1.phx.exampleuniqueID"

  // attach the boot volume as a block volume
  volume_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"
}
```
You can use these steps to move an instance to the second availability domain or to create a disaster recovery deployment in the second availability domain.

If this method is used for a pure retargeting scenario where the source volumes (and the backups) will be removed after the duplication, then the Terraform configuration must be refactored after the source volumes are removed to avoid destroying the target instances on the next apply.

If using this scenario for disaster recovery cold standby, you can regularly use the Terraform `taint` command to mark the volume for destruction and recreation on the next application of the configuration.

**Managing Default VCN Resources**

When you create an `oci_core_vcn` resource, it will also create the following associated resources by default:

- `oci_core_security_list`
- `oci_core_dhcp_options`
- `oci_core_route_table`

These default resources will be implicitly created even if they are not specified in the Terraform configuration. Their OCIDs are returned by the following attributes under the `oci_core_vcn` resource:

- `default_security_list_id`
- `default_dhcp_options_id`
• default_route_table_id

Default resources must be configured in Terraform using a separate resource type. Here are the mappings between the resource and the new resource type to use for configuring default resources:

• oci_core_security_list => oci_core_default_security_list
• oci_core_dhcp_options => oci_core_default_dhcp_options
• oci_core_route_table => oci_core_default_route_table

Default resources types are configured in the same way as their non-default counterparts. The only difference is specifying the ID of the default resource using the manage_default_resource_id argument.

Consequently, the vcn_id is no longer necessary for default resources.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

The following example modifies a VCN's default DHCP options:

```terraform
resource "oci_core_vcn" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = var.compartment_ocid
  display_name = "vcn1"
}

resource "oci_core_default_dhcp_options" "default-dhcp-options" {
  manage_default_resource_id = oci_core_vcn.vcn1.default_dhcp_options_id

  // required
  options {
    type = "DomainNameServer"
    server_type = "VcnLocalPlusInternet"
  }

  // optional
  options {
    type = "SearchDomain"
    search_domain_names = [ "abc.com" ]
  }
}
```

**Limitations**

Default resources can only be removed when the associated oci_core_vcn resource is removed. When attempting a targeted removal of a default resource, the resource will be removed from the Terraform state file but the resource may still exist in OCI with empty settings.

Examples of targeted removal include:

• Removing a default resource from a Terraform configuration that was previously applied
• Running a terraform destroy -target=<default resource> command
• Changing the manage_default_resource_id for a default resource that was previously applied

**Migrating an Exadata DB System to the New Resource Model**

The X8M generation of Exadata hardware introduces a new resource model that replaces the Exadata DB system. The new resource model uses new APIs to provision and manage its resources. The existing DB system APIs for Exadata will be deprecated by Oracle Cloud Infrastructure for all users following written notification and a transition period allowing you to switch to the new API and Console interfaces.
If you have existing Exadata DB systems in Oracle Cloud Infrastructure, you can use Terraform to switch them to the new resource model and APIs.

**Caution:**

Switching an Exadata DB system to the new resource model and APIs cannot be reversed. If you have automation for your system that utilizes the DB system APIs, you may need to update your applications prior to switching.

Switching to the new resource model:

- Does not impact the DB system's existing Exadata databases or client connections
- Does not change the underlying hardware or shape family of your Exadata Cloud Service instance
- Will not affect bare metal and virtual DB systems

After converting your DB system, you will have two new resources in place of the DB system resource: a cloud Exadata infrastructure resource, and a cloud VM cluster resource.

What to expect after switching:

- Your new cloud Exadata infrastructure resource and cloud VM cluster are created in the same compartment as the DB system they replace
- Your new cloud Exadata infrastructure resource and cloud VM cluster use the same networking configuration as the DB system they replace
- After the switch, you cannot perform operations on the old Exadata DB system resource
- Switching is permanent, and the change cannot be undone
- X6, X7, X8 and Exadata base systems retain their fixed shapes after the switch, and cannot be expanded

**To Migrate an Exadata DB System**

These migration steps use the following example, which shows an existing Exadata Cloud Service instance using the old DB system resource model:

```terraform
resource "oci_database_db_system" "test_db_system" {
    availability_domain = data.oci_identity_availability_domain.ad.name
    compartment_id      = var.compartment_ocid
    cpu_core_count      = var.cpu_core_count
    database_edition    = var.db_edition
    time_zone           = var.time_zone

    db_home {
        database {
            admin_password = var.db_admin_password
            db_name        = "TFdb1Exa"
            character_set  = var.character_set
            ncharacter_set = var.n_character_set
            db_workload    = var.db_workload
            pdb_name       = var.pdb_name

            db_backup_config {
                auto_backup_enabled = false
            }
        }

        db_version   = var.db_version
        display_name = "MyTFDBHome1Exa"
    }

    maintenance_window_details {
        preference = "CUSTOM_PREFERENCE"
    }
}
```

To migrate the system to the new resource model, first create the `oci_database_migration` resource:

```hcl
// This is 1 time action to migrate test_db_system into db ExaCS
// and the test_db_system will become 'Migrated'
resource "oci_database_migration" "test_migration" {
  #Required
  db_system_id = "${oci_database_db_system.test_db_system.id}"
}
```

Provisioning the `oci_database_migration` resource creates two new resources: `oci_database_cloud_exadata_infrastructure` and `oci_database_cloud_vm_cluster`.

You can get OCIDs of these two resources from the `oci_database_migration` resource:

```hcl
output "cloud_exadata_infrastructure_id" {
  value =
  oci_database_migration.test_migration.cloud_exadata_infrastructure_id
}
output "cloud_vm_cluster_id" {
  value =
  oci_database_migration.test_migration.cloud_vm_cluster_id
}
```
Create a Terraform configuration for the two new resources:

```terraform
resource "oci_database_cloud_exadata_infrastructure" "test_cloud_exadata_infrastructure"{}
resource "oci_database_cloud_vm_cluster" "test_cloud_vm_cluster" {}
```

Then run the Terraform import command:

```
terraform import
oci_database_cloud_exadata_infrastructure.test_cloud_exadata_infrastructure <cloud_exadata_infrastructure_id>
terraform import
oci_database_cloud_vm_cluster.test_cloud_vm_cluster <cloud_vm_cluster_id>
```

Terraform now manages the two new resources. After switching to the new Exadata resource model, remove the old `oci_database_db_system` config.

**Tip:**

After the migration, you can use `resource discovery` to create a full configuration and state file for importing these two new resources.

### Referencing Availability Domains

With respect to availability domains, we caution against a common pattern, as shown here:

```terraform
// Get all availability domains for the region
data "oci_identity_availability_domains" "ads" {
  compartment_id = "${var.tenancy_ocid}"
}

// Then either use it to get a single AD name based on the index:
resource "oci_core_instance" "nat" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ads.availability_domains[var.nat_instance_ad], "name")}"
  ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(data.oci_identity_availability_domains.ads.availability_domains)}"
  availability_domain = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")}"
  ...
}
```

The recommendation, then, is to explicitly list the availability domain names for the regions in your configuration. To do so, use a variable that you have defined as follows:

```terraform
variable "ad_list" {
  type = "list"
}
```

You can then use the variable as shown here:

```terraform
// Index:
resource "oci_core_instance" "nat" {
  availability_domain = "${var.ad_list[var.nat_instance_ad_index]}"
  ...
}
```
// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(var.ad_list)}"
  availability_domain = "${var.ad_list[count.index]}"
  ...
}

You can then set the ad_list variable directly by using the availability domain names for your tenant and region, as shown here:

```hcl
variable "ad_list" {
  type = "list"
  default = ["kIdk:PHX-AD-1","kIdk:PHX-AD-2","kIdk:PHX-AD-3"]
}
```

The advantage of using this method is that it gives you control over your availability domain usage and prevents unexpected changes over time. However, this approach is problematic when configurations are shared between tenancies and regions, since availability domain names are tenancy- and region-specific.

A convenient alternative is to instead set the ad_list value by using the `oci_identity_availability_domains` data source. You should do this in the configuration, then pass them into the modules. This effectively centralizes the list of ADs, making it is easy to switch to an explicit list later, should that become necessary: Note that the modules themselves should not use the `oci_identity_availability_domains` data source.

```hcl
data "oci_identity_availability_domains" "ad" {
  compartment_id = "${var.tenancy_ocid}"
}
data "template_file" "ad_names" {
  count = "${length(data.oci_identity_availability_domains.ad.availability_domains)}"
  template = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")}"
}
module "ssm_network" {
  ad_list = "${data.template_file.ad_names.*.rendered}" ...
}
```

**Regions with a Single Availability Domain**

Some Oracle Cloud Infrastructure regions have a single availability domain. When writing configurations that use plural data sources, like `oci_identity_availability_domains`, ensure that you account for a single domain if required by your region.

The following example uses the `oci_identity_availability_domains` data source when listing fault domains in a single-availability domain region. The `availability_domains` index must be 0. Any other index value is invalid in this region:

```hcl
data "oci_identity_availability_domains" "AvailabilityDomains" {
  compartment_id = var.tenancy_ocid
}
data "oci_identity_fault_domains" "FaultDomains" {
  availability_domain = data.oci_identity_availability_domains.AvailabilityDomains.availability_domains[0] ["name"]
  compartment_id = "${var.compartment_ocid}"
}
The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

**Referencing Images**

When launching Compute instances, your Terraform configuration should use the same image every time you run a Terraform `apply` job.

To ensure this, specify the image OCID directly, rather than locating it using the `oci_core_image` data source. This is because the `oci_core_image` data source calls into the `listImages` API, whose return values can change over time because over time images are added and older ones deleted. For a list of Oracle-provided images and their OCIDs, see Oracle-Provided Images. For more information, see Results of `oci_core_images` will change over time for Oracle-provided images.

We recommend the following pattern for specifying an image for a given region:

```hcl
variable "image_id" {
    type = "map"
    default = {
        // See https://docs.cloud.oracle.com/iaas/images/
        // Oracle-provided image "Oracle-Linux-7.4-2018.02.21-1"
        us-phoenix-1 = "ocid1.image.oc1.phx..<unique_ID>"
        us-ashburn-1 = "ocid1.image.oc1.iad..<unique_ID>"
        eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-1..<unique_ID>"
        uk-london-1 = "ocid1.image.oc1.uk-london-1..<unique_ID>"
    }
}
```

A Compute instance can use this in the following way:

```hcl
resource "oci_core_instance" "TFInstance" {
    image = "${var.image_id[var.region]}"
    ...  
}
```

**Specifying Versions**

Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules you call in your configuration files all introduce changes or add new functionality from time to time. As these changes are made, new versions are released.

In order to ensure that your configurations are applied consistently to OCI resources, you can explicitly set the version of these components in Terraform configuration files.

**Provider Version**

You can control the version of the OCI Terraform provider that Terraform uses when interacting with OCI resources. This ability is especially helpful when your configuration relies on features introduced with a particular version of the provider or it has only been tested with a particular version of the provider.

You can use the `>=` or `=` operators to specify the version, depending on your use case.

For more information, see Specifying Provider Requirements.

**Using Terraform v0.12 or earlier**

Terraform v0.12 or earlier allowed you to specify version within the provider block. For example:

```hcl
provider "oci" {
    version      = ">= 3.27.0"
    region       = "$\{var.region\}"
    ...  
}
```
Using Terraform v0.13

Terraform v0.13 deprecated version within provider blocks. Instead, versions should be specified within a required_providers block. For example:

```terraform
terraform {
  required_providers {
    oci = {
      source  = "hashicorp/oci"
      version = ">= 4.0.0"
    }
  }
  ...
}
```

Module Version

In addition to specifying the version of the Terraform CLI and the OCI Terraform provider, you can also specify the version of Terraform modules.

If a module has been upgraded to use a newer version of Terraform core, but you still use an earlier version of Terraform, you can specify a compatible version of the module. If your configurations have only been tested with a specific version of the module, you can specify that version to ensure compatibility.

Modules accept the version argument. For example:

```terraform
module "oke" {
  source  = "oracle-terraform-modules/oke/oci"
  version = "1.0.0"
  # insert required variables here
}
```

For more information, see Module Blocks.

Tagging Resources

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate them, report on them, or take bulk actions on them. Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

There are two types of tags:

- **Defined tags** are set up in your tenancy by an administrator. Only users granted permission to work with the defined tags can apply them to resources. Defined tags provide a key/value map and are organized by combining the tag namespaces with tag keys using dot notation. For example, a tag namespace called HumanResources could have a key named CostCenter. You then associate the namespace and key HumanResource.CostCenter and then assign the tag.

- **Free-form tags** can be applied by any user with permissions on the resource. Freeform tags are simple key/value map.
  - Refer to the oci_identity_tag_namespace reference for guidance on managing the lifecycle of tag namespaces.
  - Refer to the oci_identity_tag reference for guidance on managing tags.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

For more detailed information about tags and their features, see Tagging Overview.
**Propagation of Tagging on Resources**

OCI services propagate all of a primary resource's freeform tags and defined tags to secondary resources when both resources support the type of tags. For example, if your Terraform configuration has a Compute instance as a primary resource and a VNIC as a nested secondary resource, any tags on the Compute instance are propagated to the VNIC.

This propagation could cause a drift in the Terraform state resulting in a diff after apply. To avoid potential drift, explicitly add all the primary resource's freeform tags and defined tags on the secondary resources as part of the configuration.

The same behavior can be seen while using the Tag Default or Required Tags feature. Avoid drift by applying the Tag Default or Required Tags on all resources (primary and secondary, if any) in the tenancy where Tag Default or Required Tags exist.

**Targeting Multiple Regions**

You can use a single Terraform configuration to create Oracle Cloud Infrastructure (OCI) resources in multiple regions.

*Create a Provider for Each Region*

A Terraform configuration may have only a single OCI Terraform provider block, but to apply configurations to multiple regions, you need to create multiple provider blocks.

A typical OCI Terraform provider block might look like the following:

```terraform
provider "oci" {
  region           = var.region
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}
```

**Tip:**

All parameters should be set using variables.

If you want to use more than one region within a single Terraform config, multiple providers are required. Each provider must be given an alias. For example:

```terraform
provider "oci" {
  alias            = "home"
  region           = var.region
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}

provider "oci" {
  alias            = "region2"
  region           = var.region2
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}
```

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region, which is your home region. The home region has special properties. For example, IAM resources can only be created in your home region. For that reason, you should designate that region with an appropriate alias, like home. Use simple aliases for other regions so that users can easily map configurations to the regions that they want (for example, region2).
Note:
Specific regions (us-phoenix-1, us-ashburn-1, and so on) are not hardcoded into either the region or alias fields.

Provision a Resource
To provision a resource in a region, specify the aliased provider name in the resource.

For example:

```
resource "oci_core_instance" "test_instance" {
  provider = oci.home
  ...
}
```

Modules and Multiple Regions
Typically, a module should use only a single region. If more regions are needed, you should use separate modules.

If the config contains multiple providers, the module should specify the provider to use by using the following format:

```
module "compartments" {
  source       = "../compartments"
  providers = {
    oci = "oci.home"
  }
}
```

Getting Started
This page helps you get started with Resource Manager by providing an end-to-end walkthrough of the tasks required to create and deploy an Oracle Cloud Infrastructure Compute instance using either a pre-built Terraform configuration or your own Terraform configuration. For a brief introduction to Resource Manager, see Overview of Resource Manager on page 4463.

Highlights
In addition to providing a pre-built Terraform configuration for creating a Compute instance, this walkthrough provides samples that demonstrate how to write a Terraform configuration. Whichever configuration you use (pre-built or your own), Resource Manager uses Terraform to provision the defined resources. The resources are organized into stacks, which you create and provision using jobs.

The walkthrough covers the following tasks:
- Select or create a Terraform configuration.
- Provision the infrastructure:
  - Create a stack in which to provision your infrastructure.
  - Run a plan job against your stack, which parses your configuration and creates an execution plan.
  - Review the generated execution plan.
  - Run an apply job against your stack, which provisions your resources. The apply job follows the execution plan, which is based on your Terraform configuration.
  - Review the resulting infrastructure.
- Optionally provision the infrastructure in more environments, using the same Terraform configuration.

Before You Begin
Ensure that you have installed, obtained, or created the prerequisites:
• An Oracle Cloud Infrastructure tenancy for each environment where you want to provision resources. For example, you might provision the resources defined in a Terraform configuration to development, staging, and production environments.

**Note:**

It is a best practice to locate each environment in its own tenancy.

• The **OCID** for the compartment where you wish to create your stack.

• A user account that includes the following:
  
  • An API signing key. For guidance, see **Required Keys and OCIDs** on page 5303.
  
  • Required IAM permissions. For more information, see **How Policies Work** on page 2800 and **Details for Resource Manager** on page 3033.

• If you want to use the Oracle Cloud Infrastructure CLI, install and configure the CLI first. See **Quickstart** on page 5320 and **Configuring the CLI** on page 5327

**Task 1a: Select a Pre-built Terraform Configuration**

You can select the Compute Instance template with its pre-built Terraform configuration instead of writing your own configuration. These steps guide you through the stack creation process.

1. Click the following link to launch the Create Stack page with the Compute Instance template already selected.

   ![Launch stack with Compute Instance template](https://example.com)

2. In the Create Stack page, enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.

3. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.

   A compartment from the list scope is set by default.

4. Click **Next**.

   The **Configure Variables** panel displays variables from the Terraform configuration.

5. Review the variables and make changes as necessary.

   **Important:**

   Do not add your private key or other confidential information to configuration variables.

6. Click **Next**.

7. In the **Review** panel, verify your stack configuration.

8. Click **Create** to create your stack.

   The stack detail page for the new stack appears.

   Congratulations! You have created a stack with the pre-built Terraform configuration from the Compute Instance template. The next step is to provision the infrastructure.

**Task 1b: Create Your Own Terraform Configuration**

If you didn't select a pre-built Terraform configuration, then follow these steps to write your own.

A Terraform configuration is a file that codifies your infrastructure. The configuration defines your Terraform provider, the resources you intend to provision, variables, and specific instructions for provisioning the resources.

This page guides you through selecting the Compute Instance template with its pre-built Terraform configuration or alternatively writing your own configuration using several .tf files within a .zip file.

For more information about writing configurations for use with Resource Manager, see **Terraform Configurations for Resource Manager** on page 4470 and **Terraform Configuration**.
Caution:
Do not provide user credentials or other confidential information in your Terraform configuration.

Create an Oracle Cloud Infrastructure Provider

The following code sample creates a basic Oracle Cloud Infrastructure Terraform provider. You can provide values as variables that are defined either in a variables file or in the provider definition (.tf) file. For more information, see Provider Configuration.

```terraform
provider "oci" {
  region = "${var.region}"
}
```

Define Variables

Define the variables you want to use when provisioning your resources. A best practice is to create a "variables" file in the configuration package that you upload. Following is an example from a configuration file that we've named variables.tf. For more information about using variables, see Input Variables. See also Configuring Input Variables.

```terraform
variable "compartment_ocid" {
  default = "ocid1.compartment.oc1..uniqueid"
}

variable "region" {
  default = "us-phoenix-1"
}

variable "InstanceImageOCID" {
  type = "map"
  default = {
    // See https://docs.cloud.oracle.com/images/
    // Platform image "Oracle-Linux-7.5-2018.10.16-0"
    "eu-frankfurt-1" = "ocid1.image.oc1.eu-frankfurt-1.aaaaaaaaaitzn6tdyjer7jl34h2ujz74jwy5nkbukbh55ekp6oyzwrtfa4zma"
    "uk-london-1" = "ocid1.image.oc1.uk-london-1.aaaaaaaa32voyikkzfxoyo4xbdmadc2dmvorfxgdpnk6dv64fa314jh7wa"
    "us-ashburn-1" = "ocid1.image.oc1.iad.aaaaaaaaageeenzyuxgia726xur4ztaoxbxylxogdhreu3ngfj2gji3bayda"
    "us-phoenix-1" = "ocid1.image.oc1.phx.aaaaaaaaaqj42sokao42176wsyhn3k2beunrth5maj3gmmezeyr55zzrwa"
  }
}

variable "ssh_public_key" {
  default = "ssh-rsa <public_key_value>"
}

# Defines the number of instances to deploy
variable "NumInstances" {
  default = "1"
}

variable "InstanceShape" {
  default = "VM.Standard2.1"
}

# Specifies the Availability Domain
```
For more information about variables declared in the preceding examples, see the following:

- **InstanceImageOCID**: Platform Images on page 943
- **InstanceShape**: Compute Shapes on page 973
- **region** and **localAD**: Regions and Availability Domains on page 208

### Define a Schema Document (Optional)

With a schema document, you can reuse one, unedited Terraform configuration in development, staging, and production environments. Resource Manager prompts you for variable values when you create a stack with a Terraform configuration that includes a schema document.

Schema documents are recommended for Terraform configurations when using Resource Manager. Including a schema document allows you to extend pages in the Oracle Cloud Infrastructure Console. Facilitate variable entry in the Create Stack page by surfacing SSH key controls and by naming, grouping, dynamically prepopulating values, and more. Define text in the Application Information tab of the stack detail page displayed for a created stack.

Following are contents of an example schema document (*schema.yaml*) that covers the basic details in this scenario.

**Note:**

To easily reuse this schema document, specify default values for each variable.

```yaml
locale: "en"

variableGroups:
  - title: "Destination"
    variables:
      - compartment_ocid
      - $(region)
      - $(localAD)
  - title: "Instance Details"
    variables:
      - ${numInstances}
      - ${instanceImageOCID}
      - ${instanceShape}
  - title: "SSH Public Key"
    variables:
      - ${ssh_public_key}

variables:
  compartment_ocid:
    type: oci:identity:compartment:id
    required: true
    title: Compartment OCID
  region:
    type: oci:identity:region:name
    required: true
    title: Region
  localAD:
    type: oci:identity:availabilitydomain:name
    required: true
    title: Availability Domain
    dependsOn:
      compartmentId: compartment_ocid
```
numInstances:
  type: integer
  required: true
  title: Number of Instances
  minimum: 1
  maximum: 10
  multipleOf: 1

instanceImageOCID:
  type: oci:core:image:id
  required: true
  title: Instance Image OCID
  dependsOn:
    compartmentId: compartment_ocid

instanceShape:
  type: oci:core:instanceshape:name
  required: true
  title: Instance Shape
  default: "VM.Standard.E2.1.Micro"
  dependsOn:
    compartmentId: compartment_ocid

ssh_public_key:
  type: oci:core:ssh:publickey
  required: true
  title: SSH Public Key

Create a Virtual Cloud Network (VCN)

The following code sample creates an Oracle Cloud Infrastructure virtual cloud network (VCN) named "ExampleVCN."

```hcl
resource "oci_core_virtual_network" "ExampleVCN" {
  cidr_block = "10.1.0.0/16"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFExampleVCN"
  dns_label = "tfexamplevcn"
}
```

Create a Subnet in Your VCN

The following code sample creates a subnet named "ExampleSubnet" in the VCN defined in the previous code sample.

```hcl
resource "oci_core_subnet" "ExampleSubnet" {
  availability_domain = "${var.localAD}"
  cidr_block = "10.1.20.0/24"
  display_name = "TFExampleSubnet"
  dns_label = "tfexamplesubnet"
  security_list_ids = ["${oci_core_virtual_network.ExampleVCN.default_security_list_id}"]
  compartment_id = "${var.compartment_ocid}"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
  route_table_id = "${oci_core_route_table.ExampleRT.id}"
  dhcp_options_id = "${oci_core_virtual_network.ExampleVCN.default_dhcp_options_id}"
}
```
Create an Internet Gateway

The following code sample creates an internet gateway named "ExampleIG" in the VCN that we created.

```terraform
resource "oci_core_internet_gateway" "ExampleIG" {
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFExampleIG"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
}
```

Create a Core Route Table

The following code sample creates a Oracle Cloud Infrastructure core route table in the VCN and then applies two route rules.

```terraform
resource "oci_core_route_table" "ExampleRT" {
  compartment_id = "${var.compartment_ocid}"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
  display_name = "TFExampleRouteTable"
  route_rules {
    cidr_block = "0.0.0.0/0"
    network_entity_id = "${oci_core_internet_gateway.ExampleIG.id}"  
  }
}
```

Create a Compute Instance

The following extended code example creates an Oracle Cloud Infrastructure Compute instance. The code also references the image on which the Compute instance is created, sets boot volume size, adds essential metadata, and applies both free-form and defined tags.

```terraform
resource "oci_core_instance" "TFInstance" {
  count = "${var.NumInstances}"  
  availability_domain = "${var.localAD}"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFInstance${count.index}"
  shape = "${var.InstanceShape}"
  create_vnic_details {
    subnet_id = "${oci_core_subnet.ExampleSubnet.id}"
    display_name = "primaryvnic"
    assign_public_ip = true
    hostname_label = "tfexampleinstance${count.index}"  
  }
  source_details {
    source_type = "image"
    source_id = "${var.InstanceImageOCID}"
    # Apply this to set the size of the boot volume that's created for this
    # Otherwise, the default boot volume size of the image is used.
    # This should only be specified when source_type is set to "image".
    #boot_volume_size_in_gbs = "60"
  }
  # Apply the following flag only if you wish to preserve the attached
  # Setting this and destroying the instance will result in a boot volume
  # When changing this value, make sure to run 'terraform apply' so that it
  #.before the resource is destroyed.
}
```
Finalize the Configuration

Ensure that all of the configuration files are in a single directory. You can store your Terraform configuration file locally or in a source code control system. For more information on storing your file in a source code control system, see Managing Configuration Source Providers on page 4544. Wherever your file is stored, you can select it when creating a stack using the CLI or Console.

**Important:**

Make sure your Terraform configuration file is valid. See Authoring Configurations on page 4471 and Terraform Configurations for Resource Manager on page 4470.

Task 2: Provision the Infrastructure

Use your Terraform configuration to build and deploy your infrastructure by taking the following actions:
1. If you created your own Terraform configuration, follow these steps to create a stack in a tenancy compartment of your choosing. (If you selected a pre-built configuration, skip this step.)

For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

A stack is a collection of resources that you can act on as a group. All of the resources that you specify in your configuration are provisioned in the stack that you create.

You can create a stack from a remote, versioned file in a source code control system or a locally accessed file that you upload.

To create a stack from your .zip file (Console)

a. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click Create Stack.

d. On the Create Stack page, select My Configuration.

You can either drag and drop your Terraform configuration .zip file onto the control or click Browse and navigate to the location of the .zip file. You can also store your configuration remotely.

The dialog box is populated with information contained in the configuration.

e. Enter a Name for the new stack (or accept the default name provided). Avoid entering confidential information.

f. Optionally enter a Description.

g. From the Create in Compartment drop-down, select the compartment where you want to create the stack.

A compartment from the list scope is set by default.

h. Click Next.

The Configure Variables panel displays variables from the selected Terraform configuration file.

i. Review the variables and make changes as necessary.

Important:

Do not add your private key or other confidential information to configuration variables.

j. Click Next.

k. In the Review panel, verify your stack configuration.

l. To automatically provision resources when the stack is created, select Run Apply.

m. Click Create to create your stack.

The stack detail page for the new stack appears.

If Run Apply was selected, then Resource Manager runs the Apply action on the new stack.

To create a stack from your .zip file (CLI)

Use the command related to your file location.

To create a stack from a remote, versioned file

Open a command prompt and run resource-manager stack create-from-git-provider to create a stack from a file tracked with a configuration source provider:

```
oci resource-manager stack create-from-git-provider --compartment-id <compartment_OCID> --config-source-configuration-source-provider-id <configuration_source_provider_OCID> --config-source-repository-url <repository_url> --config-source-branch-name <branch_name> --display-
```
Resource Manager

name "<friendly_name>" --description "<description>" --terraform-version "<version>" --variables <var_file_path> --working-directory "<directory>"

**Note:**
You can return later to update stack settings or add variables after you have created the stack.

For example:

```
oci resource-manager stack create-from-git-provider --compartment-id ocid1.tenancy.oc1..uniqueid --config-source-configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --config-source-repository-url https://github.com/user/repo.git --config-source-branch-name mybranch --display-name "My Stack from Git" --description "My Test" --variables file://variables.json --working-directory ""
```

For a complete list of flags and options available for CLI commands, see [CLI Help](#).

**To create a stack from your .zip file**

This section describes how to create a stack from an uploaded configuration file (.zip).

**Note:**
You can also create stacks from configuration files stored in source code control systems, such as Git, and from templates.

On Windows, be sure the .zip file and variables.json files are in the same directory from which you're running the CLI. The CLI currently has a limitation on Windows that prevents correct handling of the files if either one is in a subdirectory.

Open a command prompt and run `oci resource-manager stack create` to create a stack:

```
oci resource-manager stack create --compartment-id <compartment_OCID> --config-source <config_file_name> --variables <var_file_path> --display-
```
name "<friendly_name>" --description "<description>" --working-directory ""

Note:
You can return later to update stack settings or add variables after you have created the stack.

Options
For a complete list of flags and options available for CLI commands, see CLI Help.

- **--compartment-id** is the OCID of the compartment where you want to create the stack.
- **--config-source** is the name of a .zip file that contains one or more Terraform configuration files.
- **--variables** is the path to the file specifying input variables for your resources. Optional.

The Oracle Cloud Infrastructure Terraform provider requires additional parameters when running Terraform locally (unless you are using instance principals). For more information on using variables in Terraform, see [Input Variables](#). See also [Input Variable Configuration](#).

- **--display-name** is the friendly name for the new stack. Optional.
- **--description** is the description for the new stack. Optional.
- **--working-directory** is the root configuration file in the directory. Optional. If not specified, or if null as in this example, then the service assumes that the top-level file in the directory is the root configuration file.

For example:

```bash
oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --config-source vcn.zip --variables file://variables.json --display-name "My Example Stack" --description "My Tutorial to Create a VCN" --working-directory ""
```

Example response

```json
{
   "data": {
      "config-source": {
         "working-directory": null,
         "config-source-type": "ZIP_UPLOAD"
      },
      "defined-tags": {},
      "description": "My Tutorial to Create a VCN",
      "display-name": "My Example Stack",
      "freeform-tags": {},
      "id": "ocid1.ormstack.oc1..uniqueid",
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-04-03T18:26:56.299000+00:00",
      "variables": {
         "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
         "region": "us-phoenix-1"
      }
   }
}
```
2. Generate an execution plan.

The plan job parses your configuration to create an "execution plan," which is a step-by-step representation of the planned deployment in job log entries. Once the plan job has completed, you can evaluate the execution plan by viewing the job's log entries to confirm that it performs the expected operations, and in the intended sequence.

**Note:**

You can skip this step if you selected **Run Apply** when you created the stack. In this case, the resources have already been provisioned.

**To run a plan job (Console)**

a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
c. Click the name of the stack that you want to use.

The **Stack Details** page is displayed.
d. Click **Plan**.
e. (Optional) In the **Plan** panel, review the plan job **Name** and update it if needed.
f. In the **Plan** panel, click **Plan**.

The new plan job is listed under **Jobs**, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

**To run a plan job (CLI)**

Open a command prompt and run `oci resource-manager job create-plan-job` to run a plan job on the specified stack `(--display-name is optional):

```bash
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.

**To check the current state of the plan job**

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```bash
oci resource-manager job get --job-id <plan_job_OCID>
```

**Lifecycle states**

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

**Example response**

This example shows `ACCEPTED` for `lifecycle-state`.

```json
{
    "data": {
        "compartment-id": "ocid1.compartment.oc1..uniqueid",
```
3. Review the execution plan to confirm that it represents your intentions.

The execution plan is represented in the log for the plan job you ran previously.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can skip this step if you selected Run Apply when you created the stack. In this case, the resources have already been provisioned.</td>
</tr>
</tbody>
</table>

To review an execution plan (the log for the plan job) (Console)

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the Job Details page, under Resources, click Logs.

For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

You can also download the job information.

If changes are needed, update your stack to use a revised configuration and then rerun the plan job to obtain an updated execution plan.

To update the configuration for a stack

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure that your Terraform configuration file is valid. See Authoring Configurations on page 4471 and Terraform Configurations for Resource Manager on page 4470.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>These instructions don't apply to configurations stored in source code control systems. For Terraform configuration sources supported with</td>
</tr>
</tbody>
</table>
a. If you are only changing settings for a configuration source provider, or Object Storage bucket originally set up for this stack, then skip this step.

Otherwise, ensure you have your revised Terraform configuration (.zip file or folder) ready for upload.

To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration .zip file for the update.

b. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.

c. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.

d. Click the name of the stack that you want to update.

The Stack Details page is displayed.

e. In the Stack Information tab, next to Terraform Configuration File (.zip), click Upload New File.

f. In the Edit Stack dialog, do one of the following:

- Add your revised Terraform configuration.

  You can either drag and drop it onto the dialog's control or click Browse and navigate to the location of the file or folder.

- Change settings for the configuration source provider or Object Storage bucket originally set up for this stack.

The dialog box is populated with information contained in the Terraform configuration.

g. Click Next as needed.

h. To automatically provision resources when the stack is updated, select Run Apply.

The Run Apply option is displayed on the Review page. Click Review on the left to see it.

i. Click Save Changes.

The stack detail page for the edited stack appears.

If Run Apply was selected, then Resource Manager runs the Apply action on the updated stack.

Otherwise, consider running the Plan action on the updated stack, using your revised configuration.

To review an execution plan (the log for the plan job) (CLI)

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run oci resource-manager job get-job-logs:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run oci resource-manager job get-job-logs-content:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

If changes are needed, update your stack to use a revised configuration and then rerun the plan job to obtain an updated execution plan.
4. Provision your resources by running an apply job against the execution plan.

When satisfied with the execution plan, we're ready to do the work of provisioning the stack with the resources that we've defined. The apply job takes the execution plan and "applies" it to the stack. The result is a fully provisioned stack.

**Note:**
You can skip this step if you selected **Run Apply** when you created the stack. In this case, the resources have already been provisioned.

**To run an apply job (Console)**

- Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
- Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
- Click the name of the stack that you want to use. The **Stack Details** page is displayed.
- Click **Apply**.
- (Optional) In the **Apply** panel, review the apply job **Name** and other settings and update it if needed.
- In the **Apply** panel, click **Apply**.
- The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.
- To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under **Resources**.

**To run an apply job (CLI)**

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use **FROM_PLAN_JOB_ID**:

  ```shell
  oci resource-manager job create-apply-job --stack-id <stack OCID> --execution-plan-strategy FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job OCID> --display-name "Example Apply Job"
  ```

  Use this option to "apply" your confirmed execution plan to the stack, execute the instructions, and provision the stack with the specified resources.

- To automatically approve the apply job (no plan job specified), use **AUTO_APPROVED**:

  ```shell
  oci resource-manager job create-apply-job --stack-id <stack OCID> --execution-plan-strategy AUTO_APPROVED --display-name "Example Apply Job"
  ```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from **IN_PROGRESS** to **SUCCEEDED**.

**To check the current state of the apply job**

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```shell
oci resource-manager job get --job-id <apply_job OCID>
```

**Lifecycle states**

Possible values for **lifecycle-state**:

- **ACCEPTED**: The job is queued for execution.
• **IN_PROGRESS**: The job is running.
• **FAILED**: The job has failed and stopped running.
• **SUCCEEDED**: The job has completed successfully.
• **CANCELLING**: The job has been notified to cancel, but has not yet stopped running.
• **CANCELED**: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.
5. Review the log entries and state file for the apply job you just ran.
   • See the entries in the job log for more details about the job.

To view the job log (Console)

a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the **Job Details** page, under **Resources**, click **Logs**.
   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

   You can also download the job information.

To view the job log (CLI)

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

• The job state file represents the job's output in JSON format.

The state file maps your stack's resources to your configuration and also maintains essential configuration metadata, such as resource dependencies. Resource Manager generates and updates state files automatically when you run jobs.

The Resource Manager supports state locking by allowing only one job at a time to run on a given stack. For more information about state files, see Hashicorp: **State**.

To view the state of the job (Console)

a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the job you want.

d. On the **Job Details** page, click **View State** under **Resources**.

To view the state of the job (CLI)
Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

Example response for an apply job

```

                                    "update": 300000000000
                                }
                            }
                        },
                        "tainted": false
                    }
                }
            }
        },
        "serial": 4,
```
6. When you need to release the resources that you provisioned, run a destroy job on the stack.

A destroy job tears down the stack that you created and then cleans up associated resources without deleting them. For example, the destroy job terminates Compute instances associated with the stack.

**To run a destroy job (Console)**

```plaintext
Note:
You can also import state files for resources already managed by Terraform.
```

a. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the stack that you want to use.

The Stack Details page is displayed.

d. Click Destroy.

e. (Optional) In the Destroy panel, review the job Name and update it if needed. Avoid entering confidential information.

f. In the Destroy panel, click Destroy again to confirm your action.

You can monitor the status and review the results of a destroy job by viewing the state or the logs.

g. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the Job Details page, then click View State under Resources.

h. To view the logs for the job, click the name of the job to display the Job Details page, then click Logs under Resources.

```plaintext
Note:
You can recreate destroyed resources by running an apply job. Recreated resources have different OCIDs and other metadata.
```

**To run a destroy job (CLI)**

```plaintext
Note:
We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.
```

Data cannot be recovered from destroyed resources.
spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and clean up the resources provisioned by the specified stack:

```
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_APPROVED
```

To confirm deletion of the resources, inspect resources in the compartment.

**Task 3: Repeat in More Environments**

This section describes how to build and deploy infrastructure in multiple environments.

In this scenario, you use the same Terraform configuration .zip file to provision a Compute instance in your development, staging, and production environments.

**Note:**

This scenario assumes that the Terraform configuration includes a schema document, which allows you to change variable values when creating a stack in the Console.

1. Access the tenancy for the new environment where you want to provision the infrastructure defined in your Terraform configuration.

   For example, access the tenancy for your staging or production environment.

2. Open the **Create Stack** page:

   a. Open the navigation menu and click **Developer Services**, Under **Resource Manager**, click **Stacks**.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   c. Click **Create Stack**.

3. Using the same Terraform configuration as for the first environment, complete the **Stack Information** tab:

   a. On the **Create Stack** page, select **My Configuration**.
      
      You can either drag and drop your Terraform configuration .zip file onto the control or click **Browse** and navigate to the location of the .zip file.
   b. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.
   c. Optionally enter a **Description**.
   d. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
   e. Click **Next**.

   The **Configure Variables** panel displays variables from the selected Terraform configuration file.

4. Specify the variable values for this environment:

   a. In the **Configure Variables** panel, review the variables and make changes as necessary.
      
      Default values are provided when specified in the schema document.

      **Important:**

      Do not add your private key or other confidential information to configuration variables.

   b. Click **Next**.

5. In the **Review** panel, verify your stack configuration.
6. To automatically provision resources when the stack is created, select **Run Apply**.
7. Click **Create** to create your stack.

The stack detail page for the new stack appears.

If **Run Apply** was selected, then Resource Manager runs the Apply action on the new stack.

Congratulations, you have reused your Terraform configuration to create a stack in a new environment. If you selected **Run Apply**, then you also provisioned resources in the new environment.

You can now generate and review an execution plan (and provision resources, if **Run Apply** wasn't selected). To complete these items, repeat the steps from Task 2: Provision the Infrastructure on page 4495 in the new environment.

### Managing Stacks and Jobs

This topic describes how to create, edit, and delete stacks as well as work with jobs, including generating and applying execution plans. Drift detection is also covered in this topic.

#### Prerequisites

To create or update a stack, you must have a valid Terraform configuration file. See Terraform Configurations for Resource Manager on page 4470 and Authoring Configurations on page 4471.

#### Required IAM Policy

To manage stacks and jobs, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2806.</td>
</tr>
</tbody>
</table>

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies allow a group to work with stacks and jobs. For any policies, if you want to reduce the scope of access to a particular compartment, specify the compartment instead of the tenancy.

- The following example grants a specified group permission to manage both stacks and jobs in the tenancy, and also to manage Oracle Cloud Infrastructure resources on the tenancy stacks.

  ```
  Allow group <group_name> to manage orm-stacks in tenancy
  Allow group <group_name> to manage orm-jobs in tenancy
  ```

- In addition to granting users permission to act on resources, you can also explicitly prevent users from running destroy jobs. The following policy modifies the policy we just created so that it prohibits members of the specified group from running destroy jobs.

  ```
  Allow group <group_name> to use orm-stacks in tenancy
  Allow group <group_name> to read orm-jobs in tenancy
  ```
Allow group <group_name> to manage orm-jobs in tenancy where any
{target.job.operation = 'PLAN', target.job.operation = 'APPLY'}

In this policy statement, you must include the new permission to read orm-jobs because the third statement includes a condition that uses variables that are not relevant to listing or getting jobs.

For more details about stack permissions, see orm-stacks on page 3035. For more details about job permissions, see orm-jobs on page 3034.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Moving Resources to a Different Compartment

You can move stacks from one compartment to another. When you move a stack to a new compartment, its associated jobs move with it. After you move the stack to the new compartment, inherent policies apply immediately and affect access to the stack and associated jobs through the Console. For more information, see Managing Compartments on page 3126.

Using the Console

Managing Stacks (Console)

To create a stack

This section describes how to start from the Create Stack dialog when creating stacks. For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click Create Stack.
4. In the Create Stack dialog, under Choose the origin of the Terraform configuration, select the option you want.

   • **My Configuration:** Local folder, Object Storage bucket, or local .zip file.
     
     Under Stack Configuration, select the option corresponding to the location of your Terraform configuration:

     • **Folder:** Drag and drop a folder onto the dialog's control or click Browse and navigate to the location of the folder you want.
     
     • **Object Storage Bucket:** Select a bucket from the list.
       
       The list shows buckets in the indicated compartment. To choose another compartment, click Change Compartment.
       
     • **.Zip File:** Drag and drop a .zip file onto the dialog’s control or click Browse and navigate to the location of the .zip file you want.
     
     The dialog box is populated with information contained in the local Terraform configuration.

   • **Template:** Pre-built Terraform configuration (service, architecture, or private template).

     Under Stack Configuration, click Select Template and then select the template you want. Private templates are under the Private tab.

     The dialog box is populated with information contained in the Terraform configuration for the selected template.

   • **Source Code Control System:** Remote location using a configuration source provider.

     **Steps**

     a. Under Stack Configuration, select a Configuration Source Provider.

        If you need to create one, see To create a configuration source provider on page 4546.

     b. Select a Repository.

        Example: https://gitlab.com/example

     c. Select a Branch.

        The list returned is limited to 100 branches.

     d. (Optional) Specify a Working Directory for running Terraform.

        Example (one level): Directory

        Example (two levels): Directory/Subdirectory

        If not specified, the root directory is used.

     The dialog box is populated with information contained in the remote Terraform configuration.

   • **Existing Compartment:** Generate a Terraform configuration using resource discovery.

     **Steps**

     • Select the Compartment for Resource Discovery (the compartment containing the resources that you want to capture).

        A compartment from the list scope is set by default.

     • Select the Region for Resource Discovery (the region containing the resources that you want to capture).

     • To filter for specific services supported for resource discovery, select Selected and then select the services you want.

         **Note:**

         This setting cannot be changed when editing the stack later.

     The dialog box is populated with information about the specified compartment.

5. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.

6. Optionally enter a **Description**.
7. Enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.

8. Optionally enter a **Description**.

9. For **Create in Compartment**, select the compartment where you want to create the stack.

   A compartment from the list scope is set by default.

10. For **Terraform version**, select the version you want for the Terraform configuration.

11. Optionally apply tags to the stack.

   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

12. Click **Next**.

   The **Configure Variables** panel displays variables from the Terraform configuration.

   No variables are listed for the **Existing Compartment** stack origin because no Terraform configuration exists yet.

13. Review the variables and change as needed.

   **Important:**
   Do not add your private key or other confidential information to configuration variables.

14. Click **Next**.

15. In the **Review** panel, verify your stack configuration.

16. To automatically provision resources when the stack is created, select **Run Apply**.

   **Note:**
   **Run Apply** is selected by default for stacks created from the **Deploy to Oracle Cloud button** or from **Marketplace**.

17. Click **Create** to create your stack.

   The stack detail page for the new stack appears.

   If **Run Apply** was selected, then Resource Manager runs the Apply action on the new stack.

**Existing Compartment** stack origin: A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration file for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration. You can **recreate these resources in another compartment**.

To deploy the defined resources, run an apply job on your new stack.

**To begin stack creation from the Create Compute Instance page**

You can create a stack using the configuration you specify in the Create Compute Instance page available in the Console. Use the new stack to install, configure, and manage your Compute *instance* through the "infrastructure-as-code" model.

**Note:**
Before you start, view requirements for creating Compute instances. See **Required IAM Policy** on page 1024 and the prerequisites for **Creating a Linux Instance** on page 1026 or **Creating a Windows Instance** on page 1032.

1. Open the Create Compute Instance page:

   a. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.

   b. Click **Create Instance**.

2. Populate configuration fields to specify stack details. For example, select the image you want to use in your stack.
3. Click **Save as Stack**.
   The **Create Stack** dialog window appears. The "Compute Instance" stack origin is indicated at the top of the dialog window, along with any provided instance name.

4. In the **Create Stack** dialog window, do the following.
   a. Enter a **Name** for the new stack. Avoid entering confidential information.
      Example: My Compute Instance
   b. Optionally enter a **Description**.
   c. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
      A compartment from the list scope is set by default.
   d. Select a **Terraform Version**.
      
      **Note:**
      Terraform versions are not backward compatible.
   e. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
   f. Click **Next**.
      The **Configure Variables** panel displays variables from the selected Terraform configuration file.
   g. Review the variables and make changes as necessary.
      
      **Important:**
      Do not add your private key or other confidential information to configuration variables.
   h. Click **Next**.
   i. In the **Review** panel, verify your stack configuration.
   j. To automatically provision resources when the stack is created, select **Run Apply**.
   k. Click **Create** to create your stack.
      The stack detail page for the new stack appears.
      If **Run Apply** was selected, then Resource Manager runs the Apply action on the new stack.
      If **Run Apply** was not selected, then you can **manually run the Apply action** on the stack.

**To see how Terraform represents your resources**

Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
1. Capture existing infrastructure by creating a stack from that compartment.

   Key steps in the Create Stack dialog box:

   a. Under Choose the origin of the Terraform configuration, select Existing Compartment.

   b. Select the Compartment for Resource Discovery (the compartment containing the resources that you want to capture).

      A compartment from the list scope is set by default.

   c. Select the Region for Resource Discovery (the region containing the resources that you want to capture).

   d. To filter for specific services supported for resource discovery, select Selected and then select the services you want.

      Note: This setting cannot be changed when editing the stack later.

   e. Click Next twice, and then click Create to create your stack.

      The stack detail page for the new stack appears. A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration file for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click Download.

To recreate (clone) existing infrastructure in another compartment

1. Capture existing infrastructure by creating a stack from that compartment.

   The stack detail page for the new stack appears. A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click Download.

3. Edit the vars.tf file (variables in the downloaded Terraform configuration file) to specify the destination compartment_ocid and region.

   Example:

   ```
   variable "compartment_ocid" {
       default = "ocid1.compartment.oc1..uniqueid"
   }
   variable "region" {
       default = "us-phoenix-1"
   }
   ```

4. If the destination region has more or fewer availability domains than the source region, then edit the vars.tf file to specify the correct number of availability domains.

   For example, if you cloned from a region that has 3 availability domains and you want to recreate the infrastructure in a region that has only 1 availability domain, then remove the references to the second and third availability domains.

   Example showing 3 availability domains:

   ```
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
       compartment_id = var.compartment_ocid
       ad_number      = "1"
   }
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-2 {
       compartment_id = var.compartment_ocid
       ad_number      = "2"
   }
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-3 {
   ```
Resource Manager

```python
compartment_id = var.compartment_ocid
ad_number      = "3"
```

Example showing 1 availability domain:

```python
data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
    compartment_id = var.compartment_ocid
    ad_number      = "1"
}
```

5. Create a second stack using the edited configuration file.

   a. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   c. Click Create Stack.
   d. In the Create Stack dialog, click My Configuration.
   e. Add the downloaded Terraform configuration (.zip) file.

       You can leave other fields as is for now. For reference, see To create a stack on page 4509.
   f. For Terraform Version, select a version supported by resource discovery.

       Terraform versions supported: 0.12.x, 0.13.x
   g. Click Next to display the Configure Variables panel.
   h. Update the compartment_ocid variable to specify the destination compartment for the cloned resources.
   i. If you want to clone the resources to a different region, update the region variable.
   j. Click Next to display the Review panel.
   k. To automatically provision resources when the stack is created, select Run Apply.
   l. Click Create to create your stack.

       The stack detail page for the second stack appears.

       If Run Apply was selected, then Resource Manager runs the Apply action on the new stack.

       The resources are cloned in the specified compartment and region.

6. If you didn't select Run Apply for the new stack, then run Apply now (after optionally running Plan):

   a. (Optional) To confirm that the stack will create resources as expected, run a plan job.
   b. Clone resources: Run an apply job on the new stack.

       The resources are cloned in the specified compartment and region.

To view stacks

You can view stack names, descriptions, states, and time created. The detail page for a stack lists its drift status and allows you to view the latest drift detection report.

   1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
   2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   3. To display the detail page for a stack, click the stack's name.

To check the OCI Terraform provider version

Follow these instructions to verify the version of OCI Terraform provider used by Resource Manager in the current region.
1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Ensure that the region you want to use is selected. For example, select a dedicated commercial region.

4. Click the name of a stack. The **Stack Details** page is displayed.

5. Click **Plan**. The plan job automatically includes the version of OCI Terraform provider in its log.

   You can alternatively run an apply job, which also includes this version information in its log.

6. (Optional) In the **Plan** panel, review the plan job **Name** and update it if needed.

7. In the **Plan** panel, click **Plan**. The new plan job is listed under **Jobs**. When the job is complete, the **Job Details** page appears, with the log listed.

8. In the **Job Details** page, view the provider version listed in the job log.

   To access the job log from this page, click **Log** under **Resources**.

   Example provider version:

   ```text
   *provider.oci: version = "~> 4.23"
   ```

   **To download the stack's Terraform configuration file**

   The Terraform configuration file listed on the stack detail page is the same as the Terraform configuration file listed on the job detail page for the most recent successful job.

   **Note:**

   For stacks created using **source code control systems**, configuration files are not available for download until a job is successfully run on the stack.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack to display its detail page.

4. In the **Stack Information** tab, to the right of **Terraform Configuration File (.zip)**, click **Download**.

   **To detect drift for a stack or selected resources**

   You can detect drift for new stacks created from compartments or for stacks where the last job run was **Apply** or **Import State**. When detecting drift, you can specify all resources or selected resources.

   Drift is the difference between the actual, real-world state of your infrastructure and the stack's last executed configuration. For example, drift occurs when a team member adds a production tag to your resources, or when a resource is deleted.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. Go to More Actions and select Run Drift Detection.

Alternatively, in the Stack Information tab, click Run drift detection now.
5. In the Run Drift Detection panel, select the option you want.
   - All Resource Addresses: Detects drift for all resources in the stack.
   - Selected Resource Addresses: Detects drift for the specified resources in the stack.

You can select an address from the list or enter the address. Each resource is identified by a resource address, which is a string derived from the resource type and name specified in the stack's Terraform configuration plus an optional index. For example, the resource address for the fourth Compute instance with the name "test_instance" is `oci_core_instance.test_instance[3]` (resource type of `oci_core_instance`, a period as delimiter, resource name of `test_instance`, and index of 3 in brackets). For more details and examples of resource addresses, see the Terraform documentation at https://www.terraform.io/docs/internals/resource-addressing.html#examples.

6. Click Run Drift Detection.

A work request is started. When the work request is complete, the drift status appears in the Stack Information tab. See To view the latest drift detection report on page 4518.

To add unmanaged resources to a stack

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Some steps in this procedure use the Terraform CLI.</td>
</tr>
</tbody>
</table>

1. Gather information about the unmanaged resources that you want to add: Note their OCIDs.

Unmanaged resources are created outside Resource Manager.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can generate a Terraform configuration that lists all resources in a compartment. For instructions, see To see how Terraform represents your resources on page 4512.</td>
</tr>
</tbody>
</table>
2. Gather stack information
   a. In the Console, access the detail page for the stack that you want to add the resources to.
      1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
      2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
      3. Click the name of the stack to display its detail page.
   b. Confirm that currently managed resources are up to date: Generate a drift detection report.
      1. Go to More Actions and select Run Drift Detection.
      2. In the Run Drift Detection panel, select All Resource Addresses.
      3. Click Run Drift Detection.
         A work request is started. When the work request is complete, the drift status appears in the Stack Information tab.
         A panel lists the drift status of the specified resources defined by the stack. Resources are identified by resource names.
      5. To view details of drift status for a resource, click the down arrow.
         Expected and actual properties are listed.
      6. If differences between expected and actual properties are reported, make your resources match the properties of your Terraform configuration: run an apply job. In the Stack Details page, go to Terraform Actions and select Apply.
         You can alternatively address these differences when manually editing the Terraform configuration later.
   c. Download the stack's Terraform configuration file: In the Stack Information tab, to the right of Terraform Configuration File (.zip), click Download.
   d. Download the stack's state file:
      1. Go to the detail page for the most recent apply job: Click the job link under Jobs.
      2. On the job detail page, click Download Terraform State.
3. Update the state file using Terraform CLI
   a. Set up Terraform CLI on your local machine.
      For instructions, see Terraform CLI.
   b. On your local machine, go to Terraform CLI and navigate to the directory containing the downloaded Terraform configuration and state file.
   c. For each unmanaged resource previously identified, import the state file by running the terraform import command:

```
terraform import -state=<path_to_tfstate_file> -var-file="<path_to_credentials_file>" -var-file="<path_to_env_file>" <resource_name> <resource_ocid>
```

Example:

```
terraform import -state=example.tfstate -var-file="credentials.tfvars" -var-file="environments.tfvars"
```
module.operations oci_identity_compartment.move_compartment
ocid1.compartment.oc1..exampleid

For more information about this command, see Terraform Import CLI Command.

d. Refresh the state file by running the `terraform refresh` command:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>
| To refresh for a specific resource, use the refresh target –
| target=<resource>. |

For more information about this command, see Terraform Refresh CLI Command.

4. Manually update the downloaded Terraform configuration to include the unmanaged resource previously identified.

If any unresolved drift remains in the drift detection report, address those differences in your manual update.

5. Update the stack

a. Access the stack’s detail page again.

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.

b. Import the refreshed state file to the stack.

1. Go to Terraform Actions and select Import State.
2. In the Import State File dialog, add your Terraform state file, either by dragging and dropping it onto the dialog’s control, or by clicking Browse and navigating to the file location.
3. Click Import.

c. Upload the manually edited Terraform configuration to the stack.

1. In the Stack Information tab, next to Terraform Configuration File (.zip), click Upload New File.
2. In the Edit Stack dialog, add your revised Terraform configuration.
   
   You can either drag and drop it onto the dialog’s control or click Browse and navigate to the location of the file or folder.
3. Click Next as needed and then click Save Changes.

6. Confirm that infrastructure is up to date

a. Go to Terraform Actions and select Plan.

b. In the Plan dialog, review the plan job Name and update it if needed.

c. Click Plan.

The new plan job is listed under Jobs, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, view the job log to confirm no changes.

Example of a job log reporting no changes:

```
No changes. Infrastructure is up-to-date.
This means that Terraform did not detect any differences between your configuration and real physical resources that exist. As a result, no actions need to be performed.
```

Congratulations! You have successfully added previously unmanaged resources to the stack. The added resources are now managed by Resource Manager.

To view the latest drift detection report

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. Go to More Actions and select **View Drift Detection Report**.

Alternatively, in the **Stack Information** tab, click **View drift detection report**.

A panel lists the drift status of the specified resources defined by the stack. Resources are identified by resource names.

5. To view details of drift status for a resource, click the down arrow.

   Expected and actual properties are listed.

6. (Optional) To make your resources match the properties of your Terraform configuration, run an apply job: In the **Stack Details** page, click **Apply**.

**To view an old drift detection report**

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. Click **Work Requests**.
5. Click the work request for the drift detection report you want.
6. In the **Work Requests Information** tab, click **View Drift Detection Report**.

   A panel lists the drift status of the specified resources defined by the stack at the time the drift detection was detected. Resources are identified by resource names.

7. To view details of drift status for a resource, click the down arrow.

   Expected and actual properties are listed.

To view the latest drift detection report, see **To view the latest drift detection report** on page 4518. To detect drift again, see **To detect drift for a stack or selected resources** on page 4515.

**To edit a stack**

You can edit stacks. When editing a stack, you can upload a different configuration and change its name, description, and variables.

**Note:**

If your configuration is stored in a source code control system, such as GitLab, then commit your changes there. The most recent commit is used when you run jobs on the stack.

If your configuration is stored in a bucket, you cannot change the bucket in your existing stack, but you can change the contents of the bucket. The most recent contents of the bucket are used when you run jobs on the stack.

No configuration file is available for download until a job is successfully run on the stack.

For Terraform configuration sources supported with Resource Manager, see **Where to Store Your Terraform Configurations** on page 4471.

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), and then select **Edit**.

   You can also edit a stack from its detail page. Click the name of the stack to display its detail page and then click **Edit**.
4. In the **Edit Stack** dialog box, change the properties you want. For origin-specific configuration, see the origin step in **To create a stack**.

**Note:**
The stack's Terraform version cannot be changed. For a stack that specifies an Object Storage bucket, the bucket and compartment cannot be changed.

- To edit the values assigned to variables in a stack, click **Configure Variables**.
  
  You can also edit variables from a stack's detail page. Click the name of the stack to display the **Stack Details** page, click **Variables** (under **Resources**) and then click **Edit Variables**.

**Important:**
Do not add your private key or other confidential information to configuration variables.

- To automatically provision resources when the stack is updated, select **Run Apply**.

  The **Run Apply** option is displayed on the **Review** page. Click **Review** on the left to see it.

5. Click **Save Changes**.

  The stack detail page for the edited stack appears.

  If **Run Apply** was selected, then Resource Manager runs the Apply action on the updated stack.

**To view the state of a stack**

Download the state file corresponding to the most recently run job for the stack.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack to display its detail page.
4. Go to **More Actions** and select **Download Terraform State**.

**To manage tags for a stack**

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack you want.

  The **Stack Details** page lists the details about the selected job.
4. Click **Tags** to view or edit existing tags, or click **Add Tags** to add new ones.

**To move a stack to a different compartment**

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), and then select **Move Stack**.

  You can also move a stack from its detail page. Click the name of the stack to display the **Stack Details** and then click **Move Stack**.
4. In the **Move Resource To A Different Compartment** dialog box, select the compartment that you want to move the stack to.

5. Click **Move Resource**.

**To delete a stack**

**Note:**

Associated resources persist after stack deletion. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), select **Delete**, and confirm the operation when prompted.

**Note:**

You cannot undo the delete stack operation.

You can also delete a stack from its detail page. Click the name of the stack to display the **Stack Details** page, go to **More Actions**, and then select **Delete Stack**.

**Managing Jobs (Console)**

**To view jobs and job details**

You can view name, type, status, and other key information about jobs for a given compartment or stack. You can view name, type, status, and other key information about a given job. You can also access the job's execution plan (represented by the job log), Terraform configuration, and Terraform state, as well as view the variables used in the job.

For configurations stored in a source code control system, such as GitHub or GitLab, job details include the relevant commit identifier.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Jobs**.
2. Choose a compartment you have permission to work in (on the left side of the page). Click **Stacks** and then click the name of the stack you want.
3. To view job details, click the name of the job you want.

    The **Job Details** page lists the details about the selected job.

4. To view variables used in the job, click **Variables** under **Resources**.

**To manage tags for a job**

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Jobs**.
2. Choose a compartment you have permission to work in (on the left side of the page). Click **Stacks** and then click the name of the stack you want.
3. Click the name of the job you want.
   The Job Details page lists the details about the selected job.
4. Click Tags to view or edit existing tags, or click Add Tags to add new ones.

To generate an execution plan (run a plan job)

Running a plan job parses your Terraform configuration and converts it into an execution plan listing resources and actions that will result when an apply job is run. For configurations stored in a source code control system, such as GitHub or GitLab, the job uses the most recent commit. We recommend generating an execution plan before running an apply job.

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.
   The Stack Details page is displayed.
4. Click Plan.
5. (Optional) In the Plan panel, review the plan job Name and update it if needed.
6. In the Plan panel, click Plan.

   The new plan job is listed under Jobs, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

To view the job log

   You can also access jobs from a stack detail page. Click Stacks and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the plan job that you ran.
4. On the Job Details page, under Resources, click Logs.
   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.
   You can also download the job information.

To update the configuration for a stack

**Important:**

Ensure that your Terraform configuration file is valid. See Authoring Configurations on page 4471 and Terraform Configurations for Resource Manager on page 4470.

**Note:**

If your configuration is stored in a source code control system, such as GitHub or GitLab, then commit your changes there. The most recent commit is used when you run jobs on the stack.

If your configuration is stored in a bucket, you cannot change the bucket in your existing stack, but you can change the contents of the bucket. The most recent contents of the bucket are used when you run jobs on the stack.

For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.
1. If you are only changing settings for a configuration source provider, or Object Storage bucket originally set up for this stack, then skip this step.

   Otherwise, ensure you have your revised Terraform configuration (.zip file or folder) ready for upload.

   To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration .zip file for the update.

2. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.

3. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

4. Click the name of the stack that you want to update.

   The Stack Details page is displayed.

5. In the Stack Information tab, next to Terraform Configuration File (.zip), click Upload New File.

6. In the Edit Stack dialog, do one of the following:

   • Add your revised Terraform configuration.

     You can either drag and drop it onto the dialog's control or click Browse and navigate to the location of the file or folder.

   • Change settings for the configuration source provider or Object Storage bucket originally set up for this stack.

     The dialog box is populated with information contained in the Terraform configuration.

7. Click Next as needed.

8. To automatically provision resources when the stack is updated, select Run Apply.

   The Run Apply option is displayed on the Review page. Click Review on the left to see it.

9. Click Save Changes.

   The stack detail page for the edited stack appears.

   If Run Apply was selected, then Resource Manager runs the Apply action on the updated stack.

   Otherwise, consider running the Plan action on the updated stack, using your revised configuration.

To download job information

You can download files associated with jobs: Terraform configurations, Terraform states, and logs.

   You can also access jobs from a stack detail page. Click Stacks and then click the name of the stack you want.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the job you want.

   The Job Details page appears.

   You can view the log by clicking Logs under Resources.

   You can view the state of your resources (for relevant jobs) by clicking View State under Resources.

4. Download the job information you want:

<table>
<thead>
<tr>
<th>To download this job-associated file</th>
<th>Click</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform configuration (.zip file)</td>
<td>Download Terraform Configuration</td>
</tr>
<tr>
<td>Terraform state (.json file)</td>
<td>Download Terraform State</td>
</tr>
<tr>
<td>Logs (.txt file)</td>
<td>Download Logs (Logs section under Resources)</td>
</tr>
</tbody>
</table>

To run an apply job

When you run an apply job for a stack, Terraform creates the resources and executes the actions defined in your Terraform configuration. For configurations stored in a source code control system, such as GitHub or GitLab, the job
uses the most recent commit. The time required to complete an apply job depends on the number and type of cloud resources to be created.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.

   The **Stack Details** page is displayed.

4. Click **Apply**.
5. (Optional) In the **Apply** panel, review the apply job **Name** and other settings and update it if needed.
6. In the **Apply** panel, click **Apply**.

   The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can [download its log file](#).
7. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under **Resources**.

### To view the state of a job

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Jobs**.

   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the job you want.
4. On the **Job Details** page, click **View State** under **Resources**.

### To import an existing Terraform state file (run an import job)

You can import state files for existing resources already managed by Terraform.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.

   The **Stack Details** page appears.
4. Go to **More Actions** and select **Import State**.
5. (Optional) In the **Import** panel, review the job **Name** and update it if needed. Avoid entering confidential information.
6. In the **Import** panel, add your Terraform state file, either by dragging and dropping it onto the dialog's control, or by clicking **Browse** and navigating to the file location.
7. Click **Import**.

### To release a stack's resources (run a destroy job)

Run a destroy job to tear down the resources and clean up the tenancy.

#### Note:

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Data cannot be recovered from destroyed resources.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the stack that you want to use.

The **Stack Details** page is displayed.

4. Click **Destroy**.

5. (Optional) In the **Destroy** panel, review the job **Name** and update it if needed. Avoid entering confidential information.

6. In the **Destroy** panel, click **Destroy** again to confirm your action.

You can monitor the status and review the results of a destroy job by viewing the state or the logs.

7. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the **Job Details** page, then click **View State** under **Resources**.

8. To view the logs for the job, click the name of the job to display the **Job Details** page, then click **Logs** under **Resources**.

**Note:**

You can recreate destroyed resources by **running an apply job**. Recreated resources have different OCIDs and other metadata.

To recreate a stack's destroyed resources

Use this procedure to recreate a stack's resources after the resources are destroyed. The new resources differ from previously destroyed resources by their unique OCIDs.

**Note:**

Data cannot be recovered from destroyed resources.

- Run an apply job.

**Using the CLI**

This section provides basic sample CLI commands for managing stacks and jobs. For information about using the CLI, see **Command Line Interface (CLI)** on page 5316. For a complete list of flags and options available for CLI commands, see **CLI Help**.

For a walk-through using CLI for cloud provisioning in a CI/CD pipeline, see **IaC in the Cloud: Integrating Terraform and Resource Manager into your CI/CD Pipeline - Building With the OCI CLI**.

**Managing Stacks (CLI)**

*To create a stack from a file (CLI)*

Use the command related to your file location. For Terraform configuration sources supported with Resource Manager, see **Where to Store Your Terraform Configurations** on page 4471.

**Important:**

Ensure your Terraform configuration file is valid. See **Authoring Configurations** on page 4471 and **Terraform Configurations for Resource Manager** on page 4470.

To create a stack from a file hosted on a source code control system

Open a command prompt and run `resource-manager stack create-from-git-provider` to create a stack from a file tracked with a configuration source provider:

```
oci resource-manager stack create-from-git-provider --compartment-id <compartment_OCID> --config-source-configuration-source-provider-id <configuration_source_provider_OCID> --config-source-repository-url <repository_url> --config-source-branch-name <branch_name> --display-
```
For example:

```bash
oci resource-manager stack create-from-git-provider --compartment-id ocid1.tenancy.oc1..uniqueid --config-source-configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --config-source-repository-url https://github.com/user/repo.git --config-source-branch-name mybranch --display-name "My Stack from Git" --description "My Test" --variables file://variables.json --working-directory ""
```

For a complete list of flags and options available for CLI commands, see CLI Help.

To create a stack from an uploaded file

This section describes how to create a stack from an uploaded configuration file (.zip).

```
obc resource-manager stack create --compartment-id <compartment_OCID> --config-source <config_file_name> --variables <var_file_path> --display-name "<friendly_name>" --description "<description>" --working-directory ""
```

Options

For a complete list of flags and options available for CLI commands, see CLI Help.

- `--compartment-id` is the OCID of the compartment where you want to create the stack.
- `--config-source` is the name of a .zip file that contains one or more Terraform configuration files.
- `--variables` is the path to the file specifying input variables for your resources. Optional.

The Oracle Cloud Infrastructure Terraform provider requires additional parameters when running Terraform locally (unless you are using instance principals). For more information on using variables in Terraform, see Input Variables. See also Input Variable Configuration.

- `--display-name` is the friendly name for the new stack. Optional.
- `--description` is the description for the new stack. Optional.
- `--working-directory` is the root configuration file in the directory. Optional. If not specified, or if null as in this example, then the service assumes that the top-level file in the directory is the root configuration file.

For example:

```bash
oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --config-source vcn.zip --variables file://
```
variables.json --display-name "My Example Stack" --description "My Tutorial to Create a VCN" --working-directory ""

Example response

```
{
  "data": {
    "config-source": {
      "working-directory": null,
      "config-source-type": "ZIP_UPLOAD"
    },
    "defined-tags": {},
    "description": "My Tutorial to Create a VCN",
    "display-name": "My Example Stack",
    "freeform-tags": {},
    "id": "ocid1.ormstack.oc1..uniqueid",
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-04-03T18:26:56.299000+00:00",
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To create a stack from a Terraform configuration in an Object Storage bucket

Open a command prompt and run `resource-manager stack create-from-object-storage` to create a stack from a Terraform configuration stored in an Object Storage bucket:

```
oci resource-manager stack create-from-object-storage --compartment-id <compartment_OCID> --config-source-namespace <bucket_namespace> --config-source-bucket-name <bucket_name> --config-source-region <bucket_region> --display-name "<friendly_name>" --description "<description>" --variables <var_file_path>
```

**Note:**

You can return later to update stack settings or add variables after you have created the stack.

For a complete list of flags and options available for CLI commands, see [CLI Help](#).

For example:

```
oci resource-manager stack create-from-object-storage
--compartment-id ocid1.tenancy.oc1..uniqueid
--config-source-namespace MyNamespace
--config-source-bucket-name MyBucket
--config-source-region PHX
--display-name "My Stack from Object Storage"
--description "My Test"
--variables file://variables.json
```

**To copy a stack**

Open a command prompt and run `oci resource-manager stack copy` to copy a stack to another compartment:

```
oci resource-manager stack copy --stack-id <stack_OCID> --destination-compartment-id <compartment_OCID> --destination-region <region>
```

Oracle Cloud Infrastructure User Guide 4527
Use options to specify the following fields of the copied stack:

- destination compartment
- destination region

**Note:**

Any configuration source provider used by the stack is copied to the specified destination region and the source compartment.

- display name (default when not specified: `copy-from-<source_region>-<originalStackDisplayName>`)  
- description  
- variables (existing variable values are retained unless explicitly overwritten)  
- tags, free-form and defined (existing tag values are retained unless explicitly overwritten)  
- access token for the stack's configuration source provider (required when copying to a different region)

For a complete list of flags and options available for CLI commands, see [CLI Help](#).

### Examples

**Create a copy of a stack in the current compartment and region**

```bash
oci resource-manager stack copy --stack-id <stack_OCID>
```

**Copy a stack to a different compartment**

```bash
oci resource-manager stack copy --stack-id <stack_OCID> --destination-compartment-id <compartment_OCID>
```

**Copy a stack that uses CI/CD to a different region**

In this example, the stack uses a configuration source provider specifying GitHub, which helps achieve continuous integration and continuous delivery (CI/CD). The GitHub access token is required when copying a stack to another region.

```bash
oci resource-manager stack copy --stack-id <stack_OCID> --destination-region <region> --access-token <token>
```

**To discover resources (create a stack from a compartment)**

Open a command prompt and run `oci resource-manager stack create-from-compartment` to create a stack from the specified compartment and region:

```bash
oci resource-manager stack create-from-compartment --config-source-compartment-id <source_compartment_OCID> --config-source-region <source_region> --config-source-services-to-discover [<services>] --compartment-id <compartment_OCID> --terraform-version <version> --display-name "<friendly_name>" --description "<description>"
```

For example (discovers supported resources from the core and database services; the source compartment is not a root compartment):

```bash
oci resource-manager stack create-from-compartment --config-source-compartment-id ocid1.tenancy.oc1..uniqueid1 --config-source-region PHX --config-source-services-to-discover [core, database] --compartment-id
Example response

```json
{
  "data": {
    "config-source": {
      "config-source-type": "COMPARTMENT_CONFIG_SOURCE"
    },
    "defined-tags": {},
    "display-name": "Stack from Compartment ABC",
    "freeform-tags": {},
    "id": "ocid1.ormstack.oc1..uniqueid",
    "lifecycle-state": "CREATING",
    "time-created": "2019-04-03T18:26:56.299000+00:00",
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid1",
      "region": "us-phoenix-1"
    }
  }
}
```

```json
{
  "data": {
    "compartment-id": "ocid1.compartment.oc1..uniqueid2",
    "config-source": {
      "compartment-id": "ocid1.compartment.oc1..uniqueid1",
      "config-source-type": "COMPARTMENT_CONFIG_SOURCE",
      "region": "PHX",
      "working-directory": null
    },
    "defined-tags": {},
    "description": "List of Resources to Duplicate",
    "display-name": "Stack From Compartment ABC",
    "freeform-tags": {},
    "id": "ocid1.ormstack.oc1.phx.uniqueid",
    "lifecycle-state": "CREATING",
    "stack-drift-status": "NOT_CHECKED",
    "terraform-version": "0.12.x",
    "time-created": "2020-06-01T18:25:56.102000+00:00",
    "time-drift-last-checked": null,
    "variables": {},
    "etag": "009010cb57f5162655c6a34f5ef8834f204a734df81e4bbaa696a7d830488ea25",
    "opc-work-request-id": "ocid1.ormworkrequest.oc1.phx.uniqueid"
  }
}
```

To list resources for discovery

This section describes how to determine which services are supported for resource discovery from a given compartment OCID.

When you create a stack from a compartment, the stack represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.
Open a command prompt and run `oci resource-manager stack list-resource-discovery-services --compartment-id <compartment_OCID>` to retrieve a list of services supported for resource discovery (the compartment OCID is used for authorization only):

```
oci resource-manager stack list-resource-discovery-services --compartment-id <compartment_OCID>
```

**To list stacks in a compartment**

Open a command prompt and run `oci resource-manager stack list --compartment-id <compartment_OCID>` to list the stacks in a compartment:

```
oci resource-manager stack list --compartment-id <compartment_OCID>
```

**To list full details of a stack**

Open a command prompt and run `oci resource-manager stack get --stack-id <stack_OCID>` to list the details for the specified stack:

```
oci resource-manager stack get --stack-id <stack_OCID>
```

**To detect drift for a stack**

Open a command prompt and run `oci resource-manager stack detect-drift --stack-id <stack_OCID>` to detect drift for the specified stack:

```
oci resource-manager stack detect-drift --stack-id <stack_OCID>
```

**To list resource details in the stack's last drift detection report**

Open a command prompt and run `oci resource-manager stack list-resource-drift-details --stack-id <stack_OCID>` to list the resource details for the last drift detection report of a specified stack:

```
oci resource-manager stack list-resource-drift-details --stack-id <stack_OCID>
```

**To delete a stack**

```
oci resource-manager stack delete --stack-id <stack_OCID>
```

**Managing Jobs (CLI)**

**To generate an execution plan (run a plan job)**

Open a command prompt and run `oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"` to run a plan job on the specified stack (`--display-name` is optional):

```
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.
To check the current state of the plan job

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <plan_job_OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- **ACCEPTED**: The job is queued for execution.
- **IN_PROGRESS**: The job is running.
- **FAILED**: The job has failed and stopped running.
- **SUCCEEDED**: The job has completed successfully.
- **CANCELING**: The job has been notified to cancel, but has not yet stopped running.
- **CANCELED**: The job was canceled and has stopped running.

Example response

This example shows **ACCEPTED** for `lifecycle-state`.

```json
{
  "data":
  {
    "compartment-id": "ocid1.compartment.oc1..uniqueid",
    "defined-tags": null,
    "display-name": "Example Plan Job",
    "freeform-tags": {},
    "id": "ocid1.ormjob.oc1..uniqueid",
    "lifecycle-state": "ACCEPTED",
    "operation": "PLAN",
    "jobOperationDetails":
    {
      "operation": "PLAN"
    },
    "stack-id": "ocid1.ormstack.oc1..uniqueid",
    "time-created": "2019-03-09T20:52:13.922000+00:00",
    "time-finished": null,
    "variables":
    {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To review an execution plan (view the log for a plan job)

Review the execution plan to ensure that it accurately reflects your intentions. View the log file and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

Open a command prompt and run `oci resource-manager job get-job-logs` to view the log file for the specified job:

```
oci resource-manager job get-job-logs --job-id <plan_job_OCID>
```

If you see problems or errors and wish to make changes, then update the appropriate configuration file (.tf file), update the stack to use the revised configuration, generate a new execution plan, and then review the new execution plan.

Example response
The command returns JSON objects that describe log entries. Each object has a message member with a property that displays one line of the execution plan. In the example shown below, the plan creates a single virtual cloud network (VCN); the remaining members show details about the VCN.

```json
...
{
  "level": "INFO",
  "message": "Terraform will perform the following actions:",
  "timestamp": "2018-05-24T00:57:14.170000+00:00",
  "type": "TERRAFORM_CONSOLE"
},
{
  "level": "INFO",
  "message": "",
  "timestamp": "2018-05-24T00:57:14.170000+00:00",
  "type": "TERRAFORM_CONSOLE"
},
{
  "level": "INFO",
  "message": "oci_core_virtual_network.vcn1",
  "timestamp": "2018-05-24T00:57:14.170000+00:00",
  "type": "TERRAFORM_CONSOLE"
},
{

},
...
To update an execution plan (update an uploaded configuration for a stack)

Note:
These instructions don't apply to configurations stored in source code control systems. For Terraform configuration sources supported with Resource Manager, see Where to Store Your Terraform Configurations on page 4471.

To edit a Terraform configuration that was generated from a template or existing compartment using resource discovery, first download the configuration. Then use the edited configuration .zip file for the update.

Open a command prompt and run `oci resource-manager stack update` with the option `--config-source` to update the Terraform configuration for the specified stack:

```bash
oci resource-manager stack update --stack-id <stack OCID> --config-source <config_file_name>
```

After updating the stack, regenerate and review an execution plan (run a new plan job and then view the log file).

To run an apply job

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use `FROM_PLAN_JOB_ID`:

  ```bash
  oci resource-manager job create-apply-job --stack-id <stack OCID> 
  --execution-plan-strategy FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job OCID> --display-name "Example Apply Job"
  ```

  Use this option to "apply" your confirmed execution plan to the stack, execute the instructions, and provision the stack with the specified resources.

- To automatically approve the apply job (no plan job specified), use `AUTO_APPROVED`:

  ```bash
  oci resource-manager job create-apply-job --stack-id <stack OCID> 
  --execution-plan-strategy AUTO_APPROVED --display-name "Example Apply Job"
  ```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from `IN_PROGRESS` to `SUCCEEDED`.

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```bash
oci resource-manager job get --job-id <apply_job OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.
To download or view job information

You can download Terraform configurations and Terraform states associated with jobs. You can also view logs associated with jobs.

For configurations stored in a source code control system, such as GitLab, job details include the relevant commit identifier.

To download the configuration for a job

Open a command prompt and run `oci resource-manager job get-job-tf-config` to download the Terraform configuration of the specified job to the specified file:

```
oci resource-manager job get-job-tf-config --job-id <job_OCID> --file <output_file_name>
```

To download the state file for a job

Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

Example response for an apply job

```

```

Oracle Cloud Infrastructure User Guide 4534
To view the log for a job

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```bash
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```bash
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

To import an existing Terraform state file (run an import job)

Open a command prompt and run `oci resource-manager x` to import an existing state file for resources already managed by Terraform:

```bash
oci resource-manager job create-import-tf-state-job --stack-id stack_id --tf-state-file state_file
```

To inspect resources in a compartment

Inspecting resources in a compartment allows you to confirm existence of a resource that you provisioned (by running an apply job) or absence of a resource that you released (by running a destroy job).

Open a command prompt and run the CLI command corresponding to the resources you want to inspect.

For example, run `oci network vcn list` to inspect VCN resources in the specified compartment:

```bash
oci network vcn list --compartment-id <compartment_OCID>
```

To release a stack’s resources (run a destroy job)

**Note:**

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple...
To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job. Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and clean up the resources provisioned by the specified stack:

```
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_APPROVED
```

To confirm deletion of the resources, inspect resources in the compartment.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage stacks:

- `ChangeStackCompartment`
- `CreateStack`
- `DeleteStack`
- `DetectStackDrift`
- `GetStack`
- `GetStackTfConfig`
- `GetStackTfState`
- `ListResourceDiscoveryServices`
- `ListStackResourceDriftDetails`
- `ListStacks`
- `ListTerraformVersions`
- `UpdateStack`

Use these API operations to manage jobs:

- `CancelJob`
- `CreateJob`
- `GetJob`
- `GetJobLogs`
- `GetJobLogsContent`
- `GetJobTfConfig`
- `GetJobTfState`
- `ListJobs`
- `UpdateJob`

Use these API operations to manage work requests:

- `GetWorkRequest`
- `ListWorkRequestErrors`
- `ListWorkRequestLogs`
- `ListWorkRequests`

**Upgrading Stacks from 0.11 to 0.12**

This page describes how to upgrade Resource Manager stacks from Terraform version 0.11 to 0.12.

The instructions involve confirming that the 0.11 stack is up to date and storing the stack information, upgrading the Terraform configuration, creating the 0.12 stack from the upgraded configuration, checking the 0.12 stack for issues, and finally renaming the 0.11 stack to indicate that it is no longer in use. Upgrading the Terraform configuration is completed through the command line; all other tasks are completed using the Oracle Cloud Infrastructure Console.
Resource Manager

Note:
These instructions are not applicable to Resource Manager stacks created through Marketplace.

Prerequisites
To successfully upgrade your stack, you must have the following:

- A MacOS, Linux, or Windows computer for running command line tools.
- Software to create and unpack .zip archives, such as 7-ZIP.
- IAM policies to manage stacks and jobs.

Task 1: Confirm that the 0.11 stack is up to date

1. Open the Stack Details page for the 0.11 stack:
   a. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
   b. Under List Scope, choose the Compartment that contains the 0.11 stack.
   c. Click the name of the 0.11 stack.
2. Confirm that this stack is using 0.11.x: In the Stack Details page, under Stack Information, review the Terraform version.
3. Check for pending changes:
   a. Click Plan.
      When the action completes, the Job Details page is displayed for the related job.
   b. In the Job Details page, in the Logs tab, review the log for the completed plan action.
      The log contents indicate whether the stack is up to date or has pending changes.
      Example for a stack that is up to date (no pending changes):
      No changes. Infrastructure is up-to-date.
4. If the log contents indicate pending changes, then apply pending changes:
   a. Click Stack Details to go back to the Stack Details page.
   b. Click Apply.
      When the action completes, the Job Details page is displayed for the related job.
   c. Confirm that the apply action was successful: In the Job Details page, in the Logs tab, review the log for the completed apply action.

When the 0.11 stack is up to date, you can proceed to the next task for storing the stack information.

Task 2: Store current 0.11 stack information

1. On a computer that can run command line tools, create a folder to store the 0.11 stack information.
   Example folder name: c:\StackUpgrade
   Use this folder for storing the information gathered in the following steps.
2. Open the Stack Details page for the 0.11 stack:
   a. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
   b. Under List Scope, choose the Compartment that contains the 0.11 stack.
   c. Click the name of the 0.11 stack.
3. In the Stack Details page, download the Terraform configuration: In the Stack Information tab, to the right of Terraform Configuration File (.zip), click Download.
4. Download the Terraform state file: Go to More Actions and select Download Terraform State.
5. Make a note of the stack variables: Click Variables and then use the copy and paste actions available from the browser.
6. Make a note of the stack tags: Click Tags and then use the copy and paste actions available from the browser.
7. Make a note of the region where the 0.11 stack exists.

   Use this region later to create the 0.12 stack.

When all 0.11 stack information is stored, you can proceed to the next task for upgrading the Terraform configuration.

**Task 3: Upgrade the Terraform configuration from 0.11 to 0.12**

This task provides customized steps for upgrading a Terraform configuration used with Resource Manager from 0.11 to 0.12. For general information on upgrading to 0.12, see [https://www.terraform.io/upgrade-guides/0-12.html](https://www.terraform.io/upgrade-guides/0-12.html).

1. On the same computer that you used to store 0.11 stack information, download the .zip files needed to upgrade your Terraform configuration:
   - From [https://releases.hashicorp.com/terraform/0.11.15-oci/](https://releases.hashicorp.com/terraform/0.11.15-oci/), download the .zip file for your operating system. For example, for Mac, download the Darwin version: [https://releases.hashicorp.com/terraform/0.11.15-oci/terraform_0.11.15-oci_darwin_amd64.zip](https://releases.hashicorp.com/terraform/0.11.15-oci/terraform_0.11.15-oci_darwin_amd64.zip).
   - From [https://releases.hashicorp.com/terraform/0.12.29/](https://releases.hashicorp.com/terraform/0.12.29/), download the .zip file for your operating system.

2. Extract the contents of each .zip file.

   For example, extract the contents of the Darwin version of the 0.11 CLI .zip file to access the file `terraform`.

3. To follow code examples in the rest of this procedure, rename the extracted files as follows:
   - Rename the extracted file from the 0.11 OCI download to `terraform.11-15`
   - Rename the extracted file from the 0.12 download to `terraform.12-29`

4. To make the commands (extracted files) accessible, store the files in a directory that is present in your PATH directory.

   Because they are commands, the extracted files need to be accessible from your PATH directory.

5. Open a command prompt.

6. Change directory to the folder where you stored the 0.11 stack information.

   Example:

   ```bash
   cd c:\StackUpgrade
   ```

7. To initialize Terraform 0.11, run the following command:

   ```bash
   terraform.11-15 init
   ```

8. To check for action items, run the following command:

   ```bash
   terraform.11-15 0.12checklist
   ```

   The output indicates action items (if they exist) and how to resolve them.

9. If needed, resolve action items by updating your Terraform configuration as directed.

10. To initialize Terraform 0.12, run the following command:

   ```bash
   terraform.12-29 init
   ```
11. To upgrade your Terraform configuration to 0.12 syntax:
   a. Run the following command:
      
      ```bash
      terraform.12-29 0.12upgrade
      ```
      The output indicates whether the upgrade was successful.
      If the output is successful, go to step 12.
   b. If the upgrade was not successful, then make manual changes to your Terraform configuration files as directed.
   c. If you intend to use the plan and apply Terraform actions (or any others) to test the upgrade, then update the provider configuration to add arguments such as `user_ocid`, `fingerprint`, and `private_key_path`. You may have commented out these arguments previously.
      Example of commented out arguments:
      
      ```hcl
      provider "oci" {
        tenancy_ocid = var.tenancy_ocid
        user_ocid = var.user_ocid
        fingerprint = var.fingerprint
        private_key_path = var.private_key_path
        region = var.region
      }
      ```
      
12. Create a .zip archive of your Terraform configuration files.
    
    Example .zip archive: `c:\StackUpgrade\MyConfigUpgraded.zip`
    Ensure that the archive omits the Terraform state file (`terraform.tfstate`) and the .terraform directory to satisfy the required file structure for Terraform configurations.
    
    When the Terraform configuration is successfully upgraded to 0.12, you can proceed to the next task for creating the 0.12 stack.

**Task 4: Create the 0.12 stack with noted information**

1. Select the same compartment and region used by the 0.11 stack:
   a. Open the navigation menu and click **Developer Services**, Under **Resource Manager**, click **Stacks**.
   b. Under **List Scope**, choose the **Compartment** that contains the 0.11 stack.
   c. Ensure that you are still in the region that is used for the 0.11 stack.
2. Create the 0.12 stack using the upgraded Terraform configuration and the variables noted from the 0.11 stack:
   a. In the Stacks page, click Create Stack.
   b. In the Create Stack dialog, under Choose the origin of the Terraform configuration, select My Configuration.
   d. Add the upgraded Terraform configuration from your computer (example file path: c:\StackUpgrade \MyConfigUpgraded.zip): Either drag and drop the file onto the dialog’s control or click Browse and navigate to the file location.
      The dialog box is populated with information contained in the Terraform configuration.
   e. For Name, enter a unique stack name that indicates the source and the upgrade status.
      Example: Original Stack Name - Upgraded To 0.12
   f. For Terraform version, confirm selection of 0.12
   g. Click Next.
   h. Update variables to match noted values from the 0.11 stack.
   i. Click Next.
   j. In the Review panel, verify your stack configuration.
      Leave Run Apply unselected.
   k. Click Create to create your 0.12 stack.
      The Stack Details page appears for your new 0.12 stack.
3. Import the state file from the 0.11 stack:
   a. In the Stack Details page for your new 0.12 stack, go to More Actions and select Import State.
      The Import State File dialog displays.
   b. Add the Terraform state file from your computer (the state file that you downloaded from the 0.11 stack; example file path: c:\StackUpgrade\terraform.tfstate): Either drag and drop the file onto the dialog’s control, or click Browse and navigate to the file location.
   c. Click Import.
      When the action completes, the Job Details page is displayed for the related job.
   d. In the Job Details page, in the Logs tab, review the log for the completed import action.
      The log contents indicate whether the operation was successful.
4. Add the tags noted from the 0.11 stack: In the Stack Details page for your new 0.12 stack, click Add Tags.
   When the new 0.12 stack contains all information stored from the 0.11 stack, you can proceed to the next task for checking for issues.

Task 5: Check the 0.12 stack for issues
1. In the Stack Details page for your new 0.12 stack, check for issues with the Terraform configuration or state file:
   a. Click Plan.
      When the action completes, the Job Details page is displayed for the related job.
   b. In the Job Details page, in the Logs tab, review the log for the completed plan action.
      The log contents might list issues, such as old, deprecated HCL1 syntax.
2. Resolve any listed issues:
   a. On your computer, access and manually update the Terraform configuration.
   b. Upload the newly updated Terraform configuration to the 0.12 stack:

   1. In the Stack Details page, click Edit Stack.
   2. Either drag and drop the upgraded Terraform configuration onto the dialog’s control or click Browse and navigate to the file location.

   The dialog box is populated with information contained in the Terraform configuration.
   3. Click Next twice, then click Save Changes.

3. Run the plan action again to confirm that the issues are no longer listed in the associated log contents.

When the 0.12 stack is confirmed to have no issues, you can proceed to the next task for renaming the 0.11 stack.

Task 6: Rename the 0.11 stack

1. Open the navigation menu and click Developer Services. Under Resource Manager, click Stacks.
2. Under List Scope, choose the Compartment that contains the 0.11 stack.
3. For the 0.11 stack, click the Actions icon (three dots), and then select Edit.
4. In the Edit Stack dialog, change the name to indicate that the stack is no longer in use.

   Example: OriginalStackName-DONOTUSE

5. Click Next twice, then click Save Changes.

Congratulations! The stack is now upgraded from 0.11 to 0.12.

Managing Private Templates

This topic describes how to create, edit, and delete private templates for reuse of Terraform configurations.

Required IAM Policy

To manage private templates, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Important:

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2806.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies allow a group to work with private templates. For any policies, if you want to reduce the scope of access to a particular compartment, specify the compartment instead of the tenancy.

- The following example grants a specified group permission to create, update, move, and delete private templates in the tenancy.

```
Allow group <group_name> to manage orm-template in tenancy
```

- The following example grants a specified group permission to create stacks from private templates, in addition to managing stacks and jobs.

```
Allow group <group_name> to manage orm-stacks in tenancy
Allow group <group_name> to manage orm-jobs in tenancy
```
Allow group <group_name> to read orm-templates in tenancy

For more details about private template permissions, see orm-template on page 3035.

Using the Console
To create a private template
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click Create Private Template.
4. On the Create Private Template panel, do the following.
   - **Configuration**: Select either Folder or .Zip File, then either drag and drop your configuration onto the dialog's control or click Browse and navigate to the folder or file location.
   - If needed, edit the default Name provided for your private template. Avoid entering confidential information.
   - Type a Description.
   - (Optional) In Details, type a detailed description of your private template. This text is displayed in the Console page listing templates when the template is expanded.
5. Optionally do one or more of the following:
   - To add an icon, click Show Advanced Options and then either drag and drop your icon file onto the dialog's Template Icon control or click Browse and navigate to the file location.
     Template icon file requirements: PNG format, 50 KB maximum, 110 x 110 pixels.
     The icon is displayed in the Console page listing templates when the template is expanded.
   - To choose a different compartment for storing your new private template, click Show Advanced Options and then select the compartment you want from Create in Compartment.
   - To tag the template, click Show Advanced Options and add your tag.
6. Click Create.

   Congratulations, your private template is now created. You can now share the private template with anyone in your tenancy who has sufficient permissions.

   For instructions to create a stack from your private template, see the template step.

To create a stack from a private template
This section provides instructions for starting the stack creation process from the detail page for a private template. You can alternatively select a private template from the Create Stack page.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the private template you want.
4. On the detail page for the selected private template, click Create Stack.
   The Create Stack page appears, populated with information contained in the Terraform configuration for the selected template.
6. Enter a Name for the new stack (or accept the default name provided). Avoid entering confidential information.
7. Optionally enter a Description.
8. From the Create in Compartment drop-down, select the compartment where you want to create the stack.
   A compartment from the list scope is set by default.
9. Optionally apply tags to the stack.
   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

10. Click Next.

The Configure Variables panel displays variables from the Terraform configuration.

No variables are listed for the Existing Compartment stack origin because no Terraform configuration exists yet.

11. Review the variables and make changes as necessary.

Important:

Do not add your private key or other confidential information to configuration variables.

12. Click Next.

13. In the Review panel, verify your stack configuration.

14. Click Create to create your stack.

The stack detail page for the new stack appears.

15. To automatically provision resources when the stack is created, select Run Apply.

16. Click Create to create your stack.

The stack detail page for the new stack appears.

If Run Apply was selected, then Resource Manager runs the Apply action on the new stack.

If Run Apply was not selected, then you can manually run the Apply action on the stack.

To view private templates

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

To edit a private template

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the name of the private template you want.

4. On the detail page for the selected private template, click Edit.

5. In the Edit Template panel, update the properties you want.

6. Click Save.

To delete a private template

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click the Actions icon (three dots), select Delete Private Template, and confirm the operation when prompted.

Note:

You cannot undo this operation.

You can also delete a private template from its detail page. Click the name of the template to display the Private Template Details page and then click Delete.

Using the CLI

This section provides basic sample CLI commands for managing private templates. For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see CLI Help.
To create a private template from an uploaded file

This section describes how to create a private template from an uploaded configuration file (.zip).

Open a command prompt and run `oci resource-manager template create` to create a private template:

```
oci resource-manager template create --compartment-id <compartment_OCID> --display-name "<friendly_name_for_template>" --description "<description>" --long-description "<long-description>" --logo-file <icon_file_name> --from-json <config_file_name>
```

For example:

```
oci resource-manager template create --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Template" --description "My Default VCN" --long-description "Use this template to provision the default VCN." --logo-file file://mylogo.png --from-json file://myconfig.json
```

To create a stack from a private template

This section describes how to create a stack from a private template.

Open a command prompt and run `oci resource-manager stack create-from-template` to create a stack from a private template:

```
oci resource-manager stack create-from-template --compartment-id <compartment_OCID> --template-id "<template_OCID>"
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage private templates:

- ChangeTemplateCompartment
- CreateTemplate
- DeleteTemplate
- GetTemplate
- GetTemplateLogo
- GetTemplateTfConfig
- ListTemplateCategories
- ListTemplates
- UpdateTemplate

Managing Configuration Source Providers

This topic describes how to create, edit, and delete configuration source providers for remote Terraform configurations.

Prerequisites for connecting to GitHub and GitLab

Following are the prerequisites to connect Oracle Cloud Infrastructure Resource Manager to GitHub and GitLab.
• Your GitHub or GitLab server must be accessible over the Internet by Oracle Cloud Infrastructure IP addresses. (This accessibility requirement does not apply to GitLab.com.)

• Make sure Resource Manager can resolve your GitHub or GitLab URL. Make sure that your GitHub or GitLab server is deployed with a well-known root certificate, such as digicert, so that Oracle Cloud Infrastructure can trust its endpoint.

• Configure your network to allow access from Oracle Cloud Infrastructure IP address ranges. Ensure that you include ranges for all relevant services, including the Oracle Services Network (tag: OSN).

• Enable network ingress rules on the VCN where your GitHub or GitLab server is deployed to allow access from Oracle Cloud Infrastructure IP addresses.

• You must have GitHub or GitLab admin or owner permissions for the repository.

• You must have a Personal Access Token (PAT) to your GitHub or GitLab server. To create a PAT, see the relevant guidance and documentation:

  Note:
  Resource Manager reads the customer's repository content but does not push changes to the repository.

• GitHub: The scope repo (which includes repo:status, repo_deployment, and public_repo) is required for use with Resource Manager. See https://docs.github.com/en/free-pro-team@latest/github/authenticating-to-github/creating-a-personal-access-token

• GitLab: The scope read_api is required for use with Resource Manager. For security, we recommend excluding write_repository scope. See https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html

• You must have Resource Manager permissions required for your task:

  • To create a configuration source provider, you need manage orm-config-source-providers.
  • To create a stack with an existing configuration source provider, you need manage orm-stacks and read orm-config-source-providers.

  For more information, see Policies for Managing Resources Used with Resource Manager on page 3170.

For troubleshooting information, see GitHub and GitLab Connection Issues on page 4618.

**Required IAM Policy**

To manage configuration source providers, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

**Important:**

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2806.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies allow a group to work with configuration source providers. For any policies, if you want to reduce the scope of access to a particular compartment, specify the compartment instead of the tenancy.
Resource Manager

- The following example grants a specified group permission to create, update, move, and delete configuration source providers in the tenancy.

  Allow group <group_name> to manage orm-config-source-providers in tenancy

- The following example grants a specified group permission to create stacks from configuration files in source code control systems (using existing configuration source providers), in addition to managing stacks and jobs.

  Allow group <group_name> to read orm-config-source-providers in tenancy
  Allow group <group_name> to manage orm-stacks in tenancy
  Allow group <group_name> to manage orm-jobs in tenancy

For more details about configuration source provider permissions, see orm-config-source-providers on page 3034.

Using the Console

To create a configuration source provider

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To connect to GitHub or GitLab, you must use a Personal Access Token. See Prerequisites for connecting to GitHub and GitLab on page 4544.</td>
</tr>
</tbody>
</table>

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click Create Configuration Source Provider.
4. In the Create Configuration Source Provider panel, do the following.

- Type a Name for your configuration source provider. Avoid entering confidential information.
- Type a Description.
- Select the Compartment where you want to create the configuration source provider.
- Select the Type of configuration source provider you want. Choose from the following options.

  - **GitHub:** Supported products
    - GitHub Enterprise
    - GitHub Enterprise Server
    - GitHub Enterprise Cloud
    - GitHub Free for organizations
    - GitHub Free for user accounts
    - GitHub Team
  
  - **GitLab:** Supported products
    - GitLab Community Edition
    - GitLab Enterprise Edition
    - GitLab.com
  
- Paste the Server URL.

  Example URLs:

<table>
<thead>
<tr>
<th>Product</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GitHub Enterprise Cloud</td>
<td><a href="https://github.com/org-name">https://github.com/org-name</a></td>
</tr>
<tr>
<td>GitHub Enterprise Server</td>
<td><a href="https://hostname/api/v3">https://hostname/api/v3</a></td>
</tr>
<tr>
<td>GitHub Free for Organization</td>
<td><a href="https://github.com/org-name">https://github.com/org-name</a></td>
</tr>
<tr>
<td>GitHub Free for User Accounts</td>
<td><a href="https://github.com">https://github.com</a></td>
</tr>
</tbody>
</table>
### Resource Manager

<table>
<thead>
<tr>
<th>Product</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GitHub team</td>
<td><a href="https://github.com/team-name">https://github.com/team-name</a></td>
</tr>
<tr>
<td>GitLab.com product</td>
<td><a href="https://gitlab.com/">https://gitlab.com/</a></td>
</tr>
<tr>
<td>GitLab installation (relative URL)</td>
<td><a href="https://example.com/gitlab">https://example.com/gitlab</a></td>
</tr>
<tr>
<td>GitLab installation (subdomain)</td>
<td><a href="https://gitlab.example.com/">https://gitlab.example.com/</a></td>
</tr>
</tbody>
</table>

- Paste the **Personal Access Token**.
- To tag the new configuration source provider, click **Show Advanced Options** and add your tag.

5. Click **Create**.

**Note:**

To confirm that Resource Manager can access the server URL using the provided Personal Access Token (PAT), click **Validate connection** on the detail page for your configuration source provider. For steps, see **To confirm accessibility of a configuration source provider** on page 4547.

---

### To confirm accessibility of a configuration source provider

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Configuration Source Providers**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the configuration source provider that you want.
4. On the **Configuration Source Provider Details** page, click **Validate connection**.

   This option is located on the **Configuration Source Provider Information** tab, to the right of **Server URL**.

   A message appears indicating whether Resource Manager can access the server URL using the provided Personal Access Token (PAT).

   For troubleshooting information, see **GitHub and GitLab Connection Issues** on page 4618.

---

### To edit a configuration source provider

**Note:**

To confirm that Resource Manager can access the server URL using the provided Personal Access Token (PAT), click **Validate connection** on the detail page for your configuration source provider. For steps, see **To confirm accessibility of a configuration source provider** on page 4547.

1. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Configuration Source Providers**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the configuration source provider that you want to edit.
4. Click **Edit Configuration Source Provider**.
5. In the **Edit Configuration Source Provider** dialog box, update property values as needed.
6. Click **Save**.

---

### To delete a configuration source provider

**Note:**

A configuration source provider cannot be deleted if it is associated with a stack. To remove the association from the stack, edit the stack.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.

3. Click the name of the configuration source provider that you want to delete.

4. Click Delete Configuration Source Provider and then confirm the action.

### Using the CLI

This section provides basic sample CLI commands for managing stacks and jobs. For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see CLI Help.

For a walk-through using CLI for cloud provisioning in a CI/CD pipeline, see IaC in the Cloud: Integrating Terraform and Resource Manager into your CI/CD Pipeline - Building With the OCI CLI.

### To create a configuration source provider

**Important:**

To connect to GitHub or GitLab, you must use a Personal Access Token. See Prerequisites for connecting to GitHub and GitLab on page 4544.

Choose the option for the provider type you want:

- **GitHub:**

  Open a command prompt and run `resource-manager configuration-source-provider create-github-access-token-provider` to create a GitHub configuration source provider:

  ```
  oci resource-manager stack create-github-access-token-provider --api-endpoint <github_url> --access-token <personal_access_token> --compartment-id <compartment_OCID> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack create-github-access-token-provider --api-endpoint https://api.github.com/ --access-token token --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Configuration Source Provider" --description "Department 80"
  ```

- **GitLab:**

  Open a command prompt and run `resource-manager configuration-source-provider create-gitlab-access-token-provider` to create a GitLab configuration source provider:

  ```
  oci resource-manager stack create-gitlab-access-token-provider --api-endpoint <gitlab_url> --access-token <personal_access_token> --compartment-id <compartment_OCID> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack create-gitlab-access-token-provider --api-endpoint https://gitlab.com/api/v3/ --access-token token --compartment-id ocid1.tenancy.oc1..uniqueid --display-name "My Configuration Source Provider" --description "Department 80"
  ```

For a complete list of flags and options available for CLI commands, see CLI Help.
To update a configuration source provider

Choose the option for the provider type you want:

- **GitHub:**
  
  Open a command prompt and run `resource-manager configuration-source-provider update-github-access-token-provider` to edit the specified configuration source provider:

  ```
  oci resource-manager stack update-github-access-token-provider --configuration-source-provider-id <configuration_source_provider_OCID> --api-endpoint <github_url> --access-token <personal_access_token> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack update-github-access-token-provider --configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --description "Department 99"
  ```

- **GitLab:**
  
  Open a command prompt and run `resource-manager configuration-source-provider update-gitlab-access-token-provider` to edit the specified configuration source provider:

  ```
  oci resource-manager stack update-gitlab-access-token-provider --configuration-source-provider-id <configuration_source_provider_OCID> --api-endpoint <gitlab_url> --access-token <personal_access_token> --display-name "<friendly_name>" --description "<description>"
  ```

  For example:

  ```
  oci resource-manager stack update-gitlab-access-token-provider --configuration-source-provider-id ocid.ormconfigsourceprovider.oc1..uniqueid --description "Department 99"
  ```

For a complete list of flags and options available for CLI commands, see CLI Help.

To delete a configuration source provider

**Note:**

A configuration source provider cannot be deleted if it is associated with a stack. To remove the association from the stack, edit the stack.

Open a command prompt and run `resource-manager configuration-source-provider delete` to delete the specified configuration source provider:

```
oci resource-manager configuration-source-provider delete --config-source-configuration-source-provider-id <configuration_source_provider_OCID>
```

For a complete list of flags and options available for CLI commands, see CLI Help.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage configuration source providers:

- ChangeConfigurationSourceProviderCompartment
- CreateConfigurationSourceProvider
- DeleteConfigurationSourceProvider
Using Remote Exec

With Resource Manager, you can use Terraform’s remote exec functionality to execute scripts or commands on a remote computer. You can also use this technique for other provisioners that require access to the remote resource.

Prerequisites

- The location where the script is remotely executed must be an Oracle Cloud Infrastructure resource that has a public IP and supports remote login.
- On Windows, WinRM must be enabled. On Linux or Unix, SSH must be enabled.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 5303.

Authenticating

We recommend using one of the following approaches, depending on whether you have access to the Vault service. For more information, see Overview of Vault on page 5006.

With Vault

First, use Vault to encrypt your private key. For more information, see Managing Keys on page 5017 and Using Keys on page 5056.

Next, provide the encrypted private key to Resource Manager. You can use the decrypt data source to decrypt it.

The following code sample demonstrates this process.

```hcl
data "oci_kms_decrypted_data" "private_key_decrypted" {
  ciphertext = "${file(var.encrypted_private_key_path)}"
  crypto_endpoint = "${var.decrypted_data_crypto_endpoint}"
  key_id = "${var.kms_encryption_key_id}"
}

resource "oci_core_instance" "TFInstance1" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ADs.availability_domains[var.availability_domain - 1],"name")}"n
  compartment_id      = "${var.compartment_ocid}"n
  display_name        = "TFInstance"
  hostname_label      = "instance3"
  shape               = "${var.instance_shape}"
  subnet_id           = "${oci_core_subnet.ExampleSubnet.id}"
  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
  }
  extended_metadata {
    ssh_authorized_keys = "${var.ssh_public_key}"
  }
}
resource "null_resource" "remote-exec" {
  connection {
```

---

Oracle Cloud Infrastructure User Guide 4550
Without Vault

If you do not have access to the Vault service, you can dynamically generate a key pair and store them in the state file.

1. Generate a key pair using a TLS resource.
2. When you launch the Compute instance, use the public key from the TLS resource.
3. When you establish the SSH connection, provide the private key.

**Caution:**
You should not save your private key in your Terraform configuration file because that is not a secure location.

The following sample demonstrates how to use the TLS private key resource to provision a Compute instance, then perform a remote execution on that instance.

```terraform
resource "tls_private_key" "public_private_key_pair" {
  algorithm = "RSA"
}

resource "oci_core_instance" "TFInstance1" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ADs.availability_domains[var.availability_domain - 1],"name"))}" 
  compartment_id = "${var.compartment_ocid}" 
  display_name = "TFInstance" 
  hostname_label = "instance3" 
  shape = "${var.instance_shape}" 
  subnet_id = "${oci_core_subnet.ExampleSubnet.id}"
  source_details {
    source_type = "image"
    source_id = "$\{var.instance_image_ocid[var.region]\}" 
  }
  extended_metadata {
    ssh Authorized_keys = "$\{tls_private_key.public_private_key_pair.public_key_openssh\}"
  }
}

resource "null_resource" "remote-exec" {
  depends_on = ["oci_core_instance.TFInstance1"]
  provisioner "remote-exec" {
    connection {
      agent       = false
    }
    inline = [
      "touch ~/IMadeAFile.Right.Here"
    ]
  }
}
```
Connection Construct

This example demonstrates how to use a connection construct for remote exec. Terraform uses a number of defaults when connecting to a resource, but these can be overridden using a connection block in either a resource or provisioner. For more information, see Provisioner Connections.

Templates

This topic describes Oracle-provided templates available for Resource Manager.

Templates are Oracle-provided, pre-built Terraform configurations that provision sets of resources used in common scenarios. You can access templates from the Console.

Note:
Create your own private templates to share with others in the tenancy.

Common uses of templates:
• Test-drive the idea of infrastructure as code.
• Apply proven best practices to your production workflow configuration.

<table>
<thead>
<tr>
<th>Template</th>

</tbody>
</table>

**Preinstalling the Oracle Cloud Development Kit**

This page describes how to provision a Compute instance with the Oracle Cloud Development Kit preinstalled and ready to use.

**What’s Included**

The Oracle Cloud Development Kit template preinstalls the following Oracle Cloud Infrastructure items on the Compute instance:

- Command Line Interface (CLI)
- Terraform Provider on page 5412
- Ansible (includes OCI Ansible modules)
- The following SDKs:
  - Go
  - Java
  - Python
- Git: Use the provided Git command line tool to access any Git-related version control systems, such as Bitbucket, GitHub, and GitLab.

*Instance principal authorization* is set up for installed items and the provisioned Compute instance. An upgrade script is also included.
Steps for Using the Oracle Cloud Development Kit

To provision an instance with the development kit

1. Launch the Create Stack page for the Oracle Cloud Development Kit template by clicking this button:

   ![Deploy to Oracle Cloud]

   **Alternative steps from the Console**
   a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   c. Click **Create Stack**.
   d. In the **Create Stack** dialog, click **Template**.
   e. Under **Stack Configuration**, click **Select Template** and then select Oracle Cloud Development Kit.

2. Follow the prompts to save your new stack and provision the instance
   a. In the **Create Stack** dialog, enter a **Name** for the new stack (or accept the default name provided). Avoid entering confidential information.
   b. Optionally enter a **Description**.
   c. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
   A compartment from the list scope is set by default.
   d. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

e. Click Next.

The Configure Variables panel displays the following variables:

- **Instance Shape**: Select the shape you want to use for the Compute instance.
- **Auto-Generate SSH Key Pair**: Either generates an SSH key pair or allows you to upload a public key.
  - Enabled (selected): Automatically generates an SSH key pair for accessing the instance. The private key is stored in the Terraform state file. You’ll use the private key later to connect to the instance.
  - Important:
    Do not use this option in production. The Terraform state file containing the private key is visible to anyone with access to the created stack.
  - Disabled (cleared): Allows you to upload a public key. No private key is stored. Keep the corresponding private key in a safe location. You'll use the private key later to connect to the instance.
  - For instructions on generating SSH key pairs, see Managing Key Pairs on Linux Instances on page 1021.

- **Compute Instance to Access All Resources at Tenancy Level**: Controls the level used for the dynamic group policy, which determines what resources are accessible by users of the Compute instance.
  - Enabled (selected): Tenancy level for access to all resources in the tenancy.
  - Disabled (cleared): Compartment level for access to all resources in the same compartment as the instance.

f. Click Next.
g. In the Review panel, verify your stack configuration.
h. Select the check box for **Run Apply**.

This option automatically provisions the instance on stack creation.
i. Click **Create** to create your stack and automatically provision the instance.

The new stack appears in the Stack Details page. Resource Manager runs the Apply action on the new stack, starting the process to provision the instance.

The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.

Once the instance is provisioned (indicated by a "Succeeded" status for the apply job), installation of the development kit items begins. The installation process takes a few minutes. If you connect to the instance before the installation finishes, then a warning message indicates that the installation is still in process. Once the items are installed on the instance, you can immediately use them.

j. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under Resources.

Congratulations! You’ve provisioned a Compute instance with the Oracle Cloud Development Kit already installed and ready to use. You can now connect to the instance and use the development kit.

**To connect to your newly created instance**

Run the following command:

```
ssh -i <private-key> opc@<compute-instance-public-ip>
```

<private-key> is the private key associated with the instance you provisioned from the stack created using the Oracle Cloud Developer Tools template.

<compute-instance-public-ip> is the IP address of the instance.

**To retrieve the associated private key and IP address**
1. Go to the **Stack Details** page for your newly provisioned instance:
   a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
   b. Click the name of the stack to display its detail page.
2. Click the **Application Information** tab.
3. Copy the value for **Compute Instance IP Address**.
4. For the private key, follow the steps that correspond to the key option you selected while creating your stack:
   a. If you enabled **Auto-Generate SSH Key Pair**, then retrieve the generated private key: Copy the value for **Generated Private Key for SSH Access**.
   b. If you disabled **Auto-Generate SSH Key Pair**, then reference the full path and name of the file that contains the private key corresponding to the public key that you uploaded while creating the stack.

   **Note:**

   When you connect to your instance, the private key file permissions are validated. For security, your private key must be accessible by the owner only; otherwise, you won't be allowed to connect to the instance. (Owner write permissions are required for you to add the private key to the file.)
   For Unix or Linux, use the command `chmod 600` (`-rw-------`).

   For general information about connecting to Compute instances, see [Connecting to an Instance](#) on page 1083.

   Once connected to your instance, you can use the installed development kit.

   **To use the installed development kit**

   See the following examples:

   a. CLI: See [Using the CLI](#) on page 5333
      Usage: See [Easy Provisioning, CLI Updates](#)
   b. Terraform Provider
      Usage: See [Terraform Provider](#) on page 5412.
   c. Ansible (includes OCI Ansible modules)
      Usage: See [Writing a Sample Playbook](#) on page 5487.
   d. SDKs:
      a. Go
         Usage: See [https://godoc.org/github.com/oracle/oci-go-sdk](#)
      b. Java
         Usage: See [Concepts](#) on page 5361.
   e. Python
      Setup and usage: See [Client-Side Encryption](#) on page 5375.
      Setup and usage for open source SDKs: See [Open Source SDKs](#)
      Git: Use the provided Git command line tool to access any Git-related version control systems, such as Bitbucket, GitHub, and GitLab.
      Usage: To get help on using Git, access the terminal on your new Compute instance and run `git --help`.

   **To upgrade the installed development kit**

   1. Connect to the instance that you provisioned from the **Oracle Cloud Development Kit** template.
   2. Run the upgrade command:

      ```bash
      update-kit.sh
      ```
Preconfigured Authorization

Instance principal authorization is set up for installed development kit items and the provisioned Compute instance. The template provides the following preconfiguration:

- A dynamic group
- An IAM policy, with all resource access determined by stack configuration (either tenancy or compartment level)
- Environment variables set in `.bashrc` on the Compute instance for CLI, Terraform, and Ansible

For more information about instance principal authorization, see Calling Services from an Instance on page 3106.

Using the Deploy to Oracle Cloud Button

This page describes the advanced topic of constructing a URL for Deploy to Oracle Cloud button.

When properly linked, this button provides a direct option for your users to create stacks with your Terraform configuration.

![Deploy to Oracle Cloud Button](image)

This button takes a user directly to the Create Stack page in the Oracle Cloud Infrastructure Console. The button is linked to a Terraform configuration file package that you specify, so the Terraform configuration is already selected for the user when they create the stack. You can store Terraform configuration files in a supported provider.

Example of Functioning Deploy Button

The following Deploy to Oracle Cloud button is configured to launch the template from `https://github.com/oracle-quickstart/oci-cloudnative`.

![Deploy to Oracle Cloud Button](image)

Supported Providers

The following providers are supported for forming package URLs to use with the Deploy to Oracle Cloud button:

- GitHub
  
  Example package URL 1: Direct: `https://github.com/myrepo/mydirectory/master.zip`
  
  Example package URL 2: Release: `https://github.com/myrepo/mydirectory/0.0.1.zip`

  To get the `.zip` URL to a release in GitHub, see `https://docs.github.com/en/free-pro-team@latest/github/administering-a-repository/linking-to-releases`.

- GitLab
  
  Example package URL 1: Direct: `https://gitlab.com/myrepo/mydirectory/master.zip`
  
  Example package URL 2: Release: `https://gitlab.com/myrepo/mydirectory/0.0.1.zip`

- Object Storage (pre-authenticated request URL)
  
  Example package URL: `https://objectstorage.region.oraclecloud.com/p/encrypted-string/n/object-storage-namespace/b/bucket/o/filename`

For troubleshooting information, see Troubleshooting on page 4559.
To display the linked deploy button

Important:
Ensure that your Terraform configuration file is valid. See Authoring Configurations on page 4471 and Terraform Configurations for Resource Manager on page 4470.

You can display the linked **Deploy to Oracle Cloud** button on repository pages and other web pages.

Markdown code
To display the **Deploy to Oracle Cloud** button on a repository page, add the following Markdown code to a README.md file.

```
```

<package-url> is the URL for the .zip file to a Terraform configuration that is stored in a supported provider.

Example Markdown code with a package URL from GitHub:

```
```

HTML code
To display the **Deploy to Oracle Cloud** button on a web page, add the following HTML code.

```
<a href="https://cloud.oracle.com/resourcemanager/stacks/create?zipUrl=<package-url>" target="_blank">
</a>
```

<package-url> is the URL for the .zip file to a Terraform configuration that is stored in a supported provider.

Example HTML code with a package URL from GitHub:

```
</a>
```

To create a stack from the linked deploy button

1. Click **Deploy to Oracle Cloud** (the deploy button linked to the Terraform configuration).
2. If you are not yet signed in to the Oracle Cloud Infrastructure Console, then sign in. See Signing In to the Console on page 63.

The Create Stack dialog appears with the selected package identified.

3. Enter a Name for the new stack (or accept the default name provided). Avoid entering confidential information.
4. Optionally enter a Description.
5. From the Create in Compartment drop-down, select the compartment where you want to create the stack.

A compartment from the list scope is set by default.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform versions are not backward compatible.</td>
</tr>
</tbody>
</table>

7. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

8. Click Next.

The Configure Variables panel displays variables from the selected Terraform configuration file.

9. Review the variables and make changes as necessary.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not add your private key or other confidential information to configuration variables.</td>
</tr>
</tbody>
</table>

10. Click Next.

11. In the Review panel, verify your stack configuration.

Run Apply is selected by default. Preserve this setting to automatically provision resources when the stack is created.

12. Click Create to create your stack.

The stack detail page for the new stack appears.

If Run Apply was selected, then Resource Manager runs the Apply action on the new stack.

To deploy the defined resources (if you did not select Run Apply in the Create Stack dialog box), run an apply job on your new stack.

**Troubleshooting**

When you attempt to create a stack from the linked deploy button, the error message Error code: InvalidParameter(400) might appear.

This error occurs because Resource Manager cannot access the URL, or the URL is not usable because it does not point to the downloaded zip file for the Terraform configuration (GitHub or GitLab).

To resolve this error, ensure that the URL is accessible. For GitHub and GitLab, use a URL that points to the downloaded zip file for the Terraform configuration. You can obtain the URL for a downloaded zip file by using the following methods:

- GitHub (available March 2021): Click the Code button and then right-click the Download ZIP option.
- GitLab (available March 2021): Click the Download button and then right-click the zip option.

**Resource Discovery**

You can use Oracle Cloud Infrastructure (OCI) Resource Manager to search for deployed resources in your compartment and export them to Terraform configuration and state files.
Resource discovery simplifies the move from manually managed infrastructure to Terraform-managed infrastructure. With a single command, you can generate a file that captures your existing compartment's baseline configuration and state.

**Important:**

Resource discovery is not a migration tool. When cloning or migrating resources, configurations generated by resource discovery are a starting point. They may require changes.

Common uses cases for your new Terraform configuration and state files include:

- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
- Duplication or rebuild of your existing infrastructure architecture in a new tenancy or region.
- Detection of state drift. Run reports to see if the state of your Terraform-managed resources has changed and differs from your base configuration.

To discover resources, follow the steps at [To see how Terraform represents your resources](#) on page 4512. The created stack includes a generated Terraform configuration and state file corresponding to the supported resources in the source compartment.

A stack created from a compartment represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.

Stack creation is supported from a single compartment only. Stacks cannot be created from nested compartments.

Terraform versions supported: 0.12.x, 0.13.x

**Using the Console**

**To see how Terraform represents your resources**

Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.

1. Capture existing infrastructure by creating a stack from that compartment.

   Key steps in the **Create Stack** dialog box:

   a. Under Choose the origin of the Terraform configuration, select Existing Compartment.
   b. Select the Compartment for Resource Discovery (the compartment containing the resources that you want to capture).
      
      A compartment from the list scope is set by default.
   c. Select the Region for Resource Discovery (the region containing the resources that you want to capture).
   d. To filter for specific services supported for resource discovery, select Selected and then select the services you want.

   **Note:**

   This setting cannot be changed when editing the stack later.

   e. Click Next twice, and then click Create to create your stack.

   The stack detail page for the new stack appears. A work request runs on your stack. When the work request finishes, a job runs to generate a Terraform configuration file for the stack. When the job finishes, the resources in the selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click Download.
To recreate (clone) existing infrastructure in another compartment

1. Capture existing infrastructure by creating a stack from that compartment.

   The stack detail page for the new stack appears. A work request runs on your stack. When the work request
   finishes, a job runs to generate a Terraform configuration for the stack. When the job finishes, the resources in the
   selected compartment are captured in the generated configuration.

2. Download the generated Terraform configuration file: In the Stack Information tab of the stack detail page, click
   Download.

3. Edit the vars.tf file (variables in the downloaded Terraform configuration file) to specify the destination
   compartment_ocid and region.

   Example:

   ```
   variable "compartment_ocid" {
     default = "ocid1.compartment.oc1..uniqueid"
   }
   variable "region" {
     default = "us-phoenix-1"
   }
   ```

4. If the destination region has more or fewer availability domains than the source region, then edit the vars.tf
   file to specify the correct number of availability domains.

   For example, if you cloned from a region that has 3 availability domains and you want to recreate the
   infrastructure in a region that has only 1 availability domain, then remove the references to the second and third
   availability domains.

   Example showing 3 availability domains:

   ```
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
     compartment_id = var.compartment_ocid
     ad_number      = "1"
   }
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-2 {
     compartment_id = var.compartment_ocid
     ad_number      = "2"
   }
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-3 {
     compartment_id = var.compartment_ocid
     ad_number      = "3"
   }
   ```

   Example showing 1 availability domain:

   ```
   data oci_identity_availability_domain export_NzDH-EU-FRANKFURT-1-AD-1 {
     compartment_id = var.compartment_ocid
     ad_number      = "1"
   }
   ```
5. Create a second stack using the edited configuration file.
   a. Open the navigation menu and click **Developer Services**. Under **Resource Manager**, click **Stacks**.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   c. Click **Create Stack**.
   d. In the **Create Stack** dialog, click **My Configuration**.
   e. Add the downloaded Terraform configuration (.zip) file.
      You can leave other fields as is for now. For reference, see To create a stack on page 4509.
   f. For **Terraform Version**, select a version supported by resource discovery.
      Terraform versions supported: 0.12.x, 0.13.x
   g. Click **Next** to display the **Configure Variables** panel.
   h. Update the **compartment_ocid** variable to specify the destination compartment for the cloned resources.
   i. If you want to clone the resources to a different region, update the **region** variable.
   j. Click **Next** to display the **Review** panel.
   k. To automatically provision resources when the stack is created, select **Run Apply**.
   l. Click **Create** to create your stack.

   The stack detail page for the second stack appears.

   If **Run Apply** was selected, then Resource Manager runs the Apply action on the new stack.

   The resources are cloned in the specified compartment and region.

6. If you didn't select **Run Apply** for the new stack, then run Apply now (after optionally running Plan):
   a. (Optional) To confirm that the stack will create resources as expected, run a plan job.
   b. Clone resources: Run an apply job on the new stack.

   The resources are cloned in the specified compartment and region.

**Using the CLI**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see CLI Help.</td>
</tr>
</tbody>
</table>

**To discover resources (create a stack from a compartment)**

Open a command prompt and run `oci resource-manager stack create-from-compartment` to create a stack from the specified compartment and region:

```
oci resource-manager stack create-from-compartment --config-source-compartment-id <source_compartment_OCID> --config-source-region <source_region> --config-source-services-to-discover [<services>] --compartment-id <compartment_OCID> --terraform-version <version> --display-name "<friendly_name>" --description "<description>"
```

For example (discovers supported resources from the core and database services; the source compartment is not a root compartment):

```
oci resource-manager stack create-from-compartment --config-source-compartment-id ocid1.tenancy.oc1..uniqueid1 --config-source-region PHX --config-source-services-to-discover [core,database] --compartment-id ocid1.tenancy.oc1..uniqueid2 --terraform-version 0.13.X --display-name "Stack From Compartment ABC" --description "List of Resources to Duplicate"
```

}
```

To list resources for discovery

This section describes how to determine which services are supported for resource discovery from a given compartment OCID.

When you create a stack from a compartment, the stack represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.

Open a command prompt and run `oci resource-manager stack list-resource-discovery-services` to retrieve a list of services supported for resource discovery (the compartment OCID is used for authorization only):

```
oci resource-manager stack list-resource-discovery-services --compartment-id <compartment_OCID>
```
Using the API

To discover resources (create a stack from a compartment), use the CreateStack operation, with configSourceType set to COMPARTMENT_CONFIG_SOURCE.

Output File Contents

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes are missing from some supported resources captured using resource discovery. For more information, see <a href="https://docs.cloud.oracle.com/iaas/Content/knownissues.htm#orm-attributes">https://docs.cloud.oracle.com/iaas/Content/knownissues.htm#orm-attributes</a>.</td>
</tr>
</tbody>
</table>

Resource discovery discovers resources that are in an active or usable state. Resources that have been terminated or otherwise made inactive are generally excluded from the generated configuration.

By default, the Terraform names of the discovered resources share the same name as the display name for that resource, if one exists.

The attributes of the resources are populated with the values that are returned by the OCI services.

In some cases, a required or optional attribute may not be discoverable from the OCI services and may be omitted from the generated Terraform configuration. This omission may be expected behavior from the service, which may prevent discovery of certain sensitive attributes or secrets. In such cases, a placeholder value will be set along with a comment like this:

```
admin_password = "<placeholder for missing required attribute>" #Required attribute not found in discovery, placeholder value set to avoid plan failure
```

The missing required attributes are also added to lifecycle ignore_changes. This addition is done to avoid Terraform plan failure when moving manually-managed infrastructure to Terraform-managed infrastructure. Any changes made to such fields are not reflected in the Terraform plan. If you want to update these fields, remove them from ignore_changes.

Resources that are dependent on availability domains will be generated under availability_domain.tf file. These include:

- oci_core_boot_volume
- oci_file_storage_file_system
- oci_file_storage_mount_target
- oci_file_storage_snapshot

Supported Resources

Each supported service has one or more discoverable resources.

Extend Console Pages Using Schema Documents

Schema documents are recommended for Terraform configurations when using Resource Manager. Including a schema document allows you to extend pages in the Oracle Cloud Infrastructure Console. Facilitate variable entry in the Create Stack page by surfacing SSH key controls and by naming, grouping, dynamically prepopulating values, and more. Define text in the Application Information tab of the stack detail page displayed for a created stack.

Requirements for Schema Documents

Schema documents for Resource Manager have the following requirements:

- YAML format.
- Data types must be consistent with the associated Terraform configuration.

For example, let’s say that you declare the type number for the availability variable in the schema. In this situation, availability must have the same declared type (number) in the associated Terraform configuration. (By default, variables with no declared type use string.)

- Placement under the root folder of the Resource Manager Terraform configuration. (By default, the schema document assumes that the root folder is the working directory.)

Supported Types (Dynamic Prepopulation and Controls)

This section lists the types supported by Resource Manager for dynamic prepopulation and controls.

Most types require the compartment OCID (dependsOn: required: compartmentId). Some types have additional required or optional items. To determine required and optional items for a type, see Meta Schema for Validation on page 4573.

Optionally filter dynamically prepopulated lists by other variables using dependsOn. For example, filter subnets by VCN. For more information, see Dynamic prepopulation.

Note:

When defined in the Terraform configuration, the following variables automatically prepopulate with values on the Console pages used to create and edit the stack. The stack’s values are used when you select the Terraform actions Plan, Apply, and Destroy.

- tenancy_ocid (tenancy OCID)
- compartment_ocid (compartment OCID)
- region (region)
- current_user_ocid (OCID of the current user)

**Meta Schema for Validation**

Use the following meta schema file to confirm that your schema document is using supported variable types.

**Meta Schema**

```json
# Meta JSON Schema.
#
# This is used to validate the Schema file when the package is uploaded/loaded into Resource Manager.
# For marketplace, it is also used to validate the package when the package artifact is created in Partner Portal.
#
# NOTE: additionalProperties are set to true explicitly even though this is the default. It must be set to true in
cases where we use the allOf. This is a quirk of JSON Schema. During validation, allOf means it has to match all of
the individual definitions separately. It doesn't mean it has to match a Union of the individual definitions. This
is a known issue with JSON Schema.

Example Schema Document

Following is an example schema document.

Example

```
# Title shown in Application Information tab.
title: Sample input variable schema

# Sub Title shown in Application Information tab.
description: Sample description...

# Sample informational text to display in tab...
informationalText: Sample informational text to display in tab...

# URL of Logo Icon used on Application Information tab. Logo must be 130x130 pixels.
# (Optional)
logoUrl: https://cloudmarketplace.oracle.com/marketplace/content?
contentId=53066708

# Used in Application Information tab to Hyperlink Title and Logo to the Marketplace
# Listing.
# Also used to link to Listing Usage section for "View Instructions".
# (Optional) If it is missing, Application Information uses the "marketplace-listing-id" tag for the same purpose.

How to Control Console Items

This section provides instructions and examples for controlling the display of stack variables and stack details page items in the Oracle Cloud Infrastructure Console for stacks created from your Terraform configuration file. Using a schema document, you can define how variables look and behave during stack creation and what text is displayed in the Application Information tab for a created stack.

Following are Console display items that are controlled by the schema document.

Field label and description

To render a field label and description for a variable:

- Add the lines title: <field_label> and description: <field_description>.

Example image for a variable field label and description:
Example declaration for a variable field label and description:

```yaml
functions_app_name:
  type: string
  # field label, displayed above field
  title: "Application Name"
  # field description, displayed below field
  description: "Do not use spaces."
```

**Default value**

To render a variable with a default value:

- Add the line `default: <default-value>`.

Example image for a variable with a default value:

![Default Value Example](image)

Example declaration for a check box variable:

```yaml
functions_app_name:
  type: string
  title: "Application Name"
  description: "Do not use spaces."
  required: true
  # provide a default value
  default: "DataScienceApp"
```

**Group and order**

To render a group (box) of variables, with the variables in a prescribed sequence:

- Add a `variableGroups` block.
- Add a `title` line to this block.
- Add a `variables` block to `variableGroups`.
- Add variables to the `variables` block in the order you want.

Example image for a group of variables:

![Group and Order Example](image)
Example declaration for a group of variables with a prescribed order:

```json
variableGroups:
  - title: "Network Configuration"
    variables:
    - ods_vcn_use_existing
    - ods_vcn_existing
    - ods_vcn_name
    - ods_vcn_cidr
    - ods_subnet_public_existing
    - ods_subnet_public_name
    - ods_subnet_public_cidr
    - ods_subnet_private_existing
    - ods_subnet_private_name
    - ods_subnet_private_cidr
```

**SSH key control**

To render a variable as an SSH key control:

- Add the line `type: oci:core:ssh:publickey`.

Example image for an SSH key control:

Example declaration for an SSH key control:

```json
ssh_public_key:
  title: SSH Public Key
  description: The public SSH key for the key-pair that you want to use, if you wish to
  login to the instances over SSH
  # renders variable as an SSH key control
  type: oci:core:ssh:publickey
  required: true
  pattern: "((^"ssh-rsa AAAAB3NzaC1yc2|ecdsa-sha2-nistp256
AAAEE2VjZHHlXNoYTItbmlzdHAYNT|ecdsa-sha2-nistp384
AAAEE2VjZHHlXNoYTItbmlzdHAzODQAAAAIbmldzHAzOD|ecdsa-sha2-nistp521
AAAEE2VjZHHlXNoYTItbmlzdHA1MjEAAAAIbmldzHA1Mjssh-ed25519
AAAAAC3NzaC1lZD11NTE5|ssh-dss AAAAB3NzaC1kc3)\[0-9A-Za-z+/\]+=[\0,3])
(\^\^)?)\)\)
((ssh-rsa AAAAB3NzaC1yc2|ecdsa-sha2-nistp256
AAAEE2VjZHHlXNoYTItbmlzdHAYNT|ecdsa-sha2-nistp384
AAAEE2VjZHHlXNoYTItbmlzdHAzODQAAAAIbmldzHAzOD|ecdsa-sha2-nistp521
AAAEE2VjZHHlXNoYTItbmlzdHA1MjEAAAAIbmldzHA1Mjssh-ed25519
AAAAAC3NzaC1lZD11NTE5|ssh-dss AAAAB3NzaC1kc3)\[0-9A-Za-z+/\]+=[\0,3])
(\^\^)?)\)*$"
```

**File control**

To render a variable as a file control:
- Add the line `type: file`.

**Note:**
The uploaded file is stored in Base64 format. To use the file, decode the output. For example, add the following code to an `outputs.tf` file in the Terraform configuration.

```terraform
output "generic_file_raw" {
  value = base64decode(var.generic_file)
}
```

Example image for a file control:

```
generic_file:
  type: file
  title: generic_file
  description: Drop any file or browse
  required: true
```

**Tagging control**

To render a variable as a tagging control:
- Add the line `type: oci:identity:tag:value`.

**Note:**
To prepopulate tag values in the Console, access the values from the Terraform configuration. For example, add the following code to a `main.tf` file in the Terraform configuration.

```terraform
resource "oci_logging_log_group" "sample_log_group" {
  compartment_id = var.compartment_ocid
  display_name   = "sample_log_group"
  description    = "Prepopulated tag values"
  freeform_tags  = var.tag_value.freeformTags
  defined_tags   = var.tag_value.definedTags
}
```

Example image for a tagging control:
Example declaration for a tagging control:

```json
  tag_value:
     type: oci:identity:tag:value
     title: Tag
     description: Add tag for resource
     required: true
```

**Dynamic prepopulation**

To dynamically prepopulate variables with values based on dependencies:

- Add the lines `type: <supported-type>` and `dependsOn: <other_variable>`.
  
  `<supported-type>` is a type listed at Supported Types (Dynamic Prepopulation and Controls) on page 4571.

Example image for a dynamically prepopulated variable:

![Example image for a dynamically prepopulated variable](image)

Example declaration for a dynamically prepopulated variable:

```bash
  ods_vcn_existing:
     # prepopulates available values for VCN
     type: oci:core:vcn:id
     title: "Select VCN"
     # determines values for prepopulation from selected compartment
     dependsOn:
        compartmentId: compartment_ocid
```

Example declarations for VCN depending on compartment, subnet depending on both compartment and VCN:

```bash
  vcnCompartment:
     # prepopulates available values for compartment
     type: oci:identity:compartment:id

  myVcn:
     # prepopulates available values for VCN
     type: oci:core:vcn:id
     # determines values for VCN prepopulation from selected compartment
     dependsOn:
        compartmentId: ${vcnCompartment}
```
subnetCompartment:
  # prepopulates available values for compartment
type: oci:identity:compartment:id

mySubnet:
  # prepopulates available values for subnet
type: oci:core:subnet:id
  # determines values for subnet prepopulation from selected compartment
  and VCN
dependsOn:
  compartmentId: ${subnetCompartment}
  vcnId: ${myVcn}

Image example declaration 1, where image depends on compartment only (the one mandatory dependsOn field):

instance_image:
  title: Image
description: Image
type: oci:core:image:id
required: true
dependsOn:
  compartmentId: ${compartment_ocid}

Image example declaration 2, where image depends on compartment, operating system, operating system version, and shape:

instance_image:
  title: Image
description: Image
type: oci:core:image:id
required: true
dependsOn:
  compartmentId: ${compartment_ocid}
  operatingSystem: "Oracle Linux"
  operatingSystemVersion: "7.8"
  shape: "<shape name>"

Enumerated values

To render enumerated values for a variable:

- Add the lines type: enum and add an enum block.

Example image for a variable with enumerated values:

Example declaration for a variable with enumerated values:

ods_vault_type:
  type: enum
title: "Vault Type"
default: "DEFAULT"
# enumerated values
enum:
  - DEFAULT
Check box

To render a variable as a check box:

• Add the line `type: boolean`.

Example image for a check box variable:

Example declaration for a check box variable:

```yaml
ods_vcn_use_existing:
  # renders variable as a check box
  type: boolean
  title: "Use Existing VCN?"
  required: true
  default: false
```

Visibility dependency

**Note:**

Groups have higher priority than the groups' constituent variables. For example, if a variable is visible within a group that is not visible, then the entire group is not visible.

Supported operations:

• `and`
• `eq` (equal)
• `ge` (greater than or equal)
• `gt` (greater than)
• `le` (less than or equal)
• `lt` (less than)
• `not`
• `or`

To hide or show variables or variable groups depending on other variables:

• Add the line `visible: <other_variable>`.

Example image for a set of variables, where visibility of the "Application Name" and "API Gateway Name" fields is dependent on the "Provision Functions and API Gateway?" check box:

Example declarations that show the "Application Name" and "API Gateway Name" fields (`functions_app_name` and `apigateway_name`) only when the "Provision Functions and API Gateway?" check box (`enable_functions_apigateway`) is selected:

```yaml
enable_functions_apigateway:
  type: boolean
```
<table>
<thead>
<tr>
<th>title</th>
<th>&quot;Provision Functions and API Gateway?&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>required</td>
<td>true</td>
</tr>
<tr>
<td>default</td>
<td>true</td>
</tr>
</tbody>
</table>

| functions_app_name |  |
| type | string |
| title | "Application Name" |
| description | "Do not use spaces." |
| required | true |
| default | "DataScienceApp" |
| pattern | "^[a-zA-Z0-9]+" |

# show only when enable_functions_apigateway variable is selected
visible: enable_functions_apigateway

| apigateway_name |  |
| type | string |
| title | "API Gateway Name" |
| required | true |
| default | "Data Science Gateway" |

# show only when enable_functions_apigateway variable is selected
visible: enable_functions_apigateway

### Password

To render a variable as a password:

- Add the line type: password.

To require re-entry for confirmation of the entered password:

- Add the line confirmation: true.

Example image for a password variable that requires confirmation:

![Example image for a password variable that requires confirmation](image)

Example declaration for a password variable, requiring confirmation:

| password |  |
| title | Repository Password |
| description | Must match remote repository password |
| # renders variable as a password field |
| type | password |
| # renders a second field to re-enter the password for confirmation |
| confirmation | true |
| pattern | "^[a-zA-Z]{1,8}$" |
| required | true |

### Required variables

To require a value for a variable:

- Add the line required: true.

Example image for a required variable, with validation warning:
Example declaration for a required variable:

```
availability_domain:
  type: oci:identity:availabilitydomain:name
  dependsOn:
    compartmentId: compartment_ocid
  # displays validation warning if no value is selected or entered
  required: true
  title: "Available Domain"
  description: "Available Domain"
  default: "tabw:PHX-AD-1"
```

Optional variable

To mark a variable as optional:

- Add the line `required: false`.

Example image for an optional variable:

```
BLOCK_VOLUME_GROUP_DISPLAY_NAME   OPTIONAL
Display name of the Block Volume Group
```

Example declaration for a variable with enumerated values:

```
volume_group_display_name:
  type: string
  # displays "Optional" marking to right of field label
  required: false
  title: "Block Volume Group Display Name"
  description: "Display name of the Block Volume Group"
```

Validation pattern

To validate the value entered for a variable against a regular expression pattern:

- Add the line `pattern: <regular-expression>`.

  `<regular-expression>` is the validation pattern specific to the value you want to validate.

```
Hyperlink pattern example: ^https?:\/(www\.)?[-a-zA-Z0-9:@:%_\+.~\#=]{2,256}\.[a-z]{2,4}\b([-a-zA-Z0-9:@:%_\+.~\#=\/=\-\]x\] })
```

Example image for a validation error for an entered value:

```
APPLICATION NAME
$special
Do not use spaces.
Specify a value that satisfies the following regular expression: ^[a-zA-Z0-9-]+\$
```

Example declaration for a variable with a validation pattern:

```
functions_app_name:
  type: string
  title: "Application Name"
  description: "Do not use spaces."
  required: true
```
Sensitive variables (Outputs tab, Application Information tab)

The output of a sensitive-marked variable displays as <sensitive> on the Application Information and Outputs tabs of the stack details page. In addition, an Unlock option is available on the Application Information tab. For more information about the Terraform sensitive argument, see sensitive - Suppressing Values in CLI Output.

To mark a variable as sensitive:

- Add the line sensitive: true.

Example image for a sensitive-marked variable (Generated Private Key for SSH Access) on the Application Information tab:

![Application Information Tab Example](image)

Example declaration for a sensitive-marked variable:

```terraform
ssh_private_key:
  title: Generated Private Key for SSH Access
  description: The private SSH key for the key-pair that you want to use
  sensitive: true
```

Application Information tab

To display the Application Information tab for a stack created from your Terraform configuration:

- Add lines for the schema title and description.
- Add at least one output in the outputs section.

To allow copying of an output variable field value displayed in the Application Information tab:

- Set the type: Add the line type: copyableString.

Example image for the Application Information tab:
Example declaration for a schema title, description, and outputs:

```plaintext
# heading under Application Information tab
title: "OCI Developer Tools"
# text under heading
description: "OCI Developer Tools like CLI, SDK, Terraform and Ansible are pre-installed on the compute instance."
stackDescription: "OCI Developer Tools are pre-installed on the compute instance."
# text in blue information box
informationalText: "The auto-generated SSH private key should not be used for production use, instead, the user should generate the SSH key-pair and upload the public key for the compute instance. To connect to the compute instance, copy the ssh private key pem content into a file on your machine. Run the following command from the terminal [ssh -i <path to the pem file> opc@<Public IP>]."
...
# output variable field names and values
outputs:
  compute_instance_public_ip:
    title: "Compute Instance Public IP"
    displayText:
      ${Messages.solutionsHub.solutions.ociDevTools.outputs.compute_instance_public_ip.displayText()}
    type: copyableString
    visible: true

  compartment_id:
    title: "Compartment Id"
    displayText:
      ${Messages.solutionsHub.solutions.ociDevTools.outputs.compartment_id.displayText()}
    type: string
    visible: true

  generated_instance_ssh_private_key:
    title: "Generated Private Key for SSH Access"
    displayText:
      ${Messages.solutionsHub.solutions.ociDevTools.outputs.generated_instance_ssh_private_key.displayText()}
    type: string
    visible: true
```
How to Interact with Console Items

This section describes how to interact with schema-controlled display of stack information in the Oracle Cloud Infrastructure Console.

Stack information is affected by the schema document (if any) that is included in the Terraform configuration used to create the stack. The schema document affects how variables look and behave during stack creation and what text is displayed in the Application Information tab for a created stack.

Unlock sensitive variables

An Unlock option on the Application Information tab indicates a sensitive-marked variable. This option toggles between Unlock and Lock.

- To view the value, click Unlock.
- To hide the value, click Lock.

Example image for a sensitive-marked variable (Generated Private Key for SSH Access) on the Application Information tab:

![Sensitive Variable Example](image)

Services Reference

This topic provides a reference of the Oracle Cloud Infrastructure (OCI) services that Resource Manager supports.

Full Reference Documentation

The full reference of the resources and data sources supported by Resource Manager contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

The Deprecated Resources on page 4616 reference lists the resources and data sources marked for deprecation by the Oracle Cloud Infrastructure (OCI) Terraform provider.

Supported Services

The following table lists the services supported by the OCI Terraform provider and the services supported by the resource discovery feature. This list also includes the values accepted by resource discovery's services parameter.
<table>
<thead>
<tr>
<th>Supported OCI service</th>
<th>Resource discovery support</th>

Degraded Resources

This topic covers the list of resources and data sources that have been marked deprecated by the Oracle Cloud Infrastructure (OCI) Terraform provider and their respective suggested replacements, if any. Resource Manager uses the latest version of the Terraform provider, unless you've specified a particular version of the provider in your configuration.

Resources and data sources marked for deprecation will trigger warnings during Terraform plan and apply jobs. In Resource Manager, look for these warning messages in the job logs.

For example:

The 'oci_autonomous_data_warehouse' resource has been deprecated. Please use 'oci_autonomous_database' instead.

Resources on path to deprecation may stop working in future, use the respective guide, if available, on how to migrate using the new replacements.

Deprecated Resources and Data Sources

Resources that have a migration path have deprecation guides available on how to rename and migrate them to their new replacements. Data sources do not have deprecation guide as you can directly replace them in their Terraform configuration and refresh the state.

Caution:

Before executing any deprecation guide, ensure that you have backed up your Terraform state file to avoid any data loss.

<table>

</tbody>
</table>

**Column Details**

- **Provider Version**: Provider version in which said resource or data source was marked deprecated
- **Type**: Type of the deprecated resource or data source
- **Old Deprecated Resource Name**: Deprecated resource or data source name
- **New Resource Name**: New resource or data source name that will provide the same functionality
- **Migration?**: If migration is possible to the new resource through Terraform state import
### Deprecated Fields

Deprecation notices for fields can be found in any of the previously released CHANGELOG. Deprecated fields are also shown as deprecated during Terraform `plan` and `apply` jobs. In Resource Manager, look for these warning messages in the job logs. For example:

The 'size_in_mbs' field has been deprecated. Please use 'size_in_gbs' instead.

### Supported Providers

This page lists providers supported by Resource Manager, organized by Terraform version.

#### OCI Provider Versions

Resource Manager supports the following versions of `terraform-provider-oci` for each indicated Terraform version.

<table>
<thead>
<tr>
<th>Terraform Version</th>
<th>0.11.x</th>
<th>0.12.x</th>
<th>0.13.x</th>
<th>0.14.x</th>
<th>1.0.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.16.0</td>
<td>3.16.0</td>
<td>3.16.0</td>
<td>3.16.0</td>
<td>3.16.0</td>
<td>3.30.0</td>
</tr>
</tbody>
</table>

#### Third-party Provider Versions

Resource Manager supports the following third-party Terraform providers for each indicated Terraform version.

<table>
<thead>
<tr>
<th>Third-party Terraform Provider</th>
<th>0.11.x</th>
<th>0.12.x</th>
<th>0.13.x</th>
<th>0.14.x</th>
<th>1.0.x</th>
</tr>
</thead>
<tbody>
<tr>

**GitHub and GitLab Connection Issues**

This topic describes how to troubleshoot connection issues to GitHub and GitLab.

**Symptom**

Can't connect to GitHub or GitLab.

This symptom can occur in the following situations:

- Creating a configuration source provider.
- Creating a stack from a new or existing configuration source provider.
• Running a job on a stack that uses a configuration file stored in GitHub or GitLab.
• Receiving an error message when confirming accessibility to a configuration source provider.

**Possible causes**

• Your Personal Access Token (PAT) may have been revoked or the required permission scopes changed and are insufficient.
• Your GitHub or GitLab repository permissions may have changed and become insufficient.
• Your GitHub or GitLab server is not accessible over the Internet.

**Resolution**

• Recreate your Personal Access Token (PAT) and ensure the scope for the token includes the required permissions (scopes). See the relevant documentation:
  - GitHub: https://docs.github.com/en/free-pro-team@latest/github/authenticating-to-github/creating-a-personal-access-token
  - GitLab: https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html
• Ensure that your GitHub or GitLab repository permissions meet requirements (admin or owner).
• Review prerequisites to confirm that all requirements are satisfied. See Prerequisites for connecting to GitHub and GitLab on page 4544.
Chapter 39

Search

This chapter explains how to search for resources across compartments.

Overview of Search

Oracle Cloud Infrastructure Search lets you find resources within a tenancy, pages of the Console within services, and documentation within the Oracle Cloud Infrastructure Getting Started Guide and Oracle Cloud Infrastructure User Guide. Search sorts search results by resource, service, or documentation, helping you avoid navigating through menus, the latency associated with loading a long list of results onto a single page, or the inconvenience of viewing a long list that spans multiple pages. You can also filter results by criteria specific to the search category after results are found and sorted by category.

You might find it helpful to use Search to find related resources when creating or deleting another resource. For example, you might want to find what compartments already exist before creating a new one because compartments cannot be deleted. Or, if you want to delete a volume, you can use a query to verify that a backup exists.

Another benefit of Search is that you can find resources that require action. For example, you might want to delete terminated block volumes because you no longer need them and don't want them to count against your service limits. Or, you can search for all resources that match a specific naming scheme, in case you want to act on a category of associated resources. Sometimes, resources in a specific lifecycle state, such as databases in a failed state, require troubleshooting. With Search, you can quickly identify those resources and resolve problems.

Search can also help you find pages within the Console, even if you can't recall their location among services in the navigation menu. When you find a page, if you want to know more about its contents, you can use Search to find documentation to help you. For example, you might search for "create virtual cloud network" if you want to read documentation about creating a virtual cloud network.

Search Categories and Ways to Search Them

To search for a resource, you can use a free text search based on keywords. You can also use structured resource query language to build an advanced query based on as little as a single resource attribute, such as the resource's creation date. Results for resource searches are limited to the tenancy and the currently selected region.

To find a named page in the Console without knowing the service or to locate help in the documentation, you can use a free text search. Advanced queries don't work for these types of searches.

Supported Resources

Search supports queries for the Oracle Cloud Infrastructure services and resources listed in this section. The following table will be updated as query support is added for more resources. You can refer to each resource's object reference for information about the resource, including its attributes. In some cases, where indicated, a resource might not support all attributes for search. Often, services index only the required attributes for a given resource. For current information about supported resources and resource attributes, use the ListResourceTypes API.

**Common Resource Attributes**

Although you can use the query language to search fields and values for any supported attribute, query results only provide information about the following resource attributes:

- Resource type
- Oracle Cloud Identifier (OCID)
- Compartment
- Availability domain
- Display name
- Creation date and time
- Lifecycle state
- Tags (visible in the API only)

The preceding attributes are common to most Oracle Cloud Infrastructure resources. Their meaning is consistent across resource types, so they’re provided by default for each result when you view a list of query results. Query results do not contain information specific to any resource type except where a matching search term appears. Meaning, you can query for volumes of a certain size. If there’s a match, then the search result will display the attribute with the value that matches. In this example, in addition to the common attributes, the result also provides the **Size** attribute if that’s where the match was found. You must view the details of a resource to see other resource-specific information.

**Tip:**

If you use the Console, neither query results nor resource details will include either defined tags or free-form tags, due to display constraints. Any given resource might contain hundreds of tags. If you want to see tags, use the API to view resource details.
Required IAM Permissions

The resources that you see in search or query results depend on the permissions you have in place for the resource type. You do not necessarily see results for every resource in the compartment or tenancy. For example, if your user account is not associated with a policy that grants you the ability to, at a minimum, inspect the dbsystem resource type, then you can’t query for DB systems. (The verb inspect lets you list and get resources.) Instead, Search will show no results for queries of DB system resources.

Permissions and policy language applies to resources. Searching for pages across services in the Console or documentation requires no special permissions because they aren’t resources. An administrator cannot restrict access to search results of services or documentation.

For more information about policies, see How Policies Work on page 2800. For information about the specific permissions required for the list API operation for your desired resource type, see the Policy Reference on page 2837 for the appropriate service.

Free Text Search

This topic describes how Search handles the search terms that you submit as a free text search.

By default, text entered in the Console search box is interpreted as a free text search. You can use a free text search to conduct a search of any category that Search supports. This includes searches for resources, pages across services in the Console, and documentation.

Matching

Search tries to match search terms against the values of indexed fields. For resources, this means that Search evaluates the value of all indexed resource attributes, from common attributes (except the resource type attribute) to attributes specific to a resource type. For services, this includes all page display names and service groups. For documentation, this includes the title and the contents of the topic. (Search does not query the topic description, topic category, or keyword metadata.)

To provide matching results to the text given in a free text search, Search queries all indexed fields by applying the = (equals) operator to text that you specified. If you're familiar with advanced queries, the effect is the same as using a matching clause. For example, a free text search for the term "net" queries all resource types, service pages, and documentation for the string "net" in any indexed field. If the string appears as part or the whole of a value anywhere in an indexed field, Search considers the found item a matching result. Search does not require exact matching, but an exact match does improve a result's ranking.

If the free text search includes a delimiting character (for example, a hyphen), the delimiter causes Search to treat the text on either side of the delimiter as an independent search term. For example, a free text search for "2020-04" looks for the string "2020" and the string "04". If a potential result contains either string, then it's a match.

Free text search matches individual terms from the provided text. Search does not try to match specific combinations of characters that you might group by using quotes or by presenting terms in a specific order. Likewise, proximity of search terms does not matter. However, if you have multiple search terms in a free text search, results that contain multiple matches to the search terms have a higher ranking in the search results.

Ranking of Results

To rank results, Search evaluates each potential result for how closely it can match the search term or terms provided. Exact matches occupy a higher rank in the results than partial matches. Search also considers how many matches for the exact search term the result contains. Either a close match or multiple matching terms improves the result's ranking.

Search Language Syntax

This topic describes the basics of the query language for Search, including an explanation of syntax and rules so you can create your own queries. Queries apply search conditions to specific resource types and let you sort results. If you want to search across all supported resource types and resource attributes and do not need ordered search results,
you do not need to construct a query. Instead, you can search for a partial or exact match of free-form text without applying query language syntax to your search.

When you are ready to run a query, see Querying Resources, Services, and Documentation on page 4637 for instructions.

Query Basics

The following examples show the basic syntax of a query:

```
query <resourceType> resources where <conditions> sorted by <fieldName> <order>
```

Or:

```
query <resourceType> resources matching <keywords>
```

Search ignores white space, indentation, and line breaks. Sample queries include indentation to improve readability. For the purposes of demonstrating syntax only, angle brackets (<>) and italicized text indicate variables, which can consist of one or more keywords.

In a query, clauses include the following:

- **query** - (Required) Selects which resources to return based on subsequent clauses. Query statements always begin with the word `query`.
- **where** - Matches resources to the specified conditions.
- **matching** - Matches resources to the specified text regardless of whether the text matches exactly, matches the resource type, or appears in an indexed resource attribute.
- **sorted by** - Orders resources according to `fieldName` in the order specified by `order`. If you do not include this clause, Search lists results by creation date in descending order, with the newest resources listed first.

Clauses are optional unless indicated otherwise. For matching purposes, you can use the `where` clause and the `matching` clause either separately or together.

In the `query` clause, you specify the following information:

- **resourceType** - (Required) Specifies the resource type to which the subsequent clauses apply when you run the query. You can specify either the resource type name (for example, `database` or `group`) or `all`. If you specify `all`, Search searches for the `conditions` against all resource types. You can query for individual resource types, but not family types. For a list of supported resource types, see the Supported Resources section of Overview of Search.
- **resources** - (Required) Specifies that this is a resource query.

Conditions

The `where` clause applies `conditions` that filter the results returned by Search. You can specify one or more condition statements. For more information about multiple conditions, see Grouping Conditions.

In a query, `conditions` consist of the following:

```
<fieldName> <operation> <value>
```

The `fieldName` keyword is the resource attribute against which the `operation` and chosen `value` of that attribute are evaluated. Each field is associated with a field type. The field type tells you the expected format for any value in that field. What kind of `operation` you can use in a `conditions` statement depends on the field type.

In query `conditions`, an `operation` is a comparison operator that applies to the `value` in the statement. The `value` keyword refers to the value of the `fieldName` you specified. Search evaluates whether the specified
attribute of the chosen resource type matches or does not match the *value*, according to the operation. In a query, you must enclose any string or date-time value in opening and closing straight single quotes (#) or double quotes ("").

The following table describes supported operations for resource queries:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
<th>Supported Field Types</th>
<th>Case-sensitive?</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equals, or exact matching for strings</td>
<td>String, integer, rational, Boolean, date-time</td>
<td>No</td>
<td>If the <em>value</em> was <code>#backUp#</code>, it would match &quot;backup&quot;, &quot;BACKUP&quot;, &quot;BackUp&quot;, &quot;backUp&quot;, or any other variation in casing.</td>
</tr>
<tr>
<td>!=</td>
<td>Does not equal</td>
<td>String, integer, rational, Boolean, date-time</td>
<td>No</td>
<td>If the <em>value</em> was <code>#backUp#</code>, it would match anything that does not equal &quot;backUp&quot;, &quot;backup&quot;, or any other variation in casing. It also would match anything that does not contain the characters 'backup' in that order.</td>
</tr>
<tr>
<td>==</td>
<td>Strictly equals</td>
<td>String</td>
<td>Yes</td>
<td>If the <em>value</em> was <code>#backUp#</code>, it would only match &quot;backUp&quot; and no other variation in casing.</td>
</tr>
<tr>
<td>!=</td>
<td>Strictly does not equal</td>
<td>String</td>
<td>Yes</td>
<td>If the <em>value</em> was <code>#backUp#</code>, it would match &quot;backup&quot;, &quot;BACKUp&quot;, or anything except &quot;backUp&quot;, with that exact casing.</td>
</tr>
<tr>
<td>=~</td>
<td>Contains</td>
<td>String</td>
<td>No</td>
<td>If the <em>value</em> was <code>#backUp#</code>, it would match anything that equals &quot;backup&quot;, &quot;BACKUP&quot;, &quot;BackUp&quot;, &quot;backUp&quot;, or any other variation in casing, or contains those characters in that order, alongside other characters.</td>
</tr>
<tr>
<td>Operation</td>
<td>Description</td>
<td>Supported Field Types</td>
<td>Case-sensitive?</td>
<td>Example</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>-----------------------</td>
<td>-----------------</td>
<td>---------</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
<td>Integer, rational, date-time</td>
<td>Not applicable</td>
<td>For a query where you have size &gt;= 5 as the condition, all results have a value of 5 or greater in the field named size.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
<td>Integer, rational, date-time</td>
<td>Not applicable</td>
<td>For a query where you have size &gt; 5 as the condition, all results have a value of greater than 5 in the field named size.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
<td>Integer, rational, date-time</td>
<td>Not applicable</td>
<td>For a query where you have size &lt;= 5 as the condition, all results have a value of 5 or less in the field named size.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than</td>
<td>Integer, rational, date-time</td>
<td>Not applicable</td>
<td>For a query where you have size &lt; 5 as the condition, all results have a value of 5 or less in the field named size.</td>
</tr>
</tbody>
</table>

The following table lists some examples of resource attributes that belong to each category of supported field types. (As previously described, the field type tells you the expected format for a given field and the kind of operation you can pair it with in a conditions statement.)

The table does not include every possible example for a given field type nor does it include examples from every resource-type. If you want to know what format the Search service expects for a specific resource attribute, you can use the command line interface or API to find out more about resource attributes. You can also consult the API documentation. The API documentation includes a reference for each supported resource type that specifies attributes, their field types, and any restrictions. For more information, see the Supported Resources section of Overview of Search.

<table>
<thead>
<tr>
<th>Type</th>
<th>Example Resource Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display names, lifecycle states, availability domains, tags, CIDR blocks, and URLs</td>
</tr>
<tr>
<td>Integer</td>
<td>Size or length of a resource</td>
</tr>
<tr>
<td>Rational</td>
<td>Available data storage</td>
</tr>
<tr>
<td>Boolean</td>
<td>Whether a feature is enabled or configured, whether a resource is healthy, whether a resource is public or private, whether something is the latest version, and whether something is allowed</td>
</tr>
<tr>
<td>Date-time</td>
<td>Creation dates, last-updated dates, last-indexed dates, and scheduled maintenance reboots</td>
</tr>
</tbody>
</table>
**Grouping Conditions**

By including more than one condition statement in a query, you can refine results according to multiple criteria. You can group multiple conditions by using either the logical operators `&&` (ampersands, to indicate a logical AND) or `||` (vertical bars, to indicate a logical OR). For example:

```plaintext
licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40 && lifecycleState != 'FAILED'
```

You cannot combine two different logical operators in the same query unless you wrap parentheses around one group of predicates. (Multiple conditions can only use the same logical operator otherwise.) For example:

```plaintext
(licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40) || lifecycleState != 'FAILED'
```

In the preceding example, all results returned will have either “LICENSE_INCLUDED” as the value in the field named “licenseModel” and a value greater than 40 for the field named “dataStoragePercentage” or the value of their “lifecycleState” field name is anything other than “FAILED”.

The following group is also acceptable:

```plaintext
licenseModel = 'LICENSE_INCLUDED' && (dataStoragePercentage > 40 || lifecycleState != 'FAILED')
```

In the preceding example, all results returned will have “LICENSE_INCLUDED” as the value in the field named “licenseModel” and either a value greater than 40 as the value for the field named “dataStoragePercentage” or anything that is not “FAILED” for the value of the field named “lifecycleState”.

Search does not perform left-to-right evaluation to reduce ambiguity or clarify intent.

**Date and Time Values**

You can specify date and time values by using any of the following pattern string formats:

<table>
<thead>
<tr>
<th>Format</th>
<th>Examples</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;yyyy&gt;-&lt;MM&gt;-&lt;dd&gt;</code></td>
<td>'2018-06-19 16:15:41 PDT', '2018-06-19 16:15:41 -08:00'</td>
<td>TimeZone is optional. If TimeZone is omitted, UTC is used.</td>
</tr>
<tr>
<td><code>&lt;HH&gt;:&lt;mm&gt;:&lt;ss&gt;</code></td>
<td>'2018-06-19 16:15:41'</td>
<td></td>
</tr>
<tr>
<td><code>&lt;TimeZone&gt;</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>&lt;EEE&gt;, &lt;d&gt; &lt;MMMM&gt; &lt;yyyy&gt;</code></td>
<td>'Tue, 19 Jun 2018 16:15:41 +0300', '19 June 2018 16:15:41'</td>
<td>EEE is optional. MMM can also be expressed as MMMM. TimeZone is also optional. If TimeZone is omitted, UTC is used.</td>
</tr>
<tr>
<td><code>&lt;HH&gt;:&lt;mm&gt;:&lt;ss&gt;</code></td>
<td>'2018-06-19T16:15:41'</td>
<td></td>
</tr>
<tr>
<td><code>&lt;TimeZone&gt;</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You must observe spacing. Interpret dashes, colons, commas, and the characters ‘T’ and ‘Z’ literally. To interpret placeholder values in the preceding table, you can refer to the following pattern syntax:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Date or Time Component</th>
<th>Presentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>Year</td>
<td>Year</td>
</tr>
<tr>
<td>M</td>
<td>Month in year</td>
<td>Month</td>
</tr>
<tr>
<td>d</td>
<td>Day in month</td>
<td>Day</td>
</tr>
<tr>
<td>H</td>
<td>Hour in day (from 00-23)</td>
<td>Number</td>
</tr>
<tr>
<td>Letter</td>
<td>Date or Time Component</td>
<td>Presentation</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>m</td>
<td>Minute in hour</td>
<td>Number</td>
</tr>
<tr>
<td>s</td>
<td>Seconds in minute</td>
<td>Number</td>
</tr>
<tr>
<td>E</td>
<td>Day in week</td>
<td>Text</td>
</tr>
</tbody>
</table>

Repeating pattern letters indicate their exact presentation. For example, 'HH' means you must use '00' and not '0' to represent midnight. Similarly, 'EEE' means 'Tue' and not 'Tuesday'. Likewise, 'MM' requires '09' instead of '9' to represent the month of September.

TimeZone is optional, but in your chosen format, you can specify TimeZone in any of the following ways:

- **Name.** You can specify a time zone by its name, such as **GMT** or **PDT**. Values are case-insensitive.
- **GMT offset value.** You can specify a time zone according to its GMT offset. For example, **GMT-08:00**. Values are case-insensitive.
- **ISO 8601 time zone.** You can specify a time zone according to ISO 8601 standards. For example, **-08, -0800**, or **-08:00**.

Instead of using one of the preceding formats, you can also specify a date-time value as the constant **now**. The constant **now** represents the current time to the level of granularity of seconds in a minute.

Lastly, you can add or subtract time intervals from any date-time values. For example, you can query for resources that were created within five minutes of a specific time. Search supports the following time intervals:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Date or Time Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Seconds</td>
</tr>
<tr>
<td>m</td>
<td>Minutes</td>
</tr>
<tr>
<td>h</td>
<td>Hours</td>
</tr>
<tr>
<td>d</td>
<td>Days</td>
</tr>
<tr>
<td>w</td>
<td>Weeks</td>
</tr>
</tbody>
</table>

To specify a time interval in relation to a date-time value, use one of the following formats:

- **now - 3h**
- **2018-06-19 16:15:41 PDT + 1h**

**Matching**

For matching purposes, instead of or in addition to using a where clause with conditions, you might want to use the matching clause. The matching clause obviates the need to specify conditions (that contain a field name, operation, and value). A matching clause effectively queries all indexed fields by applying the = (equals) operator along with the text you specify. However, it does so without strictly requiring an exact match. For example, the following query uses a matching clause to behave the same way as a free text search: `query all resources matching 'instance'. The query produces results that match all resources and resource attributes that contain the word "instance".

The matching clause queries all indexed fields for matches, but ignores special characters, including any punctuation.

**Sorting**

The last clause of a resource query is the sorted by clause and is optional. The sorted by clause orders the results returned by Search based on the field name and lists them according to the order you specify. By default, if you do not specify sort order, results are always sorted by date-time created in descending order.
In the sorted by clause, you can specify the following:

- **fieldName** - The field that Search uses to sort results. You can specify any field of any resource. Resources that do not contain the field you specify are listed after the resources that do.
- **order** - You can specify either **asc** or **desc**. Specifying **asc** lists results in ascending order. Specifying **desc** lists results in descending order.

### Querying Multiple Resource Types

You can query multiple resource types at once by joining queries. Each query can have its own conditional clause. If the queries that you want to join have different "where" conditions, then the syntax is different from when you have queries for multiple resource types that share the same "where" condition.

The basic syntax for a query for multiple resource types is as follows:

```plaintext
query <resourceType>, <resourceType> resources
```

For example:

```plaintext
query group, user resources
```

The preceding example query returns all groups and all users in the tenancy.

The following shows the syntax for a query for multiple resource types with conditions, but where the conditions are the same for all resource types:

```plaintext
query <resourceType>, <resourceType> resources where <conditions>
```

For example:

```plaintext
query group, user resources where displayName = 'administrator'
```

The preceding example query returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing.

If you need to apply differing conditions to any resource type, you must use a **union** keyword instead of comma separation between the joined queries. The following shows the syntax for a query for multiple resource types where some of the resource types share conditions while others do not:

```plaintext
query <resourceType>, <resourceType> resources where <conditions> union <resourceType> resources
```

For example:

```plaintext
query group, user resources where displayName = 'administrator' union compartment resources
```

The preceding example returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing, and all compartment resources.

Or, for example:

```plaintext
query group resources union user resources where displayName = 'administrator' union compartment resources
```

The preceding example returns all groups and all compartments. It also returns all users with the display name "administrator," with any variation in casing.

Optionally, you can add the **sorted by** clause to the end of the query to order all results in ascending or descending order.
Sample Queries

This topic provides an explanation of sample queries, including what results to expect from a given sample query. For more information about the syntax for constructing a query, see Search Language Syntax on page 4627.

| Note: | Example Values | Sample queries show example values for resource attributes. Replace those examples with values from your own tenancy. |

Search provides the following sample queries in the Console:

- Query for everything
- Query for everything, sorted by time created
- Query for volumes and users
- Query for volumes and users, sorted by time created
- Query for volumes and users that have any indexed field matching “production,” sorted by time created
- Query for all resources that have a specific freeform tag
- Query for all resources that have one of two specific defined tags
- Query for instances in a "Running" state
- Query for instances in either a "Terminated" or "Terminating" state
- Query for all resources in a specific compartment
- Query for all instances due for a maintenance reboot
- Query for all resources that are Always Free

Query All Resources

**Query name:** Query for everything

**Expected results:** Returns all supported resources in the tenancy across all compartments. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```
query all resources
```

Query All Resources, Sort by Time Created

**Query name:** Query for everything, sorted by timeCreated

**Expected results:** Returns all supported resources in the tenancy across all compartments, listed in order of time created, from newest to oldest.

**Sample query language:**

```
query all resources
sorted by timeCreated desc
```

Query Volumes and Users

**Query name:** Query for volumes and users

**Expected results:** Returns all block volumes and users in the tenancy. Lists results, by default, in order of time created, from newest to oldest.
Sample query language:

```query
volume, user resources
```

**Query All Volumes and Users, Sort by Time Created**

**Query name:** Query for volumes and users, sorted by timeCreated

**Expected results:** Returns all block volumes and users in the tenancy, listed in order of time created, from newest to oldest

**Sample query language:**

```query
volume, user resources
sorted by timeCreated desc
```

**Query Volumes and Users Matching "Production," Sorted by Time Created**

**Query name:** Query for volumes and users, with anything matching production, sorted by timeCreated

**Expected results:** Returns all block volumes and users in the tenancy that have any indexed fields that exactly or partially match the search string "production", irrespective of casing. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```query
volume, user resources
matching 'production'
sorted by timeCreated desc
```

**Query All Resources With Specific Freeform Tags**

**Query name:** Query for all resources that have specific freeform tags

**Expected results:** Returns all resources in the tenancy that have a freeform tag of "costcenter" with a value of "1234."

**Sample query language:**

```query
all resources
where
  (freeformTags.key = 'costcenter' && freeformTags.value = '1234')
```

**Query All Resources According to Defined Tags**

**Query name:** Query for all resources that have one of two specific defined tags

**Expected results:** Returns all resources in the tenancy that have either a tag with the key “region” and value “phx” in the tag namespace “categorization,” or all resources in the tenancy that have a tag with the key “region” and value “iad” in the namespace “categorization.” Ignores casing for all keys and values.

**Sample query language:**

```query
all resources
where
```
(definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'phx') || (definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'iad')

**Query Instances According to Specific Lifecycle State**

**Query name:** Query for running instances

**Expected results:** Returns all instances in the tenancy in a "Running" state. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```sql
query
  instance resources
where lifeCycleState = 'RUNNING'
```

**Query Instances According to One of Two Lifecycle States**

**Query name:** Query for instances terminated or terminating

**Expected results:** Returns all instances in the tenancy in either a "Terminated" or "Terminating" state. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```sql
query
  instance resources
where lifeCycleState = 'TERMINATED' || lifeCycleState = 'TERMINATING'
```

**Query All Resources According to Compartment ID**

**Query name:** Query for all resources in a compartment

**Expected results:** Returns all resources in the tenancy with a specific compartment ID. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```sql
query
  all resources
where compartmentId = 'compartmentOcid'
```

**Query All Instances Due for Maintenance Reboot**

**Query name:** Query for all instances which have an upcoming scheduled maintenance reboot

**Expected results:** Returns all instances in the tenancy with a scheduled maintenance reboot time value of "now." Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```sql
query
  instance resources
where timeMaintenanceRebootDue = 'now'
```

**Query All Always Free Resources**

**Query name:** Query for all resources that are Always Free
**Expected results:** Returns all existing resources in the tenancy that are free of charge for the life of the account. Lists results, by default, in order of time created, from newest to oldest.

**Sample query language:**

```sql
query
  all resources
  where
    systemTags.namespace = 'orcl-cloud' &&
    systemTags.key = 'free-tier-retained' &&
    systemTags.value = 'true'
```

**Querying Resources, Services, and Documentation**

This topic describes different ways you can use Search.

You can find Oracle Cloud Infrastructure resources in your tenancy by performing a free text search or running a query. A free text search locates resources with the desired text anywhere in the resource metadata. An advanced query lets you find resources according to specific fields and conditions. When finding resources, both free text searches and queries rely on resource indexing and the indexed attributes for a given resource type. Search also scopes resource results to the currently selected region.

Although queries can only be used to find resources, you can use free text searches to help you locate pages in the Console or help in the documentation. A free text search looks for search terms in the display names of Console pages and lists pages according to where they appear within services in the tenancy. A free text search can also find search terms in the Oracle Cloud Infrastructure Getting Started Guide and Oracle Cloud Infrastructure User Guide documentation. The results for both these types of searches depend on the language, but not the region.

**Note:**

Supported Resources and Using Advanced Resource Queries

The search results that you see reflect what Search considers supported resources. To see what Oracle Cloud Infrastructure services and resources Search supports, see the Supported Resources section of Overview of Search.

Furthermore, if you don't find the resource you want or expect when you submit a free text search, you might need to run a query constructed using query language syntax. For more information about syntax for advanced queries, see Search Language Syntax on page 4627. (For a documentation search, if a free text search doesn't produce the content results you expect, you might try a plural or singular form of one or more search terms or a different, supported language.)

**Using the Console**

You can find resources, services, or documentation by doing one of the following:

- typing free-form text for a free text search
- reusing recent search terms
- typing a query (for resources only)
- modifying a sample query

By default, text entered into the **Search for resources, services, and documentation** box is interpreted as a free text search.

**To perform a free text search**

1. In the top navigation bar, click **Search for resources, services, and documentation**.
2. Type the free-form text you want to search for.
3. Under one of the categories of search results, click a result. (To see all results on a full page instead, click View all next to the category name.)

4. (Optional) If you do not see the results that you expect, you can change to a different region (if searching for a resource), change to a different language (if searching for a service or documentation), view a different category of search results, or edit your search terms. If searching for a resource, you can also refine your search with a query by clicking Advanced Resource Query. Then, follow the instructions in To run a custom, free-form query or To run a sample query.

5. (Optional) If you chose to view results on a full page, the list shows results with the best matches at the beginning of the list. However, you can also do the following:
   - If you chose the Resources category specifically, you can sort results, expand individual results to see the matching text, or you can filter results more specifically. To filter results more specifically, click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include.
   - For the Services category, you can only filter or sort results. To filter results more specifically, click Choose one or more service groups to filter the results, and then type or choose the service group to include.
   - Similarly, for the Documentation category, you can only filter or sort results. To filter results more specifically, click Choose one or more topics to filter the results. (Here, "topic" refers to the subject matter rather than the topic title.)

For any category, filter options only include resource types, service groups, or documentation presented in the full list of results.

Results are eventually consistent, but might not immediately include resources that you created very recently.

To run a custom, free-form query to find a resource

1. In the top navigation bar, click Search for resources, services, and documentation, and then click Advanced Resource Query.

2. In the query text box, type a query using query language syntax, and then click Search.

3. The list shows results in groupings. From here, you can filter results more specifically: click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include in filtered results. Filter options only include resource types present in the full list of results.

4. (Optional) If you do not see the results that you expect, you can change to a different region or edit your query.

Results are eventually consistent, but might not immediately include resources that you created very recently.

To run a sample query to find a resource

1. In the top navigation bar, click Search for resources, services, and documentation, and then click Advanced Resource Query.

2. Click Select Sample Query, and then click one of the listed sample queries. For an explanation of sample queries, see Sample Queries on page 4634.

3. Verify that the query language in the query text box satisfies your needs. Change all example values. Add, delete, or modify clauses, as appropriate, and then click Search.

4. The list shows results in groupings. From here, you can filter results more specifically: click Choose one or more resource types to filter the results, and then type or choose one or more resource types to include in filtered results. Filter options only include resource types present in the full list of results.

5. (Optional) If you do not see the results that you expect, you can change to a different region or edit your query.

Results are eventually consistent, but might not immediately include resources that you created very recently.

To reuse recent search terms

1. In the top navigation bar, click Search for resources, services, and documentation.

2. Under Recent searches, click one of five recent search terms. (Recent searches only include the five most recent free text searches, not advanced searches that use the structured query language.)

3. Under one of the categories of search results, click a result. (To see all results on a full page instead, click View all next to the category name.)

4. (Optional) If you do not see the results that you expect, you can change to a different region (if searching for a resource), change to a different language (if searching for a service or documentation), view a different category
of search results, or edit your search terms. If searching for a resource, you can also refine your search with a
query by clicking **Advanced Resource Query**. Then, follow the instructions in **To run a custom, free-form query**
or **To run a sample query**.

5. (Optional) If you chose to view results on a full page, the list shows results with the best matches at the beginning
of the list. However, you can also do the following:

- If you chose the **Resources** category specifically, you can sort results, expand individual results to see the
  matching text, or you can filter results more specifically. To filter results more specifically, click **Choose one
  or more resource types to filter the results**, and then type or choose one or more resource types to include.
- For the **Services** category, you can only filter or sort results. To filter results more specifically, click **Choose
  one or more service groups to filter the results**, and then type or choose the service group to include.
- Similarly, for the **Documentation** category, you can only filter or sort results. To filter results more
  specifically, click **Choose one or more topics to filter the results**. (Here, "topic" refers to the subject matter
  rather than the topic title.)

For any category, filter options only include resource types, service groups, or documentation presented in the full
list of results.

Results are eventually consistent, but might not immediately include resources that you created very recently.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options
available for CLI commands, see the **Command Line Reference**.

**To see what resource-types you can run a query for**

Open a command prompt and run `oci search resource-type list` to see what resource-types you can run
a query for:

```bash
oci search resource-type list
```

For example:

```bash
oci search resource-type list --all
```

**To see what resource attributes you can query for a given resource-type**

Open a command prompt and run `oci search resource-type get` to see what attributes you can search for
a given resource-type:

```bash
oci search resource-type get --name <resource-type_name>
```

You must specify the resource-type by its indexed name. Pay attention to capitalization. For example:

```bash
oci search resource-type get --name VolumeBackup
```

**To perform a free text search**

Open a command prompt and run `oci search resource free-text-search` to search the text of all
searchable resource-types:

```bash
oci search resource free-text-search
```

For example:

```bash
oci search resource free-text-search --text <text_to_search_for>
```
To run a custom, free-form query to find a resource

Open a command prompt and run `oci search resource structured-search` to run an advanced resource query:

```
oci search resource structured-search --query-text "<query_text_using_query_language_syntax>"
```

For example:

```
oci search resource structured-search --query-text "query user resources"
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to search for resources or find out what resources you can search for:

- `SearchResources`
- `ListResourceTypes`

In addition to finding supported resources with `ListResourceTypes`, you can also find what attributes each resource supports for search.

Example: Finding Instance Resources With a Specific Defined Tag

This section describes how to use the API to query for a specific type of resource based on the resource's defined tags.

The following query will find instances with a defined tag within the namespace "rqs", where the tag's key is "costcenter" and the key's value is "1234".

```plaintext
query
    instance resources
where
    (definedTags.namespace = 'rqs' && definedTags.key = 'costcenter' && definedTags.value = '1234')
```

When you use the `SearchResources` operation to issue the query, the request will look similar to the following. (This example purposefully omits the authorization header and other headers.)

```plaintext
POST /20180409/resources
Host: query.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "type": "Structured",
    "query": "query instance resources where (definedTags.namespace = 'rqs' && definedTags.key = 'costcenter' && definedTags.value = '1234')",
    "matchingContextType": "HIGHLIGHTS"
}
```

If your query produces results, the response will list the resources that match the resource type and tag that you specified. The response will look similar to the following:

```plaintext
{
    "items" : [
        "resourceType": "Instance",
        "identifier": "ocid1.instance.oc1.phx.exampleawcbfhncvbh3siw2svbpgr3bopovy6hgnywfauxqo37ckdmr6hjya",
        "compartmentId": "ocid1.tenancy.oc1..examplea46vssm7l5wsk5qa7cvb163ctajep4bh61v4vaifaxz6ec7jzg4q",
```
With these results, you can take additional action, if needed. For more information about a resource type, such as its attributes, see its reference page in the API Reference Guide. For the reference pages of resource types that have been indexed for Search, see Supported Resources on page 4620.

Troubleshooting Search

This topic covers common issues related to Search and how you can address them:

- Query or Search Results are Not as Expected on page 4642

Query or Search Results are Not as Expected

There are several reasons why you might not see results that you expect from a search or query.

Not all resource types have been indexed for Search. For a list of currently supported resource types, see Supported Resources on page 4620.

You might not have the required permissions for the resource type that you want to view in search or query results. If there's no policy that grants you the permissions you need, then an administrator must create one for you or add you to a group that's already named in a policy. For more information, see Details for Search.

The query syntax you used might need adjustment. Verify that the conditions in your query language haven't restricted the results to a narrower set than you intended.

If you recently created a resource, it might not show up in search results immediately. Similarly, if you recently updated a resource, your changes might not immediately appear. At times, you might see a resource in a list view before you can see it in search results. The Search service is eventually consistent. Wait, and then try again.
Chapter 40

Security Zones

This chapter explains how to use Security Zones.

Security Zones

Security Zones let you be confident that your resources in Oracle Cloud Infrastructure, including Compute, Networking, Object Storage, and Database resources, comply with Oracle security principles.

A security zone is associated with a compartment and a security zone recipe. When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the list of policies defined in the security zone recipe. If any security zone policy is violated, then the operation is denied.

For example, a security zone policy forbids the creation of public buckets in Object Storage. If you try to create a public bucket in a security zone that has this policy, or if you try to modify an existing storage bucket and make it public, you receive an error message. Similarly, you can't move an existing resource from a standard compartment to a security zone unless all policies are met.

Security zone

An association between a compartment and a security zone recipe. Resource operations in a security zone are validated against all policies in the recipe.

Security zone recipe

A collection of security zone policies.

Security zone policy

A security requirement for resources in a security zone.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe and you can't modify it.

In general, security zone policies align with these security principles:

- Resources can't be moved from a security zone to a standard compartment because it might be less secure.
- Data in a security zone can't be copied to a standard compartment because it might be less secure.
- All the required components for a resource in a security zone must also be located in a security zone. Resources that are not in a security zone might be vulnerable. For example, a compute instance (Compute) in a security zone can't use a boot volume that is not in a security zone.
- Resources in a security zone must not be accessible from the public internet.
- Resources in a security zone must be encrypted using customer-managed keys.
- Resources in a security zone must be regularly and automatically backed up.
- Resources in a security zone must use only configurations and templates approved by Oracle.

To learn more, see Security Zone Policies on page 4647.

A security zone policy differs from an IAM policy in the following ways:

- Administrators create IAM policies to grant users the ability to manage certain resources in a compartment.
Security Zones

- A security zone policy ensures that these management operations comply with the Oracle maximum security architecture and best practices.
- A security zone policy is validated regardless of which user is performing the operation.
- A security zone policy denies certain actions; it doesn't grant capabilities.
- Administrators can't create, modify, or disable security zone policies.

To create a security zone, see Managing Security Zones on page 4645.

Managing Security Zones

You can create and delete security zones, and identify the policies enforced in your security zone.

A security zone has the following characteristics:

- Associated with a single compartment that has the same name as the security zone
- Assigned a security zone recipe

As resources are created or modified in the compartment, Oracle Cloud Infrastructure validates these operations against all policies in the security zone recipe.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe, and you can’t modify it.

A security zone compartment can only have subcompartments that are also security zone compartments.

- You can create a security zone in an existing security zone compartment.
- You can move a security zone compartment to another security zone compartment.
- You can’t create a standard compartment in a security zone compartment.
- You can’t move a standard compartment to a security zone compartment.

Caution:

To ensure the integrity of your data, you can't move certain resources from a compartment in a security zone to a compartment that isn't in a security zone.

Required IAM Policy

To work with Security Zones, an administrator must grant you access in an IAM policy.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted.

For example, the following IAM policy allows users in the group SecurityAdmins to manage security zones in the entire tenancy.

```
Allow group SecurityAdmins to manage security-zone in tenancy
```

See Security Zone IAM Policies on page 4651.

Creating a Security Zone

Create a security zone by using the Console.

All security zones are assigned the Maximum Security Recipe.

2. Click Create Security Zone.
3. Enter a name and description for the security zone.
   Oracle Cloud creates a compartment with the same name and assigns it to this security zone.
   Avoid entering confidential information.
4. For Create in Compartment, navigate to the compartment that you want to create the new compartment in.
5. Click Create Security Zone.
To create resources such as networks or compute instances in the new security zone, select the compartment with the same name when you create the resources.

**Viewing the Policies for a Security Zone**
Identify the recipe for an existing security zone, and then view its policies.

1. Open the navigation menu and click **Identity & Security**. Under **Security Zones**, click **Overview**.
2. Click the name of the security zone.
3. Click the recipe for the security zone.

To learn more about a security zone policy in the recipe, see [Security Zone Policies](#) on page 4647.

**Deleting a Security Zone**
Delete a security zone by using the Console.

To delete a security zone, you delete the *compartment* that's associated with the security zone.

Before you can delete a compartment, it must be empty of all resources. Ensure that all the compartment's resources have been moved, deleted, or terminated, including any policies attached to the compartment.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To ensure the integrity of your data, you can't move certain resources from a compartment in a security zone to a compartment that isn't in a security zone.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click **Identity & Security**. Under **Security Zones**, click **Overview**.
2. Locate the compartment whose name is the same as the security zone.
3. Click the **Actions** icon (three dots) for this compartment, and then click **Delete Compartment**.
4. At the prompt, click **OK**.

For more information, see [Deleting Compartments](#).

**Managing Recipes**
When you create a security zone you assign a recipe to it. A recipe is a collection of security zone policies.

When you perform certain resource operations in a security zone, such as creating a compute instance or a subnet, Oracle Cloud Infrastructure automatically validates the policies within the recipe that is assigned to the security zone.

Your tenancy has a predefined recipe named Maximum Security Recipe, which includes all available security zone policies. Oracle manages this recipe, and you can’t modify it.

**Required IAM Policy**
To work with Security Zones, an administrator must grant you access in an IAM policy.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted.

For example, the following IAM policy allows users in the group *SecurityAdmins* to manage security zones in the entire tenancy.

```plaintext
Allow group SecurityAdmins to manage security-zone in tenancy
```

See [Security Zone IAM Policies](#) on page 4651.

**Viewing the Policies in a Recipe**
Identify the policies in a security zone recipe by using the Console.

1. Open the navigation menu and click **Identity & Security**. Under **Security Zones**, click **Overview**.
2. Click **Recipes**.
3. Click the name of a recipe.

To learn more about a security zone policy in the recipe, see Security Zone Policies on page 4647.

**Viewing the Security Zones Associated with a Recipe**

Identify the security zones that are associated with a recipe by using the Console.

2. Click Recipes.
3. Click the name of a recipe.
4. Click Associated Security Zones.

To create a security zone, see Managing Security Zones on page 4645.

**Security Zone Policies**

When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the policies associated with the security zone. If any policy is violated, then the operation is denied.

Security zone policies are categorized by security principle. Each policy impacts one or more resources, such as Compute, Networking, Object Storage, and Database resources.

**Note:**

Database policies do not apply to Oracle Exadata Cloud@Customer.

**Restrict Resource Movement**

To ensure the integrity of your data, you can't move certain resources from a security zone to a standard compartment because it might be less secure. You also can't move an existing resource from a standard compartment to a security zone unless all security zone policies are met.

The following table describes the security zone policies that restrict resource movement.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny block_volume_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Block Volume</td>
<td>You can't move a block volume from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny boot_volume_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Block Volume</td>
<td>You can't move a boot volume from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny instance_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Compute</td>
<td>You can't move a compute instance from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny instance_not_in_security_zone_move_to_compartment_in_security_zone</td>
<td>Compute</td>
<td>You can't move a compute instance from a standard compartment to a compartment that is in a security zone.</td>
</tr>
<tr>
<td>deny subnet_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Networking</td>
<td>You can't move a subnet from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny bucket_in_security_zone_move_to_compartment_not_in_security_zone</td>
<td>Object Storage</td>
<td>You can't move a bucket from a security zone to a standard compartment.</td>
</tr>
</tbody>
</table>
### Security Zones

#### Policy

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny db_instance_move_to_compartment_not_in_security_zone</td>
<td>Database (all types)</td>
<td>You can’t move a database from a security zone to a standard compartment.</td>
</tr>
<tr>
<td>deny database_with_dataguard_association_move_to_compartment_in_security_zone</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>You can’t move a database from a standard compartment to a security zone if its Data Guard association isn’t in a security zone.</td>
</tr>
</tbody>
</table>

### Restrict Resource Association

The components of a resource that impact its security posture must also be located in a security zone. Resources that aren’t in a security zone might be vulnerable.

The following table describes the security zone policies that restrict resource association.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny block_volume_not_in_security_zone_attach_to_instance_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>All block storage volumes attached to a compute instance (Compute) in a security zone must themselves be in a security zone.</td>
</tr>
<tr>
<td>deny block_volume_in_security_zone_attach_to_instance_not_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn’t in a security zone can’t be attached to block storage volumes that are in a security zone.</td>
</tr>
<tr>
<td>deny boot_volume_not_in_security_zone_attach_to_instance_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>The boot volume for a compute instance in a security zone must also be in a security zone.</td>
</tr>
<tr>
<td>deny boot_volume_in_security_zone_attach_to_instance_not_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn’t in a security zone can’t be attached to a boot volume that is in a security zone.</td>
</tr>
<tr>
<td>deny instance_in_security_zone_launch_from_boot_volume_not_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>The boot volume for a compute instance in a security zone must also be in a security zone.</td>
</tr>
<tr>
<td>deny instance_not_in_security_zone_launch_from_boot_volume_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>A compute instance that isn’t in a security zone can’t use a boot volume that is in a security zone.</td>
</tr>
<tr>
<td>deny attached_block_volume_not_in_security_zone_move_to_compartment_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>A block volume can’t be moved to a security zone if it’s attached to a compute instance that isn’t in a security zone.</td>
</tr>
<tr>
<td>deny attached_boot_volume_not_in_security_zone_move_to_compartment_in_security_zone</td>
<td>Compute, Block Volume</td>
<td>A boot volume can’t be moved to a security zone if it’s attached to a compute instance that isn’t in a security zone.</td>
</tr>
<tr>
<td>deny instance_in_security_zone_in_subnet_not_in_security_zone</td>
<td>Compute, Networking</td>
<td>A compute instance (Compute) in a security zone must use subnets that are also in a security zone.</td>
</tr>
</tbody>
</table>
Security Zones

Deny Public Access
Resources in a security zone must not be accessible from the public internet.

When you create a private subnet, compute instances launched in that subnet can't have public IP addresses. This restriction ensures that compute instances in the subnet have no internet access. For compute instances in a private subnet, a service gateway enables private access to public services such as Object Storage. See Overview of Networking.

The following table describes the security zone policies that restrict network access.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny public_subnets</td>
<td>Networking</td>
<td>Subnets in a security zone can't be public. All subnets must be private.</td>
</tr>
<tr>
<td>deny internet_gateway</td>
<td>Networking</td>
<td>You can't add an internet gateway to a VCN (virtual cloud network) within the security zone.</td>
</tr>
<tr>
<td>deny public_buckets</td>
<td>Object Storage</td>
<td>Object Storage buckets in a security zone can't be public.</td>
</tr>
<tr>
<td>deny db_instance_public_access</td>
<td>Database (all types)</td>
<td>Databases in a security zone can't be assigned to public subnets. They must use private subnets.</td>
</tr>
</tbody>
</table>

Require Encryption
Resources in a security zone must be encrypted using customer-managed keys. Data must be encrypted while in transit and at rest.

Oracle Cloud Infrastructure Vault lets you manage the master encryption keys that protect your data and the secret credentials that you use to securely access resources. You can also regularly rotate encryption keys.

Many services integrate with the Vault service for encryption, including Object Storage and Block Volume.

The following table describes the security zone policies that enforce encryption.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny block_volume_without_vault_key</td>
<td>Block Volume</td>
<td>Block volumes in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
</tbody>
</table>
### Security Zones

<table>
<thead>
<tr>
<th>Policy</th>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny boot_volume_without_vault_key</td>
<td>Block Volume</td>
<td>Boot volumes in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
<tr>
<td>deny buckets_without_vault_key</td>
<td>Object Storage</td>
<td>Object Storage buckets in a security zone must use a customer-managed master encryption key in the Vault service. They can't use the default encryption key managed by Oracle.</td>
</tr>
</tbody>
</table>

### Ensure Data Durability

Automatic backups must be performed regularly for resources in a security zone.

The following table describes the security zone policy that enforces data durability.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny database_without_backup</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>Databases in a security zone must be configured to perform automatic backups. See Backing Up a Database to Oracle Cloud Infrastructure Object Storage.</td>
</tr>
</tbody>
</table>

### Ensure Data Security

Data in a security zone is considered privileged and can't be copied to a standard compartment.

The following table describes the security zone policies that enforce data security.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny database_not_in_security_zone_create_from_backup_in_security_zone</td>
<td>Database (Bare metal and virtual machine DB systems, Exadata DB systems)</td>
<td>You can't use a database backup in a security zone to create a database that isn't in a security zone.</td>
</tr>
<tr>
<td>deny database_in_security_zone_create_clone_not_in_security_zone</td>
<td>Database (Virtual machine DB systems, Autonomous Database)</td>
<td>You can't clone a database in a security zone to create a database that isn't in a security zone.</td>
</tr>
</tbody>
</table>

### Use Only Configurations Approved by Oracle

Oracle requires certain security features to be enabled and configured for the resources within a security zone. One example is the operating system configuration for a compute instance.

The following table describes the security zone policies that require configurations that are approved by Oracle.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Services</th>
<th>Policy Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny instance_without_sanctioned_image</td>
<td>Compute</td>
<td>All compute instances in a security zone must be created using a platform image. You can't create a compute instance from a custom image in a security zone.</td>
</tr>
<tr>
<td>deny free_database_creation</td>
<td>Database (all types)</td>
<td>You can't create an Always Free database in a security zone.</td>
</tr>
</tbody>
</table>
Security Zone IAM Policies

Create IAM policies to control who has access to security zones and recipes, and to control the type of access for each group of users.

By default, only users in the Administrators group have access to all security zone resources. If you are new to IAM policies, see Getting Started with Policies.

For a complete list of policies in Oracle Cloud Infrastructure, see the Policy Reference.

Resource-Types
The following resource types are related to security zones.

• security-zone

Supported Variables
Security zone IAM policies support all the general policy variables.

See General Variables for All Requests.

Details for Verb + Resource-Type Combinations
Identify the permissions and API operations covered by each verb for security zones.

The level of access is cumulative as you go from inspect to read to use to manage.

<table>
<thead>
<tr>
<th>Verb</th>
<th>Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>SECURITY_ZONE_INSPECT</td>
</tr>
<tr>
<td>read</td>
<td>SECURITY_ZONE_READ</td>
</tr>
<tr>
<td>use</td>
<td>SECURITY_ZONE_ATTACH</td>
</tr>
<tr>
<td></td>
<td>SECURITY_ZONE_UPDATE</td>
</tr>
<tr>
<td>manage</td>
<td>SECURITY_ZONE_CREATE</td>
</tr>
<tr>
<td></td>
<td>SECURITY_ZONE_DELETE</td>
</tr>
</tbody>
</table>

Policy Examples
Learn about security zone IAM policies using examples.

Allow users in the group SecurityAdmins to create, update, and delete security zones in the entire tenancy:

Allow group SecurityAdmins to manage security-zone in tenancy

Allow users in the group SecurityAuditors to view security zones in the compartment SalesApps:

Allow group SecurityAuditors to read security-zone in compartment SalesApps
Chapter 41

Security

This section of the Oracle Cloud Infrastructure documentation provides a guide to help you securely configure services and resources, and timely announcements relevant to emerging security issues.

- Oracle Cloud Infrastructure Security Guide on page 4652
- Oracle Cloud Security Responses to Vulnerabilities on page 4727
- Security Checklist for Oracle Cloud Infrastructure

Oracle Cloud Infrastructure Security Guide

Oracle Cloud Infrastructure enables enterprises to migrate their mission-critical workloads to the cloud while continuing to maintain the same security posture. Reduce the overhead of building and operating data center infrastructure without sacrificing security.

With Oracle Cloud Infrastructure, enterprise customers get maximum control of and transparency into their applications running in the cloud, including:

- Customer isolation that allows you to deploy your application and data assets in an environment that commits full isolation from other tenants and Oracle’s staff, as well as between the same tenant’s workloads.
- Always-on encryption that protects customer data at-rest and HTTPS-only public APIs.
- Easy-to-use IAM policies that allow you to constrain access to your services, and to segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.
- Security zone policies that allow you to be confident that your resources comply with security principles and best practices related to encryption, network access, and so on.
- Detection of security weakness in resource configuration, and detection of risky activities performed by operators and end users.
- Comprehensive log data that allows you to audit and monitor actions on your resources, helping you to meet your audit requirements while reducing security and operational risk.
- Identity federation that allows you to use your existing users and groups in the cloud.
- Fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.
- Support for third-party software solutions for protecting customer data and resources in the cloud.
- Rigorous internal processes and use of effective security controls in all phases of cloud service development and operation.
- Adherence to Oracle’s strict security standards through third-party audits, certifications, and attestations. Oracle helps customers demonstrate compliance readiness to internal security and compliance teams, and to their customers, auditors, and regulators.

All Oracle Cloud Infrastructure security capabilities have been designed with one goal in mind: allowing you to run your mission-critical workloads in the cloud with complete control and confidence. Oracle continues to invest in these areas and more to offer unmatched security and assurance to enterprise customers.

- For a general overview of Oracle Cloud Infrastructure security concepts, see Security Overview on page 4653.
- For an overview of the security services in Oracle Cloud Infrastructure, see Security Services on page 4659.
• For an overview of the security capabilities in core services like Compute, Networking, and Block Volume, see Security for Core Services on page 4666.
• For general recommendations on getting started with Oracle Cloud Infrastructure security, see Securing Your Tenancy on page 4670.
• For service-specific best practices and policy examples, see Security Best Practices on page 4671.

Security Overview

Oracle’s mission is to build cloud infrastructure and platform services for your business to have effective and manageable security to run your mission-critical workloads and store your data with confidence.

Oracle Cloud Infrastructure’s security approach is based on seven core pillars. Each pillar has multiple solutions designed to maximize the security and compliance of the platform.

CUSTOMER ISOLATION

Allow customers to deploy their application and data assets in an environment that commits full isolation from other tenants and Oracle’s staff.

DATA ENCRYPTION

Protect customer data at-rest and in-transit in a way that allows customers to meet their security and compliance requirements for cryptographic algorithms and key management.

SECURITY CONTROLS

Offer customers effective and easy-to-use security management solutions that allow them to constrain access to their services and segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.

VISIBILITY

Offer customers comprehensive log data and security analytics that they can use to audit and monitor actions on their resources, allowing them to meet their audit requirements and reduce security and operational risk.

SECURE HYBRID CLOUD

Enable customers to use their existing security assets, such as user accounts and policies, as well as third-party security solutions when accessing their cloud resources and securing their data and application assets in the cloud.

HIGH AVAILABILITY

Offer fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.

VERIFIABLY SECURE INFRASTRUCTURE

Follow rigorous processes and use effective security controls in all phases of cloud service development and operation. Demonstrate adherence to Oracle’s strict security standards through third-party audits, certifications, and attestations. Help customers demonstrate compliance readiness to internal security and compliance teams, their customers, auditors, and regulators.

Also, Oracle employs some of the world’s foremost security experts in information, database, application, infrastructure, and network security. By using Oracle Cloud Infrastructure, our customers directly benefit from Oracle’s deep expertise and continuous investments in security.

Basic Security Considerations

The following principles are fundamental to using any application securely:

• Keep software up to date. Use the latest product release and any patches that apply to it.
• Limit privileges as much as possible. Give users only the access necessary to perform their work. Review user privileges periodically to determine relevance to current work requirements.
• Monitor system activity. Establish who is expected access which system components, and how often, and monitor those components.

• Learn about and use the Oracle Cloud Infrastructure security features. For more information, see Security Services on page 4659.

• Use secure best practices. For more information, see Security Best Practices on page 4671.

• Keep up to date on security information. Oracle regularly issues security-related patch updates and security alerts. Install all security patches as soon as possible. See the Critical Patch Updates and Security Alerts website.

Understanding the Oracle Cloud Infrastructure Environment

When planning your Oracle Cloud Infrastructure deployment, consider the following:

Which resources must be protected?

• Protect customer data, such as credit card numbers.

• Protect internal data, such as proprietary source code.

• Protect system components from external attacks or intentional system overloads.

Who are you protecting data from?

For example, you must protect your subscribers’ data from other subscribers, but someone in your organization needs to access that data to manage it. Analyze your workflows to determine who needs access to the data. Consider carefully how much access to give a system administrator; A system administrator might be able to manage your system components without needing to access the system data.

What happens if protections on a strategic resource fail?

Sometimes, a fault in your security scheme is nothing more than an inconvenience. In other cases, a fault might damage you or your customers. Understanding the security ramifications of each resource helps you protect it properly.

Shared Security Model

Oracle Cloud Infrastructure offers best-in-class security technology and operational processes to secure its enterprise cloud services. However, for you to securely run your workloads in Oracle Cloud Infrastructure, you must be aware of your security and compliance responsibilities. By design, Oracle provides security of cloud infrastructure and operations (cloud operator access controls, infrastructure security patching, and so on), and you are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

In a shared, multi-tenant compute environment, Oracle is responsible for the security of the underlying cloud infrastructure (such as data center facilities, and hardware and software systems) and you are responsible for securing your workloads and configuring your services (such as compute, network, storage, and database) securely.

In a fully isolated, single-tenant, bare metal server with no Oracle software on it, your responsibility increases as you bring the entire software stack (operating systems and above) on which you deploy your applications. In this environment, you are responsible for securing your workloads, and configuring your services (compute, network, storage, database) securely, and ensuring that the software components that you run on the bare metal servers are configured, deployed, and managed securely.

More specifically, your responsibilities and Oracle's responsibilities can be divided into the following areas:

• **Identity and Access Management (IAM):** As with all Oracle cloud services, protect your cloud access credentials and set up individual user accounts. You are responsible for managing and reviewing access for your own employee accounts and for all activities that occur under your tenancy. Oracle is responsible for providing effective IAM services such as identity management, authentication, authorization, and auditing.

• **Workload Security:** You are responsible for protecting and securing the operating system and application layers of your compute instances from attacks and compromises. This protection includes patching applications and operating systems, operating system configuration, and protection against malware and network attacks. Oracle
is responsible for providing secure images that are hardened and have the latest patches. Also, Oracle makes it simple for you to bring the same third-party security solutions that you use today.

- **Data Classification and Compliance**: You are responsible for correctly classifying and labeling your data and meeting any compliance obligations. Also, you are responsible for auditing your solutions to ensure that they meet your compliance obligations.

- **Host Infrastructure Security**: You are responsible for securely configuring and managing your compute (virtual hosts, containers), storage (object, local storage, block volumes), and platform (database configuration) services. Oracle has a shared responsibility with you to ensure that the service is optimally configured and secured. This responsibility includes hypervisor security and the configuration of the permissions and network access controls, ensure that hosts can communicate correctly and that devices are able to attach or mount the correct storage devices.

- **Network Security**: You are responsible for securely configuring network elements such as virtual networking, load balancing, DNS, and gateways. Oracle is responsible for providing a secure network infrastructure.

- **Client and Endpoint Protection**: Your enterprise uses various hardware and software systems, such as mobile devices and browsers, to access your cloud resources. You are responsible for securing all clients and endpoints that you allow to access Oracle Cloud Infrastructure services.

- **Physical Security**: Oracle is responsible for protecting the global infrastructure that runs services offered in Oracle Cloud Infrastructure. This infrastructure consists of the hardware, software, networking, and facilities that run Oracle Cloud Infrastructure services.

For information about using security credentials to access Oracle Cloud Infrastructure, see **Security Credentials** on page 207.

**Infrastructure Security**

Our security model is built around people, process, tooling, and a common security “platform” of methodologies and approaches from which we build our products. We apply this model to our core security components of Security Culture, Security Design and Controls, Secure Software Development, Personnel Security, Physical Security, and Security Operations that we use to protect and secure our customers and business.

**Security Culture**

We believe that a dynamic security-first culture is vital to building a successful security-minded organization. We have cultivated a holistic approach to security culture in which all our team members internalize the role that security plays in our business and are actively engaged in managing and improving our products’ security posture. We have also implemented mechanisms that assist us in creating and maintaining a security-aware culture.

- **Security-minded leadership**: Our senior leadership is actively involved in our security planning, monitoring, and management. We define and measure ourselves against security metrics and include security as a component of our team evaluation processes.

- **Embedded expertise**: To help with driving security practices within our team, we have an embedded security-engineering model with security team members sitting and working with our product development teams. This approach enables our security organization to build deep understanding of the product-development processes and system architectures. We are also able to better assist teams in solving security challenges quickly and drive security initiatives more effectively.

- **Common security standards**: We actively work to integrate security into our products and operations. For example, we establish a security standards baseline. Our objective in creating this baseline is to provide a single security point of reference for business that establishes clear and actionable guidelines. The security baseline is updated frequently to incorporate learned lessons and reflect emerging business factors. We have also created a series of support materials to assist our teams in implementing security controls including reference architectures, implementation guides, and access to security experts.

- **Values of openness, constructive debate, and encouraged escalation**: Security issues can be addressed only when the people who can fix them are aware of them. We believe that openness and transparency, constructive debate, and encouraged escalation make us stronger. We encourage escalation, and we work to create an environment where raising issues early and often is rewarded.
• **Security training awareness:** We maintain robust security and awareness training programs that raise awareness and reinforce our security culture. We require in-depth security training sessions for all new employees and annual refresher trainings, and we provide security training that is tailored to our employees’ specific job roles. All our software developers undergo a secure development training that establishes baseline security requirements for product development and provides best practices. We also work to provide engaging and innovative forms of security awareness training such as guest speakers and interactive forums.

**Security Designs and Controls**

Security is integrated into our products and operations through our Oracle Cloud Infrastructure Methodology. This centralized methodology defines our approach for the core security areas that form the security foundation from which we build our products. This approach lends itself to agility and helps us apply best practices and lessons learned from one product across the business, thus raising the security of all our products.

• **User authentication and access control:** Least-privilege access is used to grant access to production systems, and the approved lists of service team members are periodically reviewed to revoke access when the need can't be justified. Access to production environments requires multi-factor authentication (MFA). The security team grants MFA tokens, and tokens of inactive members are disabled. All access to production systems is logged, and the logs are stored for security analysis.

• **Change management:** Oracle Cloud Infrastructure follows a defined and rigorous change management and deployment process that uses purpose-built proprietary testing and deployment tools. All changes deployed into our production environment follow a testing and approval process before they are released. This process is designed to ensure that changes operate as intended, and can otherwise be rolled back to a previous known good state to recover gracefully from unforeseen bugs or operational issues. We also track the integrity of critical system configurations to ensure that they align with expected state.

• **Vulnerability management:** We use both internal penetration testing teams and external industry experts to help us identify potential vulnerabilities in our products. These exercises help us improve the security of our products, and we work to incorporate the lessons that we learn into our future development work. Oracle Cloud Infrastructure hosts undergo periodic vulnerability scanning using industry-standard scanners. Scan results are triaged to validate applicability of findings to the Oracle Cloud Infrastructure environment, and product teams apply the required patches if applicable.

• **Incident response:** We have developed strong processes and mechanisms to enable us to respond to and address incidents as they arise. We maintain 24/7 incident response teams ready to detect and respond to events. Our critical staff members carry paging devices that enable us to call on the expertise needed to bring issues to resolution. We have also built a process to help us learn from our incidents. We perform root cause analysis through our Corrective Action/Preventative Action (CAPA) process. CAPAs are intended to discover process gaps and changes that the business can make after an incident. CAPAs act as a common language that we can use to reflect on an issue and capture concrete steps to improve future operational readiness. CAPAs capture the root cause of an issue, what is required to contain or fix the issue, and what steps we must take to ensure that the issue does not recur. Our leadership team reviews all CAPAs, looks for cross-organizational applications for learned lessons, and ensures that actions are implemented in a timely manner.

• **Security logging and monitoring:** We have created automated mechanisms to log various security-relevant events (for example, API calls and network events) in the infrastructure, and monitor the logs for anomalous behavior. The security team tracks and triages the alerts generated by monitoring mechanisms.

• **Network security:** By default, customer communications with Oracle Cloud Infrastructure services are done using the latest TLS ciphers and configuration to secure customer data in transit, and hinder any man-in-the-middle attacks. As a further defense in depth, customer commands to the services are digitally signed using public keys, to prevent any tampering. The services also deploy proven, industry-leading tools and mechanisms to mitigate distributed denial of service (DDoS) attacks and maintain high availability.

• **Control plane security:** Oracle Cloud Infrastructure backend (control plane) hosts are securely isolated from customer instances by using network ACLs. Provisioning and management of customer instances are done by software agents that must interact with the backend hosts. Only authenticated and authorized software agents can successfully interact with Oracle Cloud Infrastructure backend hosts. For backend hosts, pre-production environments (for example, development, testing, and integration) are separated from production environments so that any development and test activities do not have any impact on production systems.
Security

- **Server security and media management:** Oracle has a long history of enterprise-class secure hardware development. Our Hardware Security team is responsible for designing and testing the security of the hardware used to deliver Oracle Cloud Infrastructure services. This team works with our supply chain and tests hardware components to validate them against rigorous Oracle Cloud Infrastructure hardware security standards. This team also works closely with our product development functions to ensure that hardware can be returned to a pristine, safe state after customers release the hardware.

- **Secure host wipe and media destruction:** Oracle Cloud Infrastructure instances are securely wiped after customers release the hardware. This secure wipe restores hardware to a pristine state. We have re-engineered the platform with proprietary hardware components that allow us to wipe and reinitialize the hardware in a secure manner. When the underlying hardware has reached end-of-life, it is securely destroyed. Before leaving our data centers, drives are rendered unusable by using industry-leading media destruction devices.

Secure Software Development

Secure product development requires consistently applied methodologies that conform to clear security objectives and principles. We build security practices into every element of our product development life cycle. Oracle employs formal secure product development standards that are a roadmap and guide for developers. These standards discuss general security knowledge areas such as design principles and common vulnerabilities, and provide specific guidance on topics such as data validation, data privacy, and user management.

Oracle secure product development standards have evolved and expanded over time to address the common issues affecting code, new threats as they are discovered, and new use cases by Oracle customers. The standards incorporate insights and learned lessons; they do not live in a vacuum, nor are they an “after the fact” addendum to software development. They are integral to language-specific standards such as C/C++, Java, PL/SQL, and others, and are a cornerstone to Oracle’s secure development programs and processes.

Security assurance analysis and testing verify security qualities of Oracle products against various types of attacks. There are two broad categories of tests employed for testing Oracle products: static and dynamic analysis. These tests fit differently in the product development lifecycle and tend to find different categories of issues, so they are used together by Oracle product teams.

Personnel Security

Our people make our business. We strive to hire the best, and we invest in and continue to develop our employees. We value training, and we require not only baseline security training for all our employees but also specialized training to keep our teams abreast of the latest security technologies, exploits, and methodologies. In addition to standard annual corporate training programs that cover our information security and privacy programs (among many others), we engage with a broad spectrum of industry groups and send our employees to specialist conferences to collaborate with other industry experts on emerging challenges. The objectives of our security training programs are to help our employees better protect our customers and products, to enable employees to grow in their knowledge areas around security, and to further our mission to attract and retain the best talent.

We work to recruit the best talent for our team as we grow, and we hire people with strong ethics and good judgment. All our employees undergo pre-employment screening as permitted by law, including criminal background checks and prior-employment validation. We also maintain performance evaluation processes to recognize good performance and help our teams and employees identify opportunities for growth. We maintain both team and employee evaluation processes, and we use security as a component of our team evaluation processes. This approach provides our teams and leadership visibility into how our teams are performing against our security standards and enables us to identify best practices and improvement areas for critical security processes.

Physical Security

Oracle Cloud Infrastructure data centers are designed for security and availability of customer data. This approach begins with our site selection process. Candidate build sites and provider locations undergo an extensive risk evaluation process that considers environmental threats, power availability and stability, vendor reputation and history, neighboring facility functions (for example, high-risk manufacturing or high-threat targets), and geopolitical considerations, among other criteria.
Oracle Cloud Infrastructure data centers align with Uptime Institute and Telecommunications Industry Association (TIA) ANSI/TIA-942-A Tier 3 or Tier 4 standards and follow a N2 redundancy methodology for critical equipment operation. Data centers housing Oracle Cloud Infrastructure services use redundant power sources and maintain generator backups to prevent widespread electrical outage. Server rooms are closely monitored for air temperature and humidity, and fire suppression systems are in place. Data center staff are trained in incident response and escalation procedures to address security or availability events that might arise.

We take a layered approach to physical security that starts with the site build. Oracle Cloud Infrastructure data center facilities are durably built with steel, concrete, or comparable materials and are designed to withstand impact from a light vehicle strike. Our sites are staffed with security guards who are ready to respond to incidents 24 hours a day, 7 days a week, 365 days a year. The exterior of the sites is secured with perimeter barriers and vehicle checks are actively monitored by a guard force and cameras that cover the building perimeter.

All persons entering our data centers must first go through a layer of security at the site entrances, which are staffed with security guards. Persons without site-specific security badges entering the site must present government-issued identification and have an approved access request granting them access to the data center building. All employees and visitors must wear visible, official identification badges at all times. There are more security layers between the entrance and server rooms that vary depending on the site build and risk profile. Data center server rooms are built with other security layers including cameras that cover server rooms, two-factor access control, and intrusion-detection mechanisms. Physical barriers are in place to create isolated security zones around server and networking racks that span from the floor (including below the raised floor where applicable) to the ceiling (including above ceiling tiles where applicable).

Access to Oracle Cloud Infrastructure data centers is carefully controlled and follows a least-privilege access approach. Authorized personnel must approve all access to server rooms and access is granted only for the necessary period. Access usage is audited, and data center leadership periodically reviews access provisioned within the system. Server rooms are isolated into secure zones that are managed on a zone-by-zone basis, and access is provisioned only for those zones required by personnel.

Security Operations

The Oracle Cloud Infrastructure Security Operations team is responsible for monitoring and securing the unique Oracle Cloud Infrastructure hosting and virtual networking technologies. The team works and trains directly with the Oracle engineers who develop these technologies to use the unique security and introspection capabilities they provide.

We monitor emerging internet security threats daily and implement appropriate response and defense plans to address risks to the business. When we determine that urgent changes are recommended that are within the scope of the customers' responsibilities, we issue security alert bulletins to those customers to ensure their protection.

In the case of a detected or reported security issue that affects Oracle Cloud Infrastructure servers or networks, Security Operations staff is available 24/7 to respond, escalate, or take required corrective action. When necessary, we will escalate and coordinate with external parties (including network and hosting service providers, hardware vendors, or law enforcement) to protect Oracle Cloud Infrastructure, our customers, and our network's security and reputation.

All actions performed in response to a security issue by the Security Operations team are done according to our documented process, and are logged in accordance with compliance requirements. Care is always taken to protect the goals of service and data integrity, privacy, and business continuity.

Customer Data Protection

Data Rights and Ownership

Oracle Cloud Infrastructure customers retain all ownership and intellectual property rights in and to their content. Customer data protection is critically important, and we strive to be transparent with our data protection processes and law enforcement requests that we might receive.
**Data Privacy**

Oracle Cloud Infrastructure has features that help customers align with common data privacy principles. See Oracle Cloud Infrastructure Privacy Features

**Law Enforcement Requests**

Except as otherwise required by law, Oracle promptly notifies customers of any subpoena, judicial, administrative, or arbitral order of an executive or administrative agency or other governmental authority that it receives and which relates to the personal data Oracle is processing on the customer’s behalf. Upon customer request, Oracle provides customers with reasonable information in its possession relevant to the law enforcement request and any assistance reasonably required for them to respond to the request in a timely manner.

**Compliance**

Oracle Cloud Infrastructure is built for enterprises. We operate under practices aligned with the ISO/IEC 27002 Code of Practice for information security controls, from which we have identified a comprehensive set of security controls that apply to our business. Oracle Cloud Infrastructure is still a new product line, and we must operate for a period of time for these security controls and our operations to undergo external audit. As an enterprise cloud, we plan to pursue a broad suite of industry and government certifications, audits, and regulatory programs.

**Security Services**

Learn about the security services in Oracle Cloud Infrastructure that provide customer isolation, identity management, authorization, data encryption, vulnerability detection, monitoring, and more.

The following diagram illustrates the security services in Oracle Cloud Infrastructure.

---

Oracle Cloud Infrastructure User Guide

4659
Regions and Availability Domains

An Oracle Cloud Infrastructure region is the top-level component of the infrastructure. Each region is a separate geographic area with multiple, fault-isolated locations called availability domains. An availability domain is a subcomponent of a region and is independent and highly reliable. Each availability domain is built with fully independent infrastructure: buildings, power generators, cooling equipment, and network connectivity. With physical separation comes protection against natural and other disasters.

Availability domains within the same region are connected by a secure, high-speed, low-latency network, which allows you to build and run highly reliable applications and workloads with minimum impact to application latency and performance. All links between availability domains are encrypted.

For more information, see Regions and Availability Domains on page 208.

Oracle Cloud Infrastructure also offers regions with specific characteristics to meet the security and compliance requirements of government organizations:

- Oracle Cloud Infrastructure US Government Cloud on page 174
- Oracle Cloud Infrastructure United Kingdom Government Cloud on page 199

Identity and Access Management (IAM)

The Oracle Cloud Infrastructure Identity and Access Management service provides authentication and authorization for all Oracle Cloud Infrastructure resources and services. You can use a single tenancy shared by various business units, teams, and individuals while maintaining security, isolation, and governance.

When you join Oracle Cloud Infrastructure, a tenancy is created. A tenancy is a virtual construct that contains all Oracle Cloud Infrastructure resources that belong to the customer. The administrator of the tenancy can create users and groups and assign them least-privileged access to resources that are partitioned into compartments. A compartment is a group of resources that can be managed as a single logical unit, providing a streamlined way to manage large infrastructure.

Key IAM concepts:

Resource

A cloud object that you create and use when interacting with Oracle Cloud Infrastructure services. For example, compute *instances*, block storage *volumes*, virtual cloud networks (*VCNs*), subnets, and databases.

Policy

A set of authorization rules that define access to resources within a tenancy.

Compartment

A heterogeneous collection of resources for the purposes of security isolation and access control.

Tenancy

The root compartment that contains all of an organization's resources. Within a tenancy, administrators can create one or more compartments, create more users and groups, and assign policies that grant groups the ability to use resources within a compartment.

User

A human being or system that needs access to manage their resources. Users must be added to groups to access resources. Users have one or more credentials that must be used to authenticate to Oracle Cloud Infrastructure services. Federated users are also supported.

Group

A collection of users who share a similar set of access privileges. Administrators can grant access policies that authorize a group to consume or manage resources within a tenancy. All users in a group inherit the same set of privileges.
Identity Provider

A trusted relationship with a federated identity provider. Federated users who attempt to authenticate to the Oracle Cloud Infrastructure console are redirected to the configured identity provider. After successfully authenticating, federated users can manage Oracle Cloud Infrastructure resources in the console just like a native IAM user.

For example, you can create a compartment HR-Compartment to host a specific set of cloud networks, compute instances, storage volumes, and databases necessary for its HR applications. Use compartments to clearly separate resources for one project or business unit from another project or business unit. A common approach is to create a compartment for each major part of an organization.

All customer calls to access Oracle Cloud Infrastructure resources are first authenticated by the IAM service (or federated provider) and then authorized based on IAM policies. You can create a policy that gives a set of users permission to access the infrastructure resources (network, compute, storage, and so on) within a compartment in the tenancy. These policies are flexible and are written in a human-readable form that is easy to understand and audit. A policy contains one or more policy statements that follow this syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

The following example policy enables the GroupAdmins group to create, update, or delete any groups:

```
Allow group GroupAdmins to manage groups in tenancy
```

The following example policy enables the TestNetworkAdmins group to create, update, or delete any networks in the TestCompartment compartment:

```
Allow group TestNetworkAdmins to manage virtual-network-family in compartment TestCompartment
```

Each user has one or more credentials to authenticate themselves to Oracle Cloud Infrastructure. Users can generate and rotate their own credentials. In addition, a tenancy security administrator can reset credentials for any user within their tenancy.

- **Console password**: Used to authenticate a user to the Oracle Cloud Infrastructure Console.
- **API key**: All API calls are signed using a user-specific 2048-bit RSA private key. The user creates a public key pair, and uploads the public key in the Console.
- **Auth token**: Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. For example, use an auth token to authenticate with a Swift client. To ensure sufficient complexity, the IAM service creates the token and you cannot provide one.
- **Customer secret key**: Used by Amazon S3 clients to access the Object Storage service's S3-compatible API. To ensure sufficient complexity, the IAM service creates this password and you cannot provide one.

Oracle Cloud Infrastructure supports federation with Oracle Identity Cloud Service, Microsoft Active Directory, and Microsoft Azure Active Directory, and with other identity providers that support the Security Assertion Markup Language (SAML) 2.0 protocol. Federated groups are mapped to native IAM groups, which determine the permissions of a federated user.

For more information, see:

- **Overview of Oracle Cloud Infrastructure Identity and Access Management** on page 2788
- **How Policies Work** on page 2800
- **User Credentials** on page 3056
- **Managing Compartments** on page 3126
- **Federating with Identity Providers** on page 3058
- **Securing IAM** on page 4686
Identity Cloud Service

Oracle Identity Cloud Service (IDCS) provides identity management, single sign-on (SSO), and identity governance features for applications on-premise, in the cloud, or for mobile devices.

- Use the IAM service to control administrative access to your Oracle Cloud Infrastructure services and resources.
- Use Oracle Identity Cloud Service to secure custom applications running on those cloud resources.

Tenancies created after December 21, 2018 are automatically federated with Oracle Identity Cloud Service and configured to provision federated users in Oracle Cloud Infrastructure. Older tenancies can be manually federated with Oracle Identity Cloud Service. Federation allows IDCS users to access cloud resources and allows administrators to create IAM policies for IDCS groups.

Oracle Identity Cloud Service uses OpenID Connect and OAuth to deliver a highly scalable, multi-tenant token service for securing programmatic access to custom applications from other custom applications.

- Use OAuth 2.0 to define authorization for your custom applications. The OAuth 2.0 framework is commonly used for third-party authorization requests with consent. Custom applications can implement both two-legged and three-legged OAuth flows.
- Use OpenID Connect to externalize authentication for your custom applications. OpenID Connect has an authentication protocol that provides federated SSO, using the OAuth 2.0 authorization framework as a way to federate identities in the cloud. Custom applications participate in an OpenID Connect flow.

For more information, see:
- Typical Workflow for Using Oracle Identity Cloud Service
- Federating with Oracle Identity Cloud Service on page 3062

Cloud Guard

Use Cloud Guard to examine your Oracle Cloud Infrastructure resources for security weakness related to configuration, and to examine your operators and users for risky activities. Upon detection, Cloud Guard suggests corrective actions, and can be configured to automatically take certain actions. For example:

- Detect an instance that is publically accessible (has a public IP address or is on a public subnet) and stop the instance.
- Detect an Object Storage bucket that is publically accessible and disable the bucket.
- Detect a user login from a suspicious IP address and restrict traffic from this address.

Oracle recommends that you enable Cloud Guard in your tenancy. You can configure a Cloud Guard target to examine your entire tenancy (root compartment and all subcompartments), or you can configure targets to check only specific compartments.

Each target is associated with a detector recipe, which defines specific user actions or resource configurations that cause Cloud Guard to report a problem. Oracle provides several default Cloud Guard detector recipes, which you can use as-is or customize as needed. For example, you might want to change the risk level or settings associated with certain detector rules. As Cloud Guard adds new detector rules, they are automatically enabled in Oracle-managed recipes, and disabled in custom recipes.

A Cloud Guard responder recipe defines the action or set of actions to take in response to a problem that a detector has identified. You can also use the Events and Notifications services to send notifications whenever Cloud Guard
detects a type of problem for which you want to be notified. You can send notifications through email or Slack, or run custom code in the Functions service.

For more information, see Cloud Guard.

**Vulnerability Scanning**

Oracle Vulnerability Scanning Service helps improve your security posture by routinely checking hosts for potential vulnerabilities. The service generates reports with metrics and details about these vulnerabilities, and assigns each a risk level. For example:

- Ports that are unintentionally left open might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.
- OS packages that require updates and patches to address vulnerabilities
- OS configurations that hackers might exploit
- Industry-standard benchmarks published by the Center for Internet Security (CIS) for the target OS

You can also monitor these vulnerabilities in Cloud Guard on page 4662. Upon detection of a vulnerability, Cloud Guard suggests corrective actions, and can be configured to automatically take certain actions.

For more information, see Scanning Overview.

**Security Zones**

Security Zones let you be confident that your Compute, Networking, Object Storage, Database, and other resources comply with Oracle security principles and best practices. A security zone is associated with a compartment. When you create and update resources in a compartment that's associated with a security zone, Oracle Cloud Infrastructure validates these operations against security zone policies. If any security zone policy is violated, then the operation is denied.

Here are some examples of security zone policies:

- Subnets in a security zone can't be public. All subnets must be private.
- The boot volume for a compute instance in a security zone must also be in a security zone.
- Object Storage buckets in a security zone must use a customer-managed master encryption key.
• You can't move certain resources like block volumes and compute instances from a security zone to a standard compartment.

For more information, see Security Zones.

**Vault**

You can use the Vault service to create and manage the following resources:

- Vaults
- Keys
- Secrets

A vault includes the encryption keys and secret credentials that you use to protect your data and connect to secured resources. As customer-managed resources, you have complete control over who has access to your vaults, keys, and secrets. You also control what authorized users and services can do with Vault resources. Levels of access might range from something as granular as whether an individual key can be used by a particular service to more broadly impactful lifecycle management activities, like whether a user can delete a key from a vault to prevent its use altogether.

Keys are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. Secrets and secret versions are base64-encoded and encrypted with master encryption keys, but do not reside within the HSM.

The key encryption algorithms that the Vault service supports includes the Advanced Encryption Standard (AES), the Rivest-Shamir-Adleman (RSA) algorithm, and the elliptic curve digital signature algorithm (ECDSA). You can create and use AES symmetric keys and RSA asymmetric keys for encryption and decryption. You can also use RSA or ECDSA asymmetric keys for signing digital messages.

Security zone policies require you to encrypt resources using customer-managed keys where possible. The following services support the use of customer-managed keys for resource encryption:

- Block Volume
- Container Engine for Kubernetes
- Oracle Cloud Infrastructure Database
- File Storage
- Object Storage
- Streaming

For more information, see Overview of Vault on page 5006.

**Security Advisor**

Security Advisor helps you create cloud resources that align with Oracle's security principles and best practices. It also ensures that your resources meet the requirements enforced by security zone policies. For example, you can quickly create resources that are encrypted with a customer-managed master encryption key using the Vault on page 4664 service.

For example, you can use Security Advisor to create the following resources:

- Object Storage *bucket*
- File Storage *file system*
- Compute *instance (Compute)* (and associated boot volume)
- Block Volume block storage *volume*

For more information, see Overview of Security Advisor on page 4740.

**Bastion**

Oracle Cloud Infrastructure Bastion provides restricted and time-limited access to target resources that don't have public endpoints.
Through the configuration of a bastion, you can let authorized users connect to target resources on private endpoints by way of Secure Shell (SSH) sessions. When connected, users can interact with the target resource by using any software or protocol supported by SSH. For example, you can issue Remote Desktop Protocol (RDP) commands or connect to a database by using Oracle Net Services. Targets can include resources like Compute instances, DB systems, and Autonomous Transaction Processing databases.

Bastions reside in a public subnet and establish the network infrastructure needed to connect a user to a target resource in a private subnet. Integration with the IAM service provides user authentication and authorization. Bastions provide an extra layer of security by allowing you to specify what IP addresses can connect to a session hosted by the bastion.

For more information, see Bastion.

**Web Application Firewall**

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based, Payment Card Industry (PCI) compliant, security service that protects applications from malicious and unwanted internet traffic. WAF can protect any internet-facing endpoint, providing consistent rule enforcement across your applications.

Use WAF to create and manage protection rules for internet threats including Cross-Site Scripting (XSS), SQL Injection, and other OWASP-defined vulnerabilities. Unwanted bots can be mitigated while desirable bots are allowed to enter. You can also define and apply custom protection rules to your WAF configurations using the ModSecurity Rule Language.

Use WAF to create access rules that define explicit actions for requests that meet various conditions. For example, access rules can limit requests based on the geography or the signature of the request. A rule action can be set to log and allow, detect, block, redirect, bypass, or show a CAPTCHA for all requests that match the conditions.

For more information, see Overview of Web Application Firewall on page 5161.
Audit

The Oracle Cloud Infrastructure Audit service records all API calls to resources in a customer's tenancy and login activity from the Console. You can achieve your security and compliance goals by using the Audit service to monitor all user activity within your tenancy. Because all Console, SDK, and command line (CLI) calls go through our APIs, all activity from those sources is included. Audit records are available through an authenticated, filterable query API or they can be retrieved as batched files from Oracle Cloud Infrastructure Object Storage. Audit log contents include what activity occurred, the user that initiated it, the date and time of the request, as well as source IP, user agent, and HTTP headers of the request.

For more information, see Overview of Audit on page 598.

Security for Core Services

Learn about key security features in the core Oracle Cloud Infrastructure services.

Compute

Oracle Cloud Infrastructure Compute lets you provision and manage compute hosts, known as instances. You can launch instances as needed to meet your compute and application requirements. After you launch an instance, you can access it securely from your computer, restart it, attach and detach volumes, and terminate it when you're done with it. Any changes made to the instance's local drives are lost when you terminate it. Any saved changes to volumes attached to the instance are retained.

Oracle Cloud Infrastructure offers both bare metal and virtual machine instances:

Bare Metal

A bare metal compute instance gives you dedicated physical server access for highest performance and strong isolation. After a customer terminates their bare metal instance, the server undergoes an automated disk and firmware-level wipe process to ensure isolation between customers.

Virtual Machine

A virtual machine (VM) is an independent computing environment that runs on top of physical bare metal hardware. The virtualization makes it possible to run multiple VMs that are isolated from each other. VMs are ideal for running applications that do not require the performance and resources (CPU, memory, network bandwidth, storage) of an entire physical machine.

An Oracle Cloud Infrastructure VM compute instance runs on the same hardware as a bare metal instance, using the same cloud-optimized hardware, firmware, software stack, and networking infrastructure.

All Oracle Cloud Infrastructure instances use key-based Secure Shell (SSH) by default. Customers provide the SSH public keys to Oracle Cloud Infrastructure and use the SSH private keys for accessing the instances. Oracle recommends using key-based SSH to access Oracle Cloud Infrastructure instances. Password-based SSH could be susceptible to brute-forcing attacks, and is not recommended.

Oracle Linux images hardened with the latest security updates are available for you to run on Oracle Cloud Infrastructure instances. Oracle Linux images run the Unbreakable Enterprise Kernel (UEK) and support advanced security features such as Ksplice to apply security patches without rebooting. In addition to Oracle Linux, Oracle Cloud Infrastructure makes available a list of other OS platform images, including CentOS, Ubuntu, and Windows Server. All platform images come with secure defaults including OS-level firewalls turned on by default.

You can also bring your own custom images. However, certain security zone policies only permit the use of platform images in compartments associated with a security zone.

Use the Vulnerability Scanning service to routinely check your instances for potential security vulnerabilities like missing patches or open ports. The service generates reports with metrics and details about these vulnerabilities, and assigns each a risk level.

For more information, see:

- Overview of the Compute Service on page 927
- Securing Compute on page 4675
Networking

The Oracle Cloud Infrastructure Networking service allows you to define a customizable private network (a VCN, or virtual cloud network), which enforces logical isolation of your Oracle Cloud Infrastructure resources. As with your on-premises network in your data centers, you can set up a VCN with subnets, route tables, gateways, and firewall rules.

The following are key networking concepts associated with a VCN:

**Subnet**

The primary subdivision of a VCN. Subnets can be public or private. A private subnet prevents resources launched in that subnet from having public IP addresses.

**Internet gateway**

A virtual router that provides public internet connectivity from a VCN. By default, a newly created VCN has no internet connectivity.

**Dynamic routing gateway (DRG)**

A virtual router that provides a path for private traffic between a VCN and a data center’s network. A DRG is used with an IPSec VPN or Oracle Cloud Infrastructure FastConnect.

**Network address translation (NAT) gateway**

A virtual router that gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

**Service gateway**

A virtual router that gives cloud resources private access to Oracle services such as Object Storage without using an internet gateway or NAT gateway.

**Route table**

Virtual route tables that have rules to route traffic from subnets to destinations outside the VCN by way of gateways or specially configured Compute instances.

**Security list**

Virtual firewall rules that specify the types of traffic (protocol and port) allowed in and out of resources. Individual rules can be defined to be stateful or stateless and affect all resources in the target subnet.

**Network security group**

Virtual firewall rules that define allowed ingress and egress to resources that are members of the group. Individual rules can be defined to be stateful or stateless.

Use security lists, network security groups, or a combination of both to control packet-level traffic in and out of the resources in your VCN. For example, you can allow incoming SSH traffic from anywhere to a subnet or group of instances by setting up a stateful ingress rule with source CIDR 0.0.0.0/0, and destination TCP port 22. Every VCN has a default security list that allows only SSH and certain types of important ICMP ingress traffic, and allows all egress traffic.

Create private subnets to ensure that resources in the subnet have no internet access, even if the VCN has a working internet gateway, and even if security rules and firewall rules allow the traffic. Certain security zone policies only permit the use of private subnets. You can use the Bastion on page 4664 service to create secure, temporary SSH sessions from the internet to resources in a private subnet.

A VCN can be configured for internet connectivity, or connected to your private data center through a Site-to-Site VPN or FastConnect. FastConnect offers a private connection between an existing network's edge router and DRGs. Traffic does not traverse the internet.

For more information, see:

- Ways to Secure Your Network on page 3707
Security

- Access Control on page 3708
- Security Rules on page 3710
- Securing Networking: VCN, Load Balancers, and DNS on page 4693

Storage

Oracle Cloud Infrastructure offers multiple storage solutions to meet your performance and durability requirements:

Local Storage

NVMe-backed storage on compute instances, offering high IOPS.

Block Volume

Network-attached storage volumes, attachable to compute instances.

Object Storage

Regional service for storing large amounts of data as objects, providing strong consistency and durability. Objects are organized using buckets.

File Storage

Durable network file system that supports the Network File System version 3.0 (NFSv3) protocol.

The Oracle Cloud Infrastructure Block Volume service provides persistent storage that can be attached to compute instances using the iSCSI protocol. The volumes are stored in high-performance network storage and support automated backup and snapshot capabilities. Volumes and their backups are accessible only from within a customer's VCN and are encrypted at rest using unique keys. For more security, iSCSI CHAP authentication can be required on a per-volume basis.

The Oracle Cloud Infrastructure Object Storage service provides highly scalable, consistent, and durable storage for objects. API calls over HTTPS provide high-throughput access to data. All objects are encrypted at rest using unique keys and, by default, access to buckets and objects within them requires authentication.

Security zone policies require you to encrypt volumes, objects, and file systems using customer-managed keys in the Vault on page 4664 service. You can also use Security Advisor on page 4664 to quickly create storage resources and the required keys in a single interface.

Use IAM security policies to grant users and groups access privileges to Object Storage buckets. To allow access to buckets by users who do not have IAM credentials, the bucket owner (or a user with necessary privileges) can create pre-authenticated requests. Pre-authenticated requests allow authorized actions on buckets or objects for a specified duration.

Alternately, buckets can be made public, which allows unauthenticated and anonymous access. Object Storage enables you to verify that an object was not unintentionally corrupted by allowing an MD5 checksum to be sent with the object and returned upon successful upload. This checksum can be used to validate the integrity of the object. Given the security risk of inadvertent information disclosure, Oracle recommends that you carefully consider the business case before making a bucket public. Certain security zone policies forbid the creation of public buckets.

The Oracle Cloud Infrastructure File Storage service allows you to manage resources like file systems, mount targets, and export sets. You use IAM policies to define access to these resources. The AUTH_UNIX style of authentication and permission checking is supported for remote NFS client requests to a file system.

For more information, see:

- Securing Block Volume on page 4671
- Securing Object Storage on page 4697
- Securing File Storage on page 4685
**Database**

The Oracle Cloud Infrastructure Database service offers autonomous and co-managed Oracle Database cloud solutions. For both types of database solutions, you have full access to the features and operations available with the database, but Oracle owns and manages the infrastructure.

- Autonomous databases are preconfigured, fully managed environments that are suitable for either transaction processing or for data warehouse workloads.
- Co-managed solutions are bare metal, virtual machine, and Exadata DB systems that you can customize with the resources and settings that meet your needs.

DB systems are accessible only from your VCN, and you can configure network security groups or security lists to control network access to your databases. The Database service is integrated with IAM for controlling which users can launch and manage DB systems. By default, data is encrypted at rest using Oracle transparent data encryption (TDE) with master keys stored in an Oracle Wallet on each DB system.

RMAN backups of DB systems are encrypted and stored in customer-owned buckets in the Object Storage service. Certain security zone policies require the configuration of database backups.

Applying Oracle database security patches (Oracle Critical Patch Updates) is imperative to mitigate known security issues, and Oracle recommends that you keep patches up to date. Patchsets and Patch Set Updates (PSUs) are released on a quarterly basis. These patch releases contain security fixes and other high-impact/low-risk critical bug fixes.

For more information, see [Securing Database](#) on page 4682.

**Load Balancing**

Oracle Cloud Infrastructure Load Balancing provides automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). The service offers a load balancer with your choice of a public or private IP address, and provisioned bandwidth. A private load balancer has an IP address from the hosting subnet, which is visible only within your VCN.

You can apply the following SSL configurations to your load balancer:

**SSL TERMINATION**

The load balancer handles incoming SSL traffic and passes the unencrypted request to a backend server.

**POINT-TO-POINT SSL**

The load balancer terminates the SSL connection with an incoming traffic client, and then initiates an SSL connection to a backend server.

**SSL TUNNELING**

If you configure the load balancer's listener for TCP traffic, the load balancer tunnels incoming SSL connections to your application servers.

The Load Balancing service supports TLS 1.2 by default, and prioritizes the following forward-secrecy ciphers in the TLS cipher-suite:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

You can configure network access to load balancers by using VCN network security groups or security lists.

For more information, see [Securing Networking: VCN, Load Balancers, and DNS](#) on page 4693.
Securing Your Tenancy

Learn how to get started with securing an Oracle Cloud Infrastructure tenancy.

Before your begin, get familiar with the security concepts and features in Oracle Cloud Infrastructure. See:

- Security Overview on page 4653
- Security Services on page 4659
- Security for Core Services on page 4666
- Security Checklist for Oracle Cloud Infrastructure

In a shared, multi-tenant compute environment, Oracle is responsible for the security of the underlying cloud infrastructure (such as data center facilities, and hardware and software systems). You are responsible for securing your workloads and configuring the security of your services (such as compute, network, storage, and database).

Security of an Oracle Cloud Infrastructure tenancy is based on a combination of factors, all of which must be thought through and securely configured. Take a hierarchical view of security configuration. Start by addressing foundational security issues, and then address the security of specific infrastructure resources. The following steps provide a high-level roadmap for configuring the security of a tenancy.

1. Define a security model that meets the workload requirements for your tenancy.
   - Number of compartments
   - Number of users with administrative rights
   - Administrative roles and permissions

2. Provision users, groups, compartments, and policies in the IAM service.
   Create mechanisms for authenticating users and authorizing users to access tenancy resources in a least-privilege manner.

   See Securing IAM on page 4686.

3. (Optional) Provision security zones for hosting cloud resources that must comply with Oracle's security best practices.
   If a user attempts to create or update a resource in a security zone, and this operation violates a security zone policy, then the action is denied.

   See Security Zones on page 4663.

4. (Optional) Enable Cloud Guard to detect and respond to common security issues.

   See Cloud Guard on page 4662.

5. Provision master encryption keys and secret credentials.

   See Vault on page 4664.

   Use security lists, network security groups, or a combination of both to control packet-level traffic in and out of the resources in your VCN (virtual cloud network). Use private subnets to host resources that do not require internet access.

7. Provision and secure cloud storage.

   Depending on your data storage requirements, your options include Database, Block Volume, Object Storage, and File Storage.

   Compliance and regulatory requirements are an important factor in determining an appropriate data storage security architecture.

   Refer to the specific service in Security Best Practices on page 4671.
8. Provision and secure the other services in your tenancy that your organization requires.
   For example, Compute or Container Engine for Kubernetes.
   Refer to the specific service in Security Best Practices on page 4671.

9. Periodically review Audit logs to ensure that user actions are in accordance with your initial security configuration.
   See Audit on page 4666.
   If you enabled Cloud Guard on page 4662, it also notifies you about security problems that it detected.

Security Best Practices

This reference provides actionable guidance and recommendations for securely configuring specific services in Oracle Cloud Infrastructure.

For security best practices, choose a specific service:

- Securing Block Volume on page 4671
- Securing Cloud Advisor on page 4674
- Securing Compute on page 4675
- Securing Container Engine for Kubernetes on page 4678
- Securing Data Catalog on page 4681
- Securing Data Integration on page 4682
- Securing Data Transfer on page 4682
- Securing Database on page 4682
- Securing Email Delivery on page 4685
- Securing File Storage on page 4685
- Securing GoldenGate on page 4685
- Securing IAM on page 4686

- Securing Object Storage on page 4697
- Securing Resource Manager on page 4701

Securing Block Volume

Security Recommendations

- There are two types of volumes: block volumes and boot volumes. Block volumes allow instance storage capacity to be expanded dynamically. A boot volume contains the image used to boot the compute instance. The IAM service groups the family of related volume resource types into a combined resource type called `volume-family`.
- Assign least privilege access for IAM users and groups to resource types in `volume-family`. The resource types in `volume-family` are `volumes`, `volume-attachments`, and `volume-backups`. The `volume-family` resources are detachable block volume devices that allow dynamic expansion of instance storage capacity or contain the image for booting the instance. The `volume-attachments` resources are attachments between volumes and instances. The `volume-backups` resources are point-in-time copies of volumes that can be used to create block volumes or recover block volumes.

Data Durability

To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends to giving `VOLUME_DELETE`, `VOLUME_ATTACHMENT_DELETE` and `VOLUME_BACKUP_DELETE` permissions to a minimum possible set of IAM users and groups. `DELETE` permissions should be given only to tenancy and compartment administrators.
To minimize loss of data due to deletes or corruption, Oracle recommends that you make periodic backups of volumes. Oracle Cloud Infrastructure allows automated scheduled backups. For more information about scheduled backups, see Policy-Based Backups on page 717.

Data-at-rest Encryption

By default, volumes and their backups are encrypted at rest using AES-256. You can also encrypt your data volumes using tools like dm-crypt, veracrypt, and Bit-Locker. Instructions on dm-crypt encryption are presented in the next section.

Security Policy Examples

Prevent Delete of Volumes

The following example policy allows group VolumeUsers to perform all actions on volumes and backups, except deleting them.

```
Allow group VolumeUsers to manage volumes in tenancy
  where request.permission!= 'VOLUME_DELETE'
Allow group VolumeUsers to manage volume-backups in tenancy
  where request.permission!= 'VOLUME_BACKUP_DELETE'
```

If VolumeUsers can't detach volumes from instances, you can add the following policy to the previous example.

```
Allow group VolumeUsers to manage volume-attachments in tenancy
  where request.permission!= 'VOLUME_ATTACHMENT_DELETE'
```

Security-related Tasks

Encrypting Non-root Volumes with dm-crypt

dm-crypt is a kernel-level encryption mechanism (part of Linux device mapper framework) to provide encrypted volumes. It encrypts data passed from the filesystem (for example, ext4 and NTFS ), and stores it on a storage device in Linux Unified Key Setup (LUKS ) format. The encrypted volumes can be stored on a complete disk, disk partition, logical volume, or a file-backed storage created using loopback devices. Cryptsetup is the user-level utility used to manage dm-crypt, and used to encrypt partitions and files. dm-crypt uses the Linux crypto APIs for encryption routines.

1. Attach block storage volume to an instance (for example, /dev/sdb)
2. Format /dev/sdb for LUKS encryption. Enter LUKS passphrase when prompted. The passphrase is used to encrypt the LUKS master key used for encrypting the volume.
   ```
   cryptsetup -y luksFormat /dev/sdb
   ```
3. Verify that the LUKS formatting is successful.
   ```
   cryptsetup isLuks /dev/sdb && echo Success
   ```
4. Get encryption information about the device.
   ```
   cryptsetup luksDump /dev/sdb
   ```
5. Get LUKS UUID of the device. The UUID value is used to configure the /etc/crypttab.
   ```
   cryptsetup luksUUID /dev/sdb
   ```
6. Create a LUKS container with device name, dev_name. This also creates a device node, /dev/mapper/<dev_name>.
   ```
   cryptsetup luksOpen /dev/sdb <dev_name>
   ```
7. Get information about the mapped device.

   dmsetup info <dev_name>

8. Format the device node as ext4 filesystem.

   sudo mkfs -t ext4 /dev/sdb

9. Mount the device node.

   mount /dev/mapper/<dev_name> /home/encrypt_fs

10. Add an entry to /etc/crypttab.

    <dev_name> UUID=<LUKS UUID of /dev/sdb> none

    All the files copied to /home/encrypt_fs are encrypted by LUKS.

11. Add a keyfile to an available keyslot of the encrypted volume. This keyfile can be used to access the encrypted volume.

    dd if=/dev/urandom of=$HOME/keyfile bs=32 count=1
    chmod 600 $HOME/keyfile
    cryptsetup luksAddKey /dev/sdb ~/keyfile

12. Verify the encryption status of files.

    cryptsetup status /home/encrypt_fs

13. Unmount after you're finished.

    umount /home/encrypt_fs
    cryptsetup luksClose <dev_name>

To access the encrypted volume:

    cryptsetup luksOpen /dev/sdb <dev_name> --key-file=/home/opc/keyfile
    mount /dev/mapper/<dev_name> /home/encrypt_fs

If you lose the keyfile, or if the keyfile or passphrase gets corrupted, you can't decrypt the encrypted volume. This results in permanent loss of data. Oracle recommends that you store durable copies of the keyfile on an on-premises host.

**Remote Mounting of dm-crypt Encrypted Data Volumes**

The following steps assume that the keyfile is on an on-premises host (SRC_IP) and that <OCI_SSH_KEY> is the SSH private key of the instance.

1. Copy keyfile from the on-premises host to an instance.

   scp -i <OCI_SSH_KEY> keyfile opc@SRC_IP:/home/opc

2. Open the encrypted volume.

   ssh i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksOpen /dev/sdb <dev_name> --key-file=/home/opc/keyfile"

3. Mount the volume.

   ssh -i <OCI_SSH_KEY> opc@SRC_IP "mount /dev/mapper/<dev_name> /home/encrypt_fs"

4. Perform operations on data in the mounted volume.
5. Unmount the encrypted volume.

```bash
ssh -i <OCI_SSH_KEY> opc@SRC_IP "umount /home/encrypt_fs"
ssh -i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksClose <dev_name>"
```

6. Delete the keyfile from the instance.

```bash
ssh -i <OCI_SSH_KEY> opc@SRC_IP "\rm -f /home/opc/keyfile"
```

## Securing Cloud Advisor

This topic provides security information and recommendations for Oracle Cloud Infrastructure's Cloud Advisor service.

### Security Responsibilities

To use Cloud Advisor securely, learn about your security and compliance responsibilities.

In general, Oracle provides security of cloud infrastructure and operations, such as cloud operator access controls and infrastructure security patching. You are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

Oracle is responsible for the following security requirements:

- **Physical Security**: Oracle is responsible for protecting the global infrastructure that runs all of the services offered in Oracle Cloud Infrastructure. This infrastructure consists of the hardware, software, networking, and facilities that run Oracle Cloud Infrastructure services.

Your security responsibility includes the following area:

- **Access Control**: Limit privileges as much as possible. Users should be given only the access necessary to perform their work.

### Initial Security Tasks

Use this checklist to identify the tasks you perform to secure Cloud Advisor in a new Oracle Cloud Infrastructure tenancy.

<table>
<thead>
<tr>
<th>Task</th>
<th>More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use IAM policies to grant access to users</td>
<td>IAM Policies on page 4674</td>
</tr>
</tbody>
</table>

### Routine Security Tasks

Cloud Advisor does not have any security tasks that you need to perform regularly.

### IAM Policies

Use policies to limit access to Cloud Advisor.

A policy specifies who can access Oracle Cloud Infrastructure resources and how. For more information, see How Policies Work on page 2800.

Assign a group the least privileges that are required to perform their responsibilities. Each policy has a verb. From the least amount of access to the most, the available verbs are: inspect, read, use, and manage.

Create this policy to allow group CloudAdvisorUsers to perform all actions in Cloud Advisor except deleting profiles.

```bash
Allow group CloudAdvisorUsers to manage optimizer-api-family in tenancy where request.permission!='OPTIMIZER_PROFILE_DELETE'
```

For more information about Cloud Advisor policies and to view more examples, see Policy Details for Cloud Advisor on page 789.
Data Encryption

Cloud Advisor uses standard Oracle Cloud Infrastructure encryption for all data stored at rest in the service. No configuration is necessary.

Cloud Advisor does not use Vault keys. Internally, Cloud Advisor stores data in an Autonomous Database that uses Vault keys. Oracle manages and secures these resources.

Data Durability

Cloud Advisor creates backups daily. No configuration is necessary.

Securing Compute

Security Recommendations

Oracle Cloud Infrastructure Compute provides both bare metal and virtual machine (VM) instances, architected and managed in accordance with security best practices.

Managing Instances and Credentials

- To prevent inadvertent or malicious termination of critical instances (for example, production instances), Oracle recommends that you give INSTANCE_DELETE permissions to a minimal set of groups. Give DELETE permissions only to tenancy and compartment administrators.
- You can use the Oracle Cloud Infrastructure instance principals feature to authorize instances to access Oracle Cloud Infrastructure services (Compute, Block Volume, Networking, Load Balancing, Object Storage) on behalf of an IAM user. To use this feature, create dynamic groups and grant them access to service APIs. Dynamic groups allow you to group Oracle Cloud Infrastructure computer instances as "principal" actors (similar to user groups). You can then create policies to permit instances to make API calls against Oracle Cloud Infrastructure services.

When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of matching rules to define the group members. A short-lived private key to sign API calls is delivered through the instance metadata service (http://169.254.169.254/opc/v1/identity/cert.pem), and the key is rotated multiple times a day. For more information about accessing services from instances, see Calling Services from an Instance on page 3106.

Instance Metadata Access Control

- Instance metadata (http://169.254.169.254) provides predefined instance information, such as OCID and display name, and custom fields. The instance metadata can also provide short-lived credentials, such as dynamic group credentials. Oracle recommends that you limit instance metadata access to privileged users on the instance. The following example shows how to use iptables to restrict instance metadata access to the root user.

```bash
iptables -A OUTPUT -m owner ! --uid-owner root -d 169.254.169.254 -j DROP
```

- Instances use link local addresses to access the instance metadata service (169.254.169.254:80), DNS (169.254.169.254:53), NTP (169.254.169.254:123), kernel updates (169.254.0.3), and iSCSI connections to boot volumes (169.254.0.2:3260, 169.254.2.0/24:3260). You can use host-based firewalls, such as iptables, to ensure that only the root user is authorized to access these IPs. Make sure these operating system firewall rules are not altered.
### Instance Network Access Controls

- Harden secure shell (SSH) on all instances. The following table shows some SSH security recommendations. SSH configuration options can be set in the `sshd_config` file (located at `/etc/ssh/sshd_config` in Linux).

<table>
<thead>
<tr>
<th>Security Recommendation</th>
<th>Configuration sshd_config</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use public-key logins only</td>
<td><code>PubkeyAuthentication yes</code></td>
<td>Periodically review SSH public keys in the <code>~/.ssh/authorized_keys</code> file.</td>
</tr>
<tr>
<td>Disable password logins</td>
<td><code>PasswordAuthentication no</code></td>
<td>Mitigates password brute-force attacks.</td>
</tr>
<tr>
<td>Disable root logins</td>
<td><code>PermitRootLogin no</code></td>
<td>Prevents root privileges for remote logins.</td>
</tr>
<tr>
<td>Change SSH port to a non-standard port</td>
<td><code>Port &lt;port number&gt;</code></td>
<td>Optional. Verify that this change does not break applications using port 22 for SSH.</td>
</tr>
</tbody>
</table>

- Use secure SSH private keys to access instances and to prevent inadvertent disclosures. For more information about creating an SSH key pair and configuring an instance with the keys, see [Managing Key Pairs on Linux Instances](#) on page 1021.

- To limit instance access to authorized IP addresses, use VCN network security groups or security lists. Fail2ban is an application that blocklists IP addresses involved in brute-force sign-in attempts (that is, too many failed attempts to sign in to an instance). By default, Fail2ban inspects SSH accesses, and you can configure it to inspect other protocols. For more information about Fail2ban, see [Fail2ban Main Page](#).

- In addition to VCN network security groups and security lists, use host-based firewalls, such as iptables and firewalld, to restrict network access to instances by controlling ports, protocols, and packet types. Use these firewalls to prevent potential network security attack reconnaissance, such as port scanning and intrusion attempts. Custom firewall rules can be configured, saved, and initialized on every instance boot. The following example shows commands for iptables.

```
# save iptables rules after configuration
sudo iptables-save > /etc/iptables/iptables.rules

# restore iptables rules on next reboot
sudo /sbin/iptables-restore < /etc/iptables.rules

# restart iptables after restore
sudo service iptables restart
```

### Instance Entropy

Both bare metal and VM instances provide high-quality and high-throughput entropy source. Instances have random number generators whose output is fed into the entropy pools used by the operating system to generate random numbers. In Linux instances, `/dev/random` is non-blocking and should be used for security applications requiring random numbers. You can use the following commands to check the throughput and quality of the random numbers generated by `/dev/random` before using the output in applications.

```
# check sources of entropy
sudo rngd -v

# enable rngd, if not already
sudo systemctl start rngd

# verify rngd status
sudo systemctl status rngd

# verify /dev/random throughput and quality using rngtest
cat /dev/random | rngtest -c 1000
```
Host Security Hardening and Patching

- Establish a baseline for security hardening of Linux and Windows images running on instances. For more information about security hardening of Oracle Linux images, see Tips for Hardening an Oracle Linux Server. The Center for Internet Security Benchmarks provides a comprehensive set of operating system security hardening benchmarks for various distributions of Linux and Windows Server.

- Keep instance software up to date with security patches. Oracle recommends that you periodically apply the latest available software updates to your instances. Oracle Autonomous Linux images are automatically updated with the latest patches. For Oracle Linux images, you can run the `sudo yum update` command (`sudo dnf update` on Oracle Linux 8). On Oracle Linux, you can get information about available and installed security patches using the `yum-security` plugin. The following example provides commands for `yum-security`. For Oracle Linux instances launched after February 15, 2017, Ksplice support is available for applying patches without rebooting the instance. For more information about using Ksplice on Oracle Cloud Infrastructure instances, see Installing and Running Oracle Ksplice on page 987.

```bash
# Install yum-security plugin
yum install yum-plugin-security
# Get list of security patches without installing them
yum updateinfo list security all
# Get list of installed security patches
yum updateinfo list security all
```

Instance Security Logging and Monitoring

- Various security-related events are captured in log files. Oracle recommends that you periodically review these log files to detect any security issues. In Oracle Linux, the log files are located in `/var/log`. Some security-relevant log files are listed in the following table.

<table>
<thead>
<tr>
<th>Log File or Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/var/log/secure</code></td>
<td>Auth log showing failed and successful sign ins.</td>
</tr>
<tr>
<td><code>/var/log/audit</code></td>
<td>Audit logs capturing system calls issued, sudo attempts, user sign-ins, and so on. auresearch and aureport are two tools used to query audit logs.</td>
</tr>
<tr>
<td><code>/var/log/yum.log</code></td>
<td>Lists packages installed or updated on instances with yum.</td>
</tr>
<tr>
<td><code>/var/log/cloud-init.log</code></td>
<td>During instance boot, cloud-init can run user-provided scripts as a privileged user. For example, cloud-init can introduce SSH keys. Oracle recommends that you review the cloud-init logs for any unrecognized commands.</td>
</tr>
</tbody>
</table>

Security Policy Examples

In all the following examples, the policies are scoped to a tenancy. However, by specifying a compartment name, they can be scoped down to specific compartment in a tenancy.

Restrict Users Ability to Delete Instances

The following example allows the `InstanceUsers` group to launch instances, but not to delete them.

```bash
Allow group InstanceUsers to manage instance-family in tenancy
   where request.permission!~'INSTANCE_DELETE'
Allow group InstanceUsers to use volume-family in tenancy
Allow group InstanceUsers to use virtual-network-family in tenancy
```
Restricit Ability to Use Instance Console

For security compliance reasons, some customers do not want to expose the instance console to users in their tenancy. The following policy example restricts ability to create or read from consoles.

```
Allow group InstanceUsers to manage instance-console-connection in tenancy
where all {request.permission!= INSTANCE_CONSOLE_CONNECTION_READ,
request.permission!= INSTANCE_CONSOLE_CONNECTION_CREATE}
```

Securing Container Engine for Kubernetes

This topic provides security recommendations for using Oracle Cloud Infrastructure's Container Engine for Kubernetes (also known as OKE).

Multi-Tenant Clusters

At this time, it is not recommended to run mutually distrusted workloads in the same cluster. For example, you should not run the following workloads in the same cluster:

- Development workloads and production workloads
- Control plane and data plane
- Workloads that run arbitrary customer code

Additionally, you should consider having separate clusters if you have multiple tenants, teams, or users accessing the same cluster with differing levels of trust. As mentioned in subsequent sections, Kubernetes and OKE offer methods to isolate workloads. However, these methods are not currently sufficient for hard multi-tenancy.

Encrypt Secrets at Rest in Etcd

Please review Encrypting Kubernetes Secrets at Rest in Etcd on page 1266 for information on configuring secret encryption.

Role-Based Access Control (RBAC)

Kubernetes ships an integrated Role-Based Access Control (RBAC) component that matches an incoming user or group to a set of permissions which are bundled into roles. These permissions combine verbs (get, create, delete) with resources (pods, services, nodes) and can be scoped to a namespace or cluster. A set of preconfigured roles are provided which offer reasonable default separation of responsibility, depending on what actions a client might want to perform.

It is important to understand how updates on one object may cause actions in other places. For example, a user may not be able to create pods directly, but allowing them to create a deployment, which creates pods on their behalf, will let them create those pods indirectly. Likewise, deleting a node from the API will result in the pods scheduled to that node being terminated and recreated on other nodes. The preconfigured roles represent a balance between flexibility and the common use cases, but more limited roles should be carefully reviewed to prevent accidental privilege escalation. You can make roles specific to your use case if the preconfigured roles don’t meet your needs.

You should always follow the principle of least privilege to ensure users and Kubernetes Service Accounts have the minimal set of privileges required. By default, any user with USE CLUSTER access in Oracle Cloud Infrastructure IAM or any Kubernetes Service Account will have no access to the Kubernetes API, except to the discovery roles. See About Access Control and Container Engine for Kubernetes to learn how IAM integrates with OKE.

You must use the OCID of the Principal when creating RBAC bindings (for example, user OCID, instance OCID, and service name).

Cluster Security

You can control the operations that pods are allowed to perform on a cluster you've created with Container Engine for Kubernetes by setting up pod security policies for the cluster. Pod security policies are a way to ensure that pods meet security-related conditions before they can be accepted by a cluster. For example, you can use pod security polices to:

- limit the storage choices available to pods
- restrict the host networking and ports that pods can access
• prevent pods from running as the root user
• prevent pods from running in privileged mode

Having defined a pod security policy for a cluster, you have to authorize the requesting user or pod to use the policy by creating roles and bindings. You can then specify whether a cluster enforces the pod security policies defined for it by enabling the cluster's PodSecurityPolicy admission controller.

For more information, see Using Pod Security Policies with Container Engine for Kubernetes on page 1345.

Node Pool Security

Node Pool Compartments

Node pools in a cluster can span compartments. However, while using multiple compartments provides a convenient way to group and manage worker nodes, it does not provide any isolation between the worker nodes in the cluster. Any workload can be scheduled across any node pool regardless of the compartment. A valid use case for using more than one compartment for a node pool would be to easily create dynamic groups and IAM policies for worker nodes. An invalid use case for multiple compartments would be putting each node pool running a customer workload in a separate compartment under the assumption that the compartments are providing some type of security boundary or isolation.

Node Pool Subnets

We recommend only using private subnets for node pools. A service gateway should be configured to provide access to Oracle Cloud Infrastructure services. A service gateway cannot be used if the subnets are public with an internet gateway. If your private subnets require access to the internet, use a NAT gateway.

Controlling Which Nodes Pods May Access

By default, a pod may be scheduled on any node in the cluster. Kubernetes offers a rich set of policies for controlling placement of pods onto nodes and the taint based pod placement and eviction that are available to end users. For many clusters, the use of these policies to separate workloads can be a convention that authors adopt or enforce via tooling. These placement controls are not adequate in a multi-tenant environment when users with deployment capabilities are untrusted. If you have untrusted users deploying code then you should consider a cluster per untrusted group.

Limit Access Given to Instance Principals

By default, all pods on a node are able to access the instance principal certificates using the instance metadata endpoint. In order to avoid privilege escalation via instance principals, you should isolate workloads across node pools with different dynamic groups so that pods in a given node pool have the minimal set of privileges required to function.

For example, assume you have the following two workloads, which both require different access:

• LogArchiver - requires access to manage buckets and objects in Object Storage
• HostMonitor - requires access to the Compute API to manage Instances

The simplest approach would be to schedule them in the same node pool and provide the instance principal with all the required access. However, this increases the impact in the event one of the workloads becomes compromised. A better approach would be to schedule the workloads on separate node pools with the limited set of access the instance principals require for the applicable workload.

Block Container Access to Instance Metadata

The preferred way to block access is using a network policy plugin with a default policy of "deny all". Then you would explicitly grant access to pods and networks using NetworkPolicy resources in Kubernetes via label selectors. If you don't have a network policy plugin installed, you can use an IPTables rule to restrict access from all pods on the host. We recommend that you do not use this approach to block a subset of pods on a host.
Important: NetworkPolicies and the following IPTable rule only apply to containers in the pod overlay network. Containers and services running in the host network are not impacted by either option:

```
iptables --insert FORWARD 1 --in-interface veth+ --destination 169.254.0.0/16 --jump DROP
```

Network Security

Pods running in your OKE Cluster often need to communicate with other pods in the cluster or with services outside the cluster. Container Engine for Kubernetes offers multiple options to secure communication to and from the workloads in your cluster. For the best network security posture, you should evaluate using a combination of network policies (to secure pod-level network communication) and security lists (to secure host-level network communication).

Network Policies

Network policies in Kubernetes allow administrators to define how groups of pods are able to communicate with other pods in the cluster. Additionally, network policies allow you to define how groups of pods are able to communicate with services outside the cluster (for example, Oracle Cloud Infrastructure services).

To restrict access using network policies, you need to install a network plugin. Network plugins configure and enforce the network policies defined in Kubernetes. There are numerous network plugin options. You can follow our instructions here to install and configure Calico in your cluster. Network policy plugins work by restricting access on the host. For information on installing Calico into OKE, see Example: Installing Calico and Setting Up Network Policies on page 1310.

Node Pool Security Lists

Network administrators can define security list rules on node pool subnets to restrict access to and from worker nodes. Defining security list rules allows administrators to enforce network restrictions that cannot be overridden on the hosts in your cluster.

Because all pod-to-pod communication occurs in a VXLAN overlay network on the worker nodes, you are cannot use security list rules to restrict pod-to-pod communication. However, you can use security lists to restrict access to and from your worker nodes.

Important: There is a minimum set of security list rules that must exist on node pool subnets to ensure that the cluster can function. See Example Network Resource Configurations on page 1215 for information on the minimum set of security list rules before making any changes to your security list rules.

Workload Security Best Practices

Use Image Digests Instead of Tags

We recommend that you only pull images using the image digests, and not pull images using tags (because image tags are mutable). Image digests are the sha256 digest of your image, which allows docker to verify the image it downloaded is what you expected.

Example image digest id:

```
sha256:77af4d6b9913e693e8d0b4b294fa62ade6054e6b2f1ff617ac955dd63fb0182
```

Pull the image as shown in the following example:

```
docker pull acme@sha256:77af4d6b9913e693e8d0b4b294fa62ade6054e6b2f1ff617ac955dd63fb0182
```

You can use the following command to show all the digests for your local images:

```
docker images --digests
```
Limit Resource Utilization

Resource quota limits the number or capacity of resources granted to a namespace. This is most often used to limit the amount of CPU, memory, or persistent disk a namespace can allocate, but can also control how many pods, services, or volumes exist in each namespace.

Limit ranges restrict the maximum or minimum size of some of the resources above, to prevent users from requesting unreasonably high or low values for commonly reserved resources like memory, or to provide default limits when none are specified.

Access to resource quotas can be restricted via RBAC policies in Kubernetes. This can help an administrator ensure that users of a cluster are not able to use resources that they should not have access to. See Limiting resource usage in the on a cluster in the Kubernetes documentation for more information.

Disabling the Tiller Add-on

OKE offers an optional Tiller add-on. This provides an easy way to install and use Helm+Tiller, allowing you to quickly provision and run Kubernetes. It is not recommended to use this add-on for production clusters because of the security risks associated with Tiller. Clusters provisioned with Tiller do not have authentication or authorization for API calls made to Tiller, which means they cannot provide attribution for requests. Therefore, any operator or service that can reach Tiller can invoke its APIs with Tiller access.

To solve the security problems associated with Tiller, Helm V3 was developed. The Helm V3 release completely removed Tiller from Helm. We recommend that you consider using Helm V3 if you'd like to utilize the functionality offered by Helm+Tiller.

Note:
To disable the Tiller add-on on an existing cluster, contact Oracle Support.

Disabling the Kubernetes Dashboard Add-on

OKE offers an optional Kubernetes Dashboard add-on, providing an easy way to install the Kubernetes Dashboard. The Kubernetes Dashboard is installed by OKE with the minimal set of privileges required to run. You will not be able to use the dashboard without providing additional credentials. See Accessing a Cluster Using the Kubernetes Dashboard on page 1249 for more information.

The dashboard is particularly useful for new Kubernetes users. However, we do not recommend installing this add-on on production clusters due to the lack of extensible authentication support. Consequently, you cannot specify that you want to install the Kubernetes Dashboard when creating a cluster using the Console. If you decide you do want to install the Kubernetes Dashboard, create the cluster using the API and set the isKubernetesDashboardEnabled attribute to true.

If you do install the Kubernetes Dashboard, we recommend that you restrict access within your cluster, instead of exposing it externally via either a load balancer or an ingress controller. The Kubernetes Dashboard is a common attack vector used to gain access to a Kubernetes Cluster.

Note:
To disable the Kubernetes Dashboard add-on on an existing cluster, contact Oracle Support.

Securing Data Catalog

Oracle Cloud Infrastructure Data Catalog provides a collaborative data discovery and governance solution in accordance with industry-leading security best practices.

Security Recommendations

- Assign least privilege access for IAM users and groups to resource types in data-catalog-family.
- To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends to giving CATALOG_DELETE permission to a minimum possible set of IAM users and groups. Give CATALOG_DELETE permissions only to tenancy and compartment admins.
• To protect your data sources from any security vulnerability, provide credentials to read-only accounts only. Data Catalog only needs read access to harvest data assets.

Security Policy Examples

Prevent Delete of Data Catalogs
Create this policy to allow group DataCatalogUsers to perform all actions on data catalogs, except deleting them.

Allow group DataCatalogUsers to manage data-catalog-family in tenancy where request.permission!='CATALOG_DELETE'

For more information on creating policies, see Data Catalog Policies.

Securing Data Integration
Oracle Cloud Infrastructure Data Integration provides a collaborative data integration solution in accordance with industry-leading security best practices.

Security Recommendations
• Assign least privilege access for IAM users and groups to resource types in dis-family.
• To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends to giving DIS_WORKSPACE_DELETE permission to a minimum possible set of IAM users and groups. Give DIS_WORKSPACE_DELETE permissions only to tenancy and compartment admins.
• To protect your data sources from any security vulnerability, provide credentials to read-only accounts only. Data Integration only needs read access to ingest data from data assets.

Security Policy Examples

Prevent Delete of Workspaces
Create this policy to allow group DISUsers to perform all actions on workspaces, except deleting them.

Allow group DISUsers to manage dis-family in tenancy where request.permission!='DIS_WORKSPACE_DELETE'

For more information on creating policies, see Data Integration Policies.

Securing Data Transfer
Oracle offers offline data transfer solutions that let you migrate large amounts of data to buckets in a tenancy in Oracle Cloud Infrastructure. Data transfer solutions include:
• Disk-Based Data Import
  For more information about securely transferring data using this service, see Secure Disk Data Transfer to Oracle Cloud Infrastructure on page 1498
• Appliance-Based Data Import
  For more information about securely transferring data using this service, see Secure Appliance Data Transfer to Oracle Cloud Infrastructure on page 1547

Securing Database

Security Recommendations
This section lists security recommendations for managing Oracle Cloud Infrastructure Database instances. Recommendations for securely configuring Oracle databases are available in the Oracle Database Security Guide.
Database Access Control

- Users authenticate to the database using their password. Oracle recommends that these passwords be strong. For guidelines on choosing Oracle database passwords, see Guidelines for Securing Passwords. In addition, Oracle database provides a PL/SQL script to verify database password complexity. This script is located at $ORACLE_HOME/rdbms/admin/UTLPWDMG.SQL. For instructions on running UTLPWDMG.SQL script to verify password complexity, see Enforcing Password Complexity Verification.
- In addition to the database password, you can use VCN network security groups or security lists to enforce network access control to database instances. Oracle recommends that you configure VCN network security groups or security lists to allow least privilege access to customer databases in Oracle Cloud Infrastructure Database.
- DB systems created within a public subnet can send outbound traffic directly to the Internet. DB systems created within a private subnet do not have internet connectivity, and internet traffic (both egress and ingress) cannot reach the instance directly. If you try to define a route to a DB system within a private subnet using an internet gateway, the route is ignored.

To perform OS patching and backup for a DB system on a private subnet, you can use a service gateway or a NAT gateway to connect to your patching or backup endpoints.

In a virtual cloud network (VCN), you can use security rules along with a private subnet to restrict access to a DB system. In multi-tier deployments, a private subnet and VCN security rules can be used to restrict access to the DB system from the application tiers.

Data Durability

- Oracle recommends that you give database delete permissions (DATABASE_DELETE, DB_SYSTEM_DELETE) to a minimum possible set of IAM users and groups. This minimizes loss of data due to inadvertent deletes by an authorized user or due to malicious deletes. Only give DELETE permissions to tenancy and compartment administrators.
- You can use RMAN to do periodic backups of Database databases, where encrypted backup copies are stored in local storage (block volumes, for example) or Oracle Cloud Infrastructure Object Storage. RMAN encrypts each backup of a database with a unique encryption key. In transparent mode, the encryption key is stored in the Oracle Wallet. RMAN backups to Object Storage require internet gateway (IGW), and VCN network security groups or security lists need to be configured to allow secure access to Object Storage. For information about setting up the VCN for backing up bare metal databases, see Backing Up a Container Database to Oracle Cloud Infrastructure Object Storage on page 1956. For information about backing up and Exadata databases, see Managing Exadata Database Backups by Using bkup_api on page 1844.

Database Encryption and Key Management

- All databases created in Oracle Cloud Infrastructure are encrypted using transparent data encryption (TDE). Note that if you migrate an unencrypted database from on-premise to Oracle Cloud Infrastructure using RMAN, the migrated database will not be encrypted. Oracle requires encrypting such databases after migrating them to the cloud.

To learn how to encrypt your database with minimum downtime during migration, see the Oracle Maximum Availability Architecture white paper Converting to Transparent Data Encryption with Oracle Data Guard using Fast Offline Conversion.

Note that virtual machine DB systems use Oracle Cloud Infrastructure block storage instead of local storage. Block storage is encrypted by default.
- User-created tablespaces are encrypted by default in Oracle Cloud Infrastructure Database. In these databases, ENCRYPT_NEW_TABLESPACES parameter is set to CLOUD_ONLY where tablespaces created in a Database Cloud Service (DBCS) database are transparently encrypted with the AES128 algorithm unless a different algorithm is specified.
- The Database administrator creates a local Oracle Wallet on a newly created database instance, and initializes the Transparent Data Encryption (TDE) master key. Then the Oracle Wallet is configured to be "auto-open". However, a customer can choose to set a password for the Oracle Wallet, and Oracle recommends that you set a
strong password (eight characters or more, with at least one capital letter, one small letter, one number, and one special symbol).

- Oracle recommends that you periodically rotate the TDE master key. The recommended rotation period is 90 days or less. You can rotate the TDE master key by using native database commands ("administer key management" in 12c, for example) or dbaascli. All previous versions of TDE master key are maintained in the Oracle Wallet.
- Oracle Key Vault (OKV) is a key management appliance used for managing Oracle TDE master keys. OKV can store, rotate, and audit accesses to TDE master keys. For instructions about installing and configuring OKV in Oracle Cloud Infrastructure, see Managing Oracle Database Encryption Keys in Oracle Cloud Infrastructure with Oracle Key Vault.

Database Patching
Applying Oracle database security patches (Oracle Critical Patch Updates) is imperative to mitigate known security issues, and Oracle recommends that you keep patches up-to-date. Patchsets and Patch Set Updates (PSUs) are released on a quarterly basis. These patch releases contain security fixes and additional high-impact/low-risk critical bug fixes.

For information about the latest known security issues and available fixes, see Critical Patch Updates, Security Alerts and Bulletins. If your application does not support the latest patches and needs to use a DB system with older patches, you can provision a DB system with an older version of the Oracle Database edition you are using. In addition to reviewing the critical patch updates and security alerts for your Oracle Database, Oracle recommends that you analyze and patch the operating system provisioned with the DB system.

For information about applying patches to Oracle Cloud Infrastructure Database instances, see Patching a DB System on page 1931 and Patching Oracle Grid Infrastructure and Oracle Databases Using dbaascli on page 1813.

Database Security Configuration Checking

- The Oracle Database Security Assessment Tool (DBSAT) provides automated security configuration checks of Oracle databases in Oracle Cloud Infrastructure. DBSAT performs security checks for user privilege analysis, database authorization controls, auditing polices, database listener configuration, OS file permissions, and sensitive data stored. Oracle database images in Oracle Cloud Infrastructure Database are scanned with DBSAT before provisioning. After provisioning, Oracle recommends that you periodically scan databases with DBSAT, and remediate any issues found. DBSAT is available free of charge to Oracle customers.

Database Security Auditing
Oracle Audit Vault and Database Firewall (AVDF) monitors database audit logs and creates alerts. For instructions about installing and configuring AVDF in Oracle Cloud Infrastructure, see Deploying Oracle Audit Vault and Database Firewall in Oracle Cloud Infrastructure.

Database Backups
Oracle recommends using Managed backups (backups created using the Oracle Cloud Infrastructure Console or the API) whenever possible. When you use managed backups, Oracle manages the object store user and credentials, and rotates these credentials every 3 days. Oracle Cloud Infrastructure encrypts all managed backups in the object store. Oracle uses the Database Transparent Encryption feature by default for encrypting the backups.

If you are not using managed backups, Oracle recommends that you change the object store passwords at regular intervals.

Security Policy Examples

Prevent Delete of Database Instances
The following example policy allows the group DBUsers to perform all management actions except delete databases and any artifacts.

```
Allow group DBUsers to manage db-systems in tenancy
```
Securing Email Delivery

The Email Delivery service offers an SMTP endpoint, secured by a password generated in the Console. The SMTP password is required for sending emails using Email Delivery. Oracle recommends that you create a separate IAM user for SMTP. This user must have manage permissions for approved-senders and suppressions resource types. Oracle recommends that you securely store the SMTP credential, and periodically rotate it. For more information about generating an SMTP credential for Email Delivery, see Generate SMTP Credentials for a User on page 2341.

For Email Delivery best practices, including managing your sender reputation and help for avoiding being blocklisted, see Email Deliverability on page 2375.

Securing File Storage

The File Storage Service exposes an NFSv3 endpoint as a mount target in each customer's VCN subnet. The mount target is identified by a DNS name and is mapped to an IP address. Oracle recommends that you use VCN security lists (of the mount target subnet) to configure network access to the mount target from only authorized IP addresses.

You can mount a file system using the Console or from a Linux command line using NFS utilities. You can authorize users to mount file systems using IAM security policies, but this applies to the console only.

For data durability, Oracle recommends that you take periodic snapshots of the file system. To minimize accidental deletion of data, constrain the set of users having privileges to delete mount targets, file-systems, and snapshots.

All file-system data is encrypted at rest.

Access to mounted NFS file systems from a remote host is determined by POSIX user and group permissions. Oracle recommends that you use well-known NFS security best practices such as the all_squash option to map all users to nfsnobody, and NFS ACLs to enforce access control to the mounted file system.

Security Policy Examples

Prevent Mount Target and File System Deletion

The following example prevents group FileUsers from deleting mount targets and file-systems.

| Allow group FileUsers to manage file-systems in tenancy where request.permission!='FILE_SYSTEM_DELETE' |
| Allow group FileUsers to manage mount-targets in tenancy where request.permission!='MOUNT_TARGET_DELETE' |
| Allow group FileUsers to manage export-sets in tenancy where request.permission!='EXPORT_SET_DELETE' |

Securing GoldenGate

Oracle Cloud Infrastructure GoldenGate provides a secure and easy to use data replication solution in accordance with industry-leading security best practices.

Security Recommendations

- Assign least privilege access for IAM users and groups to resource types in goldengate-family.
- To minimize loss of data from inadvertent deletes by an authorized user or malicious deletes, Oracle recommends giving the GOLDENGATE_DEPLOYMENT_DELETE and GOLDENGATE_DATABASE_REGISTRATION_DELETE permissions to the minimum possible set of IAM users and groups. Give these permissions only to tenancy and compartment administrators.
• GoldenGate only needs USE level access to capture data from database registrations.

Security Policy Examples

Prevent deletion of deployments
Create this policy to allow the group ggs-users to perform all actions on deployments, except deleting them:

Allow group ggs-users to manage goldengate-family in tenancy where request.permission!='GOLDENGATE_DEPLOYMENT_DELETE'

For more information on creating policies, see Oracle Cloud Infrastructure GoldenGate Policies.

Securing IAM

Security Recommendations
Oracle Cloud Infrastructure Identity and Access Management (IAM) provides authentication of users, and authorization to access resources. Security-relevant IAM concepts include:

IAM concepts and descriptions

<table>
<thead>
<tr>
<th>Concept</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compartment</td>
<td>A compartment is a fundamental mechanism to aggregate resources into logical groups. They also provide isolation.</td>
</tr>
<tr>
<td>Tenancy</td>
<td>Oracle Cloud Infrastructure automatically creates a tenancy for an account created by an organization. It is the root compartment that contains all the organization's resources.</td>
</tr>
<tr>
<td>Users and groups</td>
<td>A group is an aggregation of users who need similar access to a group of resources.</td>
</tr>
<tr>
<td>Resource</td>
<td>A resource is an object created in Oracle Cloud Infrastructure services.</td>
</tr>
<tr>
<td>Security policy</td>
<td>A security policy specifies the type of access IAM groups have to resources in a specified aggregation level. An aggregation level can be the tenancy, a compartment, or a service.</td>
</tr>
<tr>
<td>Dynamic groups</td>
<td>A dynamic group allows aggregating Compute instances as principal actors (similar to user groups), in order to authorize instances to make calls to Oracle Cloud Infrastructure APIs.</td>
</tr>
<tr>
<td>Tags</td>
<td>Tags allow you to organize resources across multiple compartments for reporting purposes or for taking bulk actions.</td>
</tr>
<tr>
<td>Federation</td>
<td>Mechanism to federate IAM with other identity providers (IdP) used by an organization to authenticate their users.</td>
</tr>
</tbody>
</table>

Oracle recommends that you periodically monitor Audit logs to review changes to IAM users, groups, and security policies.
IAM Tenancy and Compartments

- Compartments are unique to IAM, and offer a mechanism that allows an enterprise customer to meet its central needs by having a single account or tenancy. This single account or tenancy provides full central control and visibility while also allowing the account or tenancy to be subdivided to meet the needs of constituent teams, projects, and initiatives.
- For security and governance reasons, users should only have access to resources they need. For example, enterprise users working on a project or belonging to a business unit should have access only to resources belonging to the project or business unit. Compartments provide an effective mechanism to group tenancy resources based on their access privileges and authorize groups of users to access the compartments on as needed basis. In the example above, a compartment can be created to include all resources belonging to a business unit, and authorize only members of the business unit to access the compartment. Similarly, a groups' access to a compartment can be revoked when they do not need it anymore.
- Keep the following in mind when you create a compartment and assign resources:
  - Every resource should belong to a compartment.
  - A resource can be reassigned to a different compartment after creation. See Managing Compartments on page 3126.
  - A compartment can be deleted after creation. See Managing Compartments on page 3126.
  - Resource tags provide a way to logically aggregate resources distributed across multiple compartments. For example, tenancy resources can be tagged as test or production depending on their use. For more information about resource tags (free-form and defined tags), see Resource Tags on page 239.
  - Every tenancy comes with a default administrators group. This group can perform any action on all resources in a tenancy (that is, they have root access to the tenancy). Oracle recommends that you keep the group of tenancy administrators as small as possible. Some security recommendations on managing tenancy administrators:
    - Have security policies granting membership of tenancy administrator group strictly on a as-needed basis.
    - Tenancy administrators should use high-complexity passwords, along with MFA, and periodically rotate their passwords.
    - After account set up and configuration, Oracle recommends that you don't use the tenancy administrator account for day-to-day operations. Instead, create less privileged users and groups.
    - Though administrator accounts are not used for daily operations, they are still needed to address emergency scenarios impacting customer tenancy and operations. Specify secure and auditable "break-glass" procedures for using administrator accounts in such emergencies.
    - Disable tenancy administration access immediately when an employee leaves the organization.
    - Because the tenancy administrator group membership is restricted, Oracle recommends that you create security policies which prevent administrator account lock-out (for example, if the tenancy administrator leaves the company and no current employees have administrator privileges).

IAM Users and Groups

- Create an IAM user for everyone in the customer organization who needs access to resources. Do not share IAM user accounts across multiple users, especially those with administrative accounts. Using distinct IAM users enables enforcing least privilege access for each user, and captures their actions in audit logs.
- The recommended unit of administration is IAM groups, which makes it easier to manage and keep track of security permissions (as opposed to individual users). Create IAM groups with permissions to do commonly needed tasks (for example, network administration, volume administration), and assign users to these groups on an as-needed basis. IAM permissions can be used to give a group access to resources across multiple compartments in a tenancy.
- Periodically review membership of IAM users in IAM groups, and remove IAM users from groups they do not need access to anymore. Using group membership to manage user access scales well with increasing number of users.
- Deactivate IAM users who do not need access to tenancy resources. Deleting an IAM user removes the user permanently. You can temporarily deactivate an IAM user by doing the following:
  - Rotate the user password and throw it away.
  - Remove all tenancy permissions of the user by removing membership from all groups.
IAM Credentials

IAM user credentials (Console password, API signing key, auth tokens, and customer secret keys) grant access to resources. It is important to secure these credentials to prevent unauthorized access to Oracle Cloud Infrastructure resources. General guidelines for handling credentials include:

- Create a strong console password for each IAM user, with sufficient complexity. Oracle recommends the following for a complex password:
  - Password has a minimum length of 12 characters
  - Password contains at least one uppercase letter
  - Password contains at least one lowercase letter
  - Password contains at least one symbol
  - Password contains at least one number
- Rotate IAM passwords and API keys regularly, every 90 days or less. In addition to a security engineering best practice, this is also a compliance requirement. For example, PCI-DSS Section 3.6.4 states, "Verify that key-management procedures include a defined cryptoperiod for each key type in use and define a process for key changes at the end of the defined crypto period(s)."
- Do not hard code sensitive IAM credentials directly in software or documents accessible to a wide audience. Examples include code uploaded to GitHub, presentations, or documents available on the internet. There have been known, highly publicized cases of hackers breaching customer cloud accounts, using credentials inadvertently disclosed on public sites. When software applications need to access Oracle Cloud Infrastructure resources, Oracle recommends that you use instance principals. If it is not feasible to use instance principals, other recommendations include using user environment variables to store credentials, and using locally stored credential files with API keys to be used by the Oracle Cloud Infrastructure SDK or CLI.
- Do not share IAM credentials between multiple users.
- By federating the Console login through Oracle Identity Cloud Service, customers can use multifactor authentication (MFA) for IAM users, especially administrators.

When rotating API keys, verify that the rotated keys work as expected before disabling older keys. For information about generating and uploading IAM API keys, see Required Keys and OCIDs on page 5303. The high-level steps in rotating an API key are:

1. Generate and upload a new API key.
2. Update the SDK and CLI configuration files with the new API key.
3. Verify that the SDK and CLI calls are working correctly with the new key.
4. Disable the old API key. Use ListApiKeys to list all active API keys.

IAM Security Policies

IAM policies are used to govern access of IAM groups to resources in compartments and in the tenancy. Oracle recommends that you assign least privilege access to IAM groups for accessing resources. The common format for IAM policies is shown in the following example.

```
Allow group <group_name> to <verb> <resource-type> in compartment
<compartment_name>
Allow group <group_name> to <verb> <resource-type> in tenancy
```

IAM policies allow four predefined verbs: inspect, read, use and manage. Inspect allows least privilege and manage allows the maximum. The four verbs are shown in increasing order of privilege in the following table.

IAM policy verbs

<table>
<thead>
<tr>
<th>Verb</th>
<th>Access Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Should only show metadata. This usually results in ability to list resources only</td>
</tr>
</tbody>
</table>
Verb | Access Type | Example User
--- | --- | ---
read | inspect plus ability to read resource and user metadata. This is the permission most users need to get work done. | internal auditors
use | read plus ability to work with resources (the actions vary by resource type). Excludes ability to create or delete resource | regular users (software developers, system engineers, dev managers, etc) setting up and configuring tenancy resources, and applications running on them
manage | All the permissions for all the resources | administrators, executives (for break-glass scenarios)

The resource types of Oracle Cloud Infrastructure resources are shown in the following table.

**IAM resource families, descriptions, and resource types**

<table>
<thead>
<tr>
<th>Resource Type Family</th>
<th>Description</th>
<th>Resource Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>all-resources</td>
<td>All resource types</td>
<td>compartments, users, groups, dynamic-groups, policies, identity-providers, tenancy tag-namespaces, tag-definitions</td>
</tr>
<tr>
<td>No name by design</td>
<td>Resource types in IAM service</td>
<td>console-histories, instance-console-connection, instance-images, instances, volume-attachments</td>
</tr>
<tr>
<td>volume-family</td>
<td>Resource types in block storage service</td>
<td>volumes, volume-attachments, volume-backups</td>
</tr>
<tr>
<td>virtual-network-family</td>
<td>Resource types in virtual networking service</td>
<td></td>
</tr>
<tr>
<td>object-family</td>
<td>Resource types in object storage service</td>
<td>buckets, objects</td>
</tr>
<tr>
<td>database-family</td>
<td>Resource types in DbaaS service</td>
<td>db-systems, db-nodes, db-homes, databases, backups</td>
</tr>
<tr>
<td>load-balancers</td>
<td>Resources in Load Balancer service</td>
<td>load-balancers</td>
</tr>
<tr>
<td>Resource Type Family</td>
<td>Description</td>
<td>Resource Types</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>file-family</td>
<td>Resources in file storage service</td>
<td>file-systems, mount-targets, export-sets</td>
</tr>
<tr>
<td>dns</td>
<td>Resources in DNS service</td>
<td>dns-zones, dns-records, dns-traffic</td>
</tr>
<tr>
<td>email-family</td>
<td>Resources in email delivery service</td>
<td>approved-senders, suppressions</td>
</tr>
</tbody>
</table>

For more information about IAM verbs and resource type permission mappings, see Details for the Core Services on page 2855.

IAM security policies can be made fine-grained through conditions. Access specified in the policy is allowed only if the condition statements evaluate to true. Conditions are specified using predefined variables. The variables use the key words request or target, depending on whether the variable is relevant to the request or the resource being acted on, respectively. For information about supported predefined variables, see Policy Reference on page 2837.

IAM dynamic groups are used to authorize Compute instances to access Oracle Cloud Infrastructure APIs. The instance principals feature can be used by applications, running on the instances, to programmatically access Oracle Cloud Infrastructure services. Customers create dynamic groups, which include instances as members, and authorize access to their tenancy resources using IAM security policies. All access by instances is captured in the audit logs available to customers.

**IAM Federation**

- Oracle recommends that you use federation to manage logins into the Console. Identity federation supports SAML 2.0 compliant identity providers, and can be used to federate on-premises users and groups to IAM users and groups. The enterprise administrator needs to set up a federation trust between the on-premises identity provider (IdP) and IAM, in addition to creating mapping between on-premises groups and IAM groups. Then, on-premises users can single sign-on (SSO) into the Console, and access resources based on authorization of IAM groups they belong to. For more information about federating to the Console, see Federating with Identity Providers on page 3058. Federation is especially important for enterprises using custom policies for user authentication (for example, multifactor authentication). For more information about managing users and groups under federation, see Federating with Identity Providers on page 3058.

- When using federation, Oracle recommends that you create a federation administrators group that maps to the federated IdP administrator group. The federation administrators group will have administrative privileges to manage customer tenancy, while being governed by the same security policies as the federated IdP administrator group. In this scenario, it is a good idea to have access to the local tenancy administrator user (that is, member of the default tenancy administrator IAM group), to handle any break-glass type scenarios (for example, inability to access resources through federation). However, you must prevent any unauthorized use of this highly privileged local tenancy administrator user. Oracle recommends the following approach to securely managing the tenancy administrator user:

1. Create a local user belonging to the default tenancy administrator group.
2. Create a highly complex Console password or passphrase (18 characters or more, with at least one lowercase letter, one uppercase letter, one number, and one special character) for the local tenancy administrator user.
3. Securely escrow the local tenancy administrator user password in an on-premises location (for example, place the password in a sealed envelope in an on-premises physical safe).
4. Create security policies for accessing the escrowed password only under specific "break-glass" scenarios.
5. Have IAM security policy to prevent the federated administrators IAM group from adding or modifying membership of the default tenancy administrator group to prevent security by-passes.
6. Monitor audit logs for accesses by default tenancy administrator and changes to the administrator group, to alert on any unauthorized actions. For additional security, the local tenancy administrator user password can be rotated after every login, or periodically, based on a password policy.

For an example that shows the way various IAM components fit together, see Example Scenario on page 2790. Periodically monitor Audit logs to review changes to IAM users, groups, policies, compartments, and tags.
Security Policy Examples

Common IAM security policy examples are available at [Common Policies](#) on page 2806. In all the examples that follow, the policies are scoped to a tenancy. However, by specifying a compartment name, you can scope down the policies to specific compartments in a tenancy.

Create Service-level Admins for Least Privilege

To implement security principle of least privilege, you can create service-level admins in the tenancy to further scope down administrative access. This means that service-level administrators can only manage resources of a specific service. For instance, network administrators need administrative (manage) access only to VCN resources, and not to other resources. The following example shows how to create administrator groups for block storage (VolumeAdmins), VCN (NetworkAdmins), databases (DBAdmins), and object storage (StorageAdmins).

| Allow group TenancyAdmins to manage all-resources in tenancy |
| Allow group VolumeAdmins to manage volume-family in tenancy |
| Allow group NetworkAdmins to manage virtual-network-family in tenancy |
| Allow group StorageAdmins to manage object-family in tenancy |
| Allow group DBAdmins to manage database-family in tenancy |

You can further constrain the security policies to a specific compartment. For example, the HR department in an enterprise can create group HRAdmins to manage resources within its compartment, HR-compartment. The HRNetworkAdmins group has administrative access to VCN resources only within the HR-compartment compartment.

| Allow group HRAdmins to manage all-resources in compartment HR-compartment |
| Allow group HRNetworkAdmins to manage virtual-network-family in compartment HR-compartment |

Compliance auditors are tasked with examining cloud resources and verifying for policy violations. The following policy allows group InternalAuditors to inspect (list) all resources in a tenancy.

| Allow group InternalAuditors to inspect all-resources in tenancy |

If you want to limit auditors to only inspect users and groups in a tenancy, you can create a group UserAuditors with the following policy:

| Allow group UserAuditors to inspect users in tenancy |
| Allow group UserAuditors to inspect groups in tenancy |

If you want to create an auditor group that can only inspect VCN firewalls in the tenancy, use the following policy:

| Allow group FirewallAuditors to inspect security-lists in tenancy |

In all the policy examples, you can constrain the policies to a compartment by specifying `Compartment <name>` (where `<name>` is the compartment name) in the policy.

Restrict Ability to Change Tenancy Administrators Group Membership

Members in the group Administrators can manage all resources in a tenancy. Membership of the Administrators group is controlled by users in the group. Usually, it's convenient to have a group to create and add users in the tenancy, but restrict them from making changes to the Administrators group membership. The following example creates a group UserAdmins to do this.

| Allow group UserAdmins to inspect users in tenancy |
| Allow group UserAdmins to inspect groups in tenancy |
| Allow group UserAdmins to use users in tenancy where target.group.name!='Administrators' |
| Allow group UserAdmins to use groups in tenancy |
Security

where target.group.name!='Administrators'

Use verb with conditions (third and fourth policy statements) allows UserAdmins to add users and groups using APIs (UpdateUser, UpdateGroup) to all groups in the tenancy except the Administrators group. However, because target.group.name!='Administrators' is not related to the list and get APIs (ListUsers, GetUser, ListGroups, and GetGroup), these APIs will fail. So you must explicitly add the inspect verb (first and second policy statements) to allow UserAdmins to get user and group membership information.

Prevent Delete or Update of Security Policies

The following example creates a group PolicyAdmins to be able to create and list security policies created by tenancy administrators, but not delete or update them.

Allow group PolicyAdmins to use policies in tenancy
Allow group PolicyAdmins to manage policies in tenancy
where request.permission='POLICY_CREATE'

This security policy statement explicitly only allows POLICY_CREATE permission, and not to POLICY_DELETE and POLICY_UPDATE.

Prevent Admins from Accessing or Altering User Credentials

Some compliance requirements need separation of duties, especially where user credential management functionality is separated from tenancy management. In this case, you can create two administration groups, TenancyAdmins and CredentialAdmins where TenancyAdmins can perform all tenancy management functions except user credential management, and CredentialAdmins can manage user credentials. TenancyAdmins can access all APIs except those that list, update, or delete user credentials. CredentialAdmins can only manage the user credentials.

Allow group TenancyAdmins to manage all resources in tenancy
where all {request.operation!='ListApiKeys',
request.operation!='ListAuthTokens',
request.operation!='ListCustomerSecretKeys',
request.operation!='UploadApiKey',
request.operation!='DeleteApiKey',
request.operation!='UpdateAuthToken',
request.operation!='CreateAuthToken',
request.operation!='DeleteAuthToken',
request.operation!='CreateSecretKey',
request.operation!='UpdateCustomerSecretKey',
request.operation!='DeleteCustomerSecretKey'}

Allow group CredentialAdmins to manage users in tenancy
where any {request.operation='ListApiKeys',
request.operation='ListAuthTokens',
request.operation='ListCustomerSecretKeys',
request.operation='UploadApiKey',
request.operation='DeleteApiKey',
request.operation='UpdateAuthToken',
request.operation='CreateAuthToken',
request.operation='DeleteAuthToken',
request.operation='CreateSecretKey',
request.operation='UpdateCustomerSecretKey',
request.operation='DeleteCustomerSecretKey'}

Useful CLI Commands

In all the following examples, environment variables $T and $C are set to tenancy OCID and compartment OCID, respectively.
List Compartments in a Tenancy

```
# list all compartments (OCID, display name, description) in tenancy $T
oci iam compartment list -c $T
# grep above command for important fields
oci iam compartment list -c $T | grep -E "name|description|"id\""
```

List IAM Users

```
# lists all users (OCID, display name, description) in tenancy $T
oci iam user list -c $T
# grep above command for important fields
oci iam user list -c $T | grep -E "name|description|"id\""
```

List IAM groups

```
# lists all groups (OCID, display name, description) in tenancy $T
oci iam group list -c $T
# grep above command for important fields
oci iam group list -c $T | grep -E "name|description|"id\""
```

List Users in a Group

The following command is helpful for listing users in groups, especially users with administrative privileges. This command requires the OCID of the group whose users are listed.

```
# list users in group with OCID <GROUP_OCID>
oci iam group list-users -c $T --group-id <GROUP_OCID>
```

List Security Policies

```
# lists all policies (OCID, name, statements) in tenancy $T. Remove pipe to
grep to get entire information
oci iam policy list -c $T
# grep above command for important fields
oci iam policy list -c $T | grep -E "name|Allow|"id\""
```

Securing Networking: VCN, Load Balancers, and DNS

Security Recommendations

The Networking service has a collection of features for enforcing network access control and securing VCN traffic. These features are listed in the following table.

<table>
<thead>
<tr>
<th>VCN Feature</th>
<th>Security Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public and private subnets</td>
<td>Your VCN can be partitioned into subnets. Subnets have historically been specific to an availability domain, but can now be regional (covering all availability domains in the region). Instances inside private subnets cannot have public IP addresses. Instances inside public subnets can optionally have public IP addresses at your discretion.</td>
</tr>
</tbody>
</table>
Security

<table>
<thead>
<tr>
<th>VCN Feature</th>
<th>Security Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security rules</td>
<td>Security rules provide stateful and stateless firewall capability to control network access to your instances. To implement security rules in your VCN, you can use network security groups (NSGs) or security lists. For more information, see Comparison of Security Lists and Network Security Groups on page 3710.</td>
</tr>
<tr>
<td>Gateways</td>
<td>Gateways let resources in a VCN communicate with destinations outside the VCN. The gateways include:</td>
</tr>
<tr>
<td></td>
<td>• Internet gateway: for internet connectivity (for resources with public IP addresses in public subnets)</td>
</tr>
<tr>
<td></td>
<td>• NAT gateway: for internet connectivity without exposing the resources to incoming internet connections (for resources in private subnets)</td>
</tr>
<tr>
<td></td>
<td>• Dynamic routing gateway (DRG): for connectivity to networks outside the VCN's region (for example, your on-premises network by way of a Site-to-Site VPN or FastConnect, or a peered VCN in another region)</td>
</tr>
<tr>
<td></td>
<td>• Service gateway: for private connectivity to Oracle services such as Object Storage</td>
</tr>
<tr>
<td></td>
<td>• Local peering gateway (LPG): for connectivity to a peered VCN in the same region</td>
</tr>
<tr>
<td>Route table rules</td>
<td>Route tables control how traffic is routed from your VCN's subnets to destinations outside the VCN. Routing targets can be VCN gateways or a private IP address in the VCN.</td>
</tr>
<tr>
<td>IAM polices for virtual-network-family</td>
<td>IAM policies specify access and actions permitted by IAM groups to resources in a VCN. For example, IAM polices can give administrative privileges to network administrators who manage the VCNs, and scoped-down permissions to normal users.</td>
</tr>
</tbody>
</table>

Oracle recommends that you periodically monitor Oracle Cloud Infrastructure Audit logs to review changes to VCN network security groups, security lists, route table rules, and VCN gateways.

**Network Segmentation: VCN Subnets**

- Formulate a tiered subnet strategy for the VCN, to control network access. A common design pattern is to have the following subnet tiers:
  1. **DMZ subnet** for load balancers
  2. **Public subnet** for externally accessible hosts such as NAT instances, intrusion detection (IDS) instances, and web application servers
  3. **Private subnet** for internal hosts such as databases

No special routing is required for the instances in the different subnets to communicate. However, you can control the types of traffic between the different tiers by using the VCN's network security groups or security lists.

- Instances in the private subnet only have private IP addresses and can be reached only by other instances in the VCN. Oracle recommends that you place security-sensitive hosts (DB systems, for example) in a private subnet, and use security rules to control the type of connectivity to hosts in a public subnet. In addition to VCN security rules, configure host-based firewalls such as iptables, firewalld for network access control, as a defense-in-depth mechanism.
You can add a service gateway to your VCN to enable DB systems in the private subnet to directly back up to Object Storage without the traffic traversing the internet. You must set up the routing and security rules to enable that traffic. For more information for bare metal or virtual machine DB systems, see Network Setup for DB Systems on page 1881. For more information for Exadata DB systems, see Network Setup for Exadata Cloud Service Instances on page 1760.

Network Access Control: VCN Security Rules

- Use your VCN's security rules to restrict network access to instances. A security rule is stateful by default, but can also be configured to be stateless. A common practice is to use stateless rules for high-performance applications. In a case where network traffic matches both stateful and stateless security lists, the stateless rule takes precedence. For more information about configuring VCN security rules, see Security Rules on page 3710.
- To prevent unauthorized access or attacks on Compute instances, Oracle recommends that you use a VCN security rule to allow SSH or RDP access only from authorized CIDR blocks rather than leave them open to the internet (0.0.0.0/0). For additional security, you can temporarily enable SSH (port 22) or RDP (port 3389) access on an as-needed basis using the VCN API UpdateNetworkSecurityGroupSecurityRules (if you're using network security groups) or UpdateSecurityList (if you're using security lists). For more information about enabling RDP access, see To enable RDP access in Creating an Instance on page 1023. For performing instance health checks, Oracle recommends that you configure VCN security rules to allow ICMP pings. For more information, see Rules to Enable Ping on page 3718.
- Bastions are logical entities that provide secured, public access to target resources in the cloud that you cannot otherwise reach from the internet. Bastions reside in a public subnet and establish the network infrastructure needed to connect a user to a target resource in a private subnet.
- VCN network security groups (NSGs) and security lists enable security-critical network access control to Compute instances, and it is important to prevent any unintended or unauthorized changes to NSGs and security lists. To prevent unauthorized changes, Oracle recommends that you use IAM policies to allow only network administrators to make NSG and security list changes.

Secure Connectivity: VCN Gateways and FastConnect Peering

- VCN gateways provide external connectivity (internet, on-premises, or peered VCN) to VCN hosts. See the table earlier in this topic for a list of the type of gateways. Oracle recommends that you use an IAM policy to allow only network administrators to create or modify VCN gateways.
- Carefully consider allowing internet access to any instances. For example, you don't want to accidentally allow internet access to sensitive database instances. In order for an instance in a VCN to be publicly accessible from the internet, you must configure the following VCN options:
  - The instance must be in a VCN public subnet.
  - The VCN containing the instance must have an internet gateway enabled and configured to be the routing target for outbound traffic.
  - The instance must have a public IP address assigned to it.
  - The VCN security list for the instance's subnet must be configured to allow inbound traffic from 0.0.0.0/0. Or if you're using network security groups (NSG), the instance must be in an NSG that allows that traffic.
- VPN IPSec provides connectivity between a customer's on-premises network and VCN. You can create two IPSec tunnels for high availability. For more information about creating VPN tunnels to connect VCN DRG to customer CPEs, see Site-to-Site VPN on page 3808.
- FastConnect peering allows you to connect your on-premises network to your VCN with a private circuit so that the traffic does not traverse the public internet. You can set up private peering (to connect to private IP addresses), or public peering (to connect to Oracle Cloud Infrastructure public endpoints, such as for Object Storage). For more information about FastConnect peering options, see FastConnect on page 4051.

Virtual Security Appliances in a VCN

- The Networking service lets you implement network security functions such as intrusion detection, application-level firewalls, and NAT (although you can instead use a NAT gateway with your VCN). You can do this by
routing all the subnet traffic to a network security host, using route table rules that use a local VCN private IP address as a target. For more information, see Using a Private IP as a Route Target on page 3703. For high availability, you can assign the gateway security host a secondary private IP address, which you can move to a VNIC on a standby host in case of primary host failure. Full network packet capture or network flow logs can be captured on the NAT instances using tcpdump, and the logs can be uploaded periodically to an Object Storage bucket.

- Virtual security appliances can be run as virtual machines (VMs) on a bring-your-own-hypervisor (BYOH) model on a bare metal instance. Virtual security appliance VMs running on the BYOH bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For information about enabling BYOH on a bare metal instance using an open-source KVM hypervisor, see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.

- Virtual security appliances can also be installed on Compute virtual machines (VMs) where VMDK or QCOW2 images of security appliances can be imported using the bring your own image (BYOI) feature. However, due to infrastructure dependencies, the BYOI feature might not work for some appliances, in which case the BYOH model would be another option to use. For more information about importing appliance images into Oracle Cloud Infrastructure, see Bring Your Own Image (BYOI) on page 999.

**Load Balancers**

- Oracle Cloud Infrastructure load balancers enable end-to-end TLS connections between a client's applications and a customer's VCN. The TLS connection can be terminated at an HTTP load balancer, or on a back-end server by using a TCP load balancer. The load balancers use TLS1.2 by default. For information about configuring an HTTPS listener, see Listener Management on page 3250. You can also upload your own TLS certificates. For more information see SSL Certificate Management on page 3308.

- You can configure network access to load balancers by using VCN network security groups or security lists. This method provides similar functionality to traditional load balancer firewalls. For public load balancers, Oracle recommends that you use a regional public subnet (for example, DMZ subnet) for instantiating the load balancers in a highly available configuration across two different availability domains. You can configure the load balancer firewall rules by setting up the load balancer's network security groups or the subnet's security lists. For more information about creating load balancer security lists, see Update Load Balancer Security Lists and Allow Internet Traffic to the Listener on page 136. Similarly, you must configure the VCN network security groups or security lists for the backend servers to limit traffic only from the public load balancers. For more information about configuring backend server security lists, see Update Rules to Limit Traffic to Backend Servers on page 138.

**DNS Zones and Records**

DNS zones and records are critical for accessibility of web properties. Incorrect updates or unauthorized deletions could result in outage of services, accessed through the DNS names. Oracle recommends that you limit IAM users who can modify DNS zones and records.

**Security Policy Examples**

**Allow Users to Only View Security Lists**

Your network administrators are the personnel who should have the ability to create and manage network security groups and security lists.

However, you may have network users who need to know what security rules are in a particular network security group (NSG) or security list.

The first line in the following example policy allows the NetworkUsers group to view security lists and their contents. This policy does not let the group create, attach, delete, or modify security lists.

The second line lets the NetworkUsers group view the security rules in NSGs, and also view what VNICs and parent resources are in NSGs. The second line does not let the NetworkUsers group change the security rules in NSGs.

```
Allow group NetworkUsers to inspect security-lists in tenancy
```
Prevent Users from Creating External Connection to the Internet

In some cases, you might need to prevent users from creating external internet connectivity to their VCN. In the following example policy, the NetworkUsers group is prevented from creating an internet gateway.

```
Allow group NetworkUsers to manage internet-gateways in tenancy
where request.permission!='INTERNET_GATEWAY_CREATE'
```

Prevent Users from Updating DNS Records and Zones

In the following example policy, the NetworkUsers group is prevented from deleting and updating DNS zones and records.

```
Allow group NetworkUsers to manage dns-records in tenancy
where all {request.permission!='DNS_RECORD_DELETE',
request.permission!='DNS_RECORD_UPDATE'}

Allow group NetworkUsers to manage dns-zones in tenancy
where all {request.permission!='DNS_ZONE_DELETE',
request.permission!='DNS_ZONE_UPDATE'}
```

Useful CLI Commands

In all the following examples, the environment variables $T, $C and $VCN are set to tenancy OCID, compartment OCID, and VCN OCID, respectively.

**List Open Security Lists in a VCN**

```
# list open (0.0.0.0/0) security lists in VCN $VCN in compartment $C
oci network security-list list -c $C --vcn-id $VCN | grep "source" | grep "\"0.0.0.0/0\""
```

**List Gateways in a VCN**

```
# list all internet gateways in VCN $VCN in compartment $C
oci network internet-gateway list -c $C --vcn-id $VCN

# list all DRGs in compartment $C
oci network drg list -c $C

# list all local peering gateways in vcn $VCN in compartment $C
oci network local-peering-gateway list -c $C --vcn-id $VCN
```

**List Route Table Rules in a VCN**

```
# list route table rules in VCN $VCN in compartment $C
oci network route-table list -c $C --vcn-id $VCN
```

**Securing Object Storage**

**Security Recommendations**

Assign least privileged access for IAM users and groups to resource types in object-family (buckets and objects). For example, the inspect verb gives the least privilege. Inspect lets you check to see if a bucket exists (HeadBucket) and list the buckets in a compartment (ListBucket). The manage verb gives all permissions on the resource. You can create IAM security policies to give appropriate bucket and object access to various IAM groups. For more information about IAM verbs and permissions for Object Storage buckets and objects, see Details for Object Storage.
Archive Storage, and Data Transfer on page 3017. For users without IAM credentials, we recommend that you use pre-authenticated requests (PARs) to give time-bound access to objects or buckets.

Public Buckets Security Controls

- A public bucket allows unauthenticated and anonymous reads to all objects in the bucket. Carefully evaluate the intended use case for public buckets before you enable public buckets. We recommend that you use pre-authenticated requests to give bucket or object access to users without IAM credentials. By defaults, buckets are created with no public access (access type is set to NoPublicAccess).
- You can make existing buckets public by updating the bucket access type to ObjectRead or ObjectReadWithoutList. To minimize the possibility of existing buckets being made public inadvertently or maliciously, restrict BUCKET_UPDATE permission to a minimal set of IAM groups.

Pre-Authenticated Requests

- Pre-authenticated requests provide a mechanism to provide access to objects stored in buckets, to users who do not have IAM user credentials. In a pre-authenticated request, an IAM user who has appropriate privileges for accessing objects, can create special URLs that grant time-bound access to these objects. For more information, see Using Pre-Authenticated Requests on page 4387.
- The creator of a pre-authenticated request must have PAR_MANAGE permission and the appropriate IAM permissions for the access type that you are granting. You can create a pre-authenticated request that grants read, write, or read/write access to one of the following:
  - All objects in the bucket.
  - A specific object in the bucket.
  - All objects in the bucket that have a specified prefix.

For requests that apply to multiple objects, you can also decide whether you want to let users list those objects.
- Pre-authenticated request accesses to a bucket are logged in Audit logs. Pre-authenticated request accesses to an object are logged in Service logs.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation, is not stored in Object Storage, and cannot be retrieved later.</td>
</tr>
</tbody>
</table>

Data Durability

- Minimize data loss because of inadvertent deletes by an authorized user or malicious deletes. We recommend the following:
  - Use object versioning to automatically create an object version each time a new object is uploaded, an existing object is overwritten, or when an object is deleted.
  - Give BUCKET_DELETE and OBJECT_DELETE permissions to a minimum set of IAM users and groups. Grant delete permissions only to tenancy and compartment administrators.
  - Write once read many (WORM) compliance requires that objects cannot be deleted or modified. Use retention rules to achieve WORM compliance. Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules).

For an independent assessment of the Object Storage retention rules feature's ability to meet regulatory requirements for record management and retention, see Cohasset Associate's SEC 17a-4(f), FINRA 4511(c), CFTC 1.31(c)-(d) and MiFID II Compliance Assessment.
**Data Encryption**

- All data in Object Storage is encrypted at rest by using AES-256. Encryption is on by default and cannot be turned off. Each object is encrypted with its encryption key, and the object encryption keys are encrypted with a master encryption key. In addition, customers can use client-side encryption to encrypt objects with their encryption keys before storing them in Object Storage buckets. An available option for customers is to use the Amazon S3 Compatibility API, along with client-side object encryption support available in AWS SDK for Java. See Amazon S3 Compatibility API on page 4408 for more details about on this SDK.

- Data in transit between customer clients (for example, SDKs and CLIs) and Object Storage public endpoints is encrypted with TLS 1.2 by default. FastConnect public peering allows on-premises access to Object Storage to go over a private network, rather than the public internet.

**Data Integrity**

- To verify object data integrity, an MD5 checksum is provided for all objects uploaded to Object Storage. We recommend that you verify that the offline MD5 checksum of an object matches the checksum value returned by the Console or API after upload. Oracle Cloud Infrastructure provides the object checksum value in base64 encoding. To covert the base64 encoded checksum value to hexadecimal, use the following command:

```python
python -c 'print "BASE64-ENCODED-MD5-VALUE".decode("base64").encode("hex")'
```

Linux provides an md5sum command line utility to compute MD5 checksum value of an object in hexadecimal format.

- Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. In a multipart upload, a large object is broken up into smaller parts by specifying a part size in MiB. Each part is uploaded separately. Object Storage then combines all the parts to create the original object. If any of the parts fail to upload, only those parts need to be retried for upload, and not the entire object. In a multipart upload, the MD5 checksum values are computed for each part, and an MD5 checksum computed over all the individual checksum values to get the output MD5 value. To verify the MD5 value returned for a multipart upload, follow the same process for offline MD5 checksum calculation. A sample script for the offline calculation of an MD5 checksum value for a multipart upload to Object Storage is available here: [https://gist.github.com/itemir/f5bc9fded6483cd79c89ebf4ca1cf3d30](https://gist.github.com/itemir/f5bc9fded6483cd79c89ebf4ca1cf3d30).

**Security Policy Examples**

In the following examples, the policies are scoped to a tenancy. However, specifying a compartment name reduces the scope to a specific compartment in a tenancy.

**Restrict Group Access to Specific Buckets**

You can restrict access by a group to a specific bucket by using the specific bucket name (target.bucket.name), regular expression matching (/*name/, /name*/, /*name*/), or defined tags (target.tag.definition.name).

The following is an example of restricting access by groups **BucketUsers** to a specific bucket.

```
Allow group BucketUsers to use buckets in tenancy
where target.bucket.name='BucketFoo'
```

You can modify this policy to restrict access by group **BucketUsers** to all buckets whose names are prefixed with **ProjectA_**.

```
Allow group BucketUsers to use buckets in tenancy
where target.bucket.name=/ProjectA_*/
```

You can also match for post-fix (/*_ProjectA/) or substring (/_*ProjectA*/).
Restrict Group Access to Read or Write to Objects in a Specific Bucket

The following example allows listing and reading objects by group BucketUsers from a specific bucket named BucketFoo.

```plaintext
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
  where all {target.bucket.name='BucketFoo',
    any {request.permission='OBJECT_INSPECT',
      request.permission='OBJECT_READ')}
```

The following policy modifies the previous policy to allow listing and writing objects to BucketFoo.

```plaintext
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
  where all {target.bucket.name='BucketFoo',
    any {request.permission='OBJECT_INSPECT',
      request.permission='OBJECT_CREATE')}
```

You can restrict this policy to read or write access to a set of buckets by using regular expressions or tags rather than a specific bucket.

Restrict Resource Access to a Particular User

You can restrict access to Object Storage resources to a specific user by adding a condition to the policy that specifies the user's OCID in a variable.

The following policy restricts access to the resources in ObjectStorage compartment to the user OCID specified:

```plaintext
Allow any-user to read object-family in compartment ObjectStorage where
  request.user.id = 'ocid1.user.oc1..<user_OCID>'
```

Restrict Access to Requests That Originate From an Allowed IP Address

You can restrict access only to requests that originate from an allowed IP address. First, you create a network source to specify the allowed IP addresses, then you add a condition to your policy to restrict access to the IP addresses in the network source.

The following policy restricts access to only IP addresses in a network source corpnet that defines the allowed IP addresses:

```plaintext
Allow group CorporateUsers to manage object-family in tenancy where
  request.networkSource.name='corpnet'
```

For information on creating network sources and using them in a policy, see Managing Network Sources on page 3123.

Prevent Delete of Buckets or Objects

In the following example, the group BucketUsers can perform all actions on buckets and objects except delete.

```plaintext
Allow group BucketUsers to manage objects in tenancy
  where request.permission!='OBJECT_DELETE'
Allow group BucketUsers to manage buckets in tenancy
  where request.permission!='BUCKET_DELETE'
```

The following example further restricts object deletion from the specific bucket (BucketFoo).

```plaintext
Allow group BucketUsers to manage objects in tenancy
  where any {target.bucket.name!='BucketFoo',
```
Enable WORM Compliance for Objects

Use retention rules to achieve WORM compliance. Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules).

The following policies let BucketUsers manage the buckets and objects in the tenancy and allow BucketUsers to create, manage, and delete retention rules. These policies also let BucketUsers lock retentions rules for a specified time.

| Allow group BucketUsers to manage buckets in tenancy |
| Allow group BucketUsers to manage objects in tenancy |

The following more restrictive policies let BucketUsers perform all actions on buckets and objects except locking retention rules.

| Allow group BucketUsers to manage buckets in tenancy where request.permission!='RETENTION_RULE_LOCK' |
| Allow group BucketUsers to manage objects in tenancy |

Prevent Public Buckets Configuration

BUCKET_CREATE and BUCKET_UPDATE permissions are required to create buckets or make existing private buckets public. Removing these permissions prevents users from creating buckets or making existing buckets public.

| Allow group BucketUsers to manage buckets in tenancy where any {request.permission='BUCKET_INSPECT', request.permission='BUCKET_READ', request.permission='PAR_MANAGE'} |

Useful CLI Commands

Here are some useful commands to determine if you have public buckets or PARS in your tenancy.

**List of Public Buckets**

The following command returns the public-access-type assigned to a bucket.

```bash
# "public-access-type" of 'NoPublicAccess' indicates a private bucket, and # anything else ('ObjectRead') indicates a public bucket
oci os bucket get -ns <your_namespace> --bucket-name <bucket_name> | grep "public-access-type"
```

**List of Bucket Pre-Authenticated Requests (PARs)**

The following command returns a list of object PARs in a bucket.

```bash
# list all PARs for objects in bucket $BUCKET_NAME
oci os preauth-request list -ns <your_namespace> -bn <bucket_name>
```

Securing Resource Manager

Resource Manager allows you to automate installing and provisioning Oracle Cloud Infrastructure resources by committing the provisioning instructions to configuration files. These configuration files capture the step-by-step provisioning instructions using a declarative language that follows the "infrastructure-as-code" model. The
provisioning instructions are executed as "jobs"; the Oracle Cloud Infrastructure resources that are provisioned when you run the jobs are organized into "stacks."

Executing jobs and provisioning stacks is gated using role-based access control (RBAC), which is enabled by Oracle Cloud Infrastructure Identity and Access Management (IAM). This gives administrators granular control over user access to Oracle Cloud Infrastructure resources and the actions that users can take on these resources.

The Resource Manager security scheme rests on three pillars:

- **Security groups.** Administrator-defined groups that have permission to perform specific operations on stacks and jobs. Individual users are assigned to security groups and can then perform operations that are allowed by that group. For more information about security policies, see Getting Started with Policies on page 2799. See also How Policies Work on page 2800 and Policy Syntax on page 2834. For recommended Resource Manager policies, see Policies for Managing Resources Used with Resource Manager on page 3170.

- **Permission sets.** Sets of permissions that are specific to jobs and stacks.

- **Operations.** The operations (or actions) that are allowed and the permissions that are required to perform each one.

For permission sets and operations used with Resource Manager, see Details for Resource Manager on page 3033.

### Potential Security Risks and Mitigations

#### Terraform State Files

Terraform state (.tfstate) can contain sensitive data, including resource IDs and in some cases sensitive user data like passwords. HashiCorp provides recommendations for handling Terraform state in the article Sensitive Data in State.

To control access to the Terraform state file, you can create a security policy that limits access to reading jobs, such as the following:

```
Allow group <group_name> to read orm-jobs in compartment
```

**Note:**

Because the permission `read orm-jobs` also affects other operations such as getting logs and Terraform configurations, you should segregate state files in a compartment on which a restrictive policy will not limit the ability to perform other operations.

#### Terraform Configurations

The Resource Manager workflow typically includes writing or generating a Terraform configuration that is then used to manage your stack. Because the Terraform configuration can be accessed using the Resource Manager API `GetJobTfConfig`, we recommend that you do not include sensitive information in your configuration files.

#### Oracle Cloud Testing Policies

This section describes the Oracle Cloud Security Testing and Functional Testing policies, tests involving data scraping tools, and how you can submit a request to schedule tests of our services.

#### Oracle Cloud Security Penetration and Vulnerability Testing

The Oracle Cloud Security Testing policy describes when and how you may conduct certain types of security testing of Oracle Cloud Infrastructure services, including vulnerability and penetration tests, as well as tests involving data scraping tools. Any such testing of Oracle Cloud services may be conducted only by customers who have an Oracle Account with the necessary privileges to file service maintenance requests, and who are signed-in to the environment that will be the subject of such testing.

Oracle regularly performs penetration and vulnerability testing and security assessments against the Oracle Cloud infrastructure, platforms, and applications. These tests are intended to validate and improve the overall security of Oracle Cloud services.
However, Oracle does not assess or test any components (including, non-Oracle applications, non-Oracle databases or other non-Oracle software, code or data, as may be applicable) that you manage through or introduce into – including introduction through your development in or creation in - the Oracle Cloud services (the “Customer Components”). This policy does not address or provide any right to conduct testing of any third-party materials included in the Customer Components.

Except as otherwise permitted or restricted in your Oracle Cloud services agreements, your service administrator who has system level access to your Oracle Cloud services may run penetration and vulnerability tests for the Customer Components included in certain of your Oracle Cloud services in accordance with the following rules and restrictions.

**Permitted Penetration and Vulnerability Testing**

The following explains where penetration and vulnerability testing of Customer Components is permitted:

- **IaaS**: Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant Oracle Infrastructure as a Service (IaaS) offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud services including the facilities, hardware, software, and networks owned or managed by Oracle or its agents and licensors.

- **PaaS**: Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant Oracle Platform as a Service (PaaS) offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud services including the facilities, hardware, networks, applications, and software owned or managed by Oracle or its agents and licensors. To be clear, you may not assess any Oracle applications that are installed on top of the PaaS service.

- **SaaS**: Penetration and vulnerability testing is not permitted for Oracle Software as a Service (SaaS) offerings.

**Oracle Cloud Security Testing Rules of Engagement**

The following rules of engagement apply to cloud penetration and vulnerability testing:

- Your testing must not target any other subscription or any other Oracle Cloud customer resources, or any shared infrastructure components.

- You must not conduct any tests that will exceed the bandwidth quota or any other subscribed resource for your subscription.

- You are strictly prohibited from utilizing any tools or services in a manner that perform Denial-of-Service (DoS) attacks or simulations of such, or any “load testing” against any Oracle Cloud asset including yours.

- Any port scanning must be performed in a non-aggressive mode.

- You are responsible for independently validating that the tools or services employed during penetration and vulnerability testing do not perform DoS attacks, or simulations of such, prior to assessment of your instances. This responsibility includes ensuring any contracted third parties perform assessments in a manner that does not violate this policy.

- Social Engineering of Oracle employees and physical penetration and vulnerability testing of Oracle facilities is prohibited.

- You must not attempt to access another customer’s environment or data, or to break out of any container (for example, virtual machine).

- Your testing will continue to be subject to terms and conditions of the agreement(s) under which you purchased Oracle Cloud services, and nothing in this policy shall be deemed to grant you additional rights or privileges with respect to such Cloud Services.

- If you believe you have discovered a potential security issue related to Oracle Cloud, you must report it to Oracle within 24 hours by conveying the relevant information to My Oracle Support. You must create a service request within 24 hours and must not disclose this information publicly or to any third party. Note that some of the vulnerabilities and issues you may discover may be resolved by you by applying the most recent patches in your instances.
Security

- In the event you inadvertently access another customer’s data, you must immediately terminate all testing and report it to Oracle within one hour by conveying the relevant information to My Oracle Support.
- You are responsible for any damages to Oracle Cloud or other Oracle Cloud customers that are caused by your testing activities by failing to abide by these rules of engagement.

Notification Process

The process for notifying Oracle of your election to conduct a penetration or vulnerability test as required by this policy can be found in Submitting a Cloud Security Testing Notification on page 4704.

Oracle Cloud Functional Testing

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You must abide by the terms of both this policy and the Oracle Cloud Security Testing policy when performing functional testing.</td>
</tr>
</tbody>
</table>

This policy outlines how and when you may conduct functional testing of Oracle Cloud services. The purpose of functional testing is to validate features of Oracle Cloud services to ensure they meet particular functional requirements or specifications. This is often referred to as black-box testing, regression testing, or unit testing whereby functionality of the application is assessed without the need to scrutinize internal structures or source code.

The following rules apply to functional testing of Oracle Cloud services:

- You must not conduct any tests in the production environment. Before deployment, you must test all changes in a test environment.
- You can perform functional testing using manual or automated tools.
- You can conduct functional tests to validate the main functions of the Oracle Cloud service to meet business requirements including usability, accessibility, and error handling.
- You must not use functional testing procedures or tools to test other aspects of the Oracle Cloud service, such as performance, reliability, and scalability.
- You can conduct unit tests, user-acceptance tests, regression tests, and black-box tests to test the functionality of the Oracle Cloud services.

Data Scraping Tools

Any use of data scraping tools or technologies with Oracle Cloud services to collect data available through any Oracle user interface or from web service calls requires the express written permission of Oracle. Oracle reserves the right to require that Oracle validates and tests your proposed data scraping tools before their use in production, and that Oracle revalidates and retests them annually.

Automated Tools

Oracle doesn’t make any recommendation on which third-party automated testing tools you can use.

Load Testing Tools

You can perform load testing on your applications and solutions within your tenancy. However you can’t perform load testing of Oracle Cloud services using the Console, APIs, SDKs, CLI, or other interfaces.

Submitting a Cloud Security Testing Notification

As a service administrator, you can run tests for some Oracle Cloud services. Before running the tests, you must first review the Oracle Cloud Testing Policies on page 4702 section. Follow these steps to notify Oracle of a penetration and vulnerability test.

Note:

You must have an Oracle Account with the necessary privileges to file service maintenance requests, and you must be signed in to the environment that is the subject of the penetration and vulnerability testing.
1. Log in to My Services.
2. From the service tile in the dashboard, click the Action menu, and then select Maintenance and Service Requests.
3. On the Service Request Details page, select Penetration & Vulnerability Testing from the Request Type list.
4. Review the information and accept the terms and conditions, and then click Next.

   The available time slots are identified with the text, “Penetration and Vulnerability Testing”.
   You can switch your view to either daily, weekly, monthly, or a list by using the respective buttons on top of the calendar. The view you select is stored as your preference and you’ll be shown the same when you log in the next time.

5. Select an available slot by clicking Penetration and Vulnerability Testing on a specific date.
   a. Provide technical contact details. If using a third party for testing, then provide the name and email address of the third party.
   b. Specify the testing details, such as duration of testing, purpose, IP addresses, services, and other information. Required fields are marked with an asterisk (*).
   c. Click Submit Request.

A service maintenance request is created and is automatically approved. Sometimes we might require your approval to confirm the time slots of your maintenance. The phrase To Review is used to indicate this requirement. The status of each filed service maintenance request is color-coded and displayed in the calendar. To view, edit, or cancel your service maintenance request, see Viewing and Editing Service Maintenance Requests. To request a secondary IDCS instance, contact My Oracle Support.

For more information, see Frequently Asked Questions About Cloud Security Testing.

Frequently Asked Questions About Cloud Security Testing

This section provides answers to frequently asked questions (FAQ) related to cloud security testing.

To fully understand how you can conduct cloud penetration and vulnerability testing of the Customer Components, you must first review the Oracle Cloud Testing Policies on page 4702 section.

Topics:
• Do I need Oracle’s permission for all penetration and vulnerability tests?
• How can I notify Oracle for penetration and vulnerability tests?
• Which instances can I test?
• What other actions on my part are required after I receive an authorization to perform my tests?
• What do I do when I believe that I have discovered a potential security issue related to Oracle Cloud?
• What limitations do I need to be aware of regarding my tests?
• Can I conduct any tests that may exceed the bandwidth quota for my subscription?
• Can I use my hosted instances to conduct assessments against other services not hosted by Oracle?

Do I need Oracle’s permission for all penetration and vulnerability tests?

No. Per the Oracle Penetration and Vulnerability Testing Policy, you do not need Oracle’s permission to conduct penetration and vulnerability tests of the customer components included in certain Oracle Cloud services. However, you will need to notify Oracle prior to commencing such penetration and vulnerability testing. You may not conduct any penetration and vulnerability testing for Oracle Software as a Service (SaaS) offerings.

How can I notify Oracle for penetration and vulnerability tests?

To notify Oracle, you must log into My Services using your administrator credentials associated with the instances you wish to test. You will need to complete and submit a form with information about the instances you wish to test, the planned start and end dates of your test, as well as the testing tools you want to use. This notification process is explained in more detail in the Oracle Cloud Testing Policies on page 4702 section.
Which instances can I test?

The Oracle Penetration and Vulnerability Testing Policy only permits testing of instances, services, and applications that are customer components. All other aspects and components of the Oracle Cloud Services (including Oracle-managed facilities, hardware components, networks, software, and database instances) must not be tested. You may not conduct any penetration and vulnerability testing of Oracle Software as a Service (SaaS) offerings. In addition, you may not attempt to socially engineer Oracle employees or perform physical penetration and vulnerability testing of Oracle facilities.

What other actions on my part are required after I receive an authorization to perform my tests?

No other actions are required before performing your tests. You may conduct your testing for the duration you requested.

What do I do when I believe that I have discovered a potential security issue related to Oracle Cloud?

If you believe you have discovered a potential security issue related to Oracle Cloud, you must report it to Oracle within 24 hours, by conveying the relevant information to My Oracle Support. You must create a service request (SR) within 24 hours and you must not disclose this information publicly or to any third party. Note that some of the vulnerabilities and issues you discovered may be resolved by you, by applying the most recent patches in your instances.

What limitations do I need to be aware of regarding my tests?

All penetration and vulnerability testing against Oracle Software as a Service (SaaS) instances is prohibited. In addition, the Oracle Penetration and Vulnerability Testing Policy sets forth certain rules applicable to the performance of penetration and vulnerability testing on Oracle Cloud Services. See the policy for limitations.

Can I conduct any tests that may exceed the bandwidth quota for my subscription?

No. You are not allowed to conduct any tests that will exceed the bandwidth quota or any other subscribed resource for your subscription.

Can I use my hosted instances to conduct assessments against other services not hosted by Oracle?

No, all testing must be directed at single-tenant Oracle Infrastructure as a Service (Oracle IaaS) or Oracle Platform as a Service (Oracle PaaS) instances hosted by Oracle. These are not to be used as a platform to test other internet-based services.

Addressing Basic Configuration Issues

This topic lists procedures to address common configuration issues that affect the security of your Oracle Cloud Infrastructure resources.

Block Volume

Block volume detached from instance

**Issue:** Ensure that only Oracle Cloud Infrastructure administrators can detach block volumes from instances.

**Basics:** When you detach a block volume it decouples the volume from its associated instance, affecting the data available to the instance. This could impact data availability from business-critical data to the successful completion of scheduled volume backups. To minimize loss of data due to inadvertent volume detachments by an authorized user or malicious volume detachments you should restrict the `VOLUME_ATTACHMENT_DELETE` permission to administrators.

**To prevent detachment of block volumes:**

The following policy allows the group `VolumeUsers` to manage volumes and volume attachments except for detaching volumes:

```allow group VolumeUsers to manage volumes in tenancy
allow group VolumeUsers to manage volume-attachments in tenancy```
This change prevents `VolumeUsers` from detaching volumes from instances.

More information:
- [Securing Block Volume](#) on page 4671
- [Getting Started with Policies](#) on page 2799
- [How Policies Work](#) on page 2800
- [For volume-family Resource Types](#) on page 2894

**Compute**

**Instance created based on unapproved custom image**

**Issue:** An instance was created from a custom image that is unsupported in your environment.

**Basics:** When users create instances they can select from platform images, boot volumes from terminated instances, or custom images. Custom images represent a wide variety of images which can include images that aren't approved for your environment. If you use tags in your Oracle Cloud Infrastructure tenancy to identify approved images, verify whether the image the instance is based on is an approved image and terminate the instance if necessary.

**To verify the tags for the image the instance was created from:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance you're interested in.
3. Click the **Image** link to view the source image.
4. Click the **Tags** tab to view the tags applied to this image.

If the custom image does not have an approved tag, and the instance needs to be terminated, see [Terminating an Instance](#) on page 1147.

More information:
- [Securing Compute](#) on page 4675
- [Resource Tags](#) on page 239
- [Creating an Instance](#) on page 1023
- [Image Import/Export](#) on page 993
- [Bring Your Own Image (BYOI)](#) on page 999

**IAM**

**Member of the Administrators group used API keys**

**Issue:** A user who is a member of the Administrators group accessed resources using an API key.

**Basics:**
- API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
- For security and governance reasons, users should only have access to resources they need to interact with.
- For individuals who are members of the Administrators group who also need access to resources through the API, create another user in IAM to which you attach the API keys. Grant the user with the API keys permissions to only the resources they need to interact with programatically.

**To create a user, group, and policy with limited permissions:**

The following set of procedures shows you how to set up an example user with limited permissions. In this example, the user needs to be able to launch instances in a specific compartment.

The following procedure is for the Oracle Cloud Infrastructure Console.

**Create a User**
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**.
2. Click **Create User**.
3. In the **New User** dialog:
   - **Name**: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Description**: Enter a description (required).
4. Click **Create User**.

### Create a Group

Next, create the group ("InstanceLaunchers") that you will create the policy for.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**.
2. Click **Create Group**.
3. In the **Create Group** dialog:
   - **Name**: Enter a unique name for your group, for example, "InstanceLaunchers". Note that the name cannot contain spaces.
   - **Description**: Enter a description (required).
4. Click **Create Group**.

### Create a Policy

In this example, the policy grants members of the group InstanceLaunchers permissions to launch instances in a specific compartment (CompartmentA).

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
2. Click **Create Policy**.
3. Enter a unique **Name** for your policy, for example, "InstanceLaunchersPolicy". Note that the name cannot contain spaces.
4. Enter a **Description** (required), for example, "Grants users permission to launch instances in CompartmentA".
5. Enter the following **Statement**:

   ```
   Allow group InstanceLaunchers to manage instance-family in compartment CompartmentA
   ```

   This statement grants members of the InstanceLaunchers group permissions to launch and manage instances in the compartment called CompartmentA.
6. Click **Create Policy**.

### Add the User to the Group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**.
2. In the **Users** list, find the user and click the name.
3. On the user detail page, click **Groups** (on the left side of the page). The list of groups that the user belongs to is displayed.
4. Click **Add User to Group**.
5. From the **Groups** list, select InstanceLaunchers.
6. Click **Add**.

### Upload an API signing key for the user

The following procedure works for a regular user or an administrator. Administrators can upload an API key for either another user or themselves.
Important:

The API key must be an **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY-----
```

For more information about generating a public PEM key, see Required Keys and OCIDs on page 5303.

1. View the user's details:
   - If you're uploading an API key for **yourself**: Open the **Profile menu** and click **User Settings**.
   - If you're an administrator uploading an API key for **another user**: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add Public Key**.
3. Paste the key's value into the window and click **Add**.

More information:

- Securing IAM on page 4686
- How Policies Work on page 2800 and Common Policies on page 2806
- Managing User Credentials on page 3150
- Managing Groups on page 3115
- Managing Users on page 3110

**Policy grants broad permissions**

**Issue**: A policy grants full management permissions for at least one service in a compartment or in the tenancy.

**Basics**:

- Access to resources is controlled through policies. A **policy** is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a **group** to work in certain ways with specific types of **resources** in a particular **compartment**.
- For security and governance reasons, users should only have access to resources they need.
- Consider carefully the access level a user needs. Policy language provides a default set of verbs (manage, use, read, inspect) that allow you to easily scope users' permissions to a set of common tasks. For example, if a user needs to be able to update resources, but does not need to create or delete them, grant them the **use** permission, rather than the **manage** permission.
- The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the permissions in the statement. For more fine-grained access control, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.
- Wherever possible, scope access to the specific compartments a user needs access to, rather than scoping it to the full tenancy.

**Tips for writing least-privilege policies**:

**Scope the policy to a compartment instead of the tenancy**
Each policy consists of one or more policy statements that follow a basic syntax. Where possible, scope policies to compartments, rather than to the tenancy. For example, update a policy like this:

```
Allow group <group_name> to <verb><resource-type> in tenancy
```

to include just the compartments needed:

```
Allow group <group_name> to <verb><resource-type> in compartment <compartment_name>
```

If the user needs access to multiple compartments, create a policy statement for each compartment. It is then easy to remove access to individual compartments, if necessary.

**Scope permissions to those required to perform a job function**

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inspect</code></td>
<td>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource.</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td><code>read</code></td>
<td>Includes <code>inspect</code> plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td><code>use</code></td>
<td>Includes <code>read</code> plus the ability to work with existing resources (the actions vary by resource type). In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td><code>manage</code></td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

Users who don't need to create or delete resources generally don't need manage permissions. If you have a policy like:

```
Allow group <group_name> to manage <resource-type> in compartment <compartment_name>
```

but the user will never create or delete the resource-type, consider rewriting the policy to:

```
Allow group <group_name> to use <resource-type> in compartment <compartment_name>
```

The **Policy Reference** on page 2837 includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.

**Service-specific links**

- Details for the Audit Service on page 2850
- Details for Container Engine for Kubernetes on page 2851
- Details for the Core Services on page 2855 (this includes Networking, Compute, and Block Volume)
- Details for the Database Service on page 2917
- Details for the DNS Service on page 2950
- Details for the Email Delivery Service on page 2958
- Details for the File Storage Service
- Details for IAM on page 2971
- Details for Load Balancing on page 2983
- Details for Object Storage, Archive Storage, and Data Transfer on page 3017
For fine-grained access control, scope access using conditions and API operations

In a policy statement, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (change their description), but not delete them. To list, get, create, and update groups, you need a policy with manage groups as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations on page 2972, the permissions covered are:

- GROUP_INSPECT
- GROUP_UPDATE
- GROUP_CREATE
- GROUP_DELETE

To restrict access to only the desired permissions, you could add a condition that explicitly states the permissions you want to allow:

```allow
Allow group XYZ to manage groups in tenancy
where any {request.permission='GROUP_INSPECT',
    request.permission='GROUP_CREATE',
    request.permission='GROUP_UPDATE'}
```

An alternative would be a policy that allows all permissions except GROUP_DELETE:

```allow
Allow group XYZ to manage groups in tenancy where request.permission != 'GROUP_DELETE'
```

Another alternative would be to write a condition based on the specific API operations. Notice that according to the table in Permissions Required for Each API Operation on page 2978, both ListGroups and GetGroup require only the GROUP_INSPECT permission. Here's the policy:

```allow
Allow group XYZ to manage groups in tenancy
where any {request.operation='ListGroups',
    request.operation='GetGroup',
    request.operation='CreateGroup',
    request.operation='UpdateGroup'}
```

It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-based policy above, that policy will already control XYZ group's access to that new API operation.

But notice that you can further scope a user's access to a permission by also specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to ListGroups.

```allow
Allow group XYZ to manage groups in tenancy
where all {request.permission='GROUP_INSPECT',
    request.operation='ListGroups'}
```

More information:

- Advanced Policy Features on page 2828
- Managing Policies on page 3144
API signing keys over 90 days old

**Issue:** A user's API signing keys are older than 90 days. Oracle recommends that you rotate API keys at least every 90 days.

**Basics:**
- API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
- It is a security engineering best practice and compliance requirement to rotate API keys regularly, every 90 days or less.
- Ensure that you test the new keys before you deactivate the old keys.

**To generate and upload new API keys:**

The following procedure is for the Oracle Cloud Infrastructure Console.

**Generate new API keys**

You can use the following OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool.

1. If you haven't already, create a `.oci` directory to store the credentials:

   ````
   mkdir ~/.oci
   ````

2. Generate the private key with one of the following commands.
   - **Recommended:** To generate the key, encrypted with a passphrase you provide when prompted:
     ````
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ````
   - **Note:** For Windows, you may need to insert `−passout stdin` to be prompted for a passphrase. The prompt will just be the blinking cursor, with no text.
     ````
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 −passout stdin 2048
     ````
   - **To generate the key with no passphrase:**
     ````
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ````

3. Ensure that only you can read the private key file:

   ````
   chmod go-rwx ~/.oci/oci_api_key.pem
   ````

4. Generate the public key:

   ````
   openssl rsa −pubout −in ~/.oci/oci_api_key.pem −out ~/.oci/oci_api_key_public.pem
   ````
   **Note:** For Windows, if you generated the private key with a passphrase, you may need to insert `−passin stdin` to be prompted for the passphrase. The prompt will just be the blinking cursor, with no text.

   ````
   openssl rsa −pubout −in ~/.oci/oci_api_key.pem −out ~/.oci/oci_api_key_public.pem −passin stdin
   ```'
5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:

```
cat ~/.oci/oci_api_key_public.pem | pbcopy
```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

**Get the key's fingerprint**

You can get the key's fingerprint with the following OpenSSL command.

**For Linux and Mac OS X:**

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

**For Windows:**

```
Note:
If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.
```

```
openssl rsa -pubout -outform DER -in \oci\oci_api_key.pem | openssl md5 -c
```

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef

**Upload the API signing key for the user**

You can upload the PEM public key in the Console, located at https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
   - If you're signed in as this user, click your username in the top-right corner of the Console, and then click **User Settings**.
   - If you're an administrator doing this for another user: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.
3. Click **Add Public Key**.
4. Paste the contents of the PEM public key in the dialog box and click **Add**.

The key's fingerprint is displayed (for example, 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef). Notice that after you've uploaded your first public key, you can also use the **UploadApiKey** API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

**Test the new key**

Test the key in a sample API call against Oracle Cloud Infrastructure.

**Delete the old key**

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.
1. View the user's details:
   - If you're deleting an API key for yourself:
     Open the Profile menu (👤) and click User Settings.
     - If you're an administrator deleting an API key for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. For the API key you want to delete, click Delete.
3. Confirm when prompted.

The API key is no longer valid for sending API requests.

More information:
- Securing IAM on page 4686
- API Signing Key on page 207

Tenancy administrator privilege grant to an IAM group

Issue: A group other than the Administrators group has been granted administrator privileges.

Basics:
- Granting the tenancy administrator privilege (manage all-resources in tenancy) to a group enables the members to have full access to all resources in the tenancy.
- This high-privilege entitlement must be controlled and restricted to only the users who need it to perform their job function.
- Verify with the Oracle Cloud Infrastructure administrator that this entitlement grant was sanctioned and that the membership of the group remains valid after the grant of the administrator privilege.
- Rather than create an alternative group with administrator privileges, consider instead adding users needing administrator privileges to the default Administrators group.

To resolve this issue:

Add users who need administrator privileges to the Administrators group:
2. In the Groups list, click Administrators.
3. Click Add User to Group.
4. In the Add User to Group dialog, select the user from the User list.
5. Click Add User.

Remove the policy or policy statement that grants the (non-Administrators) group administration privileges.
1. Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.
   If you don’t see the one you’re looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the policy you want to update.
   The policy's details and statements are displayed.
3. Find the statement that grants administrator privileges to the group. This policy will look like:
   ```
   Allow group <group_name> to manage all-resources in tenancy
   ```
   Click the the Actions icon (three dots) and then click Delete.
4. If the policy has no other statements, you can delete the policy by clicking Delete next to the policy name.

More information:
- Securing IAM on page 4686
Managing Policies on page 3144

Networking: VCN, Load Balancers, and DNS

No ingress rules in security lists

Issue: A VCN's security lists have no ingress rules. This means that the instances in the VCN can't receive incoming traffic.

Basics:
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

To add an ingress rule to an existing security list:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
5. Click the security list you're interested in.
6. Click Edit All Rules.
7. Add at least one ingress rule:
   a. In the Allow Rules for Ingress section, click + Rule.
   b. Choose whether it's a stateful or stateless rule (see Stateful Versus Stateless Rules on page 3716). By default, rules are stateful unless you specify otherwise.
   c. Enter the source CIDR. Typical CIDRs you might specify in a rule are the CIDR block for your on-premises network or a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see Task 3: (Optional) Update security rules on page 4133.
   d. Select the protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).
   e. Enter further details depending on the protocol:
      - If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20-22).
      - If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.
8. When you're done, click Save Security List Rules.

This change enables ingress access from the source CIDR block listed in the rule. Add additional rules if you want to allow ingress from other known sources.

More information:
- Securing Networking: VCN, Load Balancers, and DNS on page 4693
- Security Lists on page 3727
- UpdateSecurityList
Security list allows traffic from any IP address (open source)

**Issue:** A security list has at least one rule with an open source (0.0.0.0/0). This means that traffic could come from any source and is not controlled.

**Basics:**
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

**To change the source of a security list rule:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Locate the rule that lists 0.0.0.0/0 as the source CIDR.
8. For that rule, change 0.0.0.0/0 to the CIDR block of a known source.
9. Click **Save Security List Rules**.

This change restricts ingress so packets are allowed only from a specific CIDR block. Add additional rules if you want to allow ingress from other known sources.

**More information:**
- [Securing Networking: VCN, Load Balancers, and DNS](https://docs.oracle.com/en-us/iaas/Content/Cloud Concepts/GetStarted/VCNandDNS.htm) on page 4693
- [Security Lists](https://docs.oracle.com/en-us/iaas/Content/CloudConcepts/Tasks/security_lists.htm) on page 3727
- [UpdateSecurityList](https://docs.oracle.com/en-us/iaas/Content/CloudConcepts/Tasks/update_security_list.htm)

Security list allows traffic to sensitive ports

**Issue:** A security list has at least one rule that enables access to a sensitive port.

**Basics:**
- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

**Recommendation:** Update the subnet's security list to enable access to instances through SSH (TCP port 22) or RDP (TCP port 3389) on a temporary, as-needed basis, and only from authorized CIDR blocks (not 0.0.0.0/0). To perform instance health checks, update the security list to allow ICMP pings.

**To change an existing security list:**
The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Make one or more of these changes:
   - Delete an existing rule by clicking the X next to the rule.
   - Change an existing rule in the list. For example: change the source from 0.0.0.0/0 to the CIDR block of a known source.
   - Add a new rule by clicking + **Rule** and entering values for the new rule.
8. Click **Save Security List Rules**.

More information:
- Securing Networking: VCN, Load Balancers, and DNS on page 4693
- To enable RDP access
- Security Lists on page 3727
- UpdateSecurityList

**Internet gateway attached to VCN**

**Issue:** A VCN has an internet gateway. The gateway must be authorized to be attached to the VCN and must not unintentionally expose resources to the internet.

**Basics:**
- Gateways provide external connectivity to hosts in a VCN. For example: an internet gateway enables direct internet connectivity for instances that are in a public subnet and have a public IP address. A dynamic routing gateway (DRG) enables connectivity with the on-premises network over an Site-to-Site VPN or FastConnect.
- To enable traffic through the internet gateway from a particular subnet in the VCN, there must be a rule in the subnet's route table that lists the internet gateway as a route target. To delete the internet gateway from the VCN, you must first delete any route rules that specify the internet gateway as the target.
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted VCNs.

**To remove an internet gateway from a VCN:**

Prerequisite: Ensure that there are no route rules that specify the internet gateway as a target.

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Internet Gateways**.
5. Click the Actions icon (three dots) for the internet gateway, and then click **Terminate**.
6. Confirm when prompted.

This change disables direct internet connectivity for the VCN.

More information:
- Securing Networking: VCN, Load Balancers, and DNS on page 4693
- Internet Gateway on page 4114
- DeleteInternetGateway
- Public IP Addresses on page 3753
**Instance has a public IP**

**Issue:** An instance has a public IP address. This means the instance could be publicly addressable if other required components are present and configured correctly in the VCN.

**Basics:**

- Carefully consider allowing internet access to any instances. For example, don't accidentally allow internet access to sensitive DB systems.
- For an instance to be publicly addressable:
  - The instance must have a public IP address and reside in a public subnet in the VCN (instances in private subnets cannot have public IP addresses).
  - The subnet's security list must be configured to allow traffic for all IPs (0.0.0.0/0) and all ports.
  - The VCN must have an internet gateway and be configured to route outbound traffic from the subnet to the internet gateway.
- An instance can have more than one public IP address. A given public IP is assigned to a private IP on a particular VNIC on the instance. An instance can have more than one VNIC, and each VNIC can have more than one private IP.

**To remove a public IP address from an instance:**

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Confirm you're viewing the compartment that contains the instance you're interested in.
3. Click the instance to view its details.
4. Click **Attached VNICs**.
   - The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
   - The VNIC's primary private IP and any secondary private IPs are displayed.
6. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
7. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
8. Click **Update**.
   - The public IP is unassigned from the instance.

**More information:**

- [Securing Networking: VCN, Load Balancers, and DNS](#) on page 4693
- [Public IP Addresses](#) on page 3753
- [DeletePublicIp](#)
- [Internet Gateway](#) on page 4114

**Load balancer has no inbound rules or listeners**

**Issue:** A load balancer's subnet security lists have no ingress rules, or a load balancer has no listener. In this case, the load balancer can't receive incoming traffic.

**Basics:**

- Load balancers provide automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). Each load balancer exists in a subnet governed by security list rules. A load balancer receives incoming data traffic from one or more listeners.
- Security lists provide stateful and stateless firewall capability to control network access to your load balancer and backend servers.
  - If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
  - For defense in depth, configure ingress security list rules to state a specific known source and not an open source (0.0.0.0/0).
A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.

To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.

You can apply path route rules to a listener to route traffic to the correct backend set without using multiple listeners or load balancers. A path route is a string that the listener matches against an incoming URI to determine the appropriate destination backend set.

Ensure that your Oracle Cloud Infrastructure load balancers use inbound rules or listeners to allow access only from known resources.

Exceptions can be configured in CASB to reduce alerts from exempted load balancers.

**To enable a listener to accept traffic:**

The following procedure is for the Oracle Cloud Infrastructure Console.

To enable a listener to accept traffic, you must update your VCN's security list rules:

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   
   The list of VCNs in the current compartment appears.

2. Click the name of the VCN containing your load balancer, and then click Security Groups or Security Lists.
   
   A list of the security groups or lists in the cloud network appears.

3. Click the name of the NSG or security list that applies to your load balancer.

4. Add or edit the existing rules to allow access from the appropriate resources.
   
   An NSG's security rules appear on the Network Security Group Details page. From there you can add, edit, or remove rules.

   The Security List Details page provides access to separate tables in which you can add or edit Ingress Rules or Egress Rules.

   For details on rule configuration, see Security Rules on page 3710.

**To create a listener:**

Usually, you create a listener as part of the load balancer creation workflow. To create a listener for an existing load balancer:

1. Open the navigation menu, click Networking, and then click Load Balancers.

2. Select the Compartments from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a State from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck Load Balancer under Type to only display load balancers.

5. Select the load balancer for which you want to create a listener.

   The Load Balancer Details dialog box appears.

6. Click Listeners under Resources.

   The Listeners list appears. All listeners are listed in tabular form.

7. Click Create Listener.

   The Create Listener dialog box appears.

8. Enter the following:

   - **Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed.
   - **Hostname:** Optional. Select up to 16 virtual hostnames for this listener.

   **Note:**

   To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated
When you create a listener, you must also update your VCN's security list rules to allow traffic to that listener.

More information:

- Securing Networking: VCN, Load Balancers, and DNS on page 4693

- Listener Management on page 3250
- Request Routing Management on page 3268
Load balancer has no backend sets

Issue: A load balancer has no backend set. In this case, the load balancer has no place to distribute incoming data and no means to monitor backend server health.

Basics:
- A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers.
- The backend set determines the load balancer's traffic distribution policy, such as:
  - IP Hash
  - Least Connections
  - Weighted Round Robin
- You specify the test parameters to confirm the health of backend servers when you create a backend set.
- If you have an existing load balancer with no backend set, you can specify the backend servers that receive traffic from the load balancer after you create a backend set.
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

To create a backend set:

The following procedure is for the Oracle Cloud Infrastructure Console.

Usually, you create a backend set as part of the load balancer creation workflow. To create a backend set for an existing load balancer:

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Click the load balancer whose backend set you want to edit.
   The Load Balancer Details dialog box appears.
6. Click Backend Sets under the Resources menu, then click Create Backend Set.
   The Create Backend Set dialog box appears.
7. Enter the following:

- **Name**: Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.

  Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Traffic Distribution Policy**: Required. Choose the load balancer policy for the backend set. The available options are:
  - IP Hash
  - Least Connections
  - Weighted Round Robin

  For more information on these policies, see Load Balancing Policies on page 3199.

  **Tip:** You cannot add a backend server marked as Backup to a backend set that uses the IP Hash policy.

- **Use SSL**: Optional. Check this box to associate an SSL certificate bundle with the backend set.

  If no certificate bundles attached to the load balancer exist, this option is disabled.

  **Note:** If you check Use SSL, the SSL Policies fields appear at the bottom of the page.

  - **Certificate Name**: Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See SSL Certificate Management on page 3308 for more information.

  - **Verify Peer Certificate**: Optional. Select this option to enable peer certificate verification.

  - **Verify Depth**: Optional. Specify the maximum depth for certificate chain verification.

- **Session Persistence**: Optional. Specify how the load balancer manages session persistence.

  **Important:** See Session Persistence on page 3202 for important information on configuring these settings.

  - **Disable Session Persistence**: Choose this option to disable cookie-based session persistence.

  - **Enable Application Cookie Persistence**: Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a Set-cookie header with the cookie name you specify.

    - **Cookie Name**: The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.

    - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.

  - **Enable Load Balancer Cookie Persistence**: Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.

    - **Cookie Name**: Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is X-Oracle-BMC-LBS-Route.

      Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.

    - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.

    - **Domain Name**: Optional. Specify the domain in which the cookie is valid.

      This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.
• **Path:** Optional. Specify the path in which the cookie is valid. The default value is /.

• **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

• **Attributes**
  
  • **Secure:** Specify whether the Set-cookie header contains the Secure attribute. If selected, the client sends the cookie only using a secure protocol.

    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.

  • **HTTP Only:** Specify whether the Set-cookie header contains the HttpOnly attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

• **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.

• **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

  ```
  Important:
  
  Configure your health check protocol to match your application or service. See Health Check Management on page 3236 for more information.
  ```

• **Port:** Optional. Specify the backend server port against which to run the health check.

  ```
  Tip:
  
  You can enter the value '0' to have the health check use the backend server's traffic port.
  ```

• **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.

• **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

• **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

• **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is '3.'

• **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.

• **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

• **SSL Policy:** Optional. Specify the type of cipher suite to use:

  ```
  Note:
  
  Check Use SSL for the SSL Policy features to be displayed.
  ```

• **TLS Version:** Optional. Specify the Transport Layer Security (TLS) version(s):

  • 1.0
  • 1.1
  • 1.2 (recommended)

  You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

  • **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

    All choices present in the list have at least one cipher associated with each TLS version you selected.

  • **Click Show Cipher Suite Details** to display the individual ciphers the selected cipher suite contains.

8. Click Create.
After your backend set is provisioned, you must specify backend servers for the set. See Backend Server Management on page 3242 for more information.

More information:

• Securing Networking: VCN, Load Balancers, and DNS on page 4693
• Backend Set Management on page 3228
• Health Check Management on page 3236
• Load Balancer Management on page 3206

Load balancer SSL certificate expires in X days

Issue: A load balancer's SSL certificate expires soon. When the certificate expires, data traffic can be interrupted and security compromised.

Basics:

• To ensure continuous security and usability, SSL certificates must be rotated on a timely basis.
• You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

To rotate a load balancer's certificate bundle:

The following procedure is for the Oracle Cloud Infrastructure Console.

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The steps to update your client or backend server are unique to your system.</td>
</tr>
</tbody>
</table>
2. Upload the new SSL certificate bundle to the load balancer:
   a. Open the navigation menu, click Networking, and then click Load Balancers.
   b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. Click the load balancer you want to configure.
   d. In the Resources menu, click Certificates, and then click Add Certificate.
   e. In the Add Certificate dialog box, enter the following:
      • **Certificate Name**: Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
      • **Choose SSL Certificate File**: Required. Drag and drop the certificate file, in PEM format, into the SSL Certificate field. Alternatively, you can choose the Paste SSL Certificate option to paste a certificate directly into this field.
      • **Specify CA Certificate**: Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
      • **Choose CA Certificate File**: Drag and drop the CA certificate file, in PEM format, into the CA Certificate field. Alternatively, you can choose the Paste CA Certificate option to paste a certificate directly into this field.
      • **Specify Private Key**: Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
      • **Choose Private Key File**: Drag and drop the private key, in PEM format, into the Private Key field. Alternatively, you can choose the Paste Private Key option to paste a private key directly into this field.
      • **Enter Private Key Passphrase**: Optional. Specify the private key passphrase.
   f. Click Add Certificate.
3. Edit listeners or backend sets (as needed) so they use the new certificate bundle

   Editing a listener:
   a. Open the navigation menu, click Networking, and then click Load Balancers.
   b. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. In the Resources menu, click Listeners.
   d. For the listener you want to edit, click the Actions icon (three dots), and then click Edit Listener.
   e. In the Certificate Name list, choose the new certificate bundle.
   f. Click Submit.

   Editing a backend set:
   
<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Updating the backend set temporarily interrupts traffic and can drop active connections.</td>
</tr>
</tbody>
</table>

   a. Open the navigation menu, click Networking, and then click Load Balancers.
   b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. In the Resources menu, click Backend Sets, and then click the name of the backend set you want to edit.
   d. Click Edit Backend Set.
   e. In the Edit Backend Set dialog box, select (check) Use SSL.
   f. In the Certificate Name list, choose the new certificate bundle.
   g. Click Save Changes.

4. (Optional) Remove the expiring SSL certificate bundle

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.</td>
</tr>
</tbody>
</table>

   a. Open the navigation menu, click Networking, and then click Load Balancers.
   b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   c. Click the load balancer you want to configure.
   d. In the Resources menu, click Certificates.
   e. For the certificate you want to delete, click the Actions icon (three dots), and then click Delete.
   f. Confirm when prompted.

More information:

- Securing Networking: VCN, Load Balancers, and DNS on page 4693
- SSL Certificate Management on page 3308
- Listener Management on page 3250
- Backend Set Management on page 3228
- Load Balancer Management on page 3206

Object Storage

Public buckets detected

Issue: Public buckets were detected in your tenancy. Confirm that the creation of each public bucket is intentional and authorized. If the bucket is not sanctioned for public access, follow the procedure for changing the visibility of a bucket and make the bucket private.

Basics:
• Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, users can obtain object metadata, download bucket objects, and optionally list bucket contents.
• Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
• Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

To change the visibility of a bucket (private or public):

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name to see the bucket details.
   Visibility: shows the current bucket setting, which is Private by default.
3. Click Edit Visibility.
4. In the Edit Visibility dialog box, edit the visibility settings:
   • Visibility
     • Public
     • Private
     • If you select Public to enable public access, decide whether you want to let users list the bucket contents. To set the visibility of bucket object lists, click Allow users to list objects from this bucket.
5. Click Save Changes.

More information:
• Securing Object Storage on page 4697
• Managing Buckets on page 4298
• Using Pre-Authenticated Requests on page 4387

Oracle Cloud Security Responses to Vulnerabilities

Read about Oracle’s response to certain security vulnerabilities, and any recommended actions for customers to take.

• Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 4727
• Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities on page 4732

Oracle Cloud Security Response to Intel L1TF Vulnerabilities

Intel disclosed a set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect several Intel processors, and they have received the following CVE identifiers:

• CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
• CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
• CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.
However, vulnerability CVE-2018-3620 could enable a rogue user mode process to read privileged kernel memory within the same virtual machine. As a result, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

**Oracle Cloud Infrastructure Compute**

For details and required actions related to the Compute service’s VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service on page 4728.

**Oracle Cloud Infrastructure Database**

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to Oracle Cloud Infrastructure offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service on page 4732.

**Platform Service and Kubernetes Services on Oracle Cloud Infrastructure**

Oracle has deployed technical mitigations designed to prevent malicious attacker’s VM instance from accessing data from other VM instances on the same hypervisor.

However, vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Oracle patched all Platform Service hosts that are managed by Oracle. If you manage your own operating systems, you're advised to keep up with the OS security patches to address this vulnerability.

**Other Oracle Cloud Infrastructure Services**

Mitigations designed to protect all other Oracle Cloud Infrastructure services have been deployed. Oracle notified and coordinated directly with customers for any additional required maintenance activities.

**Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic**

For more information, see Oracle Cloud Infrastructure Classic.

Oracle is deploying technical mitigations designed for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic. Some customers might experience reboots or downtime associated while deploying these mitigations.

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Oracle patched all Platform Service hosts that are managed by Oracle. If you manage your own operating systems, you're advised to keep up with the OS security patches to address this vulnerability.

**Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service**

Intel disclosed a set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.
See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 4727 for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

You should be aware that the vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system (OS). As a result, you are advised to keep up with OS security patches to address this vulnerability. See Protecting your Compute Instance Against the L1TF Vulnerability on page 4729 for instructions to patch the OS on the instances you manage.

Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances

Bare metal instances in Oracle Cloud Infrastructure offer you full control of a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

If you're running your own virtualization stack or hypervisors on bare metal instances, the L1TF vulnerability allows a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. You should review the Intel recommendations about vulnerabilities CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646, and make changes to your configurations as you deem appropriate.

Protecting your Compute Instance Against the L1TF Vulnerability

Intel disclosed a set of speculative execution side-channel processor vulnerabilities affecting their processors, for more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615 which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620 which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646 which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 4727 for more information.

Recommended Action

Oracle recommends that you patch the operating systems for your existing bare metal and virtual machine (VM) instances, and verify that this includes the patch for the CVE-2018-3620 vulnerability. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate the CVE-2018-3646 vulnerability. For bare metal instances using virtualization technology, you should also follow these instructions to ensure that they are mitigated against the CVE-2018-3646 vulnerability.

If you're running your own virtualization stack or hypervisors on bare metal instances, you should apply the patch for the CVE-2018-3646 vulnerability.

The information in the following sections detail the commands needed to update your running instances created from platform images.

The following platform image releases have been updated with the recommended patches, so instances created from these images or new image releases include the recommended patches for the L1TF vulnerability.

Platform images updated with recommended patches for the L1TF vulnerability:

Note:

Protections against the L1TF vulnerabilities are enabled by default in Oracle Linux 8, Oracle Linux Cloud Developer 8, CentOS 8, Ubuntu 20.04, and Windows Server 2019.

- Oracle-Linux-7.5-2018.08.14-0
- Oracle-Linux-7.5-Gen2-GPU-2018.08.14-0
For your running instances created from imported custom images, refer to the operating system (OS) vendor's guidance to patch the OS for the L1TF vulnerability.

**Patching Oracle Linux Instances**

For Oracle Linux, the patches for the CVE-2018-3620 and CVE-2018-3646 vulnerabilities are addressed by the same set of patches.

Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances.

To install the latest microcode updates, run the following command:

```
# sudo yum update microcode_ctl
```

The microcode RPM should be greater than or equal to
```
microcode_ctl-2.1-29.2.0.4.el7_5.x86_64.rpm
```
This is the version of the microcode package that shipped for the Spectre v3a and Spectre v4 updates. No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

To patch the OS for bare metal and VM instances with downtime

The yum-plugin-security package allows you to use yum to obtain a list of all of the errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the yum-plugin-security package, run the following command:

   ```
   # sudo yum install yum-plugin-security
   ```

2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

   ```
   # sudo yum updateinfo list --cve CVE-2018-3620
   # sudo yum update --cve CVE-2018-3620
   ```

   A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using `yum update`, visit Installing and Using the Yum Security Plugin.
3. After the system reboots, ensure that the following file is populated.

```
cat /sys/devices/system/cpu/vulnerabilities/l1tf
```

**Patching Windows Instances**

**Protecting New Windows VM and Bare Metal Instances**

When you create a new VM or bare metal instance based on the latest Windows platform images, the image includes the Microsoft-recommended patches to protect against the L1TF vulnerability. Windows bare metal instances also include the latest microcode updates from Intel.

There is no further action required from you to protect your new Windows-based VM or bare metal instances from the L1TF vulnerability. You should ensure that you keep the your instances updated with the latest patches as recommended by your OS vendor.

**Protecting Existing Windows VM and Bare Metal Instances**

To update the microcode for existing bare metal instances

Bare metal instances launched before the Windows platform images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images on page 992 for more information.
2. Terminate your existing Windows bare metal instance.
3. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**. Find the custom image you want to use.
4. Click the Actions icon (three dots), and then click **Create Instance**.
5. Provide additional launch options as described in Creating an Instance on page 1023.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft.

To patch the OS for bare metal and VM instances with downtime

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images on page 950 and Security Lists on page 3727 for more information.

1. Verify that you have installed the latest Windows OS security update from Microsoft.
   a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
   b. To manually check for the latest update, select **Start**.
   c. In **Settings** select **Updates & security** and then select **Windows Update**.
   d. In **Windows Update**, click **Check for updates**.
   e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see Windows Update: FAQ.

For additional details see Windows Server guidance to protect against L1 terminal fault.

**Patching Ubuntu or CentOS Instances**

When you create a new VM or bare metal instance based on the latest Ubuntu or CentOS platform images, the image includes the recommended patches to protect against the L1TF vulnerability, see for more information L1 Terminal Fault (L1TF) and L1TF - L1 Terminal Fault Attack - CVE-2018-3620 & CVE-2018-3646.

For existing VM or bare metal instances you should follow the guidance provided by the OS vendor for patching systems.
Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service

Intel disclosed a set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities on page 4727 for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

Autonomous Data Warehouse and Autonomous Transaction Processing

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads. Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads. Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by the L1TF vulnerabilities, CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646. No further action is required by customers.

Guidance for the Database Service on Bare Metal Instances

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access from other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system. As a result, you need to patch these systems after these patches are available. These patches will be available shortly and Oracle will update this page when the operating system (OS) patches are published. Oracle will update the Database base images with the latest patches for new instance launches.

Once the patches are available, use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in Updating a DB System on page 1920.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure Database service, apply the OS patches following the instructions in Updating a DB System on page 1920.
- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in Applying Linux OS Security Patches by Using the dbaascli Utility.
- For Exadata DB systems, apply the OS patches following the instructions in Updating an Exadata Cloud Service Instance on page 1799.

Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities

Intel disclosed four speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)
Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

However, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

Oracle Cloud Infrastructure Compute

For details and required actions related to the Compute service's VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service on page 4733.

Oracle Cloud Infrastructure Database

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service on page 4737.

Oracle Cloud Infrastructure Container Engine for Kubernetes

To help secure your existing worker nodes for the Oracle Cloud Infrastructure Container Engine for Kubernetes, Oracle recommends replacing your current node pools with new node pools. Follow the instructions described in Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 1354. All worker nodes created or upgraded after May 14, 2019 are not impacted by this security issue.

Other Oracle Cloud Infrastructure Services

Technical mitigations designed to protect all other Oracle Cloud Infrastructure services against the MDS processor vulnerabilities have been deployed. Oracle notified customers if other maintenance activities were required.

Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic

For more information see Oracle Cloud Infrastructure Classic.

In response to the MDS processor vulnerabilities, Oracle is performing mandatory maintenance for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic.

Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems, you are advised to keep up with the appropriate OS security patches to address these vulnerabilities.

Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service

Intel disclosed four speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

• CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
• CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
• CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
• CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.
Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

You are advised to keep up with OS security patches to address this vulnerability. See Oracle Cloud Infrastructure Compute Content Impact on page 4734 for instructions to patch the OS on the instances you manage.

**Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances**

Bare metal instances in Oracle Cloud Infrastructure offer customers full control of a physical server. Oracle Cloud Infrastructure’s network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

However, for customers running their own virtualization stack on bare metal instances, the MDS vulnerabilities could allow a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. These customers should review Intel’s recommendations about these MDS vulnerabilities and make the recommended changes to their configurations, [https://www.intel.com/content/www/us/en/security-center/advisory/intel-sa-00233.html](https://www.intel.com/content/www/us/en/security-center/advisory/intel-sa-00233.html).

**Oracle Cloud Infrastructure Compute Content Impact**

Intel disclosed four speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see [https://blogs.oracle.com/security/intelmds](https://blogs.oracle.com/security/intelmds).

**Recommended Action**

Oracle recommends that customers patch the operating systems for their existing bare metal and virtual machine (VM) instances and verify that these OS updates include the patch for the MDS vulnerabilities. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate for the MDS vulnerabilities. For bare metal instances using virtualization technology, you should also follow the following instructions.

If you are running your own virtualization stack or hypervisors on bare metal instances, you should apply the appropriate patch required to address the MDS processor vulnerabilities.

The information in the following sections detail the commands needed to update your running instances created with platform images.

The following platform image releases have been updated with the recommended patches, as a result instances created using these images or subsequent images include the recommended patches for the MDS vulnerabilities.

**Platform images updated with recommended patches for the MDS vulnerability**

- **Note:**
  
  Protections against the MDS processor vulnerabilities are enabled by default in Oracle Linux 8, Oracle Linux Cloud Developer 8, CentOS 8, Ubuntu 20.04, and Windows Server 2019.

- Oracle-Linux-6.10-2019.05.14-0
- Oracle-Linux-7.6-2019.05.14-0
- Oracle-Linux-7.6-Gen2-GPU-2019.05.14-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-2019.05.14-0 (end of support)
- Windows-Server-2012-R2-Standard-Edition-VM-2019.05.15-0
Customers running instances created from imported third-party images should refer to the operating system (OS) vendor's guidance to patch the OS for the MDS vulnerability.

**Patching Oracle Linux Instances**

Oracle has released security patches for Oracle Linux 6, Oracle Linux 7, and Oracle VM Server for X86 products. In addition to the OS patches, customers should run the latest version of the microcode from Intel to mitigate these issues. For both bare metal and VM instances, please install the latest Ksplice via `uptrack-upgrade`.

**Note:**

See [Installing Ksplice Uptrack Within the Oracle Cloud Infrastructure](#) for how to install Ksplice.

For Oracle Linux, the patches for the MDS vulnerabilities are addressed by the same set of patches. For further information please see the following:

Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances.

To install the latest microcode updates on bare metal instances, run the following command:

```
# sudo yum update microcode_ctl
```

The required versions of `microcode_ctl` rpms are:

- **Oracle Linux 7**: `microcode_ctl 2.1-47.0.4`
- **Oracle Linux 6**: `microcode_ctl 1.17-1002`

No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

**To patch the OS for bare metal and VM instances with downtime**

The `yum-plugin-security` package allows you to use yum to obtain a list of all errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or
management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the `yum-plugin-security` package, run the following command:

   ```bash
   # sudo yum install yum-plugin-security
   ```

2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

   ```bash
   # sudo yum updateinfo list --cve CVE-####-####
   # sudo yum update --cve CVE-####-####
   ```

   Replace `####-####` in the above commands with the relevant CVE numbers.

3. A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using yum update, visit Installing and Using the Yum Security Plugin.

4. After the system reboots, ensure that the following file is populated:

   ```bash
   cat /sys/devices/system/cpu/vulnerabilities/mds
   ```

**Patching Windows Instances**

**Protecting New Windows VM and Bare Metal Instances**

When you create a new VM or bare metal instance based on the latest Windows platform images, the image includes the Microsoft-recommended patches to protect against the MDS vulnerability. Windows bare metal instances also include the latest microcode updates from Intel. To apply the MDS patch install the latest Windows updates and reboot the instance. You should ensure that you keep your instances updated with the latest patches as recommended by your OS vendor.

**Protecting Existing Windows VM and Bare Metal Instances**

To update the microcode for existing bare metal instances

Bare metal instances launched before the Windows platform images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images on page 992 for more information.

2. Terminate your existing Windows bare metal instance.

3. Open the navigation menu and click Compute. Under Compute, click Custom Images. Find the custom image you want to use.

4. Click the Actions icon (three dots), and then click Create Instance.

5. Provide additional launch options as described in Creating an Instance on page 1023.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft.

To patch the OS for bare metal and VM instances with downtime

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images and Security Lists for more information.
1. Verify that you have installed the latest Windows OS security update from Microsoft.
   
a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
   
b. To manually check for the latest update, select **Start**.
   
c. In **Settings** select **Updates & security** and then select **Windows Update**.
   
d. In **Windows Update**, click **Check for updates**.
   
e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see **Windows Update: FAQ**.

For additional details see **Windows Server guidance to protect against speculative execution side-channel vulnerabilities**.

**Patching Ubuntu or CentOS Instances**

The recommended patches to protect against the MDS vulnerabilities are included when you create a new VM or bare metal instance based on the latest Ubuntu or CentOS platform images, see **Microarchitectural Data Sampling (MDS)** and **MDS - Microarchitectural Store Buffer Data - CVE-2018-12130, CVE-2018-12126, CVE-2018-12127, and CVE-2019-11091**. For existing VM or bare metal instances you should follow the patching guidance provided by the original OS vendor.

**Note:**

Any images published after May 14, 2019 listed in the **image release notes** will include the MDS patches. If using earlier images already launched, follow patching instructions.

**Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service**

Intel disclosed four speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see **https://blogs.oracle.com/security/intelmds**.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

**Autonomous Data Warehouse and Autonomous Transaction Processing**

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads.

Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads.

Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by MDS vulnerabilities. These services do not run on their own hypervisor and they do not allow for the execution of untrusted code in their services enclave. Customers can execute code within their own instances and each customer instance is isolated from that of another customer. No further customer action is currently required.

**Guidance for the Database Service on Bare Metal Instances**

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure’s network virtualization is designed and configured to protect these instances from unauthorized access from other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances. As a result, the Database service on bare metal instances are not affected by the MDS vulnerabilities.
**Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems**

Customers are advised to apply available patches at the earliest possible time. Use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in [Updating a DB System](#) on page 1920.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure Database service, apply the OS patches following the instructions in [Updating a DB System](#) on page 1920.
- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in [Applying Linux OS Security Patches by Using the dbaascli Utility](#).
- For Exadata DB systems, apply the OS patches following the instructions in [Updating an Exadata Cloud Service Instance](#) on page 1799.
Chapter 42

Security Advisor

This chapter explains how to use Security Advisor to create more secure resources.

Overview of Security Advisor

Oracle Cloud Infrastructure Security Advisor supports and reinforces what’s required of the tenancy by Security Zones configurations. It does this by combining and streamlining existing workflows to efficiently create resources that meet baseline security requirements from the outset. Specifically, you can assign a new customer-managed encryption key to a resource at the time that you create the resource, even if you've never created a vault or encryption key before. Security zones require encryption using customer-managed keys where possible because no one but an authorized user can access the keys, thereby resulting in sensitive data that can only be decrypted and read by those explicitly allowed.

Streamlined workflows reduce complexity and decision-making. Where you would otherwise need to choose between configuration settings, Security Advisor provides only the more secure option. For example, Security Advisor only allows you to create master encryption keys that are 256 bits in length. Longer encryption keys provide greater security than shorter ones.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Security Advisor leverages the functionality of existing workflows, so the tenancy might not need new policies to grant permissions beyond what’s already in place. To be sure, you can compare the tenancy’s existing policies with the example permissions described in the chosen workflow. In particular, confirm that you have policies that grant access to Vault resources, especially if you haven't used the service previously.

The example policy statements make it possible for the specified groups to do anything allowed by Security Advisor. If, instead, you wanted to limit the creation of new vaults, you can write a policy that grants permission only to use vaults, rather than the level of access required to manage vaults. With permission to use vaults, a user can select an existing vault, but cannot create a new one. This does not change the options that Security Advisor presents, but it does affect whether all operations succeed when submitted.
Regions and Availability Domains

You can use Security Advisor in all Oracle Cloud Infrastructure commercial regions. For a list of regions, along with associated locations, region identifiers, region keys, and availability domains, see About Regions and Availability Domains on page 208.

Each service that integrates with Security Advisor has a single regional endpoint for all API operations, with one exception. The Vault service has one regional endpoint for the provisioning service that handles create, update, and list operations for vaults. For create, update, and list operations for keys, service endpoints are distributed across multiple independent clusters.

Limits on Resources

Security Advisor does not introduce resources and does not impose restrictions on your usage level of any resource. Security Advisor does, however, respect the limits instituted by other services.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

For instructions to view your usage level against the tenancy’s resource limits, see Viewing Your Service Limits, Quotas, and Usage on page 244. For vaults, you can also get each individual vault’s usage against key limits by viewing key and key version counts in the vault details.

Creating a Secure Bucket

This topic describes how to use Security Advisor to create a secure bucket. In this context, a secure bucket is one that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the bucket, but also the Vault key that you want to use to encrypt the bucket, and then assigning the key to the bucket. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Object Storage security features and best practices, and then implement them with your newly created resource. For more information, see Securing Object Storage on page 4697 and Using Your Own Keys for Server-Side Encryption on page 4406.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators:

• The following policy lets the specified group do everything with buckets and objects in the specified compartment:

  ```
  Allow group CreateSecureOSBucketGroup to manage object-family in compartment CompartmentABC
  ```

• The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the bucket compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

  ```
  Allow group CreateSecureOSBucketGroup to manage vaults in compartment CompartmentDEF
  ```
The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```
Allow group CreateSecureOSBucketGroup to manage keys in compartment CompartmentDEF
```

The following policy lets the Object Storage service list, view, and perform cryptographic operations with all keys in the specified compartment:

```
Allow service ObjectStorage-<region_name> to use keys in compartment CompartmentDEF
```

In the preceding example, replace `<region_name>` with the appropriate region identifier, for example:

- objectstorage-us-phoenix-1
- objectstorage-us-ashburn-1
- objectstorage-eu-frankfurt-1
- objectstorage-uk-london-1
- objectstorage-ap-tokyo-1

To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains on page 208.

For more information about how policies work, see How Policies Work on page 2800.

### Using the Console

**To create a secure bucket**

1. Open the navigation menu, click Identity & Security, and then click Security Advisor.
2. Click Create Secure Bucket.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault, click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 5007.

When you're ready, click Next.

6. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.
7. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
8. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 5034.
9. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.
10. On the **Create Bucket** page, specify the attributes of the bucket:

- **Bucket Name:** The system generates a default bucket name that reflects the current year, month, day, and time, for example `bucket-20190306-1359`. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.

- **Create in Compartment:** The compartment where you want the bucket to reside. This does not need to be the same compartment as the vault and key.

- **Storage Tier:** Select the tier in which you want to store your data. Available tiers include:
  - **Standard** is the primary, default Object Storage tier for storing frequently accessed data that requires fast and immediate access.
  - **Archive** is a special tier for storing infrequently accessed data that requires long retention periods. Access to data in the Archive tier is not immediate. Archived data must be restored before the data is accessible. For more information, see "Overview of Archive Storage" on page 566 in the *Oracle Cloud Infrastructure User Guide*.

- **Object Events:** Select **Emit Object Events** if you want to enable the bucket to emit events for object state changes. For more information about events, see Overview of Events on page 2382.

- **Object Versioning:** Select **Enable Object Versioning** if you want Object Storage to create an object version each time the content changes or the object is deleted. For more information, see Using Object Versioning on page 4350.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

When you're ready, click **Next**.

11. Review the summary of the resources that Security Advisor will create, and then click **Create Secure Bucket**.

### Creating a Secure File System

This topic describes how to use Security Advisor to create a secure file system. The process involves creating not only the file system, but also the Vault key that you want to use to encrypt the file system, and then assigning the key to the file system. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a file system comes with some limitations. You cannot use Security Advisor to create a file system with a new mount target. You must reuse an existing mount target.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure File Storage security features and best practices, and then implement them with your newly created resources. For more information, see Securing File Storage on page 4685 and About Security on page 2534.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators:

- The following policy lets the specified group do everything with file systems and mount targets in the specified compartment:

  ```
  Allow group CreateSecureFileStorageGroup to manage file-family in compartment CompartmentABC
  ```

- The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the file system compartment. (If you prefer, you can write a policy that grants the

Oracle Cloud Infrastructure User Guide 4743
use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

<table>
<thead>
<tr>
<th>Allow group CreateSecureFileStorageGroup to manage vaults in compartment CompartmentDEF</th>
</tr>
</thead>
</table>

- The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

<table>
<thead>
<tr>
<th>Allow group CreateSecureFileStorageGroup to manage keys in compartment CompartmentDEF</th>
</tr>
</thead>
</table>

- The following policy lets the File Storage service list, view, and perform cryptographic operations with all keys in the specified compartment:

<table>
<thead>
<tr>
<th>Allow service FssOc1Prod to use keys in compartment CompartmentDEF</th>
</tr>
</thead>
</table>

In the preceding example, the policy refers to the File Storage service by the service principal name FssOc1Prod.

For more information about how policies work, see How Policies Work on page 2800.

### Using the Console

#### To create a secure file system

1. Open the navigation menu, click Identity & Security, and then click Security Advisor.
2. Click Create Secure File System.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 5007.

When you're ready, click Next.

6. Click Key Name, and then enter a name to identify the key. Avoid entering confidential information.
7. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
8. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 5034.
9. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.
10. On the Create File System page, specify the attributes of the file system:

- **File System Information:**
  - **Compartment:** The compartment where you want the file system to reside. You must choose a compartment where you have the required existing mount target.
  - **Name:** File Storage creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system. Avoid entering confidential information.
  - **Availability domain:** The availability domain within the current region where you want to place the file system.
  - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Export Information**

  Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.

  - **Export Path:** The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

  **Important:**
  The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:
  
  **Acceptable:**
  
  `/example` and `/path`
  
  `/example` and `/example2`

  **Not Acceptable:**
  
  `/example` and `/example/path`
  
  `/ and /example`
  
  `/example/`
  
  `/example/path/..example1`

  **Caution:**
  If one file system associated to a mount target has `/` specified as an export path, you can't associate another file system with that mount target.

  **Note:**
  Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the
For more information, see Paths in File Systems on page 2621.

- **Use Secure Export Options:** Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options on page 2542 for more information.

  **Caution:**
  Leaving the Use Secure Export Options setting unselected lets unprivileged users read and modify any file or directory on the target file system.

- **Mount Target Information:**
  File systems must be associated with a mount target to be mounted by an instance. If you don't have a mount target in the selected availability domain in the compartment, you must choose a different availability domain or create the file system in a compartment and availability domain where you do have a mount target.

When you're ready, click Next.

11. Review the summary of the resources that Security Advisor will create, and then click Create Secure File System.

### Creating a Secure Virtual Machine Instance

This topic describes how to use Security Advisor to create a secure virtual machine (VM) instance. In this context, a secure instance is one with a boot volume that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the instance and associated boot volume, but also the Vault key that you want to use to encrypt the volume, and then assigning the key to the volume. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a virtual machine instance comes with some limitations. They include the following:

- You cannot configure private or public IP addresses for an instance.
- You cannot change the image build. It will always use the latest version.
- You cannot launch the instance on a dedicated virtual machine host, which lets you run the instance in isolation so that it is not running on shared infrastructure.
- You cannot specify the volume performance settings for the boot volume.
- You cannot use Security Advisor to generate SSH keys for you if you want to remotely connect to the instance by using Secure Shell (SSH). You must generate your own SSH keys and have the public key available when you create the instance.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Compute and Oracle Cloud Infrastructure Block Volume security features and best practices, and then implement them with your newly created resources. For more information, see Securing Compute on page 4675, Securing Block Volume on page 4671, and Best Practices for Your Compute Instance on page 931.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators:
- The following policy lets the specified group list and use all components in Networking in the specified compartment. This includes virtual cloud networks (VCNs), subnets, gateways, virtual circuits, security lists, route tables, and so on.

```plaintext
Allow group CreateSecureVMGroup to use virtual-network-family in compartment CompartmentABC
```

- The following policy lets the specified group create and manage instance images in the specified compartment:

```plaintext
Allow group CreateSecureVMGroup to manage instance-family in compartment CompartmentABC
```

- The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the instance compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

```plaintext
Allow group CreateSecureVMGroup to manage vaults in compartment CompartmentDEF
```

- The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```plaintext
Allow group CreateSecureVMGroup to manage keys in compartment CompartmentDEF
```

- The following policy lets the Block Volume service list, view, and perform cryptographic operations with all keys in the specified compartment. The Block Volume service is responsible for the boot volume attached to the instance.

```plaintext
Allow service blockstorage to use keys in compartment CompartmentDEF
```

For more information about how policies work, see How Policies Work on page 2800.

**Using the Console**

**To create a secure virtual machine instance**

1. Open the navigation menu, click **Identity & Security**, and then click **Security Advisor**.
2. Click **Create Secure Bucket**.
3. Review the prerequisites for getting started, and then click **Next** when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click **Choose existing vault**.
   - To create a master encryption key in a new vault click **Create new vault**.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the **Make it a virtual private vault** check box. For more information about vault types, see Key and Secret Management Concepts on page 5007.

When you're ready, click **Next**.
6. Click **Key Name**, and then enter a name to identify the key. Avoid entering confidential information.
7. Regarding **Key Shape: Length**, the key length value is fixed at 256 bits to maximize security based on key length.
8. Optionally, if you want to import key material to create a key, select the **Import external key** check box.
Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see [Importing Keys and Key Versions](#) on page 5034.

9. Optionally, to apply tags, click **Show Tagging Options**. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. When you're ready, click **Next**.

10. On the **Create Compute Instance** page, specify the attributes of the instance:

   - **Name**: A display name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.
   - **Create in Compartment**: The compartment where you want to create the instance. This does not need to be the same compartment as the vault and key.
   - **Image or Operating System**: By default, an Oracle Linux 7.x image is used to boot the instance. You cannot use Security Advisor to create a virtual machine instance with a different image.
   - **Availability Domain**: The availability domain where you want to create the instance.
   - **Shape**: The default shape for the selected image and availability domain combination. You cannot use Security Advisor to create a virtual machine instance with a different shape. For more information about shapes, see [Compute Shapes](#) on page 973.

11. In the **Configure networking** section, configure the network details for the instance:

   - **Virtual cloud network compartment**: The compartment containing the network in which to create the instance.
   - **Virtual cloud network**: The network in which to create the instance. You can only choose an existing virtual cloud network (VCN). You cannot use Security Advisor to create a new VCN. If you have a VCN in a different compartment, click **Change compartment**, and then select a different compartment.
   - **Subnet**: A subnet within the cloud network to attach the instance to. Subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For a more secure instance, we recommend that you choose a private subnet. For more information, see [Access to the Internet](#) on page 3609. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see [About Regional Subnets](#) on page 3694.
   - **By default**, when you create an instance in a public subnet, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. You cannot use Security Advisor to create a virtual machine instance with a public IP address.

12. In the **Boot volume** section, configure the size and encryption options for the instance's boot volume:

   - **Specify a custom boot volume size**: To specify a custom size for the boot volume, select the **Specify a custom boot volume size** check box. Then, enter a custom size from 50 GB to 32 TB. The specified size must be larger than the default boot volume size for the selected image. See [Custom Boot Volume Sizes](#) on page 690 for more information.
   - **Use in-transit encryption**: To encrypt data while the data is in transit between the instance and the attached boot volume, select the **Use in-transit encryption** check box. The Vault service encryption key that you use to encrypt the boot volume data at rest will also be used for in-transit encryption. For more information, see [Block Volume Encryption](#) on page 644. Security zones require data to be encrypted in-transit, so you must select this check box to comply with security zone requirements.
13. In the **Add SSH keys** section, generate an SSH key pair or upload your own public key. Select one of the following options:

- **Generate a key pair for me:** Oracle Cloud Infrastructure generates an RSA key pair for the instance. Click **Save Private Key**, and then save the private key on your computer. Optionally, click **Save Public Key** and then save the public key.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anyone who has access to the private key can connect to the instance. Store the private key in a secure location.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To use a key pair that is generated by Oracle Cloud Infrastructure, you must access the instance from a system that has OpenSSH installed. UNIX-based systems (including Linux and OS X), Windows 10, and Windows Server 2019 should have OpenSSH. For more information, see <a href="#">Managing Key Pairs on Linux Instances</a> on page 1021.</td>
</tr>
</tbody>
</table>

- **Upload public key files (.pub):** Upload the public key portion of your key pair. Either browse to the key file that you want to upload, or drag and drop the file into the box. To provide multiple keys, press and hold down the Command key (on Mac) or the CTRL key (on Windows) while selecting files.
- **Paste public keys:** Paste the public key portion of your key pair in the box.
- **No SSH keys:** Select this option only if you do not want to connect to the instance using SSH. You cannot provide a public key or save the key pair that is generated by Oracle Cloud Infrastructure after the instance is created.

14. Optionally, to configure tags, click **Show Tagging Options**. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

15. Review the summary of the resources that Security Advisor will create, and then click **Create Secure Instance**.

### Creating a Secure Block Volume

This topic describes how to use Security Advisor to create a secure block volume. In this context, a secure block volume is one that is encrypted with a customer-managed key and therefore meets minimum security requirements established by security zones. The process involves creating not only the block volume, but also the Vault key that you want to use to encrypt the volume, and then assigning the key to the volume. (You cannot use Security Advisor to assign existing encryption keys, but you can use an existing vault to create a new key.)

Using Security Advisor to create a block volume comes with some limitations. You cannot use Security Advisor to create a block volume with a backup policy. See [Policy-Based Backups](#) on page 717 for more information about backup policies.

Other security considerations exist outside Security Advisor, particularly regarding the use of resources after you create them. We strongly encourage you to learn more about Oracle Cloud Infrastructure Compute and Oracle Cloud Infrastructure Block Volume security features and best practices, and then implement them with your newly created resources. For more information, see [Securing Compute](#) on page 4675, [Securing Block Volume](#) on page 4671, and [Best Practices for Your Compute Instance](#) on page 931.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators:
The following policy lets the specified group do everything with block storage volumes, volume backups, and volume groups in the specified compartment:

```
Allow group CreateSecureBlockVolumeGroup to manage volume-family in compartment CompartmentABC
```

The following policy lets the specified group do everything with vaults in the specified compartment, which might not be the same compartment as the volume compartment. (If you prefer, you can write a policy that grants the use vaults permission instead. With that permission, the specified group can use existing vaults, but cannot create new ones.)

```
Allow group CreateSecureBlockVolumeGroup to manage vaults in compartment CompartmentDEF
```

The following policy lets the specified group do everything with keys in the specified compartment, which must be the same compartment as the vault compartment:

```
Allow group CreateSecureBlockVolumeGroup to manage keys in compartment CompartmentDEF
```

The following policy lets the Block Volume service list, view, and perform cryptographic operations with all keys in the specified compartment:

```
Allow service blockstorage to use keys in compartment CompartmentDEF
```

For more information about how policies work, see How Policies Work on page 2800.

**Using the Console**

**To create a secure block volume**

1. Open the navigation menu, click Identity & Security, and then click Security Advisor.
2. Click Create Secure Bucket.
3. Review the prerequisites for getting started, and then click Next when you're ready.
4. Do one of the following:
   - To create a master encryption key in an existing vault, click Choose existing vault.
   - To create a master encryption key in a new vault click Create new vault.
5. Then, do one of the following:
   - If you chose to use an existing vault in the previous step, choose the compartment where the vault resides, and then choose the vault.
   - If you chose to create a new vault in the previous step, choose the compartment where you want to create the vault, and then enter a display name to identify the vault. Avoid entering confidential information. Optionally, make the vault a virtual private vault by selecting the Make it a virtual private vault check box. For more information about vault types, see Key and Secret Management Concepts on page 5007.
6. When you're ready, click Next.
7. Regarding Key Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Regarding Key Shape: Length, the key length value is fixed at 256 bits to maximize security based on key length.
9. Optionally, if you want to import key material to create a key, select the Import external key check box. Importing key material requires you to first generate the key material and wrap it using a vault's public wrapping key. This means that you cannot use Security Advisor to create a key using imported key material without an existing vault. For more information about importing keys, see Importing Keys and Key Versions on page 5034.
10. Optionally, to apply tags, click Show Tagging Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure
whether to apply tags, skip this option (you can apply tags later) or ask your administrator. When you're ready, click Next.

10. On the Create Block Volume page, specify the attributes of the volume:

- **Block Volume Name**: A user-friendly name or description. Avoid entering confidential information.
- **Compartment**: The compartment where you want to create the volume.
- **Availability Domain**: Must be in the same availability domain as the instance you plan to use this block volume with.
- **Volume Size and Performance**: The volume size must be between 50 GB and 32 TB. You can choose in 1 GB increments within this range. The default is 1024 GB. If you choose a size outside of your service limit, you may be prompted to request an increase. For more information, see Service Limits on page 243. The default level for performance settings is Balanced. See Block Volume Performance on page 645 for more information about volume performance levels.
- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

When you're ready, click Next.

11. Review the summary of the resources that Security Advisor will create, and then click Create Secure Block Volume.
Chapter 43

Service Connector Hub

This chapter explains how to move data between Oracle Cloud Infrastructure services using Service Connector Hub.

**Service Connector Hub**

Service Connector Hub is a cloud message bus platform that offers a single pane of glass for describing, executing, and monitoring interactions when moving data between Oracle Cloud Infrastructure services.

<table>

**Overview of Service Connector Hub**

Service Connector Hub is a cloud message bus platform that offers a single pane of glass for describing, executing, and monitoring movement of data between services in Oracle Cloud Infrastructure.

**Note:**

Service Connector Hub is not available in Oracle Cloud Infrastructure Government Cloud realms.

**How Service Connector Hub Works**

Service Connector Hub orchestrates data movement between services in Oracle Cloud Infrastructure.
Data is moved using service connectors. A service connector specifies the source service that contains the data to be moved, optional tasks, and the target service for delivery of data when tasks are complete. An optional task might be a function task to process data from the source or a log filter task to filter log data from the source.

**Service Connector Hub Concepts**

The following concepts are essential to working with Service Connector Hub.

**service connector**

The definition of the data to be moved. A service connector specifies a source service, target service, and optional tasks.

**source**

The service that contains the data to be moved according to specified tasks—for example, Logging.

**target**

The service that receives data from the source, according to specified tasks. A given target service processes, stores, or delivers received data—the Functions service processes the received data; the Logging Analytics, Monitoring, Object Storage, and Streaming services store the data; and the Notifications service delivers the data.

**task**

Optional filtering to apply to the data before moving it from the source service to the target service.

**trigger**

The condition that must be met for a service connector to run. Currently, the trigger is continuous; that is, service connectors run continuously.

**Flow of Data**

When a service connector runs, it receives data from the source service, completes optional tasks on the data (such as filtering), and then moves the data to the target service.

Tasks: While a function task applies to any source, a log filter task applies to a Logging source only.
Availability

The Service Connector Hub service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Service Connector Hub

You can access the Service Connector Hub service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

Console: To access Service Connector Hub using the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.

You can also access Service Connector Hub from the following services in the Console:

- Logging: Open the navigation menu and click Observability & Management. Under Logging, click Service Connectors.
- Streaming: Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming. On the stream list page, under Analytics, click Service Connectors.

API: To access Service Connector Hub through API, use Service Connector Hub API. To access this API using the Command Line Interface (CLI), use the designation for service connectors: oci sch service-connector. For more details about the CLI, see Command Line Reference for Service Connector Hub.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Access to Service Connector Hub

Administrators: For common policies that give groups access to Service Connector Hub, see Allow a group to manage service connectors on page 2825.
Access to Source, Task, and Target Services

**Note:**
Ensure that any policy you create complies with your company guidelines.

To move data, your service connector must have authorization to access the specified resources in the source, task, and target services. Some resources are accessible without policies.

Default policies providing the required authorization are offered when you use the Console to define a service connector. These policies are limited to the context of the service connector. You can either accept the default policies or ensure that you have the proper authorizations in group-based policies.

**Default Policies**

This section details the default policies offered when you create or update a service connector in the Console.

**Functions (Task or Target)**

Applies when the service connector specifies a function task or selects Functions as its target service.

*Where this policy is created:* The compartment where the function resides. The function is selected for the task or target when you create or edit a service connector.

```plaintext
allow any-user to use fn-function in compartment
  id <target_function_compartment_ocid>
  where all {
    request.principal.type='serviceconnector',
    request.principal.compartment.id='<serviceconnector_compartment_ocid>'
  }
allow any-user to use fn-invocation in compartment
  id <target_function_compartment_ocid>
  where all {
    request.principal.type='serviceconnector',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
  }
```

**Logging (Source, Task)**

No default policies are offered because they are not required for access to resources in the Logging service, whether defined as the source or task (log filter task) of a service connector.

**Logging Analytics (Target)**

Applies when the service connector specifies Logging Analytics as its target service.

*Where this policy is created:* The compartment where the log group resides. The log group is selected or entered for the target when you create or edit a service connector.

```plaintext
allow any-user to use loganalytics-log-group in compartment
  id <target_log_group_compartment_OCID>
  where all {
    request.principal.type='serviceconnector',
    target.loganalytics-log-group.id=<log_group_OCID>,
    request.principal.compartment.id=<serviceconnector_compartment_OCID>
  }
```

**Monitoring (Target)**

Applies when the service connector specifies Monitoring as its target service.
**Service Connector Hub**

**Where this policy is created:** The compartment where the metric namespace resides. The metric namespace is selected or entered for the target when you create or edit a service connector.

```
allow any-user to use metrics in compartment
  id <target_metric_compartment_OCID>
where all {
  request.principal.type='serviceconnector',
  target.metrics.namespace='<metric_namespace>',
  request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

**Notifications (Target)**

Applies when the service connector specifies Notifications as its target service.

**Where this policy is created:** The compartment where the topic resides. The topic is selected for the target when you create or edit service connector.

```
allow any-user to use ons-topics in compartment
  id <target_topic_compartment_OCID>
where all {
  request.principal.type='serviceconnector',
  request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

**Object Storage (Target)**

Applies when the service connector specifies Object Storage as its target service.

**Where this policy is created:** The compartment where the bucket resides. The bucket is selected for the target when you create or edit service connector.

```
allow any-user to manage objects in compartment
  id <target_bucket_compartment_OCID>
where all {
  request.principal.type='serviceconnector',
  target.bucket.name='<bucket_name>',
  request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

**Streaming (Source)**

Applies when the service connector specifies Streaming as its source service.

**Where this policy is created:** The compartment where the stream resides. The stream is selected for the source when you create or edit service connector.

```
allow any-user to {STREAM_READ, STREAM_CONSUME} in compartment
  id <target_bucket_compartment_OCID>
where all {
  request.principal.type='serviceconnector',
  target.stream.id='stream_id',
  request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

**Streaming (Target)**

Applies when the service connector specifies Streaming as its target service.
Where this policy is created: The compartment where the stream resides. The stream is selected for the target when you create or edit service connector.

```
allow any-user to use stream-push in compartment
id <target_stream_compartment_OCID>
where all {
    request.principal.type='serviceconnector',
    target.stream.id='<stream_OCID>',
    request.principal.compartment.id='<serviceconnector_compartment_OCID>'
}
```

When reviewing group-based policies for required authorization to access a resource (service) in a service connector, reference the default policy offered for that service in that context (see previous section) or see the policy details for the service at Policy Reference on page 2837.

**Note:** To accept default policies for an existing service connector, simply edit the service connector. The default policies are offered whenever you create or edit a service connector. The only exception is when the exact policy already exists in IAM, in which case the default policy is not offered.

For troubleshooting information, see Troubleshooting Service Connectors on page 4780.

**Limits on Service Connector Hub**

See Service Connector Hub Limits on page 267. Logging Limits on page 260 apply when service connectors read from Logging. Streaming Limits on page 267 apply when service connectors read from Streaming.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Managing Service Connectors**

This section describes how to manage service connectors.

A service connector defines the flow of data between a source and target service.

**Prerequisites**

IAM policies: To use Service Connector Hub, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.

To move data, your service connector must have authorization to access the specified resources in the source, task, and target services. Some resources are accessible without policies.

Default policies providing the required authorization are offered when you use the Console to define a service connector. These policies are limited to the context of the service connector. You can either accept the default policies or ensure that you have the proper authorizations in group-based policies.

For more information about service connector authorization, see Access to Source, Task, and Target Services on page 4755.

If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Authentication and Authorization on page 4754.

**Using the Console**

**To create a service connector**

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

3. Click **Create Service Connector**.

4. On the **Create Service Connector** page, fill in the settings:
   - **Connector Name**: User-friendly name for the new service connector. Avoid entering confidential information.
   - **Description**: Optional identifier.
   - **Resource Compartment**: The compartment where you want to store the new service connector.
   - **Configure Service Connector**:
     - **Source**: Select the service containing the data you want to transfer from the following options.
       - **Logging**: Transfer log data from the Logging service. See **Logging Overview** on page 3348.
       - **Streaming**: Transfer stream data from the Streaming service. See **Streaming** on page 4858.
     - **Target**: Select the service that you want to transfer the data to.
       - **Functions**: Send data to a function.
       - **Logging Analytics**: Send data to a log group.
       - **Monitoring**: Send metric data points to the Monitoring service.
       - **Notifications**: Send data to a topic.
       - **Object Storage**: Send data to a bucket.
       - **Streaming**: Send data to a stream.
     - **Configure your source and task**:
       
       **Note:**

       By default, this page uses Basic mode. To switch between Basic Mode and Advanced Mode, click **Switch to Advanced mode** (to the right of **Configure source connection**) or **Switch to Basic mode** (to the right of **Configure source and task**). Complex queries cannot be displayed in Basic mode. See **I can't view my query in Basic mode** on page 4781 and **Logging Query Language Specification** on page 3431.

   - **Configure source connection**:

<table>
<thead>
<tr>
<th>Source service</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logging</td>
<td></td>
</tr>
<tr>
<td>See <strong>Logging Overview</strong> on page 3348.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Compartement</td>
</tr>
<tr>
<td></td>
<td>Log Group</td>
</tr>
<tr>
<td></td>
<td>Logs</td>
</tr>
</tbody>
</table>
### Source service

<table>
<thead>
<tr>
<th>Streaming</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>See <a href="#">Streaming</a> on page 4858.</td>
<td>Compartment</td>
</tr>
</tbody>
</table>

**Note:**

This source supports the following targets: Functions, Notifications, Object Storage, and Streaming.

### Stream Pool

### Stream

**Show Advanced Options: Read Position:**

Specify the cursor position from which to start reading the stream. For more information, see [Using Cursors](#) on page 4892.

- **Latest:** Starts reading at messages published after saving the service connector.
- **Trim_Horizon:** Starts reading at the oldest available message in the stream.

**Note:**

- For stream input schema, see [Message Reference](#).
- Notifications target with Streaming source: All messages are sent as raw JSON blobs.

### Configure task:

**Task**

<table>
<thead>
<tr>
<th>Log Filter Task (filters source logs using the Logging service)</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Audit Logs on page 3402: When _Audit is selected for Log Group:</td>
</tr>
<tr>
<td></td>
<td>• When Attribute is selected for Filter Type:</td>
</tr>
<tr>
<td></td>
<td>• Filter Type: Attribute</td>
</tr>
<tr>
<td></td>
<td>• Attribute Name</td>
</tr>
<tr>
<td></td>
<td>• Attribute Values</td>
</tr>
<tr>
<td></td>
<td>• When Event type is selected for Filter Type:</td>
</tr>
<tr>
<td></td>
<td>• Filter Type: Event type</td>
</tr>
<tr>
<td></td>
<td>• Service Name</td>
</tr>
<tr>
<td></td>
<td>• Event Type</td>
</tr>
</tbody>
</table>

**Service Logs** on page 3363, **Custom Logs** on page 3404: When another log group (not _Audit) is selected for Log Group:

- Property
- Operator
- Value
### Task

Configure Function Task (processes data from the source using the **Functions service**)

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>This task supports the following targets: Functions, Notifications, Object Storage, and Streaming.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function Application</strong>: Select the name of the function application that includes the function you want.</td>
</tr>
<tr>
<td><strong>Function</strong>: Select the name of the function you want to use to process the data received from the source.</td>
</tr>
</tbody>
</table>

For use by the service connector as a task, the function must be configured to return one of the following responses:

- List of JSON entries (must set the response header `Content-Type=application/json`)
- Single JSON entry (must set the response header `Content-Type=application/json`)
- Single binary object (must set the response header `Content-Type=application/octet-stream`)  

### Show Advanced Options: Optimal batch size:
Specify limits for each batch of data sent to the function.

- Use Automatic Settings
- Use Manual Settings
  - Batch size limit (KBs)
  - Batch time limit (seconds)

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Service Connector Hub does not parse the output of the function task. The output of the function task is written as-is to the target. For example, when using a Notifications target with a function task, all messages are sent as raw JSON blobs.</td>
</tr>
<tr>
<td>• Functions are invoked synchronously with 6 MB of data per invocation. If data exceeds 6 MB, then the service connector invokes the function again to move the over-limit data. Such over-limit invocations are handled sequentially.</td>
</tr>
<tr>
<td>• Functions can execute for up to five minutes.</td>
</tr>
</tbody>
</table>

- Click **Advanced Mode** or **Switch to Advanced Mode** to view and edit the source connector and task using the Query Code Editor.
• **Configure target connection**: Select the **Service Compartment** (where the target service resides) and fill in additional fields as needed:

<table>
<thead>
<tr>
<th>Target service</th>
<th>Additional fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Function Application</strong>: Select the name of the function application that includes the function you want.</td>
</tr>
<tr>
<td></td>
<td><strong>Function</strong>: Select the name of the function you want to send the data to.</td>
</tr>
</tbody>
</table>

**Note:**
- Functions are invoked synchronously with 6MB of data per invocation. If data exceeds 6MB, then the service connector invokes the function again to move the over-limit data. Such over-limit invocations are handled sequentially.
- Functions can execute for up to five minutes.
- Do not return data from Functions targets to service connectors. Service Connector Hub does not read data returned from Functions targets.

| Logging Analytics | Log Group: Select the log group you want. |
### Target service

**Monitoring**

### Additional fields

#### Note:
- Do not use the reserved `oci_` prefix for new metric namespaces and names. Metrics are not ingested when reserved prefixes are used. See [Publishing Custom Metrics](#) on page 3521 and [PostMetricData Reference (API)](#).
- When typing a new metric namespace or name, press ENTER to submit it.

**Namespace**: Select the metric namespace that includes the metric you want. It can be an existing or new namespace.

**Metric Name**: Select the name of the metric that you want to send the data to. It can be an existing or new metric.

**What's included with your metric**

The following dimensions are included with your metric:

- **connectorId**: The OCID of the service connector that the metrics apply to.
- **connectorName**: The name of the service connector that the metrics apply to.
- **connectorSourceType**: The source service that the metrics apply to.

The timestamp of each metric data point is the timestamp of the corresponding log message.
<table>
<thead>
<tr>
<th>Target service</th>
<th>Additional fields</th>
</tr>
</thead>
</table>
| **Notifications** | Note:  
Log Group for Notifications is limited to Audit.  
**Topic**: Select the name of the topic that you want to send the data to.  
Note:  
SMS messages exhibit unexpected results for certain service connector configurations. This issue is limited to topics that contain SMS subscriptions for the indicated service connector configurations. For more information, see Multiple SMS Messages for a Single Notification.  
**Message Format**: Select the option you want:  
Note:  
Message Format is available for service connectors with Logging source only. Not available for service connectors with function tasks. When this option is not available, messages are sent as raw JSON blobs.  
• **Send formatted messages**: Simplified, user-friendly layout.  
Note:  
To view supported subscription protocols and message types for formatted messages, see Friendly Formatting.  
• **Send raw messages**: Raw JSON blob. |
| **Object Storage** | **Bucket**: Select the name of the bucket that you want to send the data to.  
Note:  
Batch rollover details:  
• Batch rollover size: 100 MB  
• Batch rollover time: 7 minutes  
Files saved to Object Storage are compressed using gzip. |
Service Connector Hub

### Target service

<table>
<thead>
<tr>
<th>Stream</th>
<th>Additional fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Streaming</td>
<td>Stream: Select the name of the stream that you want to send the data to.</td>
</tr>
</tbody>
</table>

- **Show Advanced Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

**Default policies** are offered for any authorization required for this service connector to access source, task, and target services.

You can get this authorization through these default policies or through group-based policies. The default policies are offered whenever you use the Console to create or edit a service connector. The only exception is when the exact policy already exists in IAM, in which case the default policy is not offered. For more information about this authorization requirement, see Authentication and Authorization on page 4754.

5. To accept default policies, click the Create link provided for each default policy.

```
Note: If you don't have permissions to accept default policies, contact your administrator.
```

View links are provided for you to optionally review the newly created policies.

6. Click Create to create the service connector.

Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

### To edit a service connector

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click Edit.
5. Make your changes.

```
Note: If you did not previously create the default access policy to allow this service connector to write to the target service, you can do so now. You can get this authorization through these default policies or through group-based policies. The default policies are offered whenever you use the Console to create or edit a service connector. The only exception is when the exact policy already exists in IAM, in which case the default policy is not offered. For more information about this authorization requirement, see Authentication and Authorization on page 4754.
```

6. Click Save Changes.

If you updated the source service or tasks, then data movement may pause for a few minutes, as indicated by Data Freshness metrics. Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

### To update your service connector to use friendly message formats

Friendly message formats are available with service connectors that use Notifications as target.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click **Edit**.
5. Under **Configure target connection**, select the **Message Format** you want:
   - **Send formatted messages**: Simplified, user-friendly layout.
     
     **Note:**
     
     To view supported subscription protocols and message types for formatted messages, see **Friendly Formatting**.
   - **Send raw messages**: Raw JSON blob.
     
     **Note:**
     
     If you did not previously create the default access policy to allow this service connector to write to the target service, you can do so now. You can get this authorization through these default policies or through group-based policies. The default policies are offered whenever you use the Console to create or edit a service connector. The only exception is when the exact policy already exists in IAM, in which case the default policy is not offered. For more information about this authorization requirement, see **Authentication and Authorization** on page 4754.

6. Click **Save Changes**.

   If you updated the source service or tasks, then data movement may pause for a few minutes, as indicated by **Data Freshness metrics**. Within a few minutes, the service connector begins moving data according to its configuration. The service connector applies tasks to data from the source service and then moves the data to the target service.

### To activate a service connector

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to activate.
4. Click **Activate** and then confirm.

   The service connector immediately begins moving data according to its configuration, applying tasks to data in the source service and then moving the data to the target service.

### To deactivate a service connector

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to deactivate.
4. Click **Deactivate** and then confirm.

   The service connector stops moving data.

### To move a service connector to another compartment

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to edit.
4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

**To delete a service connector**

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Service Connector Hub**.
2. Choose the **Compartment** containing the service connector.
3. Click the name of the service connector you want to deactivate.
4. Click **Delete** and then confirm.

   The service connector stops moving data.

**Using the Command Line Interface (CLI)**

**To list service connectors**

Open a command prompt and run `oci sch service-connector list` to list service connectors in the specified compartment:

```
oci sch service-connector list --compartment-id <compartment_OCID>
```

**To get a service connector**

Open a command prompt and run `oci sch service-connector get` to get the specified service connector:

```
oci sch service-connector get --service-connector-id <service_connector_OCID>
```

**To create a service connector**

Open a command prompt and run `oci sch service-connector create` to create a service connector:

```
oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
```

**To edit a service connector**

Open a command prompt and run `oci sch service-connector update` to edit a service connector:

```
oci sch service-connector update --service-connector-id <service_connector_OCID> --display-name "<display_name>" --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
```

**To activate a service connector**

Open a command prompt and run `oci sch service-connector activate` to activate the specified service connector:

```
oci sch service-connector activate --service-connector-id <service_connector_OCID>
```

**To deactivate a service connector**

Open a command prompt and run `oci sch service-connector deactivate` to deactivate the specified service connector:

```
oci sch service-connector deactivate --service-connector-id <service_connector_OCID>
```
To move a service connector to another compartment

Open a command prompt and run `oci sch service-connector change-compartment` to move the service connector to the specified compartment:

`oci sch service-connector change-compartment --service-connector-id <service_connector_OCID> --compartment-id <destination_compartment_OCID>`

To delete a service connector

Open a command prompt and run `oci sch service-connector delete` to delete the specified service connector:

`oci sch service-connector delete --service-connector-id <service_connector_OCID>`

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage service connectors:

- ActivateServiceConnector
- ChangeServiceConnectorCompartment
- CreateServiceConnector
- DeactivateServiceConnector
- DeleteServiceConnector
- GetServiceConnector
- ListServiceConnectors
- UpdateServiceConnector

Use these API operations to manage work requests:

- GetWorkRequest
- ListWorkRequests
- ListWorkRequestErrors
- ListWorkRequestLogs

Service Connector Hub Scenarios

Here are a few basic scenarios to help you understand the Service Connector Hub service and generally how the components work together.

**Scenario: Alarm on Log Data** on page 4767

**Scenario: Send Log Data to an Autonomous Database** on page 4772

**Scenario: Archive Logs to Object Storage** on page 4776

**Scenario: Analyze Logs** on page 4778

**Scenario: Alarm on Log Data**

This topic explains how to set up alarms for log data.

This scenario involves creating a service connector and an alarm. The `service connector (Service Connector Hub)` processes and moves log data from Logging to Monitoring while the `alarm` fires when triggered by received log data.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring and Notifications.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This section walks through creating a service connector and an alarm using the Console and then updating the topic created with the alarm.

Note:
Another workflow for this scenario involves creating your topic and subscriptions first, then selecting this topic when you create your alarm.

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780 and Troubleshooting Notifications on page 4283.

Task 1: Create the service connector

This example walks through using the Console to create a service connector that filters VCN flow log data from Logging for rejected traffic and then moves this log data to a new metric in Monitoring.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the **Create Service Connector** page, filter **VCN flow log data** to a new metric:

- Type a **Connector Name** such as "VCN Flow Log Errors." Avoid entering confidential information.
- Select the **Resource Compartment** where you want to store the new service connector.
- Under **Configure Service Connector**, select your source and target services to move log data to a metric:
  - **Select Source**: Logging
  - **Select Target**: Monitoring
- Under **Configure source connection**, select your **VCN flow log**:
  - **Compartment**: The compartment containing the VCN flow log data.
  - **Log Group**: The log group containing the VCN flow log data.
  - **Logs**: The log object name for your VCN flow logs.
- Under **Configure task**, filter the log data to rejected traffic:
  - **Property**: data.action
  - **Operator**: =
  - **Value**: REJECT

If you are interested in rejected traffic for a particular port or address, add another filter. For example, select the property **data.destinationPort** or **data.destinationAddress**.

- Under **Configure target connection**, enter the metric namespace and metric name that you want to use for the filtered log data:
  - Select the **Service Compartment** where you want to store the metric data points corresponding to the VCN flow log data for rejected traffic.
  - Enter a new **Namespace**: vcnlogs.

  **Note:**
  When typing a new metric namespace, press ENTER to submit it.

  - Enter a new **Metric Name**: rejectedtraffic

5. If prompted to create a policy (required for access to create or update a service connector), click **Create**.

6. Click **Create**.

**Task 2: Create the alarm**

This example walks through using the Console to create an alarm that sends a message when Monitoring receives metric data points corresponding to VCN flow log data for rejected traffic. During this process, you'll create a topic and an email subscription.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.

2. Click **Create alarm**.

3. On the **Create Alarm** page, under **Define alarm**, set up your threshold:

   - **Metric description**:
     - **Compartment**: (select the *compartment* specified in the previous task, where you are storing the metric data points corresponding to the VCN flow log data)
     - **Metric Namespace**: (enter the metric namespace that you specified in the service connector)
     - **Metric Name**: (enter the metric name that you specified in the service connector)
     - **Interval**: 1m
     - **Statistic**: Count
   - **Trigger rule**:
     - **Operator**: greater than
     - **Value**: 0
     - **Trigger Delay Minutes**: 1
4. Under **Notifications, Destinations**, set up an email notification:
   - **Destination Service**: **Notifications Service**
   - **Compartment**: (select the *compartment* where you want to create the topic and associated subscriptions)
   - **Topic**: Click **Create a topic**

   **Note:**
   If you already created your topic and email subscription, you can select that topic here instead of creating a new one.

   - **Topic Name**: Rejected Traffic Topic
   - **Subscription Protocol**: Email
   - **Email Addresses**: (type your email address here)

5. Click **Save alarm**.

### Using the CLI

This section walks through creating the service connector, topic, subscriptions, and alarm using the CLI.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

1. Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

   ```
   oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment OCID> --source [<source_in_JSON>] --tasks [<tasks_in_JSON>] --target [<targets_in_JSON>]
   ```

2. Create a topic: Open a command prompt and run the `oci ons topic create` command:

   ```
   oci ons topic create --name "Alarm Topic" --compartment-id "<compartment-ocid>"
   ```

3. To this topic, add a subscription referencing your email address. Open a command prompt and run the `oci ons subscription create` command:

   ```
   oci ons subscription create --compartment-id "<compartment-ocid>" --topic-id "<topic-ocid>" --protocol "EMAIL" --subscription-endpoint "john.smith@example.com"
   ```

4. Create an alarm that defines the error threshold and references this topic as the destination: Open a command prompt and run the `oci monitoring alarm create` command:

   ```
   oci monitoring alarm create --display-name "My Alarm" --compartment-id "<compartment-ocid>" --metric-compartment-id "<compartment-ocid>" --namespace "oci_computeagent" --query-text "<yourmetric>[1m].count() > 0" --severity "INFO" --destinations "<topic-ocid>" --is-enabled true
   ```

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780 and Troubleshooting Notifications on page 4283.

### Using the API

This section walks through creating the service connector, topic, subscription, and alarm using the API.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:
1. **CreateServiceConnector**: Create a service connector.

**Example CreateServiceConnector request**

```json
POST /20200909/serviceConnectors
Host: service-connector-hub.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "compartmentId": "<compartment_OCID>",
    "description": "My service connector description",
    "displayName": "My Service Connector",
    "source": {
        "kind": "logging",
        "logSources": [
            {
                "compartmentId": "<compartment_OCID>",
                "logGroupId": "<log_group_OCID>",
                "logId": "<log_OCID>"
            }
        ],
    },
    "target": {
        "compartmentId": "<compartment_OCID>",
        "kind": "metrics",
        "metric": "<yourmetric>",
        "metricNamespace": "<yournamespace>"
    },
    "tasks": [
        {
            "condition": "data.action='REJECT'",
            "kind": "logRule"
        }
    ]
}
```

2. **CreateTopic**: Create a topic.

**Example CreateTopic request**

```json
POST /20181201/topics
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "name": "Alarm Topic",
    "compartmentId": "<compartment_OCID>"
}
```

3. **CreateSubscription**: To this topic, add a subscription referencing your email address.

**Example CreateSubscription request: Email**

```json
POST /20181201/subscriptions
Host: notification.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "topicId": "<topic_OCID>",
    "compartmentId": "<compartment_OCID>",
    "protocol": "EMAIL",
    "endpoint": "john.smith@example.com"
}
```
4. **CreateAlarm**: Create an alarm that defines the memory threshold and references this topic.

   **Example CreateAlarm request**

   ```
   POST /20180401/alarms
   Host: telemetry.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
     "displayName": "My Alarm",
     "compartmentId": "<compartment_OCID>",
     "metricCompartmentId": "<compartment_OCID>",
     "namespace": "<yournamespace>",
     "query": "<yourmetric>[1m].count() > 0",
     "severity": "INFO",
     "destinations":
     [
       "<topic_OCID>",
     ],
     "isEnabled": true
   }
   ```

   For help with troubleshooting, see Troubleshooting Service Connectors on page 4780 and Troubleshooting Notifications on page 4283.

**Scenario: Send Log Data to an Autonomous Database**

This topic explains how to send log data from Logging to an Autonomous Database using a function (Functions service).

This scenario involves creating a **function** and then referencing that function in a **service connector (Service Connector Hub)** to process and move log data from Logging to an Autonomous Database.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to **Functions**.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

**Setting Up This Scenario**

This scenario involves creating a **service connector (Service Connector Hub)** to send log data from Logging to an Autonomous Database (JSON).

Before you can create the service connector, you must set up an Autonomous JSON Database that you want to receive the log data and set up the function to copy that log data.

Autonomous JSON Database setup details:

- **Create the Autonomous JSON Database**
- Copy the ORDS base URL: From the detail page for the Autonomous Database, click **Service Console**, click **Development**, and then click **Copy URL** under **RESTful Services and SODA**.
• Create a "logs" collection to store the log data that will be moved by the function and service connector:

1. Go to the detail page for the Autonomous Database.
2. Click Tools and then click Open SQL Developer Web.
3. Log in with the admin user and the password you set when you created the database.
4. In SQL Developer Web, enter the following command:

   ```sql
   soda create logs
   ```

5. Click Run Statement.

To query documents in the collection after the service connector copies log data, enter the following command:

```sql
soda get logs -f {}
```

Function setup details:

• Create the function
• Deploy the function
• Set the configuration values as follows:
  • ordsbaseurl
    Use the ORDS base URL you copied during setup of the database.
  • dbschema
  • dbuser
  • dbpwd
  • collection

For more information, see Passing Custom Configuration Parameters to Functions on page 2707.

• (Optional) Invoke the function

Once the database and function are set up, you're ready to create the service connector. Creating the service connector is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Function code sample

The following code sample is for a function to send log data from the Logging service to an Autonomous Database. For instructions on creating and deploying functions, see Creating and Deploying Functions on page 2684.

```python
import io
import json
import logging
import requests
from fdk import response

# soda_insert uses the Autonomous Database REST API to insert JSON documents
def soda_insert(ordsbaseurl, dbschema, dbuser, dbpwd, collection, logentries):
    auth=(dbuser, dbpwd)
    sodaurl = ordsbaseurl + dbschema + '/soda/latest/
    bulkinserturl = sodaurl + 'custom-actions/insert/' + collection + "/
    headers = {'Content-Type': 'application/json'}
    resp = requests.post(bulkinserturl, auth=auth, headers=headers, data=json.dumps(logentries))
    return resp.json()
```

Note:
The following code sample is not meant for production workloads. Update it for your production environment.
def handler(ctx, data: io.BytesIO=None):
    logger = logging.getLogger()
    logger.info("function start")

    # Retrieving the Function configuration values
    try:
        cfg = dict(ctx.Config())
        ordsbaseurl = cfg["ordsbaseurl"]
        dbschema = cfg["dbschema"]
        dbuser = cfg["dbuser"]
        dbpwd = cfg["dbpwd"]
        collection = cfg["collection"]
    except:
        logger.error('Missing configuration keys: ordsbaseurl, dbschema, dbuser, dbpwd and collection')
        raise

    # Retrieving the log entries from Service Connector Hub as part of the Function payload
    try:
        logentries = json.loads(data.getvalue())
        if not isinstance(logentries, list):
            raise ValueError
    except:
        logger.error('Invalid payload')
        raise

    # The log entries are in a list of dictionaries. We can iterate over the list of entries and process them.
    # For example, we are going to put the Id of the log entries in the function execution log
    logger.info("Processing the following LogIds:")
    for logentry in logentries:
        logger.info(logentry["oracle"]["logid"])    
    
    # Now, we are inserting the log entries in the JSON Database
    resp = soda_insert(ordsbaseurl, dbschema, dbuser, dbpwd, collection, logentries)
    logger.info(resp)
    if "items" in resp:
        logger.info("Logs are successfully inserted")
    else:
        raise Exception("Error while inserting logs into the database: " + json.dumps(resp))

    # The function is done, we don't return any response because it would be useless
    logger.info("function end")
    return response.Response(
        ctx,
        response_data="",
        headers={"Content-Type": "application/json"}
    )

Using the Console

This section walks through creating a service connector using the Console. Your function must be deployed.

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780.
Create a service connector

This example walks through using the Console to create a service connector. In this example, the service connector moves log data from Logging to an Autonomous Database using the function you created using the function code sample.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the Create Service Connector page:
   - Type a Connector Name such as "Send Logs to My Autonomous Database." Avoid entering confidential information.
   - Select the Resource Compartment where you want to store the new service connector.
   - Under Configure Service Connector, select your source and target services to move log data to a metric:
     - Select Source: Logging
     - Select Target: Functions
   - Under Configure source connection, select a Compartment Name, Log Group, and Log.
   - Under Configure target connection, select the Function Application and Function corresponding to the function you created using the function code sample.
5. If prompted to create a policy (required for access to create or update a service connector), click Create.
6. Click Create.

Using the CLI

This section walks through creating a service connector using the CLI that moves log data to your function (which then moves the data to an Autonomous Database).

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

• Create a service connector: Open a command prompt and run the oci sch service-connector create command:

```
oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source 
[<source_in_JSON>] --tasks [/<tasks_in_JSON>] --target [/<targets_in_JSON>]
```

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780.

Using the API

This section walks through creating the service connector using the API.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:
• CreateServiceConnector: Create a service connector that moves log data to your function (which then moves the data to an Autonomous Database).

Example CreateServiceConnector request

```
POST /20200909/serviceConnectors
Host: service-connector-hub.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
   "compartmentId": "<compartment_OCID>",
   "description": "My service connector description",
   "displayName": "My Service Connector",
   "source": {
```
Scenario: Archive Logs to Object Storage

This topic explains how to archive log data to a bucket in Object Storage.

This scenario involves creating a service connector. The service connector processes and moves log data from Logging to Object Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Monitoring, Notifications, and Object Storage.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This example walks through using the Console to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780.

Create the service connector

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the **Create Service Connector** page, send subnet log data to a bucket:
   - Type a **Connector Name**, such as "Archive Logs." Avoid entering confidential information.
   - Select the **Resource Compartment** where you want to store the new service connector.
   - Under **Configure Service Connector**, select your source and target services to move log data to a metric:
     - **Select Source**: Logging
     - **Select Target**: Object Storage
   - Under **Configure source connection**, select your subnet log:
     - **Compartment**: The compartment containing the log data you want.
     - **Log Group**: The log group containing the log data you want.
     - **Logs**: The log object name for the log data you want.
   - Under **Configure target connection**, select the bucket where you want to archive this log data:
     - **Select the Service Compartment** where you want to store the received (filtered) log data.
     - **Select the Bucket** you want.

5. If prompted to create a policy (required for access to create or update a service connector), click **Create**.

6. Click **Create**.

**Using the CLI**

This example walks through using the CLI to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

- Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

  ```bash
  oci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source ...
  ```

  For help with troubleshooting, see Troubleshooting Service Connectors on page 4780.

**Using the API**

This example walks through using the API to create a service connector that receives subnet log data from Logging and then moves this data to a bucket in Object Storage.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

- **CreateServiceConnector**: Create a service connector.

**Example CreateServiceConnector request**

```
POST /20200909/serviceConnectors
Host: service-connector-hub.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "compartmentId": "<compartment_OCID>",
    "description": "My service connector description",
    "displayName": "My Service Connector",
    "source": {
        "kind": "logging",
        "logSources": [
            {
                "compartmentId": "<compartment_OCID>",
                "logGroupId": "<log_group_OCID>",
            }
        ]
    }
}
Scenario: Analyze Logs

This topic explains how to send log data to Logging Analytics.

This scenario involves creating a log group and a service connector. The service connector (Service Connector Hub) processes and moves log data from Logging to the log group in Logging Analytics.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to execute this scenario. Otherwise, you need access to Logging Analytics to create the log group and access to Service Connector Hub to create the service connector.

The workflow for creating the service connector includes a default policy when needed to provide permission for writing to the target service.

Setting Up This Scenario

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure CLI or API, which lets you execute the individual operations yourself.

Using the Console

This section walks through creating a log group and a service connector using the Console.

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780.

Task 1: Create the log group

Use Logging Analytics to create the log group. For instructions, see Create Log Groups.

Task 2: Create the service connector

This example walks through using the Console to create a service connector that sends log data from Logging to the log group you created using Logging Analytics. In this example, the service connector filters VCN flow log data.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the Compartment where you want to create the service connector.
3. Click Create Service Connector.
4. On the Create Service Connector page, filter VCN flow log data to your log group:
   - Type a Connector Name such as "VCN Flow Log Error Analysis."
   - Select the Resource Compartment where you want to store the new service connector.
   - Under Configure Service Connector, select your source and target services to move log data to the log group:
     - Select Source: Logging
     - Select Target: Logging Analytics
   - Under Configure source connection, select your VCN flow log:
     - Compartment: The compartment containing the VCN flow log data.
     - Log Group: The log group containing the VCN flow log data.
     - Logs: The log object name for your VCN flow logs.
   - Under Configure task, filter the log data to rejected traffic:
     - Property: data.action
     - Operator: =
     - Value: REJECT

   If you are interested in rejected traffic for a particular port or address, add another filter. For example, select the property data.destinationPort or data.destinationAddress.
   - Under Configure target connection, enter the log group that you want to send the filtered log data to:
     - Select the Service Compartment containing the log group.
     - Select the Logging Analytics Log Group (the log group you created).

5. If prompted to create a policy (required for access to create or update a service connector), click Create.
6. Click Create.

Using the CLI

This section walks through creating the log group and service connector using the CLI.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

1. Create a log group: Open a command prompt and run the `oci log-analytics log-group create` command:

   ```bash
coci log-analytics log-group create --display-name "<display_name>" --compartment-id <compartment_OCID> --namespace-name "<namespace_name>"
   ```

2. Create a service connector: Open a command prompt and run the `oci sch service-connector create` command:

   ```bash
coci sch service-connector create --display-name "<display_name>" --compartment-id <compartment_OCID> --source [source_in_JSON] --tasks [tasks_in_JSON] --target [targets_in_JSON]
   ```

For help with troubleshooting, see Troubleshooting Service Connectors on page 4780 and Troubleshooting Notifications on page 4283.

Using the API

This section walks through creating the log group and service connector using the API.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:
1. **CreateLogAnalyticsLogGroup**: Create a log group.

   **Example CreateLogAnalyticsLogGroup request**
   ```
   post /20200601/namespaces/<namespaceName>/logAnalyticsLogGroups
   Host: loganalytics.us-phoenix-1.oci.oraclecloud.com
   <authorization and other headers>
   {
       "compartmentId": "<compartment_OCID>",
       "displayName": "My Log Group"
   }
   ```

2. **CreateServiceConnector**: Create a service connector.

   **Example CreateServiceConnector request**
   ```
   POST /20200909/serviceConnectors
   Host: service-connector-hub.us-phoenix-1.oraclecloud.com
   <authorization and other headers>
   {
       "compartmentId": "<compartment_OCID>",
       "description": "My service connector description",
       "displayName": "My Service Connector",
       "source": {
           "kind": "logging",
           "logSources": [
               {
                   "compartmentId": "<compartment_OCID>",
                   "logGroupId": "<log_group_OCID>",
                   "logId": "<log_OCID>"
               }
           ],
           "target": {
               "compartmentId": "<compartment_OCID>",
               "kind": "loggingAnalytics",
               "logGroupId": "<logging_analytics_log_group_OCID>"
           },
           "tasks": [
               {
                   "condition": "data.action='REJECT'",
                   "kind": "logRule"
               }
           ]
       }
   }
   ```

For help with troubleshooting, see [Troubleshooting Service Connectors](#) on page 4780 and [Troubleshooting Notifications](#) on page 4283.

**Troubleshooting Service Connectors**

This topic covers troubleshooting techniques for Service Connector Hub.

**No data is being moved**

This section provides troubleshooting information for service connectors that don't appear to be moving data. For example service connectors, see [Service Connector Hub Scenarios](#) on page 4767.

Check these items:
- **Error metrics**: Determine if errors exist at the source service, target service or Service Connector Hub service.

  **To view error metrics for a service connector**

  1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Service Connector Hub**.
  2. Choose the **Compartment** that contains the service connector you want to view, and then click the service connector's name.
  3. In the **Resources** menu, click **Metrics** (if necessary).

    The **Metrics** page displays a default set of charts for the current service connector.

  4. Review the following metric charts:

    - Errors at Source
    - Errors at Target
    - Service Connector Hub Errors

- **Authorization to write to the target service**: Make sure you have authorization, either through the default policy offered when creating or updating the service connector or through a group-based policy. See **Access to Source, Task, and Target Services** on page 4755.

  **Note:**

  Your accepted default policies might take a few minutes to propagate to regions that are not your home region. The service connector does not move data until the policies are propagated.

**I can't view my query in Basic mode**

Check these items:

- **Query simplicity**: Update the query so that it only includes elements supported in Basic mode:

  - **Audit logs only**: Type-based filters can use the OR operator. Other filters must use the AND operator.

    Example:

    ```
    ((type = value1 OR type = value2) AND field = value3 AND field1 = value4)
    ```

  - **Any combination of logs (Service logs, custom logs, and Audit logs)**: Filters joined with the AND operator.

    Example:

    ```
    (field = value AND field1 != value1)
    ```

  Examples of query complexity that are not supported in Basic mode:

  - OR operator (except with type-based filters when only Audit logs are used)
  - Functions (for example: `isNull()`)
  - `select`
  - `summarize`

**How do I know when issues occur?**

Check these items:
• **Data freshness**: Look for unexpected lapses of time between data movement.

**To view data freshness for a service connector**

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Service Connector Hub.
2. Choose the **Compartment** that contains the service connector you want to view, and then click the service connector's name.
3. In the **Resources** menu, click **Metrics** (if necessary).

   The **Metrics** page displays a default set of charts for the current service connector.
4. Review the following metric charts:
   - **Data Freshness**

**To view data freshness for all service connectors in the tenancy**

2. For **Metric Namespace**, select oci_service_connector_hub.
3. Review the following metric charts:
   - **Data Freshness**

**Viewing the State of a Work Request**

This topic describes how to view the state of work requests associated with a given service connector.

**Note:**

The Service Connector Hub service does not use the common Work Requests API to support work request operations. Instead, Service Connector Hub work requests are supported by the Service Connector Hub API. See Using the Console to View Work Requests on page 303 for information on viewing work requests for other services.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

**Monitoring Work Requests**

Many of the Service Connector Hub service requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment. To provide visibility for in-progress workflows, the Service Connector Hub service creates a work request object.

The work request states are:

**ACCEPTED**

The request is in the work request queue to be processed.

**IN_PROGRESS**

A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.

**SUCCEEDED**

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.
FAILED

A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

CANCELING

The work request is in the process of canceling.

CANCELED

The work request has been canceled.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these operations to monitor the state of work requests:

- GetWorkRequest
- ListWorkRequests
- ListWorkRequestErrors
- ListWorkRequestLogs

Example Messages

This topic shows examples of messages sent by service connectors that use Notifications as target.

A service connector with a Notifications target sends messages to all subscriptions for the specified topic. The contents and appearance of each message depends on the subscription protocol, such as Email.

For friendly formatting of email messages, select Formatted for the service connector's message format.

Email (Raw) and Slack

You are receiving notifications as a subscriber to the topic: sch_integ_test_topic_email (Topic OCID: ocid1.onstopic.oc1.ap-chuncheon-1.exampleid). To stop receiving notifications from this topic, unsubscribe.

Please do not reply directly to this email. If you have any questions or comments regarding this email, contact your account administrator.
You can monitor the health, capacity, and performance of your service connectors by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the Service Connector Hub service in the oci_service_connector_hub metric namespace.

Resources: Service connectors.

Overview of the Service Connector Hub Service Metrics

The Service Connector Hub service metrics help you measure the number and type of connections between services in Oracle Cloud Infrastructure. You can use metrics data to diagnose and troubleshoot service connector issues.

To view a default set of metrics charts in the Console, navigate to the service connector you're interested in, and then click Metrics. You can also use the Monitoring service to create custom queries.
Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Administrators: For common policies that give groups access to Service Connector Hub, see Allow a group to manage service connectors on page 2825.

Available Metrics: oci_service_connector_hub

The metrics listed in the following tables are automatically available for any service connectors you create. You do not need to enable monitoring on the resource to get these metrics.

Service Connector Hub service metrics include the following dimensions:

- **connectorId**
  The OCID of the service connector that the metrics apply to.

- **connectorName**
  The name of the service connector that the metrics apply to.

- **errorType**
  The type of error.

  **Note:**

  For information about common errors, see API Errors on page 5532.

- **partitionId**
  The partition of the stream that the metrics apply to.

- **region**
  The region that the metrics apply to.

- **sourceName**
  The name of the source service that the metrics apply to.

- **targetName**
  The name of the target service that the metrics apply to.

- **taskName**
  The name of the task service that the metrics apply to.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>BytesReadFromSource</td>
<td>Bytes Read from Source</td>
<td>Bytes</td>
<td>Number of bytes read from the source.</td>
<td>connectorId, connectorName</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Note: The value for this metric is cumulative. For example, when a service connector reads 1MB from the source, the service connector emits a BytesReadFromSource metric with a value of 1MB. However, let's say that the service connector is unable to write to the target. The next time the service connector reads (1MB) from the source, it will emit a BytesReadFromSource metric with a cumulative value of 2MB, which includes the 1MB from the first read. Let's say the service connector successfully writes to the target. The third time the service connector reads (1MB) from the source, it will emit the BytesReadFromSource metric with a cumulative value of 1MB.</td>
<td>partitionId, region, sourceName</td>
</tr>
<tr>

</tr>
<tr>
<td>BytesWrittenToTarget</td>
<td><strong>Bytes Written to Target</strong></td>
<td>Bytes</td>
<td>Number of bytes written to the target</td>
<td>connectorId region targetName</td>
</tr>
</tbody>
</table>

**Note:**

Use this metric as a general indicator of success. BytesWrittenToTarget may not match BytesReadFromSource for data read from Logging to the following target services.

- Monitoring may translate multiple records into a single metric data point.
- Object Storage compresses data. For example, 10MB read may be converted into 1MB written.

<tr>
<td>MessagesReadFromSource</td>
<td>Messages Read from Source</td>
<td>Count</td>
<td>Number of records read from the source</td>
<td>connectorId, connectorName, partitionId, region, sourceName</td>
</tr>
</tbody>
</table>

**Note:**
The value for this metric is cumulative. For example, when a service connector reads a single message from the source, the service connector emits a `MessagesReadFromSource` metric with a value of 1. However, let's say that the service connector is unable to write to the target. The next time the service connector reads (1 message) from the source, it will emit a `MessagesReadFromSource` metric with a cumulative value of 2, which includes the message from the first read. Let's say the service connector successfully writes to the target. The third time the service connector reads (1 message) from the source, it will emit the `MessagesReadFromSource` metric with a cumulative value of 1.

### Using the Console

**To view default metric charts for a single service connector**

1. Open the navigation menu and click *Analytics & AI*. Under *Messaging*, click *Service Connector Hub*.
2. Choose the *Compartment* that contains the service connector you want to view, and then click the service connector's name.
3. In the *Resources* menu, click *Metrics* (if necessary).

   The *Metrics* page displays a default set of charts for the current service connector.

For more information about monitoring metrics and using alarms, see *Monitoring* on page 3458. For information about notifications for alarms, see *Notifications Overview* on page 4248.

**To view default metric charts for multiple service connectors**

2. For *Metric Namespace*, select *oci_service_connector_hub*.

   The *Service Metrics* page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoringservice to create custom queries.

For more information about monitoring metrics and using alarms, see *Monitoring* on page 3458. For information about notifications for alarms, see *Notifications Overview* on page 4248.

### Using the API

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

### Query Reference for Service Connector Hub

Service Connector Hub supports a subset of the *Logging Query Language Specification* on page 3431.

Stream expressions are limited to following streaming operators:

- **search**

  Constructs a log stream from actual log objects.

  Example:

  ```
  search "<compartment_OCID>/loggroup1/logname1" "<compartment_OCID>/loggroup2/logname2" "<compartment_OCID>/loggroup3/logname3"
  ```

- **where**

  Filters the current log stream using a Boolean expression.

  Example 1:

  ```
  search "<compartment_OCID>/Audit"
  | where type = 'com.oraclecloud.objectstorage.deleteobject'
  ```
Example 2: Complex Boolean expression:

```cpp
search "<compartment_OCID>/Audit"
  | where type = 'com.oraclecloud.objectstorage.deleteobject' or 'com.oraclecloud.objectstorage.getobject'
  | where source = 'myBucket'
output:
  {"specversion": "1.0", "type": "com.oraclecloud.objectstorage.deleteobject", "source": "<compartment_OCID>/myBucket",.....}
  {"specversion": "1.0", "type": "com.oraclecloud.objectstorage.getobject", "source": "<compartment_OCID>/myBucket",.....}
```

Example 3: search without where:

```cpp
search "<compartment_OCID>/application"
  | level = 'ERROR'
```

Example 4: Full text search. You can perform a full text search by specifying a filter on the entire content of the log. A search on logContent returns any log line where a value matches your string. This functionality supports wildcards:

```cpp
search "<compartment_OCID>/application"
  | where logContent = 'ERROR' -- returns log lines with a value matching "ERROR"

search "<compartment_OCID>/application"
  | where logContent = '*ERROR*' -- returns log lines with a value containing "ERROR"
```

Functions are limited to scalar functions.
This chapter explains how to use Storage Gateway to connect your on-premise applications with Oracle Cloud Infrastructure.

Overview of Storage Gateway

Storage Gateway is a cloud storage gateway that lets you connect your on-premises applications with Oracle Cloud Infrastructure. Applications that can write data to an NFS target can also write data to the Oracle Cloud Infrastructure Object Storage, without requiring application modification to uptake the REST APIs.

Important:

Storage Gateway is the evolution of the Storage Software Appliance that was launched with Oracle Cloud Infrastructure Classic. By migrating to Oracle Cloud Infrastructure Object Storage, you are using Storage Gateway with its enhanced file-to-object transparency and improved scale and performance.

Availability

The Storage Gateway service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Storage Gateway and Oracle Cloud Infrastructure Concepts

The following concepts are essential to working with Oracle Cloud Infrastructure Storage Gateway.

FILE SYSTEM

A Storage Gateway file system on a local host maps its files and directories to objects with the same names in a corresponding Oracle Cloud Infrastructure Object Storage bucket.

FILE SYSTEM CACHE

Storage Gateway's configurable file system cache enables asynchronous and optimized movement of data to the cloud. The file system cache serves as both a write buffer and a read cache for data storage and retrieval. The write buffer contains data that copied to the disk cache and queued for upload to Oracle Cloud Infrastructure. The read cache contains frequently retrieved data that’s accessible locally for read operations. Proper file system cache configuration is critical to Storage Gateway performance. See Configuring the Cache for File Systems on page 4804 for details.

METADATA

The metadata associated with a Storage Gateway file is stored as custom metadata for the corresponding object in Oracle Cloud Infrastructure Object Storage. Examples of file metadata include object id, creation date, modification date, size, and permissions. Storage Gateway caches all metadata for the file system locally.
NFSV4

NFS is an established and widely adopted distributed file system protocol for handling network storage. NFS lets client computers mount file systems on remote servers and access those remote file systems over the network as though they were local file systems. Storage Gateway performs the NFS to REST API translation needed to interact with Oracle Cloud Infrastructure Object Storage.

ORACLE CLOUD INFRASTRUCTURE

Oracle Cloud Infrastructure is a set of complementary cloud services that lets you build and run a wide range of applications and services in a highly available hosted environment. Oracle Cloud Infrastructure offers high-performance compute capabilities (as physical hardware instances) and storage capacity in a flexible overlay virtual network that is securely accessible from your on#premises network.

TENANCY

A tenancy is a secure and isolated partition within Oracle Cloud Infrastructure where you can create, organize, and administer your cloud resources.

OBJECT STORAGE AND ARCHIVE STORAGE

Oracle Cloud Infrastructure offers two distinct storage tiers for you to store your unstructured data. Use the Object Storage Standard tier for data to which you need fast, immediate, and frequent access. Use the Archive Storage service's Archive tier for data that you access infrequently, but which must be preserved for long periods of time. Both storage tiers use the same manageable resources (for example, objects and buckets). The difference is that when you upload a file to Archive Storage, the object is immediately archived. Before you can access an archived object, you must first restore the object to the Standard tier.

Note:

In the Storage Gateway documentation, generic references to Object Storage encompass both the Standard and Archive storage tiers.

Both storage tiers are simple to use, perform well, and scale to an unlimited capacity.

bucket

An Object Storage bucket is a logical container for storing objects. A file system created in Storage Gateway maps to a corresponding bucket by the same name in Object Storage. A bucket is associated with a single Oracle Cloud Infrastructure compartment. The compartment has policies that determine what actions a user can perform on the bucket the objects it contains.

object

An individual file or directory written to a Storage Gateway file system on an NFS share creates an identically named object in the target Object Storage bucket. An object is composed of the object itself and metadata about the object.

NAMESPACE

A logical entity that serves as a top-level container for all Oracle Cloud Infrastructure Object Storage buckets and objects. The namespace enables you to control bucket naming within your tenancy. Each tenancy has one unique and uneditable Object Storage namespace that is global, spanning all compartments and regions. Bucket names must be unique within your tenancy.

COMPARTMENT

A collection of Oracle Cloud Infrastructure-related resources. Only users and groups with access permissions explicitly granted by an administrator can access the resources. Compartments help you organize resources and make it easier to control access to those resources. Oracle Cloud Infrastructure automatically creates a root compartment when a tenancy is provisioned. An administrator can then create more compartments within the root compartment and add access rules for those compartments. A bucket can exist in only one compartment.
How Storage Gateway Works

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through file systems that you create in Storage Gateway.

Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket.

There is file-to-object transparency between Storage Gateway and Object Storage:

• A Storage Gateway file system directory on a local host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage.
• Any file written to a Storage Gateway file system is written as an object with the same name in the associated Object Storage bucket. The system stores associated file attributes as object metadata.
  
  The files written are uploaded to the associated Object Storage bucket asynchronously.
• You can access Object Storage objects directly using native APIs, SDKs, third-party tools, the HDFS connector, and the Oracle Cloud Infrastructure CLI and Console. You use the Refresh operation in Storage Gateway to ingest any data that was added or modified directly in Object Storage.

Enterprise applications typically work with files in nested directories. Object Storage buckets, and the objects within those buckets, exist in a flat hierarchy. Storage Gateway flattens the directory hierarchy into nested object prefixes in Object Storage. See Interacting With Object Storage on page 4812 for details.

FastConnect

Learn about using FastConnect with Storage Gateway tasks.

You can use Oracle Cloud Infrastructure FastConnect with your Storage Gateway tasks. FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

See FastConnect on page 4051 for more information.

Site-to-Site VPN

Learn about using Site-to-Site VPN with Storage Gateway tasks.

You can use Oracle Cloud Infrastructure Site-to-Site VPN with your Storage Gateway tasks. Site-to-Site VPN provides an IPSec connection between your on-premises network your virtual cloud network (VCN).

See Site-to-Site VPN on page 3808 for more information.

Recommended Uses and Workloads

The following summarizes some of the ways that you can use Storage Gateway.

DATA TRANSFER

Use Storage Gateway to move data from your on-premises host to Oracle Cloud Infrastructure. Storage Gateway is not a replacement for general-purpose network attached storage (NAS), though it behaves similarly to NAS. Use Storage Gateway's integrated Cloud Sync feature to transfer and synchronize data to Oracle Cloud Infrastructure.

CLOUD TIERING

Use Storage Gateway to expand the capacity of on-premises storage solutions without capital expenditures. Configuring and connecting a Storage Gateway file system with a large cache to Oracle Cloud Infrastructure Object Storage provides unlimited scale to create a workflow in which files get automatically moved to the cloud and retrieved only on demand. Even though on-demand retrieval is slower than access to local storage, capital expenditures or changes to existing tools and software are not required.
BACKUPS
Use Storage Gateway to move files to Oracle Cloud Infrastructure Archive Storage as a cost-effective backup solution. You can move individual files and compressed or uncompressed ZIP or TAR archives. Storing secondary copies of data is an ideal use case for Storage Gateway.

ARCHIVAL
Storage Gateway is ideal for archive use cases.

DISASTER RECOVERY
Storage Gateway lets traditional applications move data to highly durable object storage. When you need to recover data, create a fresh instance of Storage Gateway to return the data from Object Storage.

Uses and Workloads Not Supported
Storage Gateway does not support the following uses and workloads.

WINDOWS OPERATING SYSTEM
Storage Gateway does not currently support the Windows operating environment or Windows solutions.

Note:
See Ways to Access Object Storage on page 4292 for more information on accessing Object Storage. You can also consult with your architecture team on solutions for working with Windows and Oracle Cloud Infrastructure Object Storage.

GENERAL-PURPOSE NETWORK STORAGE
Storage Gateway isn’t a general-purpose storage filer and must not be used as a replacement for traditional network storage appliances.

FILE SYNC AND SHARE
Though Storage Gateway is an effective data mover, it’s not a replacement for file sync and share services. Evaluate Oracle services like Oracle Document Cloud service if you need file sync and share functionality.

CONTENT COLLABORATION
Storage Gateway does not support multiple Storage Gateway instances simultaneously reading from and writing to a single Object Storage bucket. Do not use Storage Gateway as a tool for distributed teams to collaborate on creating and managing content.

FREQUENTLY MODIFIED FILES
Do not use Storage Gateway if you expect your data to be modified frequently. Each time a file is modified and closed, Storage Gateway creates an updated version and uploads it to Object Storage as a new object. Frequently modified data results in substantial inefficiency, in terms of both bandwidth consumption and capacity utilization.

SYNCHRONOUS WORKLOADS
Storage Gateway asynchronously uploads files to your Object Storage bucket to offer eventual consistency. Files uploaded directly to an Object Storage bucket are not reflected back to the local Storage Gateway file system in real time. Click Refresh in the Storage Gateway management console or use autorefresh to ingest any data that was added or modified directly in Object Storage.

If autorefresh is configured at an aggressive interval, refreshes only occur when in-progress refreshes finish. That means the elapsed time between the beginning of any two successive refreshes is equal to the specified auto-refresh interval plus the time required to run a file system refresh, thus making the Storage Gateway NFS mount and Object Storage bucket contents asynchronous. Also, if any network connectivity issues exist, files uploaded directly to the bucket might not have synced.
See Managing File Systems on page 4827 for more information.

RENAME LARGE DIRECTORY TREES

Renaming directories in the Storage Gateway works well for a small directory tree. However, renaming a parent directory with many children can be slow. The service updates the object ID of every corresponding child object in the object store to reflect the new path. If you do start a rename, ensure that the action finishes by monitoring the Pending Uploads field in the Storage Gateway user interface.

Security Considerations

ADMIN PASSWORD

Because Storage Gateway administrators can create, modify, and delete file systems, follow these password guidelines:

- Set a strong password.
- Ensure that the password is secure.
- Share passwords with others only on a need-to-know basis.

DOCKER

Storage Gateway runs inside a Docker container for security and isolation. Follow these Docker-related guidelines and recommendations:

- Avoid or minimize Docker instance operations.
- Avoid logging in to the Docker container. If there is a genuine requirement to log in to the Docker container, use extreme caution to avoid service disruption. Do not change the Docker configuration or the Docker instance unless instructed to do so by Oracle support personal.
- Although the NFS protocol controls access to the file system from clients, Storage Gateway file systems are also locally mounted inside the Docker container. To prevent unauthorized access to file system data, ensure that a Docker container is accessible only by an administrator or an authorized user.
- Configure the Docker host to limit user access to the Storage Gateway Docker container.
- Files and directories in a Docker container are also visible in the Docker host - typically file systems and directories that are provisioned in the Docker host and mapped to the container. Set the appropriate ownership and modes to ensure that only an administrator or an authorized user can access these folders. We recommend the following:
  - A dedicated Storage Gateway host.
  - Limit who can access the Storage Gateway host.
  - Set firewall rules to limit access to the Docker host and Docker container.
  - Implement backup and retention policies for the files associated with Storage Gateway.

ACCESS CONTROL

Default file system export options are too permissive. Set more restrictive export options so that only trusted NFS clients can access the file system data and metadata. Modify the advanced file system settings for NFS Allowed Hosts and NFS Export Options to restrict access to a file system. In addition to NFS protocol security, you can also set up and configure a firewall on the host to further control access to the file system. UID/GID/modes control access to files and directories. Set the appropriate ownership mode to protect sensitive data.

OBJECT STORAGE

Files in a file system are uploaded to Oracle Cloud Infrastructure and stored as objects in an Object Storage bucket. Associated file attributes are stored as object metadata. Access control for Object Storage is different from access control for a traditional file system. Anyone with permission to read or modify any object in the bucket can read or modify all objects in the bucket. To protect sensitive data, set up Oracle Cloud Infrastructure IAM policies to limit who can access objects in the bucket.
Storage Gateway transfers data to Oracle Cloud Infrastructure using HTTPS, which encrypts data packets in flight between Storage Gateway and the cloud. Data written to Object Storage is always automatically encrypted in the cloud.

**NETWORKING**

Only use open network port access to networks that you trust. Oracle strongly recommends that you do not open network ports to the public internet. Instead, use a private connection to the machine hosting the Storage Gateway management console, for example a VPN or SSH local forward tunnel. See [Site-to-Site VPN](#) on page 3808 for more information.

Use the following syntax for SSH local forward tunnel:

```
ssh -L localHost:localPort:remoteHost:remotePort remoteHost
```

See [https://www.ssh.com/ssh/tunneling/example#local-forwarding](https://www.ssh.com/ssh/tunneling/example#local-forwarding) for more information.

**Limits on Storage Gateway Resources**

See [Service Limits](#) on page 243 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- Ensure that the number of file systems per Storage Gateway doesn't exceed 10. For best performance, host each file system on a dedicated Storage Gateway.
- Ensure that the number of objects stored in a Storage Gateway file system doesn't exceed 100 million. For datasets that consist of more than 100 million objects, distribute the objects across multiple Storage Gateways.
- Ensure that you configure adequate local storage for file system cache. Storage Gateway warns you if you have configured less than the recommended 500 GB.
- The minimum amount of memory required for any Storage Gateway file system is 16 GB.
  - File systems with up to 50 million files require 32 GB of memory.
  - Large file systems with up to 100 million files require 64 GB of memory.
- The number of files in the cache is limited to 20,000 regardless of the specified cache size in bytes.
- To improve the efficiency of file ingestion, cloud upload operations, and to reduce the number of objects in the namespace, bin-pack or zip small files before writing them to Storage Gateway.

**Storage Gateway Release Notes**

Release notes provide version-specific release information and important Storage Gateway issues that you need to be aware of:

[https://docs.cloud.oracle.com/iaas/releasenotes/services/storage-gateway/](https://docs.cloud.oracle.com/iaas/releasenotes/services/storage-gateway/)

**Features of Storage Gateway**

This topic highlights key features of Storage Gateway.

**POSIX-Compliant NFS Access to Oracle Cloud Infrastructure Object Storage**

Using Storage Gateway, your applications can interact with Oracle Cloud Infrastructure Object Storage through standard NFSv4 protocols. You connect Storage Gateway file systems to Object Storage buckets. Storage Gateway stores files as objects in an Oracle Cloud Infrastructure Object Storage bucket and supports multipart uploads for large objects. Object Storage does not, however, support symbolic links, hard links, or special device files.

Note:

Storage Gateway does not support the setgid POSIX function.
**Data Integrity with Checksum Verification**

The built-in data integrity checks ensure that data is validated as it moves through the data path from Storage Gateway to Oracle Cloud Infrastructure Object Storage. Checksum verification helps ensure data integrity. Metadata integrity checks ensure that the metadata is in a consistent state. The checksum for each file can be read using a custom interface.

**Large File Support**

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for faster, more efficient, and resilient uploads. Storage Gateway can use multipart upload for files larger than 128 MB. With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload. See **Using Multipart Uploads** on page 4382 for details.

Beginning with version 1.3, Storage Gateway provides partial update capabilities to:

- Reduce upload latency.
- Improve the use of available network bandwidth.
- Reduce the minimum required cache size.
- Enable ingestion of single files that are larger than the Storage Gateway cache size.

Storage Gateway's partial update capability leverages the Object Storage service multipart upload functionality to break a large file into smaller parts, and then upload the parts in parallel. After uploading, the service reconstructs them as a single object. With partial update, the service can upload only the modified file parts and reconstruct the object using the unchanged parts that already exist in Object Storage. The service does not need to overwrite the existing object by uploading the entire file.

Since the full file does not have to exist within the Storage Gateway cache at one time, partial update enables the service to ingest single files that are larger than the allocated cache size.

The default file part size is 1GB, with a maximum size of 10TB for the full file. Although the part size is configurable per file system, Oracle does not recommend that you use custom sizes. Custom part sizes do not improve upload performance, but can reduce the maximum supported full file size. The maximum file size is 10,000 times the file part size, with a hard cap of 10TB. If you customize the file part size, you do not need to restart the Storage Gateway, but you must reconnect to the affected file system.

All file parts in the cache are managed by the least recently used (LRU) cache management policy.

To use partial update for objects stored in the Archive Storage tier, you must first restore the object. See **Upgrading Storage Gateway** on page 4852 for information about upgrading your Storage Gateway system to use partial update.

**Support for Data Archival**

In addition to uploading to buckets in the Object Storage Standard tier, Storage Gateway supports uploading to and restoring objects from buckets in the Archive Storage tier.

When you create a file system, you specify the storage tier in which to create the corresponding Object Storage bucket.

- The default Standard Object Storage tier is used for storing data to which you need fast, immediate, and frequent access.
- The Archive Storage tier is used for storing data that is accessed infrequently and requires long retention periods.

While Archive Storage is more cost effective than Object Storage for preserving cold data, you must first **restore** the objects before you can access them. The restoration process can take up to four hours depending on the size of the object. See **Overview of Archive Storage** on page 566 and **Restoring Files and Objects from Archive Storage** on page 4839 for details.
Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management on page 4370 for details.

Automated Object Deletion
When you delete a Storage Gateway file from a file system, the corresponding object in Object Storage is automatically deleted.

Quick Access to Select Files with Cache Pinning
Storage Gateway lets you pin files to the file system cache for quick access. You can pin files to the cache for file systems connected to either the Object Storage Standard or Archive tier.

When you write a file to your Storage Gateway file system, the file is initially stored in the file system cache, and then asynchronously uploaded to your Oracle Cloud Infrastructure bucket. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the Least Recently Used (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can pin the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them.

Storage Gateway Health Check
The Storage Gateway performs automated "health checks" on the system to monitor the status of the following:

- Storage Gateway services and resources
- Local storage, file system cache, metadata storage, and log storage

Integrated Cloud Transfer and Synchronization (Cloud Sync)
Storage Gateway provides an integrated cloud transfer and synchronization feature called Cloud Sync that lets you back up and transfer files on local storage to and from Oracle Cloud Infrastructure Object Storage buckets. This new feature replaces the independent, downloadable cloud sync utility that was available in the previous Storage Gateway version.

You can use the Storage Gateway management console or CLI to create, monitor, and manage Cloud Sync jobs similar to other enterprise NAS backup/replication offerings. Cloud Sync runs as part of the Storage Gateway software inside the Docker instance on the host.

Getting Started With Storage Gateway
This topic provides recommendations for getting started with Storage Gateway.

Recommended Reading

- If you have not done so already, read Overview of Storage Gateway on page 4796. That topic describes:
  - Key concepts for understanding both Storage Gateway and Object Storage.
  - Important security considerations.
  - Recommended uses and workloads.
  - Uses and workloads to avoid.
  - Configuring the cache for file systems is key to Storage Gateway. Read Configuring the Cache for File Systems on page 4804 to understand the importance of the file system cache and the guidelines for configuring the cache when you add a file system.
  - To understand the prerequisite tasks and requirements for interacting with Object Storage, read Interacting With Object Storage on page 4812.
Next Steps for Setting Up Storage Gateway

Key topics for setting up Storage Gateway include:

- Installing Storage Gateway on page 4814
- Logging In to the Storage Gateway Management Console on page 4823
- Creating Your First File System on page 4824
- Mounting File Systems on Clients on page 4830

Next Steps for Using Storage Gateway

Key topics for using and managing Storage Gateway include:

- Managing File Systems on page 4827
- Managing Storage Gateway on page 4835
- Monitoring Storage Gateway on page 4842

Configuring the Cache for File Systems

Storage Gateway caches frequently retrieved data on the local host, minimizing the number of REST API calls to Oracle Cloud Infrastructure Object Storage and enabling faster data retrieval. You configure the cache for a file system when you create the file system. See Creating Your First File System on page 4824 and Adding a File System on page 4827.

About File System Cache

The file system cache serves as both a read cache and a write buffer for data storage and retrieval. The read cache contains frequently retrieved data that’s accessible locally for read operations. The write buffer contains data that has been copied to the disk cache and queued for upload to your Oracle Cloud Infrastructure tenancy.

When you retrieve data from Oracle Cloud Infrastructure, the data is stored in the Storage Gateway read cache. The read cache allows subsequent I/O operations to that data at local disk speed.

When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

For more information on how to preserve files in the read cache, see Preserving Files in the File System Cache on page 4808.

When an application transfers files through an NFS share, the files are written to the write buffer. The write buffer can contain many files that are queued and pending upload. If the host on which Storage Gateway is installed fails or Storage Gateway stops abruptly, the pending upload operations persist on the local disk. When Storage Gateway restarts, the pending upload operations resume and the data is uploaded to Oracle Cloud Infrastructure.

Configuring Local Storage for File Systems and Cache

Storage Gateway uses local storage attached to the server (or virtual server) for hosting the file systems and cache. Files written to a file system in Storage Gateway are uploaded to the associated Object Storage bucket, with a portion of the file set maintained locally in the file system as a warm cache.

For optimal performance, reliability, and fault tolerance, follow these guidelines when configuring the local Storage Gateway storage:

- Allocate dedicated local storage for each Storage Gateway file system, and associated metadata and logs.
• Multiple disks (hard disk drives or solid-state drives) in a RAID10 set provide an optimal balance of performance, reliability, and fault tolerance. Alternatively, you can use RAID6.

Important:
Avoid RAID0 or single disk (no RAID) because of the potential for data loss upon disk failure.

• Provision sufficient space to accommodate the read cache and the write buffer (for ingesting new files) without ever becoming more than 80% full.

In general, provision file system cache storage that is at least 1.5 times the size of the file set that you want to hold in the read cache. For example, assume that the entire file set requires 50 TB of space. You expect frequent access to 10% (5 TB) of that file set. Ensure that the file system cache storage has at least 7.5 TB of usable capacity. If the cache size reaches a near-full threshold, any data ingestion results in an out of space error in Storage Gateway.

• When you provision local storage at installation time, Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size. If the file system cache is less than 300 GB, Storage Gateway generates a warning message.

Determining File System Cache Size

The Storage Gateway file system cache serves as both a read cache and a write buffer. You can specify the maximum size of the read cache. The write buffer uses any remaining available space in the file system cache. You do not explicitly specify a size for the write buffer.

Important:
Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size.

Read Cache Size

The default maximum read cache size is 300 GB if the file system cache size is greater than 300 GB. Changing the default maximum read cache size is optional. The appropriate size depends on Storage Gateway workload. While the default setting for the read cache is appropriate for most workloads, consider increasing the size if Storage Gateway must retrieve a significant amount of data from the cloud.

Use the following guidelines to determine the appropriate setting for the read cache size:

• Do not set the read cache maximum equal to the size of the file system cache. Doing so allocates 100% of the space for the read cache and leaves no capacity for ingesting new files. If there is no available space for new file ingestion, Storage Gateway stops ingesting data and begins evicting files from the read cache to create space. Always preserve some space in the file system cache for ingestion.

• Set the read cache size to equal the amount of data that you anticipate to be accessed frequently, while leaving enough capacity for the write buffer.

Note:
If the total file system cache size is less than 300 GB, Storage Gateway automatically sets the read cache maximum size to 20% of the file system cache. The system does not honor custom read cache configuration settings for a file system cache less than 300 GB.

After you calculate the optimal file system cache size, you can configure the read cache when creating the file system or adjust it after monitoring the workload. See Adding a File System on page 4827 and Changing the Properties of a File System on page 4833.
**Write Buffer Size**

Optimizing the space available for the write buffer is an important part of determining the appropriate file system cache size. The write buffer size increases when data is ingested in Storage Gateway and decreases after the data is uploaded to the cloud.

### Important:

- When the write buffer uses all available file system cache space, further data ingestion is blocked until a portion of the existing files are uploaded and evicted from the cache.
- Oracle recommends that you allow a minimum of 300 GB for the write buffer under any circumstances.

Use the following guidelines to determine the space needed for the write buffer:

- Identify the amount of data to be uploaded in Storage Gateway. If a large amount of data is uploaded, the Storage Gateway write buffer can reach its maximum size. Exceeding the write buffer leads to I/O failure as the file system cache has no space available. If you cannot regulate data ingestion, you can increase the file system cache space to avoid I/O failure. You can regulate I/O by pausing after a certain amount of data is ingested or by periodically allowing uploads to complete before ingesting more data. For example, you can use this approach for backups run as cron jobs when the file system cache space is less than the amount of data to be ingested.
- Calculate the amount of data that is ingested on any typical day or week in Storage Gateway. Also, calculate the amount of data that is uploaded over a time period, based on the available bandwidth or historical data. Ensure that the difference between these calculations does not exceed the write buffer size.
- Some applications can handle I/O failure, and then resume writing data. In this case, consider setting the cache size to the amount of data that you’d like the application to tolerate before the cache space can be reclaimed.

As stated earlier, you want to avoid completely filling the file system cache. The write buffer grows by the difference between the ingest rate and the upload rate. The file system cache size must be larger than the read cache plus the total number of bytes buffered at any point during the job. If you have workloads that upload large amounts of data in parallel, you can use the following equation to determine the amount of space needed by the write buffer.

\[
\text{WB} \geq D \times (1 - \frac{UR}{IR}) + E
\]

- **WB** = Recommended write buffer size
- **D** = Total uploaded dataset size
- **UR** = Upload rate (The upload rate is the lesser of the actual upload rate or the disk read speed.)
- **IR** = Ingestion rate (disk write speed)
- **E** = Extra margin (Oracle recommends at least 50 GB.)

### Note:

This equation applies only if the upload rate is less than the ingest rate.

Run the following command to measure your system's ingestion rate:

```bash
sudo docker exec -it ocisg python /opt/oracle/gateway/python/packages/ocisg_helper/disk_speed_test.py
```

**Example output:**

```
Write speed:
2.1 GB copied in 9.4 seconds (228 MB/s)
Read speed:
2.1 GB copied in 6.8 seconds (315 MB/s)
```

If read and writes occur in parallel during the job, the read and write speeds are about 50% of the returned values.
Run the following command to measure your system's upload rate:

```sh
sudo docker exec ocisg cat /mnt/gateway/cache-phoenix/:::diag:oci-network-speed-test
```

Example output:

```
Average Upload Speed = 125 MB/s
```

**Example 1**

Daily dataset is 500 GB  
Upload rate = 2 MB/s  
Disk read = 600 MB/s  
Ingestion rate (Disk write) = 600 MB/s  
Apply the equation:  
\[ WB \geq 500 \text{ GB} \times (1 - \frac{2}{600}) + 50 \text{ GB} \]  
\[ WB \geq 549 \text{ GB} \]  
In this case, the upload rate is very slow compared to the ingestion rate, so the entire dataset needs to fit in the write buffer.

**Example 2**

Daily dataset is 1 TB  
Upload rate = 300 MB/s  
Disk read = 400 MB/s  
Ingestion rate (Disk write) = 100 MB/s  
In this case, we recommend the minimum write buffer size of 300 GB, since the upload rate is higher than the ingestion rate.

**Example 3**

Daily dataset is 5 TB  
Upload rate = 250 MB/s  
Disk read = 400 MB/s  
Ingestion rate (Disk write) = 300 MB/s  
Apply the equation:  
\[ WB \geq 5 \text{ TB} \times (1 - \frac{250}{300}) + 50 \text{ GB} \]  
\[ WB \geq 0.88 \text{ TB} \]  
WB is 880 GB.

**Note:**

Storage Gateway begins throttling I/O when the free cache space falls below 15 GB. Determine if the application is able to handle the throttling or if you want to provision more cache space.
Preserving Files in the File System Cache

When you write a file to your file system, the file is initially stored in the file system cache, and then uploaded to your Oracle Cloud Infrastructure tenancy. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the Least Recently Used (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can pin the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them. You can view the Maximum Read Cache Size in GiB for a selected file system in the management console under Settings.

You can pin files connected to both Standard and Archive storage tiers to file system cache. Files that you write to a file system are always uploaded to your tenancy, regardless of whether the files are pinned to the cache.

If the file that you want to pin to cache is not present in the cache, the file is automatically downloaded to the cache if the file system is connected to a Standard storage tier. If that file belongs to a file system connected to an Archive storage tier, you must first restore the file before the file can be downloaded to the cache. See Restoring Files and Objects from Archive Storage on page 4839 for details.

Important:

- By default, the cache pinning feature is enabled on all file systems.
- When selecting the files for cache pinning, consider the overall cache threshold and calculate the residual cache space that remains available for normal cache operations. For example, assume that your cache threshold is 1 TB and you estimate that the files you want to pin to cache occupy 300 GB. That leaves 700 GB of usable space in your cache after pinning the files.
- When you restore a file from the Archive storage tier, the file moves to the Standard storage tier. The file remains in Standard storage for 24 hours or the retention duration you specify. The continued availability of the file in the cache depends on the LRU operation. However, if you pin such a file to the cache, the restored file remains in the cache until you unpin the file.

Enabling and Managing Cache Pinning

To perform cache pinning operations for a file system, run the following command from the NFS client on which the file system is mounted:

```
cat /path/to/mountpoint/<file_path>:::cache:cache_command[:argument]
```

The following table lists the cache pinning operations and the corresponding command and argument for each operation:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Cache Command</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable cache pinning for a file system.</td>
<td>set-preserve-option</td>
<td>true</td>
</tr>
<tr>
<td>By default, cache pinning is enabled for all file systems.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Get the cache pinning status for a file system.</td>
<td>get-preserve-option</td>
<td>No argument</td>
</tr>
<tr>
<td>Disable cache pinning for a file system.</td>
<td>set-preserve-option</td>
<td>false</td>
</tr>
<tr>
<td>List the files that are pinned to the cache.</td>
<td>list-preserve</td>
<td>No argument</td>
</tr>
</tbody>
</table>
### Storage Gateway

#### Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Cache Command</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove deleted files from the preserve list.</td>
<td>list-preserve-update</td>
<td>No argument</td>
</tr>
<tr>
<td>Add a file to the preserve list.</td>
<td>add-preserve</td>
<td>No argument</td>
</tr>
<tr>
<td>Remove a file from the preserve list.</td>
<td>remove-preserve</td>
<td>No argument</td>
</tr>
<tr>
<td>Clear the preserve list.</td>
<td>clear-preserve</td>
<td>No argument</td>
</tr>
</tbody>
</table>

#### Example Commands

- To enable cache pinning for the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:set-preserve-option:true
  ```

- To get the cache pinning status for myFS:

  ```
  cat /mnt/gateway/myFS/:::cache:get-preserve-option
  ```

  If cache pinning is enabled for the file system, the output of this command is `true`. Otherwise, the output is `false`.

- To disable cache pinning for the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:set-preserve-option:false
  ```

- To add a file myFile of the myFS file system to the preserve list:

  ```
  cat /mnt/gateway/myFS/myFile:::cache:add-preserve
  ```

- To find out which files are added to the preserve list of the myFS file system:

  ```
  cat /mnt/gateway/myFS/:::cache:list-preserve
  ```

  Sample output of the preceding command:

  ```
  ["/doNotDelete.txt", "/myFileMetadata", "/myFile"]
  ```

- To remove the file myFile from the preserve list

  ```
  cat /mnt/gateway/myFS/myFile:::cache:remove-preserve
  ```
• To update the preserve list when the output of the `cache:list-preserve` command indicates that a pinned file has been removed from the file system:

```bash
cat /mnt/gateway/myFS/:::cache:list-preserve-update
```

Sample of the original preserve list:

```
["/doNotDelete.txt", "/myFileMetadata"]
```

Output of the `cache:list-preserve` command after the file `myFileMetadata` is removed from the cache:

```
["/doNotDelete.txt", "Status: 1 files appear to no longer exist. Please run list-preserve-update"]
```

Output of the `cache:list-preserve-update` command:

```
["/doNotDelete.txt"]
```

• To clear the preserve list for a file system:

```bash
cat /mnt/gateway/myFS/:::cache:clear-preserve
```

---

### Understanding Storage Gateway Performance

This topic covers the performance characteristics of Storage Gateway and the ways you can maximize its efficiency.

#### Performance Characteristics

This section describes the basic performance characteristics of Storage Gateway:

- Because a transactional overhead cost for each file exists, Storage Gateway generally exhibits better performance with large files than with small files. Storage Gateway can only upload data as fast as your connection and the storage host allows. Storage Gateway buffers the data in local disk storage while waiting to upload to Oracle Cloud Infrastructure. After a file is uploaded, the file's local copy can be removed from the cache to free up space. If file system cache space falls below 10 GB, application I/O and file/directory creation can fail.
- Storage Gateway does not support frequently modified files such as logs, databases, or virtual disks. Storage Gateway depends on the closing of a file to trigger an upload of that file. If a file never closes or is modified frequently, the upload event cannot successfully occur.
- Upload throughput to Object Storage (WAN) is typically slower than NFS client throughput (LAN). As a result, Storage Gateway can accumulate a large amount of data that is pending upload.
- You can attach Storage Gateway to an existing Object Storage bucket that contains data. The service is optimized for this type of initialization. Storage Gateway can initialize about 700 thousand files per hour with a hard disk drive-based cache. It can initialize about 7 million files per hour with an NVMe SSD-based cache.

**Note:**

Because Storage Gateway enables asynchronous movement of data to and from Object Storage, the performance level does not update in real time.

#### Factors That Affect Performance

To get the maximum performance benefits from Storage Gateway, follow the practices documented at Best Practices for Using Storage Gateway on page 4849.

In addition to having sufficient memory and file system cache space, Oracle recommends that you use SSDs to help improve NFS ingestion rate.
Storage Gateway is tuned for maximum upload and download performance by default. No additional tuning is needed.

**Performance Testing**
While measuring performance is complex and open to variability, we have observed the following in performance benchmark tests with 10-Gb/s link speed:

<table>
<thead>
<tr>
<th>Workload (Upload/Download)</th>
<th>Configuration</th>
<th>Average Upload Throughput</th>
<th>Average Download Throughput</th>
</tr>
</thead>
</table>
| Single large file of 400 GB | CPU: 8 cores  
Memory: 32GB  
Disk Read: 340 MB/s  
Disk Write: 234 MB/s  
Link Speed: 10 Gb/s (1.25 GB/s) | 239 MB/s | 195 MB/s |
| Multiple files of 10-50 GB (Total data = 400GB) | CPU: 8 cores  
Memory: 32GB  
Disk Read: 340 MB/s  
Disk Write: 234 MB/s  
Link Speed: 10 Gb/s (1.25 GB/s) | 260 MB/s | 225 MB/s |

**Note:**
Using FastConnect with Storage Gateway makes optimal use of full link speed. We have customers using FastConnect with 10-Gb/s link speed and have seen each gateway achieve 400–450 MB/s uploads to Oracle Cloud Infrastructure.
See [FastConnect Overview](#) on page 4052 for more information.

**Testing Network Bandwidth**
Storage Gateway provides a diagnostic command that you can use to test the bandwidth in your environment and ensure that you get the expected upload and download speeds. The amount of data transferred depends on these factors:

\[ \text{Bandwidth} \times \text{Delay Product (bits)} = \text{total\_available\_bandwidth (bits/sec)} \times \text{round\_trip\_time (sec)} \]

**Note:**
Different buckets can have different upload and download speeds.
The round_trip_time can vary by region.

**To run the diagnostic command:**
You need `root` permissions to run the `diag` command.
1. Using SSH, log in to the host on which you installed Storage Gateway.
2. Run the `diag` command, specifying the Storage Gateway file system name:

```
[root@ocisg-ashburn opc]# sudo docker exec ocisg cat /mnt/gateway/<file_system_name>/:::diag:oci-network-speed-test
```

The `diag` command responds with the average upload speed, for example:

```
Average Upload Speed = 217 MB/s
```

**Interacting With Object Storage**

This topic helps you understand the Oracle Cloud Infrastructure Object Storage environment and how it interacts with a Storage Gateway.

**Creating the Required IAM Users, Groups, and Policies**

An Oracle Cloud Infrastructure administrator must perform prerequisite tasks in preparation for data movement between Storage Gateway and Object Storage. If you are new to Oracle Cloud Infrastructure, we recommend that you read Setting Up Your Tenancy on page 144.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. For details on creating groups, see Managing Groups on page 3115.

For Storage Gateway, an administrator creates these groups with the following policies:

```
Allow group <group_name> to manage buckets in compartment <compartment_name>
```

```
Allow group <group_name> to manage objects in compartment <compartment_name>
```

**Content Consistency Between Storage Gateway and Object Storage**

Changes to the files in Storage Gateway, including create, write, update, and delete, eventually are consistent with Object Storage. Uploads are asynchronous and buffered for performance, so Storage Gateway file changes might not yet be reflected in Object Storage.

You can access, modify, and upload objects directly to a bucket using Object Storage native APIs, SDKs, the CLI, the Console, or the HDFS connector. Objects modified in these ways do not appear as files in Storage Gateway until you click **Refresh** in the Storage Gateway management console.

**Name Restrictions**

Storage Gateway file and file system names must adhere to Object Storage bucket and object name restrictions and guidelines.

Use the following guidelines for naming file systems:

- Use from 1 to 256 UTF-8 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

  **Important:**

  Names cannot contain a slash (/) character because this character delimits Object Storage bucket and object names.

- Avoid entering confidential information.
• Make the name unique within a Storage Gateway instance.

Use the following guidelines for naming files:
• Use from 1 to 1024 characters.
• Valid characters are letters (upper or lower case), numbers, and characters other than linefeed, newline, and NULL.
• Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
• Avoid entering confidential information.
• Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

Custom Metadata
POSIX file and directory attributes are stored in custom metadata. These attributes include uid, gid, mode, atime, ctime, and mtime. If existing objects in Object Storage are missing the required custom metadata, Storage Gateway assigns the following default values:
• uid=0
• gid=0
• mode=0644 for file and 0755 for directory

The custom metadata is not updated in Object Storage until a file operation triggers Storage Gateway to update the file in Object Storage. Timestamp metadata (atime, ctime, and mtime) are expressed in milliseconds. Access modes are expressed in octal and include file/directory bit.

The custom metadata names follow these guidelines:
• Only ASCII characters.
• A maximum of 128 bytes.

The custom metadata values follow these guidelines:
• Only UTF-8 characters.
• A maximum of 256 bytes.

Understanding Directory and File Hierarchy Translations in Object Storage
Within an Object Storage namespace, buckets and objects exist in a flat hierarchy. Storage Gateway flattens the file system directory hierarchy into nested object prefixes in Object Storage.

For directories:
• A Storage Gateway file system called myFS that contains a directory called myDir, appears in Object Storage as:
  \n/<os_namespace>/b/myFS/o/myDir/

• A Storage Gateway file system called myFS that contains a myDir subdirectory called mySubDir, appears in Object Storage as:
  \n/<os_namespace>/b/myFS/o/myDir/mySubDir/

You can distinguish a Storage Gateway directory from a Storage Gateway file in the following ways:
• Directories have a trailing slash /.
• Directory size or length is 0 (zero).

For files:
• A Storage Gateway file system called `myFS` that contains a directory called `myDir` with a file called `file1`, appears in Object Storage as:

```
/n/<os_namespace>/b/myFS/o/myDir/file1
```

• A Storage Gateway file system called `myFS` that contains a `myDir` subdirectory called `mySubDir` with a file called `file2`, appears in Object Storage as:

```
/n/<os_namespace>/b/myFS/o/myDir/mySubDir/file2
```

You can distinguish a Storage Gateway file from a Storage Gateway directory in the following ways:

- Directories have a trailing `/` and files do not.
- File length can be 0 (zero) or non-zero, but directory length is always 0 (zero).

### Internal Storage Gateway Objects

Storage Gateway creates some special internal objects in Object Storage. These objects have a `/gateway` directory prefix. For example:

```
/n/<object_storage_namespace>/b/<bucket>/o//gateway
```

**Important:**

Do not modify or remove the objects in the special `/gateway` directory. These objects are critical for Storage Gateway operation.

### Installing Storage Gateway

This topic provides instructions for installing the Storage Gateway software.

### Prerequisites

These instructions assume that you are familiar with the administration and configuration commands of the operating system on your host machine. To install Storage Gateway, your host system must meet certain hardware and software requirements.

#### Hardware Recommendations and Requirements

To run Storage Gateway, the host machine must meet the following requirements:

- Two dual-core CPUs or better. Oracle recommends 4-core CPUs.
- Minimum memory requirements:
  - 16 GB for required for any Storage Gateway file system.
  - 32 GB for file systems up to 50 million files.
  - 64 GB for file systems up to 100 million files.
- The recommended local storage disk size is 600 GB, which includes 500 GB for the file system cache, 80 GB for metadata storage, and 20 GB for log storage.

**Important:**

Provision local storage before installing Storage Gateway. For best performance, allocate dedicated local storage file systems for the Storage Gateway cache, the metadata, and the logs. The installation script prompts you for the paths to your Storage Gateway file system cache, metadata storage, and log storage locations. Follow the disk size recommendations provided by the installer.
Oracle recommends that you use the XFS file system for the file system cache, metadata, and logs. XFS is a 64-bit file system designed for parallel I/O. Parallel I/O allows a system to scale based on the number of I/O threads and file system bandwidth.

Software Requirements

- Oracle Linux 7 with UEK Release 4 or later.

**Note:**

If you create an Oracle Cloud Infrastructure Compute instance to host Storage Gateway, the instance creation wizard provides an option to choose the operating system image.

- Docker 1.12.6 or newer. Docker is an open platform for building, shipping, and running distributed applications. For more information, see https://www.docker.com/.
- NFSv4.

**Note:**

The Storage Gateway installation software automatically installs Docker and the NFS protocol.

Hosting Storage Gateway on an Oracle Cloud Infrastructure Compute Instance

To host Storage Gateway on an Oracle Cloud Infrastructure Compute instance, you need:

- An SSH key pair in PEM format.
  - To create a key pair, see Managing Key Pairs on Linux Instances on page 1021.
  - If your public key is not in PEM format, use the following command to convert it:
    
    ```bash
    ssh-keygen -f <key_name>.pub -e -m pem
    ```
- An Oracle Cloud Infrastructure user account with an API signing key (the public key from your SSH key pair).
  - If you need to create a user account, see To create a user on page 3113.
  - To upload an API signing key to an existing user account, see To add an API signing key on page 3154.
- A virtual cloud network (VCN) and related resources. For help with creating a VCN, see VCNs and Subnets on page 3693.
  
  The following configuration points apply to your VCN:
  - Do not select the Use DNS Hostnames in this VCN check box unless you plan to use DNS hostnames for your Storage Gateway Compute instance.
  - The security list must include a rule to allow SSL (443) ingress.
  - After you install the Storage Gateway software your host machine, you must add a security list rule to allow communication with the management console port. More information appears on this page after the Storage Gateway installation instructions.

  The VM.Standard2.4 Compute shape meets the minimum required specifications for Storage Gateway. Large file systems might require an image with more resources.
  - The recommended disk size is 600 GB.
  - Attach the volume to your Compute instance. See Attaching a Volume on page 657.
  - If you specify Volume Attachment Types on page 641 as the volume attachment type, you must also connect and mount the volume from the instance for the volume to be usable. For more information, see Volume Attachment Types on page 641 and Connecting to a Volume on page 672.
Installing Storage Gateway

You can install Storage Gateway on an Oracle Cloud Infrastructure Compute instance or an on-premises host that meets the hardware and software requirements.

To install the Storage Gateway software

1. Connect to your Compute instance or on-premises host.
   
   For help with connecting to an Oracle Cloud Infrastructure Compute instance, see Connecting to an Instance on page 1083.

2. If your host volume is new, you might need to format and mount the disk.

   Tip:
   
   This task describes the simplest way to create a functional file system to host a Storage Gateway. It uses one device and file system to host the cache, metadata, and log volumes. You specify the paths to those volumes later in this procedure. To optimize performance for your system, you can:
   
   • Create a separate device and file system for each of the cache, metadata, and log volumes.
   • Create a single device, but create logical volumes and file systems for the cache, metadata, and log volumes.

To format the disk and create a file system:

   a. Run `fdisk`:

   ```bash
   sudo fdisk /dev/sdb
   ```
   
   (Optional) Press `m` to view the `fdisk` options.

   b. Choose command `g` - create a new empty GPT partition table.

   c. Choose command `w` - write table to disk and exit.

   d. Create an XFS (file system).

   To make file system volume extensive, we recommend using LVM to create logical partitions that can span across one or more physical hard drives. First, the hard drives are divided into physical volumes, then those...
Storage Gateway

Physical volumes are combined to create the volume group and finally the logical volumes are created from volume group. Follow these steps:

1. Create a volume group.

   ```bash
   sudo vgcreate <volume_group_name> <device>
   ```

2. Create a logical volume.

   ```bash
   sudo lvcreate -l 100%FREE -n <logical_volume_name> <volume_group_name>
   ```

3. Create an XFS file system.

   ```bash
   sudo mkfs.xfs /dev/<volume_group_name>/<logical_volume_name>
   ```

4. Mount the XFS file system.

   ```bash
   sudo mount /dev/<volume_group_name>/<logical_volume_name> <directory_path>
   ```

To mount the formatted volume:

   a. Create a mount directory:

      ```bash
      sudo mkdir /ocisg
      ```

   b. Mount the drive:

      ```bash
      sudo mount /dev/sdb /ocisg
      ```

3. Download the Storage Gateway tar archive.

4. Use the SFTP tool of your choice to copy the tar archive into the /tmp folder of the host machine.

5. On the host machine, change directory to /tmp and extract the files from the tar archive:

   ```bash
   cd /tmp
   sudo tar xvfz ocisg-version.tar.gz
   ```

   This command extracts the files from the tar archive into a subdirectory named ocisg-1.3.

6. Change directory to ocisg-version and run the installation script as sudo or root user:

   ```bash
   cd ocisg-version
   ```
sudo ./ocisg-install.sh

Optionally, you can specify the following `ocisg-install.sh` script flags:

- `a` Runs the installation in advanced configuration mode, which lets you specify ports and the Docker network mode.

  In addition to prompting you for the paths to the metadata storage, cache storage, and log storage, advanced configuration mode also prompts you for:

  - The Docker network mode (host or bridge).
    Bridge mode is the default. It allows multiple instances of Storage Gateway to run on the same host.
    Host mode improves network performance. If you plan to run only one instance of Storage Gateway on the host, Oracle recommends host mode. If you encounter issues with host mode, try bridge mode or contact My Oracle Support.
  - The host port to use for the management console.
  - The host port to use for NFS access.
  - The host port to use for the HTTP REST service.

<table>
<thead>
<tr>
<th><strong>Tip:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>For each host port specification, you can designate a port or press Enter to let Storage Gateway dynamically allocate the port. You can use the <code>ocisg configure port</code> command to change the ports</td>
</tr>
</tbody>
</table>
• -d Installs Storage Gateway at the location you specify instead of the default location of /opt/ocisg. For example:

```
sudo ./ocisg-install.sh -d /opt/storagegateway
```

• -h Displays the installation script help information.

• -p Specifies that Storage Gateway is running behind a proxy server. You can specify multiple proxy arguments. For example:

```
```

• -q Runs the installation in quiet mode.

If you supply the paths to the Storage Gateway cache, metadata, and log storage locations using -m <path_to_metadata_storage>, -c <path_to_cache_storage>, and -l <path_to_log_storage>, you are not prompted for input. For example:

```
sudo ./ocisg-install.sh -q -m /ocisg/metadata -c /ocisg/cache -l /ocisg/log
```

**Note:**

Ignore the devicemapper warning message if it appears during the installation.

The script guides you through the Storage Gateway installation. Depending on your host machine configuration, some steps can require your input:

**a.** Docker does not appear to be installed. Do you want to install docker engine with yum? [y/N]

Press y, and then press **Enter**.

The installation script automatically installs Docker and configures the storage driver for use with Storage Gateway.

**Important:**

If Docker is already installed on your system, the installation script does not automatically configure the storage driver and returns a warning message:

```
Checking that docker is installed and using the correct version
Found docker version Docker version 18.03.1-01, build 0d51d18
The storage appliance requires to set devicemapper as the docker storage driver.
Please follow the setup link below to enable devicemapper and rerun the install.
```
Manually verify and update the Docker storage driver to be `devicemapper` as required. See Verifying and Updating the Storage Driver in Docker on page 4821.

b. NFS server does not appear to be enabled. Do you want to enable NFS? [y/N]

Press `y`, and then press Enter.

c. When prompted, press Enter to accept the default installation location.

d. When prompted, specify the paths to your Storage Gateway cache, metadata, and log storage locations.

The following examples represent paths for a simple system. Your setup might include paths to separate devices and file systems for each location.

1. Enter a path for the file system cache. For example:

   `/ocisg/sg/cache`

2. Enter the path for metadata storage. For example:

   `/ocisg/sg/metadata`

3. Enter the path for log storage. For example:

   `/ocisg/sg/log`

If you receive warnings about cache, metadata, and log storage existing on the same volume, enter `y` to proceed with the installation.

After a successful installation, the script provides the following information:

- The URL to log in to the Storage Gateway management console.
- The NFS port number.
- An example command for mounting your Storage Gateway file systems.

If you installed Storage Gateway on a Compute instance, see Security List Requirements for Compute Instance Installations on page 4820.

**Security List Requirements for Compute Instance Installations**

If you installed Storage Gateway on an Oracle Cloud Infrastructure Compute instance, that instance must be able to receive HTTPS connections from other hosts and allow communication with the Storage Gateway management console. To open the necessary port, add an ingress rule to the security list governing the instance's host subnet. To learn about VCN security control, see Security Lists on page 3727.

**Important:**

This installation task assumes that your existing security list already allows traffic to port 443, as described in the Prerequisites on page 4814 section of this page. If port 443 is not open, you must add a security list rule to open it.

Only use open network port access to networks that you trust. Oracle strongly recommends that you do not open network ports to the public internet. Instead, use a private connection to the machine hosting the Storage Gateway management console, for example a VPN or SSH local forward tunnel. See Site-to-Site VPN on page 3808 for more information.

Use the following syntax for SSH local forward tunnel:

```
ssh -L localhost:localPort:remoteHost:remotePort remoteHost
```

See [https://www.ssh.com/ssh/tunneling/example#local-forwarding](https://www.ssh.com/ssh/tunneling/example#local-forwarding) for more information.
To add a security list rule
1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the name of the cloud network (VCN) that hosts your Compute instance.
3. Click Security Lists.
4. Click the name of the security list that governs the subnet hosting your Compute instance.
5. Click Edit All Rules.
6. Add an ingress rule:
   a. Leave Stateless unmarked.
   b. Select TCP as the IP Protocol.
   c. Select CIDR for the Source Type and enter a source CIDR block for your on-premises network or the CIDR block where you access the Storage Gateway management console. Oracle strongly recommends limiting the rule to the most specific criteria as possible and not opening the rule to all networks.
   d. Enter All in the Source Port Range field.
   e. Specify your Storage Gateway management console port in the Destination Port Range field. For example:

      32769

      If you do not know the management console port for your Storage Gateway installation, run the following command on the host machine:

      sudo ocisg info

      The management console port appears at the end of the management console URL:

      Management Console: https://exampleCompute:32769

   You can now connect to the compute instance using the public IP address (https:<public_IP_address>). See Getting the Instance Public IP Address and Initial Windows Password on page 102 for details.

Verifying and Updating the Storage Driver in Docker

To verify the storage driver in Docker:
1. Start docker:

   sudo systemctl start docker

2. Verify the information in docker:

   sudo docker info

3. Look for Storage Driver in the output. For example:

   Containers: 0
   Running: 0
   Paused: 0
   Stopped: 0
   Images: 0
   Server Version: 18.03.1-01
   Storage Driver: overlay2
   Backing Filesystem: xfs
   Supports d_type: true
   Native Overlay Diff: false
   Logging Driver: json-file
   Cgroup Driver: cgroupfs
   Plugins:
   Volume: local
Network: bridge host macvlan null overlay
Log: awslogs fluentd gcplogs gelf journald json-file logentries splunk syslog
Swarm: inactive
Runtimes: runc
Default Runtime: runc
Init Binary: docker-init
containerd version: 773c489c9c1b21a6d78b5c538cd395416ec50f88
runc version: 4fc53a81fb7c994640722ac585fa9ca548971871
init version: 949e6fa
Security Options:
  seccomp
Profile: default
selinux
Kernel Version: 4.1.12-124.15.4.el7uek.x86_64
Operating System: Oracle Linux Server 7.5
OSType: linux
Architecture: x86_64
CPUs: 4
Total Memory: 13.45GiB
Name: ocisg-mahesh
Docker Root Dir: /var/lib/docker
Debug Mode (client): false
Debug Mode (server): false
Registry: https://index.docker.io/v1/
Labels:
  Experimental: false
Insecure Registries:
  127.0.0.0/8
Live Restore Enabled: false
Registries: docker.io (secure)

Note:
Ignore the devicemapper warning message if it appears.

If Storage Driver is not devicemapper, do the following:

a. Stop docker:

    sudo systemctl stop docker

b. Look for /etc/docker/daemon.json in the host.

    If the file daemon.json does not exist, create it.

c. In the daemon.json file, set the storage-driver variable to devicemapper:

    {
      "storage-driver": "devicemapper"
    }

d. Restart docker:

    sudo systemctl start docker

e. Verify the information in docker:

    sudo docker info

    Look for Storage Driver in the output and verify that the storage driver is devicemapper.
Next Step
Logging In to the Storage Gateway Management Console on page 4823

Logging In to the Storage Gateway Management Console

Use the Storage Gateway management console to create, manage, and monitor file systems.

Storage Gateway provides the URL to access the management console after a successful installation. When you access the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

**Note:**
Storage Gateway uses a self-signed certificate for the HTTPS connection. Your browser might warn that the SSL certificate couldn’t be verified. If you entered the correct IP address of the Storage Gateway instance, you can safely ignore this warning. The steps to ignore this warning and go to the management console vary depending on the browser you use.

To log in to the management console:

1. Enter one of the following URLs in a supported web browser:
   - If you installed the software on an on-premises host, enter the URL provided at the end of the Storage Gateway installation script:

   ```
   https://<storagegateway_hostname>:<port_number>
   ```
   For example:
   ```
   https://myStorageGatewayHost:3775
   ```
   **Note:**
   If you cannot access Storage Gateway using the hostname, contact your network administrator. Depending on your network configuration, your Storage Gateway hostname might need to be added to DNS or you might need to use an IP address rather than the hostname.

   - If you installed the software in an Oracle Cloud Infrastructure compute instance, enter the URL as follows:

   ```
   https://<instance_IP_address>:<port_number>
   ```
   For example:
   ```
   https://192.168.14.5:3775
   ```

   The console log-in page appears. The page prompts you to set and confirm a password for the Storage Gateway admin user.

2. Enter a password that meets the following requirements:
   - From 8 to 32 characters.
   - At least one special character, one numerical character, one uppercase character, and one lowercase character.

Next Step
Creating Your First File System on page 4824
Creating Your First File System

This topic guides you through creating your first Storage Gateway file system.

Think of a file system as a namespace containing a dataset that’s accessible through Storage Gateway. A Storage Gateway file system in this context represents a mapping between a directory on your on-premises host and a bucket in Oracle Cloud Infrastructure Object Storage. When you create a Storage Gateway file system, you define the connection credentials that Storage Gateway uses to connect to your Oracle Cloud Infrastructure tenancy.

When you log in to the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

To create your first file system

1. Log in to the management console.
2. Click File Systems on the upper-right area of the management console.
3. Click Create File System.
4. Enter the required information in Create a File System:

   • **File System Name:** A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
     - Use from 1 to 256 characters.
     - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

     **Important:**
     The name **cannot** contain the following:
     - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
     - The strings "pub" or "priv"

     If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.
     If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

   • **Select the Object Storage tier in which you want to store your data**

     **Important:**
     Once set, you cannot change the storage tier in which a bucket resides.
     You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management on page 4370 for details.

     • **Standard**: The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage on page 4290 for more information.

     • **Archive**: The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage on page 566 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see Restoring Files and Objects from Archive Storage on page 4839).

     • **Object Storage endpoint**: Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

     **Important:**
     The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and
OCIDs on page 5303 for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
- **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

**Note:**

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.

Enter the required configuration information or click **Use Default** to accept the default values:

- **NFS Allowed Hosts**: A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64,192.0.2.0/24

- **NFS Export Options**: The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

  **Important**: Do not specify the fsid option.

- **Concurrent Uploads**: The number of concurrent uploads to Oracle Cloud Infrastructure.
  
  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

  The allowed range is from 1 to 30.

- **Sync Policy**: The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead**: The number of blocks to be downloaded and used to read ahead when reading files for improved performance.
  
  Default value: 50

- **Maximum Read Cache Size in GiB**: The maximum read cache.
  
  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  **Note:**
  
  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

  See **Configuring the Cache for File Systems** on page 4804 for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

**Next Steps**

Connect the file system to a directory on the Storage Gateway host. For more information, see **Connecting a File System** on page 4829.

You can also do the following in the management console:

- Set up the NFS export. This directory acts as a mount point. For more information, see **Mounting File Systems on Clients** on page 4830.
- Add more file systems. For more information, see **Adding a File System** on page 4827.
- View the details of a file system. For more information, see **Viewing the Details of a File System** on page 4832.
Managing File Systems

A Storage Gateway file system connects a directory on a local host to an Object Storage bucket in Oracle Cloud Infrastructure. This topic describes how to manage Storage Gateway file systems.

Adding a File System

You can add file systems in Storage Gateway and connect each file system to an Object Storage bucket in your tenancy.

To add a file system

1. Log in to the management console.
2. Click File Systems on the upper-right area of the management console.
3. Click Create File System.
4. Enter the required information in Create a File System:

   - **File System Name:** A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
     - Use from 1 to 256 characters.
     - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

     **Important:**
     The name cannot contain the following:
     - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
     - The strings "pub" or "priv"

If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.

If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

- **Select the Object Storage tier in which you want to store your data**

  **Important:**

  Once set, you cannot change the storage tier in which a bucket resides.

  You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management on page 4370 for details.

  - **Standard:** The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage on page 4290 for more information.
  - **Archive:** The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage on page 566 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see Restoring Files and Objects from Archive Storage on page 4839).

  - **Object Storage endpoint:** Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

  **Important:**

  The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and
Storage Gateway

OCIDs on page 5303 for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
- **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

**Note:**

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.

Enter the required configuration information or click **Use Default** to accept the default values:

- **NFS Allowed Hosts**: A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64, 192.0.2.0/24

- **NFS Export Options**: The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

<table>
<thead>
<tr>
<th><strong>Important:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not specify the fsid option.</td>
</tr>
</tbody>
</table>

- **Concurrent Uploads**: The number of concurrent uploads to Oracle Cloud Infrastructure.

  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

  The allowed range is from 1 to 30.

- **Sync Policy**: The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead**: The number of blocks to be downloaded and used to read ahead when reading files for improved performance.

  Default value: 50

- **Maximum Read Cache Size in GiB**: The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.</td>
</tr>
</tbody>
</table>

  See [Configuring the Cache for File Systems](#) on page 4804 for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

   The file system is created and appears in the **File Systems** listing.

### Connecting a File System

After you create a file system, you must connect the file system to an Oracle Cloud Infrastructure Object Storage bucket before you can store and retrieve data through the file system.

<table>
<thead>
<tr>
<th><strong>Caution:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>If network connectivity with Oracle Cloud Infrastructure is lost, your file system is disconnected.</td>
</tr>
</tbody>
</table>

**To connect a file system**

1. Log in to the Storage Gateway management console.
2. On the **Dashboard** tab, identify the file system that you want to connect to your Object Storage bucket.
3. Click **Connect**.

If a bucket with the same name as the file system exists in Object Storage, the file system is connected to that bucket. Any existing data cached in the Storage Gateway file system is deleted to ensure consistency with the data stored in the bucket. If a bucket by that name doesn’t exist, the bucket is created and the file system is connected to the bucket. If the compartment OCID was specified during file system creation, then the bucket is created in that compartment. Otherwise, the bucket is created in the *root* compartment by default.

**Important:**

You can mount a read/write file system on only one Storage Gateway at a time.

If the file system that you're importing is connected to another Storage Gateway, the **File System: Claim Ownership** window appears. You can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information, and then click **Claim Ownership**:

- Public key fingerprint
- Private key
- Private key passphrase

Claiming ownership ensures that you don't inadvertently connect a new file system to a bucket that's already connected to another Storage Gateway file system.

### Mounting File Systems on Clients

Each Storage Gateway file system maps a directory to an Oracle Cloud Infrastructure Object Storage bucket. To establish the connection between Storage Gateway and an NFS client, you must mount the Storage Gateway file system on the NFS client.

Any Linux/UNIX NFS client certified to work with NFSv4 server running on Oracle Linux 7.x is compatible with Storage Gateway.

**Note:**

Storage Gateway does not currently support NFS clients running on Windows or Mac OS.

**To mount a Storage Gateway file system**

1. Log in to the Storage Gateway host.
2. Start Storage Gateway:

   ```bash
   sudo ocisg up
   ```
3. Find the NFS port number:

   ```bash
   sudo ocisg info
   ```

   Note the NFS port number from the output. For example:

   ```
   Management Console: https://myStorageGatewayHost.example.com:32775
   If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.
   NFS Port: 32774
   ```
Example: mount -t nfs -o vers=4,port=32774
myStorageGatewayHost.example.com:/<OCISG File System name> /local_mount_point

In the sample output:
• myStorageGatewayHost.example.com is the Storage Gateway host name.
• 32775 is the management console port number.
• 32774 is the NFS port number.

4. Log in to the NFS client from which you want to access your service instance through Storage Gateway.
5. Create a directory on the NFS client.
6. Mount the file system on the directory that you created on the NFS client:

```bash
sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file_system_name> /<local_mount_point>
```

In this command:
• Replace `<NFS_port_number>` with the NFS port number you noted earlier.
• Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
• Replace `<ocisg_file_system_name>` with the file system name that you want to mount.
• Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

For example:

```bash
sudo mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
```

In this example,
• 32774 is the NFS port.
• myStorageGatewayHost.example.com is the Storage Gateway host name.
• myFirstFS is the file system name.
• /home/xyz/abc is the path to the directory abc on the NFS client.

The Storage Gateway file system is now mounted on the NFS client directory. You can now access the Storage Gateway file system from the NFS client.

For more information, see Using Storage Gateway File Management Operations on page 4838.

To mount a Storage Gateway file system automatically after a reboot

You can mount a Storage Gateway NFS share either on directly to the host or remotely. When Storage Gateway restarts, the mount point may encounter residual file handle issues depending on the readiness of the fuse mount. The fuse mount takes some time to be available for a Storage Gateway restart.

Using an `/etc/fstab` entry to automount a Storage Gateway file system is not supported. Instead, you can set up an optional `cron` job for this purpose.

The `cron` job ensures the NFS share to be mounted only when the fuse mount is ready. However, this solution only works when the mount point is on the same Storage Gateway host. You must remount the NFS share to address file handling issues if it is mounted remotely.

1. Log in to the Storage Gateway host.
2. Create an executable script called `mountSgFilesystem.sh` and save it to an accessible location:

```bash
#!/bin/sh
#$1 - ip address
#$2 - nfs port
```
### Viewing the Details of a File System

You can view the configuration details of a file system and monitor the upload activity through the management console of Storage Gateway.

**To view the details of a file system**

1. Log in to the management console.
2. Click the name of the file system.

   - The **Details** tab displays the Oracle Cloud Infrastructure service type, storage tier, and the identity domain associated with your tenancy. If the file system is connected, you can see mount point connection information to help you with mounting that file system. For example:

     **NFS Client Mount Command:** `mount -t nfs -o vers=4,port=<nfs_mount_port> 129.213.122.84:/perftest01 /<local_mount_point>`

   - The **Settings** tab displays the following details:
     - Details of the tenancy and scope specified for the file system.
     - File system properties.
     - NFS and cache settings for the file system.

     You can edit these settings. If you make changes, remember to click **Save**.

     If your file system is connected, you can also see:

     - The **Activity** tab, which shows ongoing and pending file upload activity.

     If you contact Oracle Support Services about any issue with the file system, you might need to provide the file system log to help diagnose the issue. To view or download the file system log, click **View Streaming Logs** near the lower-right corner of the **Details** tab.

     - The **Completed Uploads** tab, which shows the last 100 files that were uploaded to Oracle Cloud Infrastructure Object Storage during the current browser session.

     **Note:**

     The file list doesn’t persist across browser sessions. If you refresh the page or open the **Completed Uploads** tab in another browser after the files are uploaded, the list will be empty.

     - You can also disconnect the file system. See **Disconnecting a File System** on page 4834.
Changing the Properties of a File System

You can change the properties of a file system using the Storage Gateway management console.

To change the properties of a file system

1. Log in to the management console.
2. In the **Dashboard**, click the name of the file system that you want to edit.
3. In the **Settings** tab, edit the file system properties and advanced settings, such as the cache limits.
4. Click **Save**.
5. For the changes to take effect, disconnect and reconnect the file system.

Refreshing a File System

The auto-refresh feature triggers file system refreshes based on a time interval you specify. The system schedules the next refresh after any in-progress refresh completes. That means the elapsed time between the beginning of any two successive refreshes is equal to the specified auto-refresh interval plus the time required to run a file system refresh.

**Note:**

Storage Gateway enables asynchronous movement of data to and from Object Storage. The Storage Gateway product currently cannot make commitments as to when files can be synced from an Object Storage bucket to the Storage Gateway NFS mount.

When an aggressive refresh interval is set that refreshes only occur when in-progress refreshes finish, so there will typically be a lag between contents of the Storage Gateway NFS mount and Object Storage bucket. As the volume of objects in the bucket grows the refresh time will start to increase.

Use the following command to configure the auto-refresh feature:

```
ocish set <file_system_name> dataset.refreshInterval=<interval_in_minutes>
```

The configuration command works on created and connected file systems. The configuration does not take effect until the file system is disconnected and reconnected or the Storage Gateway application restarts. To apply the changes, run:

```
ocish down
nocish up
```

Attribute caching can cause NFS clients to be unaware of files, corresponding to new objects in the bucket, that are created in a Storage Gateway file system during a refresh. You can use the `noac` mount option to turn off attribute caching. Turning off attribute caching can affect system performance.

When you run a refresh, the system reads attributes and fetches information about all objects in the corresponding bucket. Use a larger refresh interval for buckets with many objects.

**Note:**

After you refresh a file system, or create one for a bucket that already contains objects, Oracle recommends that you check for any files that might have been missed due to network connectivity issues.

To check for missing files, run the following command:

```
zgrep -ni "failed to get the object for" <path_to_gateway_logs>/<file_system_name>.*
```
For example, if the path to the gateway logging directory is `/ocisg/log` and the file system name is `my-fs-1`, the command is:

```
zgrep -ni "failed to get the object for" /ocisg/log/my-fs-1.*
```

Files listed in the output of this command were not successfully registered with the gateway. If any file names appear in the list, refresh the file system again.

### Disconnecting a File System

When a file system is disconnected, no one can access or modify that file system. We recommend disconnecting file systems that are not in use. Disconnecting a file system frees up the resources associated with that file system, making those resources available to file systems that are active (connected).

**To disconnect a file system**

1. Log in to the management console.
2. In the **Dashboard**, click the name of the file system that you want to disconnect.
3. Click **Disconnect**.

   When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.
4. For the changes to take effect, disconnect and reconnect the file system.

You can resume storing and retrieving data by connecting the file system again. You can delete the disconnected file system when you no longer need it. For more information, see [Deleting a File System](#) on page 4835.

### Importing an Existing File System

Before you import an existing file system from another Storage Gateway, ensure that any pending file uploads to Oracle Cloud Infrastructure Object Storage are complete.

**To import an existing file system**

1. Log in to the management console.
2. Click the **Create File System** navigation link.
3. Click **Create File System** in the navigation pane on the left.

   The **Create a File System** page appears.
4. Enter the required information in **Create a File System**.

   For the file system name, enter the name of the existing file system that you want to import to this Storage Gateway.
5. Click **Save**.
6. Select the options that you’d like to enable in the file system.
7. Click **Show Advanced** and enter the required information.
8. Click **Save**.

   The file system is created and appears on the **Dashboard** tab.
9. Click Connect for the file system that you want to import.

   a. If the file system that you're importing is connected to another Storage Gateway, the File System: Claim Ownership window appears so you can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information and click Claim Ownership:
      • Public key finger print
      • Private key
      • Private key passphrase

   b. If you connect to a file system that previously belonged to a different gateway, you must restart the new owning gateway:

```
    ocisg down
    ocisg up
```

10. Mount the file system to a directory on the Storage Gateway host and set up the NFS export. For example:

```
    sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file_system_name> </local_mount_point>
```

In this command:
   • Replace `<NFS_port_number>` with the NFS port number you noted earlier.
   • Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
   • Replace `<ocisg_file_system_name>` with the file system name that you want to mount.
   • Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

**Deleting a File System**

You can delete a file system from Storage Gateway when you no longer need it.

**To delete a file system:**

1. Log in to the management console.
2. On the **Dashboard**, identify the file system that you want to delete.

   **Important:**
   When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.

   Deleting a file system does not automatically delete the objects in the bucket. If you want to remove objects from the Object Storage bucket, set the Delete Old File Versions property for the file system and delete all the files before disconnecting the file system.

3. Ensure that the file system is disconnected. If it’s still connected, click **Disconnect**.
4. After the file system is disconnected, click its name.

   The details of the file system appear.

5. Click **Delete**.

   The file system is deleted from Storage Gateway.

**Managing Storage Gateway**

This topic describes some basic Storage Gateway management tasks.
Managing Storage Gateway Using the CLI

You can use the `ocisg` command line interface (CLI) to manage Storage Gateway. To use the CLI, open an `ssh` connection and log in to the host on which you installed Storage Gateway.

**Note:**

You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Storage Gateway Cloud Sync jobs. See Using Storage Gateway Cloud Sync on page 4844 for details.

The CLI supports the following Storage Gateway management tasks:

- **To start Storage Gateway:**
  ```
  sudo ocisg up
  ```

- **To stop Storage Gateway:**
  ```
  sudo ocisg down
  ```

**Note:**

If the server with a Storage Gateway system fails, you can reinstall and start a new one. All the configuration and system data is automatically downloaded and applied. The pending upload and download activities resume when the new Storage Gateway system runs.

If a disk cache is unrecoverable on the Storage Gateway server, data might be lost since the file might not have been transferred to the bucket in your tenancy. To ensure efficient data protection, see Best Practices for Using Storage Gateway on page 4849.

- **To view details about Storage Gateway and how to access the management console:**
  ```
  sudo ocisg info
  ```

- **To find the version of Storage Gateway:**
  ```
  sudo ocisg version
  ```

- **To configure Storage Gateway to use a proxy server for connections to Oracle Cloud Infrastructure Object Storage:**
  ```
  sudo ocisg configure proxy <proxy_server_URL>
  ```

**Note:**

After configuring the proxy server, you must stop and restart Storage Gateway.

By default, no proxy server is specified.

- **To remove previously configured proxy server details in Storage Gateway:**
  ```
  sudo ocisg configure proxy [remove]
  ```
To configure Storage Gateway to use SSL when communicating with the management console and REST APIs:

```bash
sudo ocisg configure ssl true
```

SSL is enabled by default.

**Note:**
After configuring Storage Gateway to use SSL, you must stop and restart Storage Gateway.

To disable SSL:

```bash
sudo ocisg configure ssl false
```

To specify ports for the Storage Gateway services:

```bash
sudo ocisg configure port <service> <port_number>
```

- `<service>`: Specify admin, nfs, or rest.
- `<port_number>`: Ensure that the port number you specify is not already in use on the Storage Gateway host.

By default, the port number is assigned dynamically for the Storage Gateway services when you start Storage Gateway.

**Note:**
For the port assignment to take effect, you must stop and start Storage Gateway.

To remove the static port assignment for a service:

```bash
sudo ocisg configure port <service> remove
```

To allocate memory for the Storage Gateway host:

```bash
sudo ocisg configure memory <memory_in_GB>
```

To remove the memory allocation:

```bash
sudo ocisg configure memory remove
```

By default, Storage Gateway uses 4 GB of the available memory on the host server. You can delete the memory information by using the `remove` parameter.

**Note:**
After configuring memory for Storage Gateway, you must stop and restart Storage Gateway.
To specify the docker network mode:

```
sudo ocisg configure network mode
```

The mode can be either `host` or `bridge`.

The default mode is `bridge`. In this mode, you can run multiple instances of Storage Gateway on your host. In the `host` mode, you can run only a single instance of Storage Gateway. Network performance is better in `host` mode.

**Note:**

After specifying the docker network mode, you must stop and restart Storage Gateway.

To change the Storage Gateway admin password:

```
sudo ocisg do password:reset
```

Set a new password:

```
sudo ocisg password:set <new_password>
```

Enter a password that meets the following requirements:

- Uses from 8 to 32 characters.
- Includes at least one special character, one numerical character, one uppercase character, and one lowercase character.

To view help for the available commands:

```
sudo ocisg help
```

---

**Using Storage Gateway File Management Operations**

This topic describes how to use the Storage Gateway file management operations.

**Important:**

Exercise caution when using the REST API, Java library, or any other client to retrieve, create, update, or delete objects directly in a bucket that’s mapped to a file system in Storage Gateway. Until you Refresh the Storage Gateway file system, Storage Gateway is not aware of the changes and data is inconsistent between Storage Gateway and Object Storage.

**Uploading Files to Buckets**

Before you connect the file system to the Oracle Cloud Infrastructure Object Storage bucket, make a note of the Oracle Cloud Infrastructure Object Storage tenancy details such as namespace, tenant OCID, and compartment OCID.

Copy the files to the mounted directory on the Storage Gateway or the NFS client host. Storage Gateway writes the files to the disk cache. The system queues and asynchronously uploads the files to an Object Storage bucket. Corresponding objects are created in the storage tier you specified during file system creation, either Standard or Archive. See Creating Your First File System on page 4824 or Managing File Systems on page 4827 for details.

**Note:**

Storage Gateway automatically performs multipart upload for files larger than 128 MB. See Using Multipart Uploads on page 4382 for details.

You can view files uploaded to your tenancy during the current browser session. See the Completed Uploads tab in Viewing the Details of a File System on page 4832.
Reading Files

When you write a file to a Storage Gateway file system, the system stores the file in the local disk cache. You can read the file directly from the mounted directory. Storage Gateway asynchronously copies the file to the corresponding Object Storage bucket in your tenancy. To retrieve the data from the bucket using Storage Gateway, read the files from the mounted directory.

If space is available, Storage Gateway automatically places the files in the read cache. If the file is in the read cache, you can retrieve the file immediately. If the file is not available in the read cache and it is stored in the Archive tier, you must restore the object. For more information, see Restoring Files and Objects from Archive Storage on page 4839.

Note:

You cannot read or write to a file that is stored in the Archive tier and does not exist in the read cache. This action returns an Input/Output error.

Storage Gateway checks data integrity using checksum verification on uploads. The system might not be able to perform data integrity validation on a partial read, since checksum verification works only on a whole file or object.

To read the upload checksum for a file in a file system, run the following command from the NFS client on which the file system is mounted:

```
sudo docker exec ocisg bash -c "cd /mnt/gateway/${filesystem} && cat ${filepath}:::meta:csm"
```

Restoring Files and Objects from Archive Storage

You can initiate a file restore from the Storage Gateway command line. You can also initiate an object restore from Archive Storage in Oracle Cloud Infrastructure. You can read the corresponding file using Storage Gateway after the object has been restored to Object Storage.

Note:

Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management on page 4370 for details.

Restoring Archived Files Using the Storage Gateway Command Line

To restore one or more archived files

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore` command. Specify the full path to a directory or to a file.

```
ocisg archive restore <file_system_name> <full/path/to/directory/or/file> [<<#_of_hours>>]
ocisg archive restore myFS myDir/mySubDir 240
```
For example, to restore a single file:

```
oci sg archive restore myFS myDir/mySubDir/file2 240
```

To check the archive status of one or more files

You can get the archive status for all files in a file system, for all files in a directory, or for an individual file.

Open a command prompt on the Storage Gateway host and run the `oci sg archive restore-status` command.

```
oci sg archive restore-status <file_system_name> [<full/path/to/directory/or/file]
```

The status can be one of the following:

- Archived
- In progress
- Restored

For example, to check the archive status for all files in a file system:

```
oci sg archive restore-status myFS
```

To check the archive status for all files in directory:

```
oci sg archive restore-status myFS myDir/mySubDir
```

To check the archive status for an individual file:

```
oci sg archive restore-status myFS myDir/mySubDir/file2
```

To check the restoration job status for a file system

You can get the status for all restoration jobs that have been initiated for a file system.

Open a command prompt on the Storage Gateway host and run the `oci sg archive restore-jobs` command.

```
oci sg archive restore-jobs <file_system_name>
```

For example:

```
oci sg archive restore-jobs myFS
```

**Restoring Archived Files Using Oracle Cloud Infrastructure**

**Important:**

If you use Oracle Cloud Infrastructure to restore archived objects, use the Refresh operation in Storage Gateway to display the data that was added or modified directly in Object Storage.

To restore an archived object using the Oracle Cloud Infrastructure Console

**Tip:**

You need OBJECT_RESTORE permissions to restore Archive Storage objects.

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of folders (if enabled) and objects in the bucket are displayed.
5. Expand any folders and subfolders as needed to locate the object that you want to restore.
6. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.
7. Optionally, specify the **Time Available for Download in Hours**.
   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object **Details** or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.
   After the alloted download time expires, the object returns to Archive Storage.
8. Click **Restore Objects**.
   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option**.

**To check the status of an object restoration using the Oracle Cloud Infrastructure Console**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. Click the Actions icon (three dots) to the right of the object you want to check the restoration or download status of, then click **Details**.
6. Check the **Status**.
   **Status** displays one of the following:
   - Archived
   - Restoring
   - Restored

**To restore an archived object using the Oracle Cloud Infrastructure CLI**

**Tip:**
You need **OBJECT_RESTORE** permissions to restore Archive Storage objects.

```
oci os object restore --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]
```

By default, you have 24 hours to download an object after restoration. However, you can optionally specify --hours with an integer value of download time of from 1 to 240 hours.

**To check the status of an object restoration using the Oracle Cloud Infrastructure CLI**

```
oci os object restore-status --namespace <object_storage_namespace> --bucket-name <archive_bucket_name> --name <archived_object_name>
```
Deleting Files

Remove the files that you no longer need from the NFS client by deleting them from the directory on which the file system is mounted.

Monitoring Storage Gateway

This topic describes how to monitor Storage Gateway file system upload activity, system health, and storage usage. The topic also describes how to view system notifications and how to receive notifications in email.

Important:

Monitoring file system activity in the Storage Gateway management console consumes system resources. Monitoring file system activity is not recommended when Storage Gateway is under high load.

Monitoring Upload Activity

When you upload a file to a file system, you can view the status of the upload activity. The Activity tab shows the ongoing and pending upload activity in a file system.

To monitor upload activity

1. Log in to the management console.
2. Click File Systems in the upper-right corner of the management console.
3. On the File Systems page, select a file system.
4. Click Activity.

You can see the upload progress of the file in the Uploading pane.

Monitoring System Health Status

You can monitor the overall system health status using System Status on the right side of the management console.

Storage Gateway performs an automated “health check” on the system to monitor the status of:

- Storage Gateway resources and services.
- Local storage, file system cache, metadata storage, and log storage.

System Status shows the result of Storage Gateway health analysis, either Healthy or Unhealthy.

System Status also provides information on:

- Any system warnings or errors.
- Local I/O Mode, which depends on local disk usage:
  - Normal
    The available disk space is greater than 10 GB in Storage Gateway. You can upload files in Storage Gateway and upload them to your Oracle Cloud Infrastructure tenancy.
  - Rejecting I/O
    The available disk space is less than 10 GB in Storage Gateway. Storage Gateway runs in protection mode and does not allow any writes to its local disk. All read operations work normally. All Storage Gateway metadata operations fail except for deletions and truncation.
    To return to Normal mode, you must wait until all ongoing upload activities complete and the files are removed from the read cache.
  - Throughput
    The approximate upload throughput to Object Storage. If there is no recent activity, Throughput shows Idle.
• **Available Read Cache**
  The amount of read cache available. For optimal performance, reliability, and fault tolerance, follow the guidelines for configuring cache storage. See Configuring Local Storage for File Systems and Cache on page 4804 for details.

• **Pending Uploads**
  The number of files or directories, for all file systems, awaiting upload to Object Storage. If Pending Uploads is 0 (zero), all files and directories have been uploaded.

### Monitoring Storage Usage

You can track the storage usage and availability.

**To monitor storage usage**

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Stats**.

   The system data appears in three panes:
   
   • **Local Storage**
   • **Local I/O**
   • **Local Resources**

**Local Storage**

This pane provides a graphical representation of the amount of storage being used and the available free storage on the Storage Gateway host. You can see:

- Available local storage.
- Storage used for pending uploads and preserved cache files.
- Storage used for metadata.
- Storage used for logging.
- Storage used for other applications.

**Local I/O**

This pane displays the local I/O mode of Storage Gateway based on the local disk space usage on the Storage Gateway host.

**Local Resources**

This pane shows the overall memory usage and availability for Storage Gateway from the following fields:

- **Available Cores**: The number of CPUs being used by Storage Gateway.
- **Maximum Memory Available to Storage Gateway**: The total RAM available for Storage Gateway.
- **Memory Used by Storage Gateway**: The amount of memory being used by the file systems in Storage Gateway.
- **Free Memory**: The amount of free RAM available in Storage Gateway host.

### Viewing System Notifications

The **System Notifications** tab shows system notifications and helps you track overall system performance.

**To view system notifications**

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.
   
   You can view a list of warnings or critical system notifications.

**Configuring Email Notification**

You can configure Storage Gateway to notify you by email about system health and Cloud Sync job completion.

**To configure email notification**

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.
4. If email notifications are not yet configured, click **Click here to configure**.
5. Enter the required information for the following fields:
   - SMTP server.
   - Email addresses to receive notifications.
6. Click **Show Advanced Options** and enter the required information in the advanced configuration fields:
   - SMTP port.
   - SMTP User name.
   - SMTP Password.
   - Sender’s Email Address.
   
   The default value is: noreply@oracle.com
7. Click **Save**.
8. Click **Test Email Notification** to verify that the specified email address receives a system notification email.

**Using Storage Gateway Cloud Sync**

Use Cloud Sync to move on-premises datasets from a local NFS-mounted file system to Storage Gateway, where the data is then moved asynchronously to Oracle Cloud Infrastructure Object Storage. You can also use Cloud Sync to synchronize Storage Gateway file system changes back to the local file system.

Cloud Sync generates the following for each sync job:
- Sync status (Created, Running, Completed, Failed, or Canceled).
- Number of files and directories to be copied from the source to the target.
- File and directory upload progress.
- Number of files and directories uploaded to the target.
- Time the job started, the time the job ended, and the run duration.
- The number of files skipped. (Cloud Sync skips non-regular files, such as symlinks, in the source directory.)
- A list of skipped files.

You can use the Storage Gateway management console or the command line interface (CLI) to create, manage, and monitor Cloud Sync jobs.

**About Cloud Sync**

Cloud Sync is an enhanced wrapper around the Linux `rsync` command and relies on `rsync` to detect new and changed files using size and modification time. Cloud Sync also relies on `rsync` to verify the files once the data transfer is complete using checksums of the files. Cloud Sync calls the Storage Gateway diagnostic commands to provide detailed data movement progress and status between your local server, Storage Gateway, and Oracle Cloud Infrastructure.

**Understanding Failure Behavior**

Because the file system is mounted over NFS locally, the NFS client running on the host handles any issues resulting from file system availability or connectivity.
Cloud Sync does the following:

- Reports and logs any failures to list or copy specific files (for example, resulting from permission issues).
- Monitors and reports on the pending and completed uploads to Object Storage.

Storage Gateway handles any connectivity and access issues to Object Storage and performs retry operations as needed.

**Prerequisites for Cloud Sync**

- Create the Storage Gateway file system that serves as either the source or target destination for the sync operation. A file system on the Storage Gateway host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage. See [Creating Your First File System](#) on page 4824 or [Adding a File System](#) on page 4827 for details.
- Obtain the proper credentials to mount the file system share from the local server.
- The local server source must:
  - Have names services set up correctly so that UIDs and GIDs are preserved and are not remapped to `nobody`.
  - Be exported with root permissions to read and traverse the entire source tree.
  - The filesystem to be synced needs to be NFS mounted to a mount point under `/cloudsync/mounts/`

**Important:**

If a Storage Gateway file system serves as the source, set the auto-refresh for new objects in the bucket to be synced using CloudSync. Use the following command to set the file system refresh at regular intervals:

```
ocisg set file_system_name
dataset.refreshInterval=interval_in_minutes
```

Restart Storage Gateway, then run the following commands to apply the changes:

```
ocisg down
ocisg up
```

See [Managing File Systems](#) on page 4827 for more information.

**Using the Management Console**

You can use the Storage Gateway management console to create, manage, and monitor Cloud Sync jobs.

**To create a Cloud Sync job that syncs all files and directories at the specified source location**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
   - By default, a list of all the Cloud Sync jobs that have already been created is displayed.
3. Click **Create Cloud Sync Job**.
4. In Create Cloud Sync Job page, specify the attributes of the job:

- **Job Name**: Required. A unique, user-friendly name for the job. Avoid entering confidential information.
- **Source Path**: Path to the Cloud Sync source directory containing the files to sync.
  - If your are syncing a local file system to Oracle Cloud Infrastructure, specify the source path as:
    `/cloudsync-mounts/<user_mount>[/<path_to_directory>]`
  - If your are syncing Oracle Cloud Infrastructure to a local file system, specify the source path as:
    `<storage_gateway_file_system>/</path_to_directory>`
- **Target Path**: Path to the Cloud Sync target directory for the synced files.
  - If your are syncing a local file system to Oracle Cloud Infrastructure, specify the target path as:
    `<storage_gateway_file_system>/</path_to_directory>`
  - If your are syncing Oracle Cloud Infrastructure to a local file system, specify the target path as:
    `/cloudsync-mounts/<user_mount>[/<path_to_directory>]`
- **Enable Auto-Deletion**: Enable this option if you want Cloud Sync to automatically delete files from the target when:
  - Files are deleted from the source.
  - Source files have been renamed.

By default, when a file is deleted on the source, Cloud Sync does not automatically delete the file on the target unless you enable **Enable Auto-Deletion**. Also, when a source file is renamed, the file with the old name is deleted and a file with the new name is created. By default, Cloud Sync does not delete the file with the old name on the target (retaining both a file with the old name and a file with the new name) unless you choose **Enable Auto-Deletion**.

The names of all deleted files are stored in a job-specific log directory.

5. Click **Create Cloud Sync Job**.

A Cloud Sync job is created and displayed in the list of jobs.

**To list Cloud Sync jobs**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.

   By default, a list of all the Cloud Sync jobs is displayed.
3. Optionally, you can filter the job listing by status (Created, Running, Completed, Failed, or Canceled) and type of Cloud Sync job (upload or download) by clicking one of the **Quick Filters**.

**To run a Cloud Sync job**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job that you want to run.
4. Click **Run** to the right of the job name.

Cloud Sync runs the job. The management console displays the status of the job just below the job name.

**To get the status of a Cloud Sync job**

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job for which you want status.

   The management console displays the status of the job (Created, Running, Completed, Failed, or Canceled) just below the job name.

**To cancel a Cloud Sync job**

You can only cancel a job if it is running.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job that you want to cancel.

   **Tip:**
   
   Use **Quick Filters** to get a list of **Running** jobs.

4. Click **Cancel** to the right of the job name.

**To delete a Cloud Sync job**

You cannot delete a running job.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the created, canceled, or failed Cloud Sync job that you want to delete.
4. Click **Delete** to the right of the job name.

**Using the CLI**

You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Cloud Sync jobs. Using ssh, log in to the host on which you installed Storage Gateway to use the CLI.

**To create a Cloud Sync job that syncs all files and directories at the specified source location**

Open a command prompt and run `ocisg cloudsync create` to create a job:

```
```

--schedule is an option to automate the Cloud Sync job so it runs according to the specified schedule. Set the schedule value using the format used for cron jobs. For example, `--schedule="*/5 * * * *"` runs the job every five minutes.

--auto-delete is an option to direct Cloud Sync to automatically delete files from the target when files are deleted from the source, and old names of files that have been renamed. By default, Cloud Sync does not automatically delete the files on the target unless you specify this option. The names of all deleted files are stored in a job-specific log directory.

--parallel=<number> is an option to specify the number of processes for data synchronization. By default, the number of processes is set to one. With a single process using a hard disk drive, you can expect a sync rate of 60-70 MB/s. If your system has higher disk throughput, you can use the number of processes that is proportional to the available bandwidth. Oracle recommends from two to five processes for optimal performance. The maximum number of processes allowed is 10.

--files-from=<file> is an option to specify a set of files that you want to sync to the target. If you do not set this option, the service syncs all files. The <file> should be a file under the `/cloudsync/` directory. For example, `--files-from="/cloudsync/files.list"`. 

--exclude-from=<file> is an option to specify a set of files that you want to exclude from the Cloud Sync job. The <file> should be a file under the /cloudsync/ directory. For example, --exclude-from="/cloudsync/exclude.list".

--verify-contents is an option to enable verification of the destination contents against the source. If you do not explicitly enable verification, new files added to Cloud Sync sources after the job has started are not reported as errors when they do not appear in the destination.

Avoid entering confidential information.

The Cloud Sync job is created and displayed in the list of jobs.

**To list Cloud Sync jobs**

Open a command prompt and run `ocisg cloudsync list` to list jobs:

```bash
sudo ocisg cloudsync list [-s <status>] [<job_name_or_type>]
```

Optionally, you can filter the list of jobs by specifying job status (Created, Running, Completed, Failed, or Canceled). You can also list a single job by specifying the name of that job.

For example:

```bash
sudo ocisg cloudsync list sync_to_os1
```

**To run a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync run` to run a job:

```bash
sudo ocisg cloudsync run <job_name>
```

For example:

```bash
sudo ocisg cloudsync run sync_to_os1
```

**To get the status of a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync status` to get the status of a job:

```bash
sudo ocisg cloudsync status <job_name>
```

For example:

```bash
sudo ocisg cloudsync status sync_to_os1
```

**To cancel a Cloud Sync job**

You can cancel a job only if the job is in progress.

Open a command prompt and run `ocisg cloudsync cancel` to cancel a job:

```bash
sudo ocisg cloudsync cancel <job_name>
```

For example:

```bash
sudo ocisg cloudsync cancel sync_to_os1
```

**To delete a Cloud Sync job**

Open a command prompt and run `ocisg cloudsync delete` to delete a job:

```bash
sudo ocisg cloudsync delete <job_name>
```
For example:

```bash
sudo ocisg cloudsync delete sync_to_os1
```

## Best Practices for Using Storage Gateway

Apply the recommendations found in the following topics to optimize the manageability, performance, reliability, and security of your Storage Gateway.

- [Security Considerations](#) on page 4800
- [Understanding Storage Gateway Performance](#) on page 4810
- [Configuring Local Storage for File Systems and Cache](#) on page 4804
- [Determining File System Cache Size](#) on page 4805
- [Recommended Uses and Workloads](#) on page 4798
- [Uses and Workloads Not Supported](#) on page 4799
- [Renaming Directory Trees](#)
- [Limits on Storage Gateway Resources](#) on page 4801

## Troubleshooting Storage Gateway

This topic covers some common Storage Gateway issues and how to address them.

### I installed docker and NFS on my host, but I can’t install Storage Gateway

1. Add the docker group to the existing groups in your host:

   ```bash
   sudo groupadd docker
   ```

2. Add your user id to the docker group:

   ```bash
   usermod -a -G docker <username>
   ```

3. Shut down your host:

   ```bash
   shutdown -r now
   ```

4. Log in to your host and run the Storage Gateway installation script:

   ```bash
   sudo ./ocisg-install.sh
   ```

### I can’t access the management console

1. Run the `ocisg info` command:

   ```bash
   sudo ocisg info
   ```

   If Storage Gateway is not running, start Storage Gateway:

   ```bash
   sudo ocisg up
   ```

2. Make a note of the management console port number from the output:

   ```
   Management Console: https://myStorageGatewayHost.example.com:32775
   ```
   
   If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.

   ```
   NFS Port: 32774
   ```
Example: `mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/<OCISG File System name> /local_mount_point`

In the example, `myStorageGatewayHost.example.com` is the Storage Gateway host name and 32774 is the management console port number.

3. Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
4. Check that the management console port number in the output from `ocisg info` matches the port you’re using to access the management console.
5. Ensure that you are using `https` if you have enabled SSL. SSL is enabled by default.

I am unable to mount a file system

1. Run the `ocisg info` command:
   
   ```bash
   sudo ocisg info
   ```

   If Storage Gateway is not running, start Storage Gateway:

   ```bash
   sudo ocisg up
   ```

2. Make a note of the management console port number and NFS port number from the output:

   ```
   Management Console: https://myStorageGatewayHost.example.com:32775
   
   If you have already configured a OCISG File System via the Management Console, you can access the NFS share using the following port.
   
   NFS Port: 32774
   ```
Example: `mount -t nfs -o vers=4,port=32774
myStorageGatewayHost.example.com:/<OCISG File System name> /<local_mount_point>`

In the sample output:
- `myStorageGatewayHost.example.com` is the Storage Gateway host name.
- 32775 is the management console port number.
- 32774 is the NFS port number.
- Log in to the NFS client from which you want to access your service instance through Storage Gateway.
- Create a directory on the NFS client.
- Mount the file system on the directory that you created on the NFS client:

```
sudo mount -t nfs -o vers=4,port=<NFS_port_number>
<storage_gateway_host_name>:/<ocisg_file_system_name>/<local_mount_point>
```

In this command:
- Replace `<NFS_port_number>` with the NFS port number.
- Replace `<storage_gateway_host_name>` with the server name or IP address of the server on which Storage Gateway is installed.
- Replace `<ocisg_file_system_name>` with the name of the file system you want to mount.
- Replace `<local_mount_point>` with the path to the directory you created on the NFS client.

For example:
```
sudo mount -t nfs -o vers=4,port=32774
myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
```

In this example,
- 32774 is the NFS port number.
- `myStorageGatewayHost.example.com` is the Storage Gateway host name.
- `myFirstFS` is the file system name.
- `/home/xyz/abc` is the path to the directory `abc` on the NFS client.
- Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
- Ensure that the NFS protocol is running:

```
sudo systemctl enable nfs-server
```

Check that the NFS port number in the output from `ocisg info` matches the port you’re using to connect to with your NFS client.

---

**I cannot delete a bucket after canceling a Cloud Sync job**

If you cancel an active or stalled Cloud Sync job and disconnect the file system, you might not be able to delete the associated Object Storage bucket. If file uploads were in progress when you canceled the job, the Object Storage service might expect a commit that never completed. In this case, the service does not allow bucket deletion and returns the error "multipart upload pending". You can use the CLI to resolve the issue.

1. List the bucket’s pending multipart uploads:

```
oci os multipart list -bn <bucket_name>
```

Be sure to note the relevant object names and upload IDs.
2. Delete all pending uploads:

   `oci os multipart abort -bn <bucket_name> --object-name <object_name> --upload-id <upload_id>`

3. Delete the bucket:

   `oci os bucket delete -ns <object_storage_namespace> --name <bucket_name>`

**Additional NFS Troubleshooting**

The Storage Gateway installation software installs the NFS, if needed, and automatically configures it. After the installation, the NFS is configured and a file system created. You can then mount the filesystem from a remote client. Sometimes this mount can fail.

To troubleshoot a mount failure:

1. Ensure that the NFS port is included in the Storage Gateway's subnet security list and that it is available there. If the port does not appear in the subnet security list, add it and retry the mount.
2. Run `rpcinfo -p`. The command should return:

   ```
   100003 4 tcp 2049 nfs
   ```

   This result means that NFS is ready, available, and the mount succeeds.
3. If `nfs` does not appear in the response to the `rpcinfo -p` command, enable and restart both `rpcbind` and `NFS`:

   ```
   sudo systemctl enable rpcbind
   sudo systemctl enable nfs
   sudo systemctl start rpcbind
   sudo systemctl start nfs
   ```
4. Run the `rpcinfo -p` command again to verify that NFS is now available.
   a. If NFS still is not available, reboot the Storage Gateway.
   b. Run the `rpcinfo -p` command again to confirm.
5. If you remain unable to mount the file system, contact My Oracle Support.

**Contacting Oracle Support**

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Using the Console to Manage Support Tickets on page 151 for information.

**Upgrading Storage Gateway**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are upgrading from Storage Gateway 1.0, underlying database and schema changes require you to recreate your Storage Gateway file systems. See Recreating Your File Systems on page 4853 for details.</td>
</tr>
</tbody>
</table>

**Before You Begin**

- Plan for downtime appropriately since the upgrade takes some time to complete. The downtime varies depending on the system resources, the number of file systems, and the number of files.
- Wait for any pending or ongoing write operations from the NFS client instances to complete, then unmount all file systems.
- Wait for pending uploads to Oracle Cloud Infrastructure Object Storage to complete. On the Dashboard under System Status, ensure that the Pending Uploads field shows 0.
• Disconnect all of the file systems.
• Ensure that there is no ongoing activity in the Activity tab for each file system in the management console.

**Important:**
To enable partial update capabilities in Storage Gateway, there must be no pending uploads for any associated file systems before the upgrade. The upgrade process purges the existing local cache across all Storage Gateway file systems.

### Upgrading Storage Gateway

To upgrade to Storage Gateway:

1. Log in to your Storage Gateway host.
2. Download the latest version of the Storage Gateway tar archive.
3. Extract the files from the downloaded `ocisg-version.tar.gz` file:
   ```sh
tar xvzf ocisg-x.x.tar.gz
   
   This command extracts the file’s contents to a subdirectory named `ocisg-version`.
```
4. Change directory to `ocisg-version`:
   ```sh
cd ocisg-x.x
   
   Change directory to `ocisg-version`:
```
5. Run the installation script as `sudo` or `root` user:
   ```sh
sudo ./ocisg-install.sh
   
   Run the installation script as `sudo` or `root` user:
```

If you encounter any interruption during the upgrade, such as lost connectivity, rerun the installation script to resume the upgrade.

If you are upgrading from Storage Gateway 1.0, you must recreate the file systems that were created in the 1.0 version of the Storage Gateway software. Connect the file systems in the management console and claim ownership if there’s a bucket ownership prompt. The Storage Gateway upgrade rebuilds the local metadata for existing buckets in Object Storage. The more objects there are in the buckets, the more time it takes to rebuild the metadata.

### Recreating Your File Systems

When you created file systems in Storage Gateway 1.0, corresponding Oracle Cloud Infrastructure Object Storage buckets were created. Recreate those file systems in Storage Gateway so that you can connect to the same buckets and automatically see the files that have already been uploaded to Object Storage.

When you recreate Storage Gateway file systems, data that you already uploaded to Oracle Cloud Infrastructure Object Storage is automatically included in the newly created file system.

**To recreate your file systems**

1. Log in to the management console.
2. Click File Systems on the upper-right area of the management console.
3. Click Create File System.
4. Enter the required information in **Create a File System**:

- **File System Name**: A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
  - Use from 1 to 256 characters.
  - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

  **Important:**

  The name **cannot** contain the following:
  - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
  - The strings "pub" or "priv"

If an Object Storage bucket by this file system name doesn’t exist in your tenancy, the bucket is created.

If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

- **Select the Object Storage tier in which you want to store your data**

  **Important:**

  Once set, you cannot change the storage tier in which a bucket resides.

  You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management on page 4370 for details.

  - **Standard**: The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage on page 4290 for more information.
  - **Archive**: The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage on page 566 for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it’s accessible (see Restoring Files and Objects from Archive Storage on page 4839).

- **Object Storage endpoint**: Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

  **Important:**

  The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and OCIDs on page 5303 for detailed information on how to generate the required keys and where to obtain these OCIDs.

  - **Compartment OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
  - **Tenant OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
  - **User OCID**: Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
  - **Public Key's Finger Print**: Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
  - **Private Key**: Required. Your Oracle Cloud Infrastructure Object Storage private key.
  - **Private Key Passphrase**: Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

  **Note:**

  Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair...
of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click Save.

The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click Save again.

6. Click Show Advanced File System Configuration.

Enter the required configuration information or click Use Default to accept the default values:

- **NFS Allowed Hosts:** A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
  
  For example: 2001:db8:9:e54::/64,192.0.2.0/24

- **NFS Export Options:** The NFS export options.
  
  Example: rw, sync, insecure, no_subtree_check, no_root_squash

  **Important:**
  
  Do not specify the fsid option.

- **Concurrent Uploads:** The number of concurrent uploads to Oracle Cloud Infrastructure.
  
  This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

  The allowed range is from 1 to 30.

- **Sync Policy:** The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only Posix Standard is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.

- **Cloud Read-ahead:** The number of blocks to be downloaded and used to read ahead when reading files for improved performance.
  
  Default value: 50

- **Maximum Read Cache Size in GiB:** The maximum read cache.
  
  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  **Note:**
  
  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

See Configuring the Cache for File Systems on page 4804 for details.

The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click Save.

The file system is created and appears in the File Systems listing.

Uninstalling Storage Gateway

This topic describes how to uninstall Storage Gateway.

Uninstalling

To uninstall Storage Gateway
1. Log in to the on-premises host or compute instance from which you want to uninstall Storage Gateway.
2. Stop Storage Gateway:
   ```
sudo ocisg down
   ```
3. If the ocisg_data container exists in docker ps -a output, remove it:
   ```
sudo docker rm -v ocisg_data
   ```
4. Delete the image in docker:
   ```
sudo docker rmi $(sudo docker images| grep ocisg | awk '{print $3}')
   ```
5. Delete all the files in /usr/bin/ that begin with ocisg:
   ```
sudo rm /usr/bin/ocisg*
   ```
6. View the contents of the file gateway_config:
   ```
cat /etc/gateway_config
   ```
   Sample output:
   ```
$ cat /etc/gateway_config
DATASTORAGE=/ocisg/cache
MDSTORAGE=/ocisg/metadata
LOGSTORAGE=/ocisg/log
PROXY=
USE_SSL=
MEMORY=
NETWORK=bridge
HTTP_FRAMEWORK=
ADMINPORT=443
NFSPORT=32769
RESTPORT=32768
• Delete the DATASTORAGE directory, for example:
  ```
sudo rm -rf /ocisg/cache
  ```
• Delete the MDSTORAGE directory, for example:
  ```
sudo rm -rf /ocisg/metadata
  ```
• Delete the LOGSTORAGE directory, for example:
  ```
sudo rm -rf /ocisg/log
  ```
• Delete the gateway_config file:
  ```
sudo rm /etc/gateway_config
  ```
• Delete the Storage Gateway installation directory ocisg:
  ```
sudo rm -rf /opt/ocisg
  ```

**Getting Help with Storage Gateway**

This topic provides information about getting help with Oracle Cloud Infrastructure Storage Gateway.
Contacting Oracle Support

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Using the Console to Manage Support Tickets on page 151 for information.

Downloading the Support Bundle

If you contact Oracle Support about any issue with Storage Gateway, you might need to provide a support bundle to help the Oracle Support technicians diagnose the issue.

1. Log in to the management console.
2. Click System in the upper-right corner of the management console.
3. Click Help.
4. Click Download Support Bundle in System Logs.

You can download and save the support bundle.

Contents of the Support Bundle

The support bundle contains the following information:

• All of the logs needed for diagnostics.
• Local storage usage information.
• Basic system information such as memory size, Docker version, and the Storage Gateway version.
• A list of file systems.
• Cloud Sync job details.
Chapter 45

Streaming

The Oracle Cloud Infrastructure Streaming service provides a fully managed, scalable, and durable solution for ingesting and consuming high-volume data streams in real-time. Use Streaming for any use case in which data is produced and processed continually and sequentially in a publish-subscribe messaging model.

You can use Streaming for:

**Messaging**

Use Streaming to decouple the components of large systems. Producers and consumers can use Streaming as an asynchronous message bus and act independently and at their own pace.

**Metric and log ingestion**

Use Streaming as an alternative for traditional file-scraping approaches to help make critical operational data more quickly available for indexing, analysis, and visualization.

**Web or mobile activity data ingestion**

Use Streaming for capturing activity from websites or mobile apps, such as page views, searches, or other user actions. You can use this information for real-time monitoring and analytics, and in data warehousing systems for offline processing and reporting.

**Infrastructure and apps event processing**

Use Streaming as a unified entry point for cloud components to report their lifecycle events for audit, accounting, and related activities.
Infrastructure and apps event processing

Use Streaming as a unified entry point for cloud components to report their lifecycle events for audit, accounting, and related activities.

Streaming Features

Streaming provides the following features:

Fully managed

Streaming is fully managed, from the underlying infrastructure to its provisioning, deployment, maintenance, security patching, and replication. Integration with Monitoring and default metrics make operations easy.

Oracle manages stream partitions and consumer groups can handle your message offsets.

Durability and Availability

Messages published to the Streaming service are synchronously replicated across three availability domains when available. In regions with a single availability domain, the data is replicated across multiple fault domains. This ensures that even the failure of an availability domain or fault domain does not result in data loss. The result is highly durable data.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for Streaming. Refer to the Oracle Cloud Infrastructure Service Level Agreement page for details.

Security

Streaming data is encrypted both at rest and in transit, ensuring message integrity. You can let Oracle manage encryption, or use the Oracle Cloud Infrastructure Vault service to securely store and manage your own encryption keys if you need to meet specific compliance or security standards.

Integration with Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who and what services can access which keys and what they can do with those resources.

Private endpoints restrict access to a specified virtual cloud network (VCN) within your tenancy so that its streams cannot be accessed through the internet.

For more information, see Securing a Stream on page 4866.

Stream processing

Streaming’s integration with Oracle Cloud Infrastructure Service Connector Hub means that you can designate a stream as a data source, use Oracle Cloud Infrastructure Functions to transform the stream’s messages, and output the transformed messages to Object Storage or any other supported Service Connector Hub target while maintaining Streaming’s order guarantees.

Kafka compatibility

Streaming makes it possible to offload the setup, maintenance, and management of the infrastructure that hosting your own Apache Kafka cluster requires.

Streaming is compatible with most Kafka APIs, allowing you to use applications written for Kafka to send messages to and receive messages from the Streaming service without having to rewrite your code. See Using Kafka APIs on page 4899 for more information.

Streaming also takes advantage of the Kafka Connect ecosystem to interface directly with first-party and third-party products by using out-of-the-box Kafka source and sink connectors. See Using Kafka Connect on page 4901 for more information.

For More Information

Refer to the Streaming Service Overview on page 4860 and Getting Started with Streaming on page 4862 topics for more information.
Streaming Service Overview

Familiarize yourself with how Streaming works, its most important concepts, and some of its main benefits.

Then get started with Streaming.

How Streaming Works

Here's how Streaming works:

A producer publishes messages to a stream, which is an append-only log. These messages are distributed among Oracle-managed partitions for scalability.

Partitions allow you to distribute a stream by splitting messages across multiple nodes (or brokers). Each partition can be placed on a separate machine, allowing multiple consumers to read a stream in parallel.

A consumer reads messages from one or more partitions. Consumers can read from any partition regardless of where the partition is hosted. Each message within a stream is marked with an offset value, so a consumer can pick up where it left off if it is interrupted. Messages from a partition are guaranteed to be delivered in the same order they were produced.

Consumers can read messages explicitly by providing the partition and offset, or as a member of a consumer group, which coordinates the consumption of an entire stream by the members of the group.

Streaming Concepts

The following concepts are essential to understanding and working with Streaming.
stream

A partitioned, append-only log of messages.

stream pool

A grouping that you can use to organize and manage streams, including any shared Kafka or security settings.

partition

A section of a stream. Partitions allow you to distribute a stream by splitting messages across multiple nodes. This also allows multiple consumers to read from a stream in parallel.

cursor

A pointer to a location in a stream. This location could be a pointer to a specific offset or time in a partition, or to a group's current location.

message

A Base64-encoded message that is published to a stream. Streaming is schema-agnostic and accepts any message format, including XML, JSON, CSV, and even compressed formats such as gzip. Producers and consumers should agree upon the message format.

producer

An entity that publishes messages to a stream.

consumer

An entity that reads messages from one or more streams.

consumer group

A set of instances which coordinate to consume messages from all partitions in a stream. At any given time, the messages from a specific partition can only be consumed by a single consumer in the group.

instance

A member of a consumer group. Instances are defined when a group cursor is created. Group membership is maintained through interaction; lack of interaction results in a timeout, removing the instance from the consumer group.

key

An identifier used to group related messages.

offset

The location of a message within a partition. Each message within the partition is identified by its offset. Consumers can read messages starting from any chosen offset. You can use the offset to restart reading from a stream if interrupted.

Benefits of Streams

Streams have several advantages over traditional messaging queues, including:

Configurable message persistence

You control how long your data is retained. Messages in a stream are immutable and available for the entirety of the stream's configured retention time.

Replay

Because a stream's messages are not removed immediately when processed by consumers, you can replay any and all messages in the stream at any time within the configured retention limit.
Message guarantees
Each message is guaranteed to be delivered at least once. In some cases, such as a consumer's failure to commit messages before going offline, messages may be delivered multiple times.

Order guarantees
Messages within a stream, per partition, are always delivered in the same order that they were produced.

Client-side cursors
Your client applications control and track which messages are read and can move the cursor as needed for maximum flexibility.

Horizontal scale
Partitions provide an opportunity to scale up throughput to meet the needs of multiple consumers, resulting in increased flexibility.

Consumer groups
Consumer groups handle all of the coordination that is required to deliver messages to multiple consumers in a balanced manner. Because this management is handled by a consumer group on behalf of all of its members, you can enjoy reduced overhead and operational ease.

Getting Started with Streaming
Get started with Streaming by familiarizing yourself with the service and the ways you can access it:

- Streaming Service Overview on page 4860
- Accessing Streaming on page 4862
- Limits on Streaming Resources on page 4864

Then, move on to stream creation, production, and consumption:

- For instructions on how to create and manage streams, see Creating and Managing Streams on page 4867.
- For information about publishing messages to a stream, see Publishing Messages on page 4888.
- For information on how to consume messages, see Consuming Messages on page 4891.
- For information on Apache Kafka compatibility, see Using Streaming with Apache Kafka on page 4898.

Accessing Streaming
You can access Streaming using any of the following options, based on your preference and use case, provided you are authenticated and authorized to do so.

Ways to Access Streaming

- Oracle Cloud Infrastructure REST APIs provide the most functionality, but require programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs on page 5528. The Streaming service is accessible with the Streaming API.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Because Streaming is compatible with the Apache Kafka API, applications written for Kafka can also access Streaming.</td>
</tr>
</tbody>
</table>

- Oracle Cloud Infrastructure provides SDKs so that you can interact with Streaming without having to create a framework. Basic Streaming usage examples are included with our SDKs. For more information about using the SDKs, see the SDK Guides.

- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Using the CLI on page 5333.
• The Console is an easy-to-use, browser-based interface. You can use the Console to create and manage streams, stream pools, and Kafka Connect configurations, but you cannot publish or consume messages using the Console.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:
• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model. You can use Resource Manager to create streams, stream pools, and Kafka Connect configurations.

Authentication and Authorization
Regardless of the method you use to access Streaming, you must be authorized to interact with the service's resources.

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize Streaming users, see Common Policies on page 2806. For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with Streaming and related Streaming service resources.

For in-depth information on granting users permissions for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

Accessing Streaming Resources Across Tenancies
This topic describes how to write policies that let your tenancy access Streaming resources in other tenancies.

If you're new to policies, see Getting Started with Policies on page 2799 and refer to Details for the Streaming Service on page 3040.

Cross-Tenancy Policies
Your organization might want to share Streaming resources with another organization that has its own tenancy. It could be another business unit in your company, a customer of your company, a company that provides services to your company, and so on. In cases like these, you need cross-tenancy policies in addition to the required user and service policies described previously.

Endorse, Admit, and Define statements
To access and share resources, the administrators of both tenancies need to create special policy statements that explicitly state the resources that can be accessed and shared. These special statements use the words Define, Endorse, and Admit.

Here's an overview of the special verbs used in cross-tenancy statements:

• **Endorse**: States the general set of abilities that a group in your own tenancy can perform in other tenancies. The Endorse statement always belongs in the tenancy with the group of users crossing the boundaries into the other tenancy to work with that tenancy's resources. In the examples, we refer to this tenancy as the source.

• **Admit**: States the kind of ability in your own tenancy that you want to grant a group from the other tenancy. The Admit statement belongs in the tenancy who is granting "admittance" to the tenancy. The Admit statement
Streaming identifies the group of users that requires resource access from the source tenancy and identified with a corresponding Endorse statement. In the examples, we refer to this tenancy as the destination.

- **Define**: Assigns an alias to a tenancy OCID for Endorse and Admit policy statements. A Define statement is also required in the destination tenancy to assign an alias to the source IAM group OCID for Admit statements.

Define statements must be included in the same policy entity as the endorse or the admit statement.

The Endorse and Admit statements work together, but they reside in separate policies, one in each tenancy. Without a corresponding statement that specifies access, a particular Endorse or Admit statement grants no access. Agreement is required from both tenancies.

**Source policies**
The source administrator creates policy statements that endorse a source IAM group allowed to manage resources in the destination tenancy.

Here is an example of a broad policy statement that endorses the IAM group StreamingAdmins group to do anything with all Streaming resources in any tenancy:

```
Endorse group StreamingAdmins to manage streams in any-tenancy
```

To write a policy that reduces the scope of tenancy access, the destination administrator must provide the destination tenancy OCID. Here is an example of policy statements that endorse the IAM group StreamingAdmins group to manage Streaming resources in the DestinationTenancy only:

```
Define tenancy DestinationTenancy as ocid1.tenancy.oc1..<unique_ID>
Endorse group StreamingAdmins to manage streams in tenancy DestinationTenancy
```

**Destination policies**
The destination administrator creates policy statements that:

- Define the source tenancy and IAM group that is allowed to access resources in your tenancy. The source administrator must provide this information.
- Admit those defined sources to access Streaming resources that you want to allow access to in your tenancy.

Here is an example of policy statements that endorse the IAM group StreamingAdmins in the source tenancy to do anything with all Streaming resources in your tenancy:

```
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StreamingAdmins as ocid1.group.oc1..<unique_ID>
Admit group StreamingAdmins of tenancy SourceTenancy to manage streams in tenancy
```

Here is an example of policy statements that endorse the IAM group StreamingAdmins in the source tenancy to manage Streaming resources only the SharedStreams compartment:

```
Define tenancy SourceTenancy as ocid1.tenancy.oc1..<unique_ID>
Define group StreamingAdmins as ocid1.group.oc1..<unique_ID>
Admit group StreamingAdmins of tenancy SourceTenancy to manage streams in compartment SharedStreams
```

**Limits on Streaming Resources**
The Streaming service has the following limits:

- The maximum retention period for messages in a stream is seven days. The minimum retention period is 24 hours. All messages in a stream are deleted after the retention period passes, whether or not they have been read.
- The retention period for a stream cannot be changed after creation of the stream.
- A tenancy has a default limit of five partitions (Monthly Universal Credits) or zero partitions (Pay-as-You-Go or Promo). If your throughput requires additional partitions, you can request more.
• The number of partitions for a stream cannot be changed after creation of the stream.
• A single stream can support up to 50 consumer groups reading from the stream.
• Each partition can support:
  • A total data write rate of 1 MB per second. There is no limit on the number of PUT requests, provided the limit of 1 MB per second per partition is not exceeded.
  • 5 GET requests per second per consumer group. Since a single stream can support up to 50 consumer groups, and a single partition in a stream can be read by at-most one consumer in a consumer group, a partition can support up to 250 GET requests per second (5 GET requests per second per consumer in all 50 consumer groups).
• The maximum size of a unique message that producers can publish to a stream is 1 MB.
• The maximum size of any single request is 1 MB. A request's size is the sum of its keys and messages after they've been decoded from Base64.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Partitioning a Stream

To take full advantage of the Streaming service's ability to operate at scale, configure the number of partitions in the stream based on the following considerations.

Before creating a stream, consider the expected stream throughput, partition key strategy, and how your stream will be consumed. Most configuration values cannot be changed after the stream has been created. For example, after a stream is created, you can't change the message retention time or number of partitions.

Partitions and Throughput

When you create a stream, you must specify how many partitions the stream has. The expected throughput of your application can help you determine the number of partitions for your stream.

Multiply the average message size by the maximum number of messages written per second to estimate your expected throughput. Since a single partition is limited to a 1 MB per second data write rate, and 5 GET requests per second per consumer group, a higher throughput requires additional partitions to avoid throttling. Keep additional Streaming limits in mind when making your design decisions.

Tip:

To help you manage application spikes, we recommend allocating partitions slightly higher than your maximum throughput.

Publishing to Partitions

The content of the messages you intend to publish to a stream can also help you determine how many partitions your stream should have.

A message is published to a partition in the stream. If there is more than one partition, the partition where the message is published is calculated using the message's key.

For more information, see Publishing Messages on page 4888.

Key to partition mapping

Messages with the same key go to the same partition. Messages with different keys might go to different partitions or to the same partition. If you do not specify a key, Streaming recognizes the null key and generates a random key on the behalf of the user. If a user publishes the same message twice, it could go to different partitions, since a completely new key is generated. Do not expect all messages with a null key to go to the same partition.

By default, Streaming provides uniform and predictable distribution of messages to a stream's partitions. Streaming APIs do not let you specify exactly which partition data is published to, since this can introduce a risk of hotspotting a single partition if a user is not aware of the nuances of Streaming. However, if you use Kafka APIs to interact with
Streaming, you may choose to do custom partitioning and explicitly map messages to partitions, although we do not recommend it.

**Effective partitioning keys**

To ensure uniform distribution of messages, you need effective values for your message keys. To create an effective value, consider the selectivity and cardinality of your Streaming data.

**Cardinality:** Consider the total number of unique keys that could potentially be generated based on the specific use case. Higher key cardinality generally means better distribution.

**Selectivity:** Consider the number of messages with each key. Higher selectivity means more messages per key, which can lead to hotspots.

Always aim for high cardinality and low selectivity.

**Ordering**

Messages with the same key are guaranteed to be stored in the order they are published, and delivered to consumers in the same order they were produced. Because messages with the same key go to the same partition, this guarantee only applies at the partition level.

**Partitions and Consumer Groups**

If your stream will be consumed by one or more consumer groups, you should factor that into your decision on how many partitions it should have. Partition reads are balanced among the instances in a consumer group.

Consumer groups can only utilize a single instance at a time if the stream has only one partition. If your stream has multiple partitions, you can scale the number of instances up to the number of the partitions and have one instance in the group reading from one partition in the stream.

For more information, see Using Consumer Groups on page 4893.

**Securing a Stream**

Streaming data is encrypted both at rest and in transit. Private endpoints within your virtual cloud network (VCN) can be used to restrict access to your streams so they cannot be accessed through the internet.

Both encryption and private access are configured at the stream pool level to make managing groups of streams easier. See Creating Stream Pools on page 4870 and Updating the Master Encryption Key Assigned to a Stream Pool on page 4885 for more information.

**Encryption**

By default, all encryption-related matters are handled by Oracle, but you can manage your own encryption keys using Oracle Cloud Infrastructure Vault. Vault allows you to bring your own Advanced Encryption Standard (AES) symmetric keys and manage, rotate, disable, and delete them as needed.

Because encryption keys are managed at the stream pool level, you can use a different encryption key for each logical stream grouping or virtual Kafka cluster.

To use your own encryption key:

- Ensure that you have the required IAM policies.
- Import your key.
- Change the master encryption key assigned to the stream pool.

For more information, see Overview of Vault on page 5006 and Managing Keys on page 5017.

**Private Endpoints**

Private endpoints associate a private IP address within a VCN to the stream pool, allowing Streaming traffic to avoid traversing the internet.
To create a private endpoint for Streaming, you need access to a VCN with a private subnet when you create the stream pool. See About Private Endpoints on page 4125 and VCNs and Subnets on page 3693 for more information.

To use private endpoints:

• Ensure that you have the required IAM policies.
• Select Private Endpoint and provide the required information when you create your stream pool.

Because streams using private endpoints are not accessible from the internet, you cannot use the Console to show their latest messages.

Creating and Managing Streams

Before publishing messages to a stream, or consuming messages from a stream, you must first create a stream.

When creating a stream, consider your partitioning and security strategies.

You can use the Oracle Cloud Infrastructure (OCI) Console, the Command Line Interface (CLI) on page 5316, the Streaming API, the OCI SDKs, and Resource Manager to create your Streaming resources.

Stream Pools

Stream pools are logical groupings for streams. Every stream needs to be a member of a stream pool. If you don't create a stream pool, the Streaming service uses a default pool to contain your streams.

You can use stream pools to:

• Organize streams into groups matching your organizational structure or a specific solution
• Restrict access to a specified virtual cloud network (VCN) inside your tenancy so that streams in the pool are not accessible through the internet
• Specify whether the data in the pool's streams should be encrypted using your own Vault encryption key or an Oracle-managed key

When you create a stream, you need to specify whether it should become a member of an existing stream pool, or a member of a new, automatically created stream pool. There is no limit to the number of stream pools you can create. See Creating Stream Pools on page 4870 for more information.

Note:

Stream names must be unique within a stream pool.

Stream Pools and Apache Kafka

Stream pools serve as the root of a virtual Apache Kafka cluster when you use Kafka with Streaming. All streams within the pool share the same Kafka configuration, encryption, and access control settings. Every action on that virtual cluster is scoped to that stream pool.

You can configure the stream pool to automatically create streams, or Kafka topics, and call KafkaAdminClient::createTopic to create a stream or topic in that stream pool.

For more information, see Using Streaming with Apache Kafka on page 4898.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.
Streaming

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

Creating Streams

Before publishing messages to a stream, or consuming messages from a stream, you must first create a stream. The following sections describe how to create a stream:

- Using the Console on page 4868
- Using the Command Line Interface (CLI) on page 4869
- Using the API on page 4869
- Using OCI SDKs on page 4869
- Using Resource Manager and Terraform on page 4870

When creating a stream, consider the expected stream throughput, message retention period, partition key strategy, and how your stream will be consumed. Most configuration values cannot be changed after the stream has been created. For example, after a stream is created, you can't change the message retention time or number of partitions.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

Using the Console

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
   A list of existing streams is displayed.
2. Click Create Stream at the top of the list.
3. Stream Name: Required. Specify a friendly name for the stream. It does not have to be unique within the compartment, but it must be unique to the stream pool. The stream name cannot be changed. Avoid entering confidential information.
4. Compartment: Choose the compartment in which the stream will be created. To change the compartment, select a different compartment from the drop-down list.
5. Stream Pool: Choose the stream pool that will contain your stream.
   a. If your chosen compartment has an existing stream pool, you can select it from the drop-down list or click Create new stream pool and configure the stream pool manually.
   b. If no stream pool exists in the chosen compartment, select Auto-create a default stream pool or click Create a new stream pool and configure the stream pool manually.
6. In the Define Stream Settings panel:
   a. Retention (in Hours): Enter the number of hours (from 24 to 168) to retain messages. The default value is 24.
   b. Number of Partitions: Enter the number of partitions for the stream. The maximum number is based on the limits for your tenancy.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The maximum Total Write Rate and Total Read Rate of your stream are displayed as you adjust the number of partitions.</td>
</tr>
</tbody>
</table>
7. Click **Show Advanced Options** to optionally define **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

8. Click **Create**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**
The examples in this section use the full syntax for all parameters, for example --compartment-id. For some parameters, there are shortened versions that you can use instead, like -c. See the CLI online help for instances of a shortened parameter associated with a command.

You can create a stream in a compartment or a stream pool. The --compartment-id and --stream-pool-id parameters cannot be specified at the same time.

```bash
oci streaming admin stream create --name <stream_name> --partitions <number_of_partitions> --compartment-id <compartment_OCID>
```

```bash
oci streaming admin stream create --name <stream_name> --partitions <number_of_partitions> --stream-pool-id <stream_pool_OCID>
```

For example:

```bash
oci streaming admin stream create --name MyStream --partitions 5 --compartment-id ocid1.tenancy.oc1..exampleuniqueID

{  
  "data": {  
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",  
    "defined-tags": {},  
    "freeform-tags": {},  
    "id": "ocid1.stream.oocl.phx.exampleuniqueID",  
    "lifecycle-state": "CREATING",  
    "lifecycle-state-details": null,  
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",  
    "name": "MyStream",  
    "partitions": 5,  
    "retention-in-hours": 24,  
    "stream-pool-id": "ocid1.streampool.oocl.phx.exampleuniqueID",  
    "time-created": "2020-11-02T19:12:22.385000+00:00"
  },  
  "etag": "\"d72d8103-f1ae-442a-822d-10f86cd097c5-25e61a9b-cc08-4fad-9908-40c9636d31d8\""
}
```

**Using the API**

Use the CreateStream API operation to create streams.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

**Using OCI SDKs**

To create a stream, use the createStream method of StreamAdminClient.

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.
Using Resource Manager and Terraform

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the OCI Terraform provider to provision Streaming resources like streams and stream pools.

Stream Resource

You can use the `oci_streaming_stream` resource in Terraform configurations to create a stream in your compartment.

For example:

```terraform
resource "oci_streaming_stream" "stream" {
  compartment_id     = var.compartment_ocid
  name               = "<stream_name>
  partitions         = "<number_of_partitions>
  retention_in_hours = "<retention_in_hours>
}
```

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 4470 and Terraform Configuration.

Creating Stream Pools

Stream pools are logical groupings for streams. Every stream needs to be a member of a stream pool. If you don’t create a stream pool, the Streaming service uses a default pool to contain your streams.

The following sections describe how to create a stream pool:

- Using the Console on page 4871
- Using the Command Line Interface (CLI) on page 4872
- Using the API on page 4873
- Using OCI SDKs on page 4873
- Using Resource Manager and Terraform on page 4873

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

Policies for Private Endpoints

To set up a private endpoint, you must have access to a VCN with a private subnet where DNS resolution is enabled. For general information about policies and permissions to do this, see IAM Policies for Networking on page 3709. Specifically, you need use permissions for a VNIC, a network security group, if you specify one, and a subnet. For example:

```bash
allow user group ServiceWriters to use vnics in compartment ABC
allow user group ServiceWriters to use network-security-groups in compartment ABC
```
Policies for Encryption Keys

To use your own encryption key, you must let the Streaming service use a Vault key to encrypt data in streams in this stream pool. For example:

```
allow service streaming to use keys in compartment ABC where target.key.id = '<key_OCID>'
```

The preceding policy also requires a companion policy to let Streaming use a key on behalf of a user group to create a stream pool that uses the key for cryptographic purposes. For example:

```
allow user group StreamWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

Using the Console

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Stream Pools on the left side of the screen. A list of existing stream pools is displayed.
3. Click Create Stream Pool to display the Create Stream Pool page.
4. Enter a name for the stream pool in the Stream Pool Name text box. Avoid entering confidential information.
5. Select a compartment from the Resource Compartment drop-down list.
6. In the Configure Stream Pool panel:
   a. Select Endpoint Type: Click Public Endpoint or Private Endpoint, depending on whether you want to restrict traffic to streams in this stream pool to a private endpoint that does not require traffic to traverse the internet. To create a private endpoint, you need access to a virtual cloud network (VCN) with a private subnet. Select a VCN with a private subnet where DNS resolution is also enabled, and then select the subnet. Optionally, if you want to assign a specific private IP address, you must choose one that belongs to the subnet's CIDR. By default, the Networking service assigns a random private IP address on your behalf and applies no security rules to the stream pool. For more information about VCNs and subnets, see VCNs and Subnets on page 3693.
   b. Configure Encryption Settings: By default, Encrypt using Oracle-managed keys is selected. If you want to encrypt the data in the streams in this stream pool using your own Vault encryption key, click Encrypt using customer-managed keys. To use the Vault service for your encryption needs, you need access to a vault and key and you need to allow the Streaming service to use the key.
      1. Vault: Choose the vault that contains the master encryption key you want to use from the drop-down list.
      2. Master Encryption Key: Choose the master encryption key you want to use from the drop-down list.

   For more information, see Securing a Stream on page 4866. For more information about encryption with a Vault key that you manage, see Overview of Vault on page 5006 and Managing Keys on page 5017.
7. If you would like to add tags or intend to use Kafka with this stream pool, click Show Advanced Options.
8. Add Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
9. To use the stream pool with Kafka, select the **Auto Create Topics** checkbox and configure your stream settings:
   a. Add a number of hours for the stream’s retention period in **Default Retention Period (hours)** text box.
   b. Specify the **Default Number of Partitions** for the stream.
   c. Select the **View Kafka settings after the stream pool is created** checkbox to display the Kafka Connection settings for the stream pool when it is created.

10. Click **Create**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**
The examples in this section use the full syntax for all parameters, for example `--compartment-id`. For some parameters, there are shortened versions that you can use instead, like `-c`. See the CLI online help for instances of a shortened parameter associated with a command.

```bash
oci streaming admin stream-pool create --name <stream_pool_name> --compartment-id <compartment OCID>
```

For example:

```bash
oci streaming admin stream-pool create --name MyStreamPool --compartment-id ocid1.tenancy.oc1..exampleuniqueID
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "custom-encryption-key": {
      "key-state": "NONE",
      "kms-key-id": null
    },
    "defined-tags": {},
    "endpoint-fqdn": null,
    "freeform-tags": {},
    "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "is-private": false,
    "kafka-settings": {
      "auto-create-topics-enable": false,
      "bootstrap-servers": null,
      "log-retention-hours": 24,
      "num-partitions": 1
    },
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": null,
    "name": "MyStreamPool",
    "private-endpoint-settings": {
      "nsg-ids": null,
      "private-endpoint-ip": null,
      "subnet-id": null
    },
    "time-created": "2020-11-02T23:01:59.429000+00:00"
  },
  "etag": "\"b0066564-4bf4-4e27-9255-9055e69a7808-03668273-b0d5-4b8b-9370-74522c29eb56\""
}
```
Using the API

Use the CreateStreamPool API operation to create stream pools.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using OCI SDKs

To create a stream pool, use the createStreamPool method of StreamAdminClient.

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.

Using Resource Manager and Terraform

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the OCI Terraform provider to provision Streaming resources like streams and stream pools.

Stream Pool Resource

You can use the oci_streaming_stream_pool resource to create a stream pool with optional private endpoint and Kafka compatibility settings. Private endpoint settings require a VCN, a subnet, and a network security group. This example Terraform configuration creates those resources as well.

For example:

```
resource "oci_streaming_stream_pool" "test_stream_pool" {
  #Required
  compartment_id = var.compartment_ocid
  name = "<stream_pool_name>"

  #Optional
  private_endpoint_settings {
    nsg_ids = [oci_core_network_security_group.test_nsg.id]
    private_endpoint_ip = "10.0.0.5"
    subnet_id = oci_core_subnet.test_subnet.id
  }

  kafka_settings {
    #Optional
    auto_create_topics_enable = true
    log_retention_hours = 24
    num_partitions = 1
  }
}

resource "oci_core_vcn" "test_vcn" {
  cidr_block = "10.0.0.0/16"
  compartment_id = var.compartment_ocid
  display_name = "testvcn"
  dns_label = "dnslabel"
}
```
Streaming

```hcl
resource "oci_core_subnet" "test_subnet" {
  cidr_block     = "10.0.0.0/24"
  compartment_id = var.compartment_ocid
  vcn_id         = oci_core_vcn.test_vcn.id
}
resource "oci_core_network_security_group" "test_nsg" {
  compartment_id = var.compartment_ocid
  vcn_id         = oci_core_vcn.test_vcn.id
}
```

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 4470 and Terraform Configuration.

### Listing Streams and Stream Pools

The following sections describe how to list and retrieve the details of streams and stream pools:

- **Using the Console** on page 4874
- **Using the Command Line Interface (CLI)** on page 4875
- **Using the API** on page 4878
- **Using OCI SDKs** on page 4878
- **Using Resource Manager and Terraform** on page 4879

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a _policy_ by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which _compartment_ to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

### Using the Console

#### To Get a List of Streams

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.

   A list of existing streams is displayed.

#### To View Stream Details

Stream details include the Messages endpoint and the stream OCID.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.

   A list of existing streams is displayed.
2. Click a stream to display the stream details page.

#### To Get a List of Stream Pools

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Stream Pools on the left side of the screen.

   A list of existing stream pools is displayed.
To View Stream Pool Details

Stream pool details include encryption and Kafka Connect settings.

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Stream Pools on the left side of the screen.
   A list of existing stream pools is displayed.
3. Click a stream pool to display the stream pool details page.
4. Click on Kafka Connection Settings on the left side of the screen.
   The Kafka Connect configuration values are displayed.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Note:
The examples in this section use the full syntax for all parameters, for example --compartment-id. For some parameters, there are shortened versions that you can use instead, like -c. See the CLI online help for instances of a shortened parameter associated with a command.

Tip:
Provide input for --custom-encryption-key-details, --private-endpoint-details, and --kafka-settings as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

To get a list of streams in a compartment

oci streaming admin stream list --compartment-id <compartment_OCID>

For example:

oci streaming admin stream list --compartment-id ocid1.tenancy.oc1..exampleuniqueID

"data": [
  {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "ACTIVE",
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "name": "example_stream_2",
    "partitions": 1,
    "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "time-created": "2020-08-21T21:19:35.707000+00:00"
  },
  {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "DELETED",
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
  }
]
By default, getting a list of streams returns up to the first 10 streams in the compartment.

To get a list of streams in a stream pool

`oci streaming admin stream list --stream-pool-id <stream_pool_OCID>`

For example:

```
oci streaming admin stream list --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID
{
  "data": [
  {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "ACTIVE",
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "name": "example_stream_2",
    "partitions": 1,
    "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "time-created": "2020-08-21T21:19:35.707000+00:00"
  },
  {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "DELETED",
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "name": "example_stream_1",
    "partitions": 5,
    "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "time-created": "2020-07-16T20:59:32.904000+00:00"
  }
  ]
}
```

By default, getting a list of streams returns up to the first 10 streams in the stream pool.

To get a list of stream pools

`oci streaming admin stream-pool list --compartment-id <compartment_OCID>`

For example:

```
oci streaming admin stream-pool list --compartment-id ocid1.tenancy.oc1..exampleuniqueID
{
  "data": [
```

Oracle Cloud Infrastructure User Guide 4876
By default, getting a list of streams returns up to the first 10 streams in the compartment.

To view stream details

oci streaming admin stream get --stream-id <stream_OCID>

For example:

oci streaming admin stream get --stream-id
oci1.stream.oc1.phx.exampleuniqueID

{  "data": {  "compartment-id": "oci1.tenancy.oc1..exampleuniqueID",  "defined-tags": {},  "freeform-tags": {},  "id": "oci1.streampool.oc1.phx.exampleuniqueID",  "is-private": false,  "lifecycle-state": "ACTIVE",  "name": "MyStream",  "time-created": "2020-11-02T19:12:22.385000+00:00"  },  "etag": "0613d634-86ab-4446-973f-268d175313d4-12e9725e-5574-4f6b-995b-7dcc80271666"}
To view stream pool details

`oci streaming admin stream-pool get --stream-pool-id <stream_pool_OID>`

For example:

```
oci streaming admin stream-pool get --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "custom-encryption-key": {
      "key-state": "NONE",
      "kms-key-id": null
    },
    "defined-tags": {},
    "endpoint-fqdn": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "freeform-tags": {},
    "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "is-private": false,
    "kafka-settings": {
      "auto-create-topics-enable": false,
      "bootstrap-servers": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com:9092",
      "log-retention-hours": 24,
      "num-partitions": 1
    },
    "lifecycle-state": "ACTIVE",
    "lifecycle-state-details": null,
    "name": "MyStreamPool",
    "private-endpoint-settings": {
      "nsg-ids": null,
      "private-endpoint-ip": null,
      "subnet-id": null
    },
    "time-created": "2020-11-02T23:01:59.429000+00:00"
  },
  "etag": "\6934531c-efaa-40ba-b083-94eb2350d737-a8b10bda-09cc-45e1-800b-b66b4bc29353"
}
```

Using the API

Use the following API operations to list streams and stream pools and retrieve details:

- ListStreams
- ListStreamPools
- GetStream
- GetStreamPool

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using OCI SDKs

Use the listStreams method to return a list of streams for a given compartment or stream pool. To get details about a stream, use the getStream method and then examine the properties of the stream.

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.
Using Resource Manager and Terraform

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the OCI Terraform provider to see how your streams and stream pools are represented in Terraform configuration files.

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 4470 and Terraform Configuration.

Streams

If you're using Resource Manager to manage streams in a stack, the streams are represented as oci_streaming_stream resources.

For example:

```terraform
resource oci_streaming_stream export_example_stream {  
  compartment_id = var.compartment_ocid  
  defined_tags = {  
  }  
  freeform_tags = {  
  }  
  name               = "example_stream"  
  partitions         = "1"  
  retention_in_hours = "24"  
  #stream_pool_id = <<Optional value not found in discovery>>  
}
```

Listing Streams

You can use the oci_streaming_streams data source to retrieve the streams in your compartment if you're using the Terraform provider.

For example:

```terraform
data "oci_streaming_streams" "test_streams" {  
  #Optional  
  compartment_id = var.compartment_id  
  id = var.stream_id  
  name = var.stream_name  
  state = var.stream_state  
  stream_pool_id = oci_streaming_stream_pool.test_stream_pool.id
}
```

Stream Pools

If you're using Resource Manager to manage streams in a stack, the streams are represented as oci_streaming_stream_pool resources.

For example:

```terraform
resource oci_streaming_stream_pool export_test_stream_pool {  
  compartment_id = var.compartment_ocid  
  name           = "test_stream_pool"  
  #Optional  
  private_endpoint_settings {
```
ns_g_ids = [oci_core_network_security_group.test_nsg.id]
private_endpoint_ip = "10.0.0.5"
subnet_id = oci_core_subnet.test_subnet.id
}

kafka_settings {
  #Optional
  auto_create_topics_enable = true
  log_retention_hours = 24
  num_partitions = 1
}
}

resource "oci_core_vcn" "test_vcn" {
  cidr_block = "10.0.0.0/16"
  compartment_id = var.compartment_ocid
  display_name = "testvcn"
  dns_label = "dnscn"
}

resource "oci_core_subnet" "test_subnet" {
  cidr_block = "10.0.0.0/24"
  compartment_id = var.compartment_ocid
  vcn_id = oci_core_vcn.test_vcn.id
}

resource "oci_core_network_security_group" "test_nsg" {
  compartment_id = var.compartment_ocid
  vcn_id = oci_core_vcn.test_vcn.id
}

Stream Details

Terraform provider users can use the `oci_streaming_stream` data source to retrieve the details of a stream.
For example:

data "oci_streaming_stream" "test_stream" {
  #Required
  stream_id = oci_streaming_stream.stream.id
}

Stream Pool Details

Terraform provider users can use the `oci_streaming_stream_pool` data source to retrieve the details of a stream pool.
For example:

data "oci_streaming_stream_pool" "test_stream_pool" {
  #Required
  stream_pool_id = oci_streaming_stream_pool.test_stream_pool.id
}

Updating Streams and Stream Pools

The following topics describe how to update streams and stream pools:

- [Modifying Stream Pools](#) on page 4881
- [Moving Streams and Stream Pools](#) on page 4883
- [Updating the Master Encryption Key Assigned to a Stream Pool](#) on page 4885
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

**Policies for Private Endpoints**

To set up a private endpoint, you must have access to a VCN with a private subnet where DNS resolution is enabled. For general information about policies and permissions to do this, see IAM Policies for Networking on page 3709. Specifically, you need use permissions for a VNIC, a network security group, if you specify one, and a subnet. For example:

```plaintext
allow user group ServiceWriters to use vnics in compartment ABC
allow user group ServiceWriters to use network-security-groups in compartment ABC
allow user group ServiceWriters to use subnets in compartment XYZ
```

**Policies for Encryption Keys**

To use your own encryption key, you must let the Streaming service use a Vault key to encrypt data in streams in this stream pool. For example:

```plaintext
allow service streaming to use keys in compartment ABC where target.key.id = '=\<key_OCID>''
```

The preceding policy also requires a companion policy to let Streaming use a key on behalf of a user group to create a stream pool that uses the key for cryptographic purposes. For example:

```plaintext
allow user group StreamWriters to use key-delegate in compartment ABC where target.key.id = '=\<key_OCID>''
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

**Modifying Stream Pools**

The following sections detail how to modify stream pools:

- Using the Console on page 4881
- Using the Command Line Interface (CLI) on page 4882
- Using the API on page 4882
- Using OCI SDKs on page 4882
- Using Resource Manager and Terraform on page 4883

**Using the Console**

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Stream Pools on the left side of the screen.
   A list of existing stream pools is displayed.
3. Click the stream pool you want to edit to bring up the stream pool details page.
4. Click Edit Settings.
5. Click Edit Settings or Cancel when finished.
Using the Command Line Interface (CLI)

`oci streaming admin stream-pool update --stream-pool-id <stream_pool_OCID>`

For example:

```bash
oci streaming admin stream-pool update --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID --name MyUpdatedStreamPool
{
    "data": {
        "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
        "custom-encryption-key": {
            "key-state": "NONE",
            "kms-key-id": null
        },
        "defined-tags": {},
        "endpoint-fqdn": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
        "freeform-tags": {},
        "id": "ocid1.streampool.oc1.phx.exampleuniqueID",
        "is-private": false,
        "kafka-settings": {
            "auto-create-topics-enable": false,
            "bootstrap-servers": "cell-1.streaming.us-phoenix-1.oci.oraclecloud.com:9092",
            "log-retention-hours": 24,
            "num-partitions": 1
        },
        "lifecycle-state": "UPDATING",
        "lifecycle-state-details": null,
        "name": "MyUpdatedStreamPool",
        "private-endpoint-settings": {
            "nsg-ids": null,
            "private-endpoint-ip": null,
            "subnet-id": null
        },
        "time-created": "2020-11-02T23:01:59.429000+00:00"
    },
    "etag": "6ad44a83-4804-4cb5-87ae-2100d3a7012c-9679fcb9-37b7-48c5-9114-d514f132d363"
}
```

Tip:
Provide input for `--custom-encryption-key-details`, `--private-endpoint-details`, and `--kafka-settings` as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

Using the API

Use the following API operations to update streams and stream pools:

- UpdateStream
- UpdateStreamPool

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using OCI SDKs

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.
**Using Resource Manager and Terraform**

*Resource Manager* is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the *OCI Terraform provider* to provision Streaming resources like streams and stream pools.

**Stream Pool Resource**

If you're using Resource Manager or Terraform to manage stream pools, you can modify the *oci_streaming_stream_pool* resource in your Terraform configuration and edit your stack or run a terraform apply job.

For more information about writing configurations for use with Resource Manager, see *Terraform Configurations for Resource Manager* on page 4470 and *Terraform Configuration*.

**Moving Streams and Stream Pools**

The following sections describe how to move streams and stream pools:

- **Using the Console** on page 4883
- **Using the Command Line Interface (CLI)** on page 4883
- **Using the API** on page 4885
- **Using OCI SDKs** on page 4885
- **Using Resource Manager and Terraform** on page 4885

**Using the Console**

To move a stream to a different compartment

1. Open the navigation menu and click *Analytics & AI*. Under *Messaging*, click *Streaming*.
2. Click a stream to display the stream details page.
3. Find the stream you want to move in the list, click the the Actions icon (three dots), and then click *Move Resource*.
4. Choose the destination compartment from the list.
5. Click *Move Resource*.

To move a stream pool to a different compartment

1. Open the navigation menu and click *Analytics & AI*. Under *Messaging*, click *Streaming*.
2. Click on *Stream Pools* on the left side of the screen.
   A list of existing stream pools is displayed.
3. You can move a stream pool in two ways:
   a. Click the the Actions icon (three dots) on the right side of the stream pool you want to move and select *Move Resource*.
   b. Click the stream pool you want to move. The stream pool details screen displays. Click *Move Resource*.
4. In the *Move Resource to a Different Compartment* dialog box, choose the destination compartment from the drop-down list.
5. Click *Move Resource*.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see *Command Line Interface (CLI)* on page 5316. For a complete list of flags and options available for CLI commands, see the *Command Line Reference*. 
To move a stream to a different stream pool

oci streaming admin stream update --stream-id <stream_OCID> --stream-pool-id <stream_pool_OCID>

For example:

oci streaming admin stream update --stream-id ocid1.stream.oc1.phx.exampleuniqueID --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID

```
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "UPDATING",
    "lifecycle-state-details": null,
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "name": "MyStream",
    "partitions": 1,
    "retention-in-hours": 24,
    "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
    "time-created": "2020-11-02T19:12:22.385000+00:00"
  },
  "etag": "\"25b49cb2-f0c0-4421-b39f-899846b9d7c9-0c3a8572-1719-44ba-840d-19843352c9ba\""
}
```

To move a stream to a different compartment

oci streaming admin stream change-compartment --stream-id <stream_OCID> --compartment-id <compartment_OCID>

For example:

oci streaming admin stream change-compartment --stream-id ocid1.stream.oc1.phx.exampleuniqueID --compartment-id ocid1.tenancy.oc1..exampleuniqueID

```
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.stream.oc1.phx.exampleuniqueID",
    "lifecycle-state": "UPDATING",
    "lifecycle-state-details": null,
    "messages-endpoint": "https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com",
    "name": "MyStream",
    "partitions": 5,
    "retention-in-hours": 24,
    "stream-pool-id": "ocid1.streampool.oc1.phx.exampleuniqueID",
  },
  "etag": "\"25b49cb2-f0c0-4421-b39f-899846b9d7c9-0c3a8572-1719-44ba-840d-19843352c9ba\"
}
```
To move a stream pool to a different compartment:

```bash
oci streaming admin stream-pool change-compartment --stream-pool-id <stream_pool_OCID> --compartment-id <target_compartment_OCID>
```

For example:

```bash
oci streaming admin stream-pool change-compartment --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

Using the API

Use the following API operations to manage streams and stream pools:

- UpdateStream
- ChangeStreamCompartment
- ChangeStreamPoolCompartment

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using OCI SDKs

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.

Using Resource Manager and Terraform

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the OCI Terraform provider to provision Streaming resources like streams and stream pools.

Stream Pool Resource

If you're using Resource Manager or Terraform to manage stream pools, you can modify the `oci_streaming_stream_pool` resource in your Terraform configuration and edit your stack or run a `terraform apply` job.

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 4470 and Terraform Configuration.

**Updating the Master Encryption Key Assigned to a Stream Pool**

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

**Policies for Encryption Keys**

To use your own encryption key, you must let the Streaming service use a Vault key to encrypt data in streams in this stream pool. For example:

```bash
allow service streaming to use keys in compartment ABC where target.key.id = '<key_OCID>'
```

The preceding policy also requires a companion policy to let Streaming use a key on behalf of a user group to create a stream pool that uses the key for cryptographic purposes. For example:

```bash
allow user group StreamWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

**Using the Console**

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click Stream Pools.
3. Click a stream pool to display the stream details page.
4. In **Stream Pool Information**, next to Encryption Key, do one of the following:
   - To stop using an Oracle-managed key in favor of a Vault master encryption key that you manage, click **Assign**, select a vault and encryption key you have access to, and then click **Assign**.
   - To select a different Vault master encryption key that you manage, click **Update**, select a vault and encryption key you have access to, and then click **Update**.
   - Click **Unassign** to remove the assigned Vault master encryption key and let Oracle manage the encryption key, and then click **Unassign** again to confirm the removal of the existing key assignment.

**Deleting Streams and Stream Pools**

Refer to the following sections to delete streams and stream pools:

- Using the Console on page 4887
- Using the Command Line Interface (CLI) on page 4887
- Using the API on page 4888
- Using OCI SDKs on page 4888
- Using Resource Manager and Terraform on page 4888

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

**Using the Console**

*To delete a stream*

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. You can delete a stream in two ways:
   a. Click the Actions icon (three dots) on the right side of the stream you want to delete and select Delete Stream.
   b. Click the stream you want to delete. The stream details screen displays. Click Delete.
3. Confirm when prompted.

*To delete a stream pool*

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Stream Pools on the left side of the screen.
   A list of existing stream pools is displayed.
3. You can delete a stream pool in two ways:
   a. Click the Actions icon (three dots) on the right side of the stream pool you want to delete and select Delete Stream Pool.
   b. Click the stream pool you want to delete. The stream pool details screen displays. Click Delete.
4. Confirm when prompted.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Note:**

The examples in this section use the full syntax for all parameters, for example --compartment-id. For some parameters, there are shortened versions that you can use instead, like -c. See the CLI online help for instances of a shortened parameter associated with a command.

*To delete a stream*

**Caution:**

Stream contents are deleted immediately. You cannot recover a deleted stream.

```
oci streaming admin stream delete --stream-id <stream_OCID>
```

For example:

```
oci streaming admin stream --delete --stream-id ocid1.stream.oc1.phx.exampleuniqueID
Are you sure you want to delete this resource? [y/N]:
```

Select y and press Enter. The stream is deleted with no further prompting.
To delete a stream pool

Caution:
The stream pool and all streams within the pool are deleted immediately. You cannot recover a deleted stream pool.

```
oci streaming admin stream-pool delete --stream-pool-id <stream_pool_OCID>
```

For example:

```
oci streaming admin stream-pool delete --stream-pool-id ocid1.streampool.oc1.phx.exampleuniqueID
```

Are you sure you want to delete this resource? [y/N]:

Select y and press Enter. The stream pool is deleted with no further prompting.

Using the API

Use the following API operations to delete streams and stream pools:

- DeleteStream
- DeleteStreamPool

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Using OCI SDKs

See the Developer Guide to Streaming on page 4908 for detailed SDK examples.

Using Resource Manager and Terraform

Resource Manager is an Oracle Cloud Infrastructure (OCI) service that allows you to automate the process of provisioning your OCI resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

A Terraform configuration codifies your infrastructure in declarative configuration files. The configuration defines the resources you intend to provision, variables, and specific instructions for provisioning the resources.

You can use Resource Manager or the Terraform CLI with the OCI Terraform provider to manage Streaming resources like streams and stream pools.

To delete a Streaming resource:

- If you're using Resource Manager to manage streams and stream pools, you can run a destroy job and then delete your stack.
- If you use the Terraform CLI, you can run terraform destroy.

For more information about writing configurations for use with Resource Manager, see Terraform Configurations for Resource Manager on page 4470 and Terraform Configuration.

Publishing Messages

Once a stream is created and active, you can publish messages. See Publishing with the Console, CLI, and API on page 4889 or the Developer Guide to Streaming on page 4908 for details on publishing, and familiarize yourself with partitioning, large messages, and batching and throttling for additional context.

Tip:

You can also use Oracle Cloud Infrastructure Service Connector Hub to publish data to a stream from supported source services, such as Logging.
**Messages and Partitions**

Messages are published to a single partition in a stream. If there is more than one partition in the stream, the decision of which partition to publish the message to depends on whether your producers are using the Streaming API and `PutMessages`, or taking advantage of Streaming's Kafka compatibility and using the Kafka API.

If your producers are using the Streaming API, partitioning is handled server-side by the Streaming service. If your producers are using the Kafka API, partitioning is handled client-side by Kafka.

**Server-side Partitioning**

The partition where a message is published is calculated using the message's key. If the key is null, the partition is calculated using a random 16-byte value. You cannot specify which partition a key uses.

Passing a null key puts the message in a random partition. If a user publishes the same message twice, it could go to different partitions, since a completely new key is generated. Do not expect all messages with a null key to go to the same partition. If you want to ensure that messages with the same value go to the same partition, you should use the same key for those messages.

For more information, see Publishing to Partitions on page 4865.

**Handling Large Messages**

If your messages are larger than the 1 MB limit, you can either use chunking or send the message by using Oracle Cloud Infrastructure Object Storage.

- **Chunking**: You can split large payloads into multiple, smaller chunks that the Streaming service can accept. The chunks are stored in the service in the same way that ordinary (non-chunked) messages are stored. The only difference is that the consumer must keep the chunks and combine them into the message when all the chunks have been collected. The chunks in the partition can be interwoven with ordinary messages.

- **Object Storage**: A large payload is placed in Object Storage and only the pointer to that data is transferred. The receiver recognizes this type of pointer payload, transparently reads the data from Object Storage, and provides it to the end user.

**Batching and Throttling**

We recommend batching messages to avoid throttling and enable better throughput. The size of a batch of messages shouldn't exceed 1 MB. If this limit is exceeded, the message fails to validate.

The throttling mechanism for `PutMessages` is activated when data write rates exceed 1 MB per second per partition. There is no limitation on the number of writes to a stream, as long as you are under the 1 MB per second per partition throughput.

See Limits on Streaming Resources on page 4864 for more information.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a `policy` by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which `compartment` to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

**Publishing with the Console, CLI, and API**

While you can use the Console to publish test messages to a stream, you should use the CLI, API, or an SDK to populate your stream.
To publish messages using the Oracle Cloud Infrastructure (OCI) SDKs, see the Developer Guide to Streaming on page 4908.

If you take advantage of Streaming's Kafka compatibility, see Developing with Kafka and Streaming on page 4935.

Tip:
You can also use Oracle Cloud Infrastructure Service Connector Hub to publish data to a stream from supported source services, such as Logging.

**Using the Console to Produce a Test Message**

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click a stream to display the stream details page.
3. Click **Produce Test Message**.
4. On the Test Stream dialog, enter the text-only message to produce in the Data text box.
5. Click **Produce**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To publish a message

```
oci streaming stream message put --stream-id <stream_id> --messages <JSON_messages> --endpoint <messages_endpoint>
```

Tip:
Provide input for --messages as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information about JSON formatting.

For example, `file.txt` contains the properly formatted JSON. Its values are Base64-encoded:

```
[
  {
    "key": "a2V5MQ==",
    "value": "dmFsdWUx"
  },
  {
    "key": "a2V5Mg==",
    "value": "dmFsdWUy"
  }
]
```

The --messages parameter takes the file as its value:

```
```

```
{
  "data": {
    "entries": [
      {
        "error": null,
        "error-message": null,
        "offset": 0,
        "partition": "0",
        "timestamp": "2020-11-03T21:35:03.837000+00:00"
      },
```
Using the API

Use the following API operations to produce messages:

- **PutMessages**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Consuming Messages

Consuming messages from a stream requires you to:

- Create a cursor.
- Use the cursor to read messages.
- Use the returned cursor to continue reading messages.

You can use an individual consumer to read messages from one or more streams, or use consumer groups to read messages from a stream.

**Tip:**

You can also use Oracle Cloud Infrastructure Service Connector Hub to consume data from a stream and pass messages to Object Storage or any other supported Service Connector Hub target.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: The policy in [Let streaming users manage streams](#) on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

You can create a policy that gives a tenant **stream-pull** access to consume data from a stream in another tenant. See [Accessing Streaming Resources Across Tenancies](#) on page 4863 and [Details for the Streaming Service](#) if you want to dig deeper into writing policies for the Streaming service.

If you're new to policies, see [Getting Started with Policies](#) on page 2799 and [Common Policies](#) on page 2806.

Using Individual Consumers

If you choose to use individual consumers to consume messages from your streams instead of using **consumer groups**, you can't take advantage of many of the benefits of Streaming, such as service-managed coordination, horizontal scaling, and offset management. Your applications will need to handle these scenarios, and many more, programmatically.

For these reasons, we recommend using **consumer groups** in a production environment, but it may be useful to use individual consumers for testing or proof-of-concept applications.
Using Cursors

A cursor is a pointer to a location in a stream. The location could be a specific offset or time in a partition.

Before you start to consume messages, you need to indicate the point from which you want to start consumption. You can do this by creating a cursor using the CreateCursor API.

There are five supported cursor types:

- **TRIM_HORIZON** - Start consuming from the oldest available message in the stream. Create a cursor at the TRIM_HORIZON to consume all messages in a stream.
- **AT_OFFSET** - Start consuming at a specified offset. The offset must be greater than or equal to the offset of the oldest message and less than or equal to the latest published offset.
- **AFTER_OFFSET** - Start consuming after the given offset. This cursor has the same restrictions as the AT_OFFSET cursor.
- **AT_TIME** - Start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- **LATEST** - Start consuming messages that were published after you created the cursor.

When you create a cursor for an individual consumer, you need to specify the partition in the stream that the cursor should use. If your stream has more than one partition with messages, you need to create multiple cursors to read them.

Once you've created a cursor, you can start to consume messages using GetMessages.

As long as you keep consuming messages, there is no need to re-create a cursor, so cursors should be created outside of your loops to get messages.

Getting Messages

Once you've created a cursor, call GetMessages and specify that cursor to start consuming messages. The service responds with your messages and the opc-next-cursor header value that you should use in your next GetMessages call. The returned cursor is never null, but it expires in five minutes. If you stop consuming messages for longer than five minutes, you will need to re-create a cursor.

If you have more than one consumer reading from the same partition, they will receive the same messages. Your application should decide how to process messages.

If there are no more unread messages in the partition, Streaming returns an empty list of messages.

GetMessages batch sizes are based on the average message size published to the stream. By default, the service returns as many messages as possible. You can use the limit parameter to specify any value up to 10,000, but consider your average message size to avoid exceeding throughput on the stream.

Falling behind

To determine if your consumer is falling behind (you're producing faster than you're consuming), you can use the timestamp of the message. If the consumer is falling behind, consider spawning additional consumers to take over some of the partitions from the first consumer. There's no way to recover if you're falling behind on a single partition.

Consider the following options:

- Create a new stream with more partitions.
- Use consumer groups.
- If the issue is caused by a hotspot, change the message key strategy.
- Reduce message processing time, or handle requests in parallel.

If you want to know how many messages are left to consume in a given partition, use a cursor of type LATEST, get the offset of the next published message, and make the delta with the offset that you are currently consuming.

Managing Offsets

Offsets indicate the location of a message within a partition. If your consumer restarts or you need to recover from a failure, you can use the offset to restart reading from the stream.
Streaming Tip:

Consumer groups can manage offset commits automatically.

When you use individual consumers, your consumer application must manage processed offsets. The consumer is responsible for storing which offsets it reached or stopped at, for each partition. When your consumer restarts, read the offset of the last message that you processed, and then create a cursor of type \texttt{AFTER\_OFFSET} and specify the offset that you just got. We don't provide any guidance for storing the offset of the last message that you processed. You may use any method, such as another stream, a file on your machine, or Object Storage.

Note:

Message offsets aren't dense. Offsets are monotonically increasing numbers. They do not decrease, and sometimes they increase by more than one. For example, if you publish two messages to the same partition, the first message could have an offset of 42 and the second message could have an offset of 45 (offsets 43 and 44 being non-existent).

Using Consumer Groups

Consumers can be configured to consume messages as part of a group. In a production environment with multiple partitions, using a consumer group is our recommended method of consuming Streaming messages.

Each stream partition is assigned to a member of a consumer group. An individual member of a consumer group is called an \textit{instance}. Each instance in a consumer group receives messages from one or more partitions, unless there are more instances than partitions. Instances in excess of the partition count for the stream do not receive messages.

Consumer groups handle the coordination that is required for multiple consumers to share the consumption of a stream. A consumer group automatically:

\begin{itemize}
\item Assigns one or more partitions to an instance
\item Tracks the messages received by the group and manages commits
\item Requests the proper partition(s) and offset(s) on behalf of each instance
\item Balances the group as instances join or leave
\end{itemize}

Up to 50 consumer groups can read from a single stream. Each consumer group receives all of the messages in the stream at least once.

Consumer groups are ephemeral. They disappear when they're not used for the retention period of the stream.

Creating a Consumer Group

A consumer group is created on the first \texttt{CreateGroupCursor} request. Group cursors define a group name/instance name pair. When you create your group cursor, you should provide the ID of the stream, a group name, an instance name, and one of the following supported cursor types:

\begin{itemize}
\item \texttt{TRIM\_HORIZON} - The group will start consuming from the oldest available message in the stream.
\item \texttt{AT\_TIME} - The group will start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
\item \texttt{LATEST} - The group will start consuming messages that were published after you created the cursor.
\end{itemize}

Group cursor types are ignored on \texttt{CreateGroupCursor} calls that include the name of an existing group. That group's committed offsets are used instead of the provided cursor type.

Streaming uses the instance name to identify members of the group when managing offsets. Use unique instance names for each instance of the consumer group.

If you want the Streaming service to handle committing offsets, you should leave the group cursor's \texttt{commitOnGet} value set to \texttt{true}. We recommend using this method to reduce application complexity since your application does not have to handle commits.
Streaming

Consuming as a Group

After your instances join the consumer group, they can read messages from the stream using GetMessages. Each call to GetMessages returns the cursor to use in the next GetMessages call as the opc-next-cursor header value. The returned cursor is never null, but it expires in five minutes. As long as you keep consuming, you should never have to re-create a cursor.

When Streaming receives a request for messages from an instance, the service:

- Checks to see whether a group rebalance is necessary
- Commits the offset(s) from that instance's previous request, if any
- Responds with the messages defined by the request's cursor

GetMessages batch sizes are based on the average message size published to that stream. By default, the service returns as many messages as possible. You can use the limit parameter to specify any value up to 10,000, but consider your average message size to avoid exceeding throughput on the stream or timeouts.

If there are no more unread messages in the partition, Streaming returns a list of empty messages.

Because consumer groups remove instances that have stopped consuming messages for more than 30 seconds, you should request fewer messages to avoid timeouts, or extend the timeout using ConsumerHeartbeat.

A partition cannot be assigned to multiple instances within the same consumer group. If you have more instances than partitions, the unassigned instances can send GetMessages requests, but they won't receive any messages. They remain otherwise idle until the consumer group needs to replace an instance, such as when an existing member of the group does not act within the timeout period.

If you need to manually update the group's position, you can use UpdateGroup to reset the location of all consumers in the group to the specified location in the stream.

Offsets and Commits

Offsets indicate the location of a message within a partition. If a consumer restarts or you need to recover from a failure, you can use the offset to restart reading from the stream.

When you use a consumer group, Streaming handles offsets automatically. The default behavior of commitOnGet=true means that offsets from the previous request are committed. For example:

For consumer A:

- A calls GetMessages and receives messages from an arbitrary partition, with offsets of 1–100.
- A processes all 100 messages successfully.
- A processes 15 messages, and then goes offline unexpectedly (for more than 30 seconds).

A new consumer B:

- B calls GetMessages, and the Streaming service uses the latest committed offset and returns messages with offsets 101–200.
- B continues the message loop.

In this example, a portion (15) of the messages were processed at least once, which means that they could have been processed more than once, but no data is lost.

Streaming provides 'at-least-once' semantics for consumer groups. Consider when offsets are committed in a message loop. If a consumer goes offline before committing a batch of messages, that batch might be given to another consumer. When a partition is given to another consumer, the consumer uses the latest committed offset to start consumption. The consumer doesn't get messages before the committed offset. We recommend that consumer applications take care of duplicates.

Note:

Message offsets aren't dense. Offsets are monotonically increasing numbers. They do not decrease, and sometimes they increase by more than one. For
Streaming example, if you publish two messages to the same partition, the first message could have an offset of 42 and the second message could have an offset of 45 (offsets 43 and 44 being non-existent).

If you want to override the default offset behavior and implement a custom offset commit mechanism, set commitOnGet to false when creating the group cursor. You can use ConsumerCommit to commit messages without reading more messages. ConsumerCommit returns a cursor for you to use in your next request.

**Caution:**
Writing custom commit logic is complicated and full of race conditions and considerations. Many cases exist in which some internal state is changed, and the client is required to handle the situation.

**Balancing and Rebalancing**
Streaming considers the number of partitions in the stream and the number of instances in the consumer group when assessing balance. Group balancing is automatic. Each consumer is assigned to one or more partitions based on the following calculation:

\[
\left(\frac{n_{\text{Partitions}}}{n_{\text{Consumers}}}\right) \pm 1
\]

For example, if there are eight partitions in the stream and four consumers in the group, each consumer is assigned to two partitions. If there are 10 partitions in the stream and four consumers in the group, two consumers are assigned to two partitions, and two consumers are assigned to three partitions.

As instances join or leave a consumer group and requests are made for messages, partition assignments are reassessed. If the stream has at least one partition more than the number of current instances in the group, and a new instance joins, partitions are reassigned to all instances, including the new one. If an instance in the group stops consuming messages for more than 30 seconds, or fails to send a ConsumerHeartbeat within 30 seconds, that instance is removed from the consumer group and its partition is reassigned, if possible, to another instance.

These events are called *rebalancing*. The instances in the group are not aware of the rebalancing process, but the group has coordinated to own a mutually exclusive set of partitions in the stream.

At the end of a successful rebalance operation for a consumer group, every partition within the stream is owned by an instance within the group.

In this way, you can *scale the number of instances up to the number of the partitions* until each instance is consuming messages from only one partition. This configuration maximizes your stream's available throughput. After that point, any new instance joining the group remains in an idle state without being assigned to any partition.

**Consuming with the Console, CLI, and API**
While you can use the Console to view the latest messages in a stream, you should use the CLI, API, or an SDK to manage cursors and consume from your stream.

To consume messages using the Oracle Cloud Infrastructure (OCI) SDKs, see the Developer Guide to Streaming on page 4908.

If you take advantage of Streaming's Kafka compatibility, see Developing with Kafka and Streaming on page 4935.

**Tip:**
You can also use Oracle Cloud Infrastructure Service Connector Hub to consume data from a stream and pass messages to Object Storage or any other supported Service Connector Hub target.

**Using the Console**
You cannot use the Console to consume messages, but you can use it to show recent messages on a stream:

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click a stream to display the stream details page.
3. In the Recent Messages panel, click Load messages.

Note:
Streams using private endpoints are not accessible from the internet, so their messages do not display in the Console.

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To create a cursor

oci streaming stream cursor create-cursor --stream-id <stream_OCID> --partition <partition> --type <cursor_type> --endpoint <messages_endpoint>

For example:

oci streaming stream cursor create-cursor --stream-id ocid1.stream.oc1.phx.exampleuniqueID --partition 0 --type TRIM_HORIZON --endpoint https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com
{
  "data": {
    "value": "examplecursorvalue"
  }
}

To create a group cursor

oci streaming stream cursor create-group-cursor --stream-id <stream_OCID> --group-name <consumer_group_name> --type <cursor_type> --endpoint <messages_endpoint>

For example:

oci streaming stream cursor create-group-cursor --stream-id ocid1.stream.oc1.phx.exampleuniqueID --group-name MyConsumerGroup --type TRIM_HORIZON --endpoint https://cell-1.streaming.us-phoenix-1.oci.oraclecloud.com
{
  "data": {
    "value": "examplegroupcursorvalue"
  }
}

To get messages

oci streaming stream message get --stream-id <stream_OCID> --cursor <cursor> --endpoint <messages_endpoint>

Your first request to get messages should use the value returned when you created a cursor. Each subsequent request should use the opc-next-cursor value returned in the previous response.

For example:

{
  "data": [
To send a heartbeat

oci streaming stream group heartbeat --stream-id <stream_OCID> --cursor <cursor> --endpoint <messages_endpoint>

Your first heartbeat request should use the value returned when you created a group cursor. Each subsequent request should use the value returned in the previous response.

For example:

{
   "data": {
      "value": "examplenextcursorvalue"
   }
}

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations to consume messages:

• CreateCursor
Using Streaming with Apache Kafka

Oracle Cloud Infrastructure Streaming lets users of Apache Kafka offload the setup, maintenance, and infrastructure management that hosting your own Zookeeper and Kafka cluster requires.

Streaming is compatible with most Kafka APIs, allowing you to use applications written for Kafka to send messages to and receive messages from the Streaming service without having to rewrite your code. See Using Kafka APIs on page 4899 for more information.

Streaming can also utilize the Kafka Connect ecosystem to interface directly with external sources like databases, object stores, or any microservice on the Oracle Cloud. Kafka connectors can easily and automatically create, publish to, and deliver topics while taking advantage of the Streaming service's high throughput and durability. See Using Kafka Connect on page 4901 for more information.

Use cases for Streaming and Kafka include:

- Move data from Streaming to Autonomous Data Warehouse via the JDBC Connector to perform advanced analytics and visualization.
- Use the Oracle GoldenGate connector for Big Data to build an event-driven application.
- Move data from Streaming to Oracle Object Storage via the HDFS/S3 Connector for long term storage, or to run Hadoop/Spark jobs.

Kafka API Support

Streaming is fully upstream compatible with the latest versions of Kafka APIs. Streaming supports the following Kafka APIs:

- **Producer** (v0.10.0 and later)
- **Consumer** (v0.10.0 and later)
- **Connect** (v0.10.0.0 and later)
- **Admin** (v0.10.1.0 and later)
- **Group Management** (v0.10.0 and later)

The following Kafka APIs and features are not yet implemented in the Streaming service:

- **Kafka Streams**
- **Compaction**
- **Transactions**
- **Dynamic Partition Addition**
- **Idempotent production**

Kafka Clients

While many Kafka clients are available, we recommend those that have been fully tested and certified to work with the Streaming service.

Streaming supports all versions of these Kafka clients:

- **librdkafka**
- **apache-kafka-java**
- **confluent-kafka-python**

Requirements and Limitations

The implementation of Streaming's Kafka compatibility results in the following configurations, limitations, and behaviors.
**Lossless Configuration**

Streaming only supports lossless Kafka configurations. Data is replicated three ways. Messages from producers do not initiate an acknowledgment (ACK) from Streaming until at least two replicas are in sync.

**Unique Stream Names**

If you have streams with the same names in a compartment, you can't use Kafka with Streaming until you delete the duplicated streams, unless the streams are in different stream pools. Two streams with the same name can exist in the same compartment only if the streams are in different stream pools.

Duplicate stream names otherwise manifest through an "authentication failed" error. If you do not want to delete your streams, contact the Streaming team so we can rename your streams without data loss.

**Load Balancing Connection Recycling**

Because the Kafka protocol uses long-lived TCP connections, the Streaming Kafka compatibility layer implements a load balancing mechanism to periodically balance connections between front-end nodes. This mechanism periodically closes connections to force new ones. Most Kafka SDKs handle these disconnections automatically when consuming, but producing to Streaming using the Kafka API might raise disconnection errors. Disconnections can be mitigated by adding retries to your requests. Retries are part of the Kafka SDK and are automatically enabled, and you can explicitly configure their behavior.

**Using Kafka APIs**

This topic describes how to configure Apache Kafka for API compatibility with Oracle Cloud Infrastructure Streaming. When your producers use Kafka APIs to interact with Streaming the decision of which partition to publish a unique message to is handled client-side by Kafka.

Please refer to Kafka API Support on page 4898 for additional information.

**Endpoints**

For bootstrap servers, use your region endpoint on port 9092. For example:

```
streaming.us-phoenix-1.oci.oraclecloud.com:9092
```

**Authentication**

Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. You can generate tokens in the Console user details page. See Working with Auth Tokens on page 3150 for more information.

**Tip:**

Create a dedicated group/user and grant that group the permission to manage streams in the appropriate compartment or tenancy. The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources. You then can generate an auth token for the user you created and use it in your Kafka client configuration.

Your username must be in the following format:

```
tenancyName/username/streamPoolId
```

**Tip:**

If you are using the Java SDK, you can also use instance principal authorization.
**Kafka Configuration**

Set the following properties for your Kafka client.

**For the Java SDK**

Recommended settings for Java SDK:

```java
Properties properties = new Properties();
properties.put("bootstrap.servers", "streaming.
{region}.oci.oraclecloud.com:9092");
properties.put("security.protocol", "SASL_SSL");
properties.put("sasl.mechanism", "PLAIN");
properties.put("sasl.jaas.config", "org.apache.kafka.common.security.plain.PlainLoginModule required username=""{tenancyName}/"{username}/"{streamPoolId}" password=""{authToken}";";

Recommended settings for Java SDK producers:

```java
properties.put("retries", 5); // retries on transient errors and load balancing disconnection
properties.put("max.request.size", 1024 * 1024); // limit request size to 1MB
```

Recommended settings for Java SDK consumers:

```java
properties.put("max.partition.fetch.bytes", 1024 * 1024); // limit request size to 1MB per partition
```

**For the Librdkafka SDK**

Recommended settings for Librdkafka SDK:

```java
'metadata.broker.list': 'streaming.{region}.oci.oraclecloud.com:9092',
'security.protocol': 'SASL_SSL',
'sasl.mechanisms': 'PLAIN',
'sasl.username': '{tenancyName}/'username}/{streamPoolID}',
'sasl.password': '{authToken}'
```

Recommended settings for Librdkafka SDK producers:

```java
'message.send.max.retries': 5 // retries on transient errors and load balancing disconnection
'max.request.size': 1024 * 1024 // limit request size to 1 MB
```

Recommended settings for Librdkafka SDK consumers:

```java
'max.partition.fetch.bytes': 1024 * 1024 // limit request size to 1 MB per partition
```

**Instance Principal Authorization for the Java SDK**

If you are using the Java SDK, you can authorize an instance to interact with Streaming instead of using auth tokens.

To configure the Java SDK for instance principal authorization:

1. Verify that you have a valid Oracle Cloud Infrastructure (OCI) SDK and CLI configuration file.
2. Import the Oracle Cloud Infrastructure SDK for Java into your project. See Getting Started with the SDK for Java for more information.
3. Add the following Oracle Cloud Infrastructure SDK for Java dependency:

```xml
<dependency>
  <groupId>com.oracle.oci.sdk</groupId>
  <artifactId>oci-java-sdk-addons-sasl</artifactId>
  <optional>false</optional>
  <version>1.13.1</version> <!-- that's the minimum version to use -->
</dependency>
```

4. Modify the `sasl.mechanism` property of your Kafka client configuration:

```java
properties.put("sasl.mechanism",
  OciMechanism.OCI_RSA_SHA256.mechanismName());
```

5. Modify the `sasl.jaas.config` property of your Kafka client configuration using one of the following options:

```java
properties.put("sasl.jaas.config",
  "com.oracle.bmc.auth.sasl.InstancePrincipalsLoginModule required intent=
  \"streamPoolId:\<streamPoolId>\";\");

properties.put("sasl.jaas.config",
  "com.oracle.bmc.auth.sasl.UserPrincipalsLoginModule required
  config=\"<pathToConfig>\" profile=\"<profile>\" intent=
  \"streamPoolId:\<streamPoolId>\";\";");
```

- If `config` is not specified, the default config path is used (`~/.oci/config`).
- If `profile` is not specified, the default profile is used (DEFAULT).

Using Kafka Connect

To use your Kafka connectors with Oracle Cloud Infrastructure Streaming, create a Kafka Connect configuration using the Console or the command line interface (CLI). The Streaming API calls these configurations harnesses.

**Note:**

Kafka Connect configurations created in a given compartment work only for streams in the same compartment.

You can use multiple Kafka connectors with the same Kafka Connect configuration. In cases that require producing or consuming streams in separate compartments, or where more capacity is required to avoid hitting throttle limits on the Kafka Connect configuration (for example: too many connectors, or connectors with too many workers), you can create more Kafka Connector configurations.

For more information on managing Kafka Connect configurations using the Console and Streaming API, see Managing Kafka Connect Configurations on page 4903.

Kafka Connectors

Streaming’s Kafka Connect compatibility means that you can take advantage of the many existing first- and third-party connectors to move data from your sources to your targets.

Kafka connectors for Oracle products:
• Oracle Cloud Infrastructure Object Storage (Using Kafka Connect for S3)
  • Kafka Connect Amazon S3 source connector, for producers
  • Kafka Connect Amazon S3 sink connector, for consumers
• Oracle Integration Cloud
• Oracle Database (Using Kafka Connect JDBC)
• Oracle GoldenGate

For a complete list of third-party Kafka source and sink connectors, refer to the official Confluent Kafka hub.

**Kafka Connect Topics**

The Streaming service automatically creates the three topics (`config`, `offset`, and `status`) that are required to use Kafka Connect when you create the Kafka Connect configuration. These topics contain the OCID of the Kafka Connect configuration in their names.

Place these topic names in the `connect-distributed.properties` file of the Kafka connector that you want to use with Streaming.

For example:

```java
# Relevant Kafka Connect setting
cfg.storage.topic:<connect_configuration_OCID>-config
offset.storage.topic:<connect_configuration_OCID>-offset
status.storage.topic:<connect_configuration_OCID>-status
```

**Note:**

These three compacted topics are meant to be used by Kafka Connect and Streaming to store configuration and state management data, and should not be used to store your data. To ensure that the Kafka Connect configuration topics are being used for their intended purpose by the connectors, there are hard throttle limits of 50 kb/s and 50 rps in place for these topics.

**Bootstrap Server**

Set the bootstrap server in your Kafka connector properties file to the endpoint for Streaming on port 9092. For example:

```
streaming.us-phoenix-1.oci.oraclecloud.com:9092
```

**Note:**

For a list of endpoints for Streaming, see the Streaming section in API Reference and Endpoints.

**Authentication**

Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. You can generate tokens in the Console user details page. See Working with Auth Tokens on page 3150 for more information.

**Tip:**

It's a good idea to create a dedicated group/user and grant that group the permission to manage streams in the appropriate compartment or tenancy. You then can generate an auth token for the user you created and use it in your Kafka client configuration.
Example Kafka Connector Properties File

The following shows an example Kafka connector `connect-distributed.properties` file:

```properties
bootstrap.servers=<streaming_endpoint>:9092
sasl.mechanism=PLAIN
security.protocol=SASL_PLAINTEXT
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
producer.sasl.mechanism=PLAIN
producer.security.protocol=SASL_PLAINTEXT
producer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
consumer.sasl.mechanism=PLAIN
consumer.security.protocol=SASL_PLAINTEXT
consumer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
    required username="<userid>" password="<authToken>";
config.storage.topic:<connect_configuration_OCID>-config
offset.storage.topic:<connect_configuration_OCID>-offset
status.storage.topic:<connect_configuration_OCID>-status
```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

- Blog post: Oracle Streaming Service with Kafka Connect

Managing Kafka Connect Configurations

This topic describes how to work with Kafka Connect configurations. The Streaming API calls these configurations harnesses.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

To allow a group to manage Kafka Connect configurations, you need to create the correct policy in your tenancy. For example:

```bash
allow group KafkaAdmins to manage connect-harnesses in tenancy
```

For administrators: The policy in Let streaming users manage streams on page 2819 lets the specified group do everything with streaming and related Streaming service resources.
Streaming

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference and Accessing Streaming Resources Across Tenancies on page 4863.

Using the Console
To create a Kafka Connect Configuration

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. Click Create Kafka Connect Configuration to display the Create Kafka Connect Configuration page.
4. Select a compartment in the Compartment drop-down list.
5. Enter a name for the configuration in the Kafka Connect Configuration Name text box. Avoid entering confidential information.
6. Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click Create Kafka Connect Configuration.
8. The details page for the new Kafka Connect configuration has a read-only text box labeled Kafka Connect Storage Topics.
   a. Click Copy to copy the connector configuration so you can paste it into the connect-distributed.properties file for your Kafka connector. For more information, see the official Kafka Connect documentation.

To delete a Kafka Connect Configuration

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. You can delete a Kafka Connect configuration in two ways:
   a. Click the the Actions icon (three dots) on the right side of the configuration you want to delete and select Delete Kafka Connect Configuration.
   b. Click the configuration you want to delete. The Kafka Connect Configuration Details page displays. Click Delete.
4. Confirm when prompted.

To move a Kafka Connect Configuration to a different compartment

1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click on Kafka Connect Configurations on the left side of the screen.
   A list of existing Kafka Connect configurations is displayed.
3. You can move a Kafka Connect configuration in two ways:
   a. Click the the Actions icon (three dots) on the right side of the configuration you want to move and select Move Resource.
   b. Click the configuration you want to move. The Kafka Connect Configuration Details screen displays. Click Move Resource.
4. In the Move Resource to a Different Compartment dialog box, choose the destination compartment from the drop-down list.
5. Click Move Resource.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316. For a complete list of flags and options available for CLI commands, see the Command Line Reference.
Note:

The examples in this section use the full syntax for all parameters, for example `--compartment-id`. For some parameters, there are shortened versions that you can use instead, like `-c`. See the CLI online help for instances of a shortened parameter associated with a command.

To get a list of Kafka Connect configurations

```bash
ci streaming admin connect-harness list --compartment-id <compartment_OCID>
```

For example:

```bash
ci streaming admin connect-harness list --compartment-id exampleuniqueID
{
  "data": [
    {
      "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
      "defined-tags": {},
      "freeform-tags": {},
      "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
      "lifecycle-state": "ACTIVE",
      "name": "MyKafkaConnectConfig",
      "time-created": "2020-08-31T17:26:09.640000+00:00"
    }
  ]
}
```

By default, getting a list of Kafka Connect configurations returns up to the first 10 configurations in the compartment.

To create a Kafka Connect configuration

```bash
ci streaming admin connect-harness create --name <kafka_connect_configuration_name> --compartment-id <compartment_OCID>
```

For example:

```bash
ci streaming admin connect-harness create --name MyKafkaConnectConfig --compartment-id exampleuniqueID
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
    "defined-tags": {},
    "freeform-tags": {},
    "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": null,
    "name": "MyKafkaConnectConfig",
    "time-created": "2020-11-04T17:36:44.323000+00:00"
  },
  "etag": "\"48886b1f-333f-4142-a335-ed42e88b37f8-0e7d329d-c6df-47fc-b814-f1237b414281\""
}
```

To view Kafka Connect configuration details

```bash
ci streaming admin connect-harness get --connect-harness-id <kafka_connect_configuration_OCID>
```
For example:

```bash
oci streaming admin connect-harness get --connect-harness-id exampleuniqueID
{
        "data": {
            "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
            "defined-tags": {},
            "freeform-tags": {},
            "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
            "lifecycle-state": "ACTIVE",
            "lifecycle-state-details": null,
            "name": "MyKafkaConnectConfig",
            "time-created": "2020-08-31T17:26:09.640000+00:00"
        },
        "etag": "\5cca5a19-ad06-42f4-b11e-3945d1b0ece5-a3cec7b6-7b84-4056-b411-10fd9f4b1763"
    }
```

To update a Kafka Connect configuration

```bash
oci streaming admin connect-harness update --connect-harness-id <kafka_connect_configuration_OCID> --defined-tags <JSON_tags>
```

For example:

```bash
oci streaming admin connect-harness update --connect-harness-id exampleuniqueid --defined-tags "{"tagNamespace": {"tagKey1": "tagValue1","tagKey2": "tagValue2"}}"
```

WARNING: Updates to freeform-tags and defined-tags will replace any existing values. Are you sure you want to continue? [y/N]: y

Select y and press Enter. The Kafka Connect configuration is updated:

```json
{
    "data": {
        "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
        "defined-tags": {
            "tagNamespace": {
                "tagKey1": "tagValue1",
                "tagKey2": "tagValue2"
            }
        },
        "freeform-tags": {},
        "id": "ocid1.connectharness.oc1.phx.exampleuniqueID",
        "lifecycle-state": "UPDATING",
        "lifecycle-state-details": null,
        "name": "MyKafkaConnectConfig",
        "time-created": "2020-08-31T17:26:09.640000+00:00"
    },
    "etag": "\f3b74455-2584-4f20-a8bd-24068b1d0cba-2f66ecfe-2e34-4c92-90d6-5c643b2be3fb"
}
```

To delete a Kafka Connect configuration
Caution:
Kafka Connect configurations are deleted immediately. You cannot recover a deleted configuration.

oci streaming admin connect-harness delete --connect-harness-id <kafka_connect_configuration_OCID>

For example:

oci streaming admin connect-harness delete --connect-harness-id ocid1.connectharness.oc1.phx.exampleuniqueID
Are you sure you want to delete this resource? [y/N]:

Select y and press Enter. The Kafka Connect configuration is deleted with no further prompting.

To move a Kafka Connect configuration to a different compartment

oci streaming admin connect-harness change-compartment --connect-harness-id <kafka_connect_configuration_OCID> --compartment-id <target_compartment_OCID>

For example:

oci streaming admin connect-harness change-compartment --connect-harness-id ocid1.connectharness.oc1.phx.exampleuniqueID --compartment-id ocid1.compartment.oc1..exampleuniqueID

{
  "etag": "69aae3a1-e5f0-4289-bbbf-950c0fdddf2e-cbdd76e0-9a97-49be-a747-812ba28248d1"
}

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations to manage Kafka Connector configurations:

- CreateConnectHarness
- ListConnectHarnesses
- GetConnectHarness
- UpdateConnectHarness
- DeleteConnectHarness
- ChangeConnectHarnessCompartment

Using the SDKs

In order to use Kafka Connect with Streaming, you need a Kafka Connect configuration, or Kafka Connect harness. You can retrieve the OCID for a harness when you create a new harness or use an existing one. For more information, see Using Kafka Connect on page 4901.

Creating a Kafka Connect harness

The following code example shows how to create a Kafka Connect harness using the OCI SDK for Java:

CreateConnectHarnessDetails createConnectHarnessDetails =
CreateConnectHarnessDetails.builder()
  .compartmentId(compartment)  //compartment where you want to create connect harness
  .name("myConnectHarness")  //connect harness name
  .build();
CreateConnectHarnessRequest connectHarnessRequest =
CreateConnectHarnessRequest.builder()
    .createConnectHarnessDetails(createConnectHarnessDetails)
    .build();

CreateConnectHarnessResponse createConnectHarnessResponse =
streamAdminClient.createConnectHarness(connectHarnessRequest);
ConnectHarness connectHarness =
createConnectHarnessResponse.getConnectHarness();

while (connectHarness.getLifecycleState() !=
  ConnectHarness.LifecycleState.Active &&
  connectHarness.getLifecycleState() != ConnectHarness.LifecycleState.Failed)
{
    GetConnectHarnessRequest getConnectHarnessRequest =
GetConnectHarnessRequest.builder().connectHarnessId(connectHarness.getId()).build();
    connectHarness =
streamAdminClient.getConnectHarness(getConnectHarnessRequest).getConnectHarness();
}

Listing Kafka Connect harnesses

The following code example shows how to list Kafka Connect harnesses using the OCI SDK for Java:

ListConnectHarnessesRequest listConnectHarnessesRequest =
ListConnectHarnessesRequest.builder()
    .compartmentId(compartment) // compartment id to list all the connect
    .lifecycleState(ConnectHarnessSummary.LifecycleState.Active)
    .build();

ListConnectHarnessesResponse listConnectHarnessesResponse =
streamAdminClient.listConnectHarnesses(listConnectHarnessesRequest);
List<ConnectHarnessSummary> items = listConnectHarnessesResponse.getItems();

Developer Guide to Streaming

Oracle Cloud Infrastructure (OCI) provides SDKs so that you can interact with Streaming without having to create a framework.

The OCI SDKs let you manage streams and stream pools and Kafka Connect configurations, and publish and consume messages. Refer to the Streaming Service Overview on page 4860 for key concepts and additional information.

This section includes the following topics to help you get started quickly with Streaming and the OCI SDK of your choice:

- [SDK for Java Streaming Quickstart](#) on page 4909
- [SDK for Python Streaming Quickstart](#) on page 4915
- [SDK for JavaScript Streaming Quickstart](#) on page 4918
- [SDK for TypeScript Streaming Quickstart](#) on page 4922
- [SDK for .NET Streaming Quickstart](#) on page 4926
- [SDK for Go Streaming Quickstart](#) on page 4931

For more information about using the OCI SDKs, see the [SDK Guides](#).

Because Oracle Cloud Infrastructure Streaming is compatible with most Kafka APIs, you can use applications written for Kafka to send messages to and receive messages from the Streaming service. See Developing with Kafka and Streaming on page 4935 for more information.
Streaming Clients

The SDKs encapsulate the Streaming service in two clients: the StreamAdminClient and the StreamClient.

StreamAdminClient

The StreamAdminClient incorporates the control plane operations of Streaming. You can use it to create, delete, update, modify, and list streams.

To instantiate the StreamAdminClient object:

```java
StreamAdminClient adminClient = new StreamAdminClient([authProvider]);
adminClient.setEndpoint("<streaming_endpoint>");
```

StreamClient

The StreamClient is used to publish and consume messages.

To instantiate a StreamClient object:

```java
// First you have to get the stream you want to consume from/publish to.
// You can either make a CreateStream, GetStream, or ListStream call. They all return a "messagesEndpoint" as part of a Stream object.
// That endpoint needs to be used when creating the StreamClient object.
GetStreamRequest getStreamRequest = GetStreamRequest.builder().streamId(streamId).build();
Stream stream = adminClient.getStream(getStreamRequest).getStream();

StreamClient streamClient = new StreamClient([authProvider]);
streamClient.setEndpoint(stream.getMessagesEndpoint());
```

SDK for Java Streaming Quickstart

This quickstart shows you how to use the Oracle Cloud Infrastructure (OCI) SDK for Java on page 5351 and Oracle Cloud Infrastructure Streaming to publish and consume messages.

Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the SDK Guides.

Prerequisites

1. To use the SDK for Java, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. The user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key.
   - Java 8

   **Note:**
   For more information, see Configuring the SDK on page 5355.

2. Collect the Messages endpoint and OCID of a stream. See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint and let Oracle manage encryption. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream.

3. JDK 8 or above installed. Ensure that Java is in your PATH.
4. Maven 3.0 or installed. Ensure that Maven is in your PATH.
5. IntelliJ (recommended) or any other integrated development environment (IDE).
6. Add the latest version of maven dependency or jar for OCI Java SDK for IAM to your pom.xml as follows:

```xml
<dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-common</artifactId>
    <version>LATEST</version>
</dependency>
```

7. Add the latest version of maven dependency or jar for OCI Java SDK for OSS to your pom.xml as follows:

```xml
<dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-streaming</artifactId>
    <version>LATEST</version>
</dependency>
```

8. Assuming wd as your working directory for your Java project of this example, your pom.xml will look similar to the following:

```xml
<?xml version="1.0" encoding="UTF-8"?>
    <modelVersion>4.0.0</modelVersion>
    <groupId>oci.example</groupId>
    <artifactId>StreamsJava</artifactId>
    <version>1.0-SNAPSHOT</version>
    <properties>
        <maven.compiler.source>8</maven.compiler.source>
        <maven.compiler.target>8</maven.compiler.target>
    </properties>
    <dependencies>
        <dependency>
            <groupId>com.oracle.oci.sdk</groupId>
            <artifactId>oci-java-sdk-common</artifactId>
            <version>1.33.2</version>
        </dependency>
        <dependency>
            <groupId>com.oracle.oci.sdk</groupId>
            <artifactId>oci-java-sdk-streaming</artifactId>
            <version>1.33.2</version>
        </dependency>
    </dependencies>
</project>
```

9. Ensure that you have a valid SDK configuration file. For production environments, you should use instance principal authorization.

**Producing Messages**

1. Open your favorite editor, such as Visual Studio Code, from the directory wd. You should already have oci-sdk dependencies for Java as part of the pom.xml of your Maven Java project after you've met the prerequisites.
2. Create a file named Producer.java in directory wd with following code. Replace values of variables configurationFilePath, profile, ociStreamOcid, and ociMessageEndpoint in the following code snippet with the values applicable for your tenancy.

```java
package oci.sdk.oss.example;
```
import com.oracle.bmc.ConfigFileReader;
import com.oracle.bmc.auth.AuthenticationDetailsProvider;
import com.oracle.bmc.auth.ConfigFileAuthenticationDetailsProvider;
import com.oracle.bmc.streaming.StreamClient;
import com.oracle.bmc.streaming.model.PutMessagesDetails;
import com.oracle.bmc.streaming.model.PutMessagesDetailsEntry;
import com.oracle.bmc.streaming.model.PutMessagesResultEntry;
import com.oracle.bmc.streaming.requests.PutMessagesRequest;
import com.oracle.bmc.streaming.responses.PutMessagesResponse;
import org.apache.commons.lang3.StringUtils;
import java.util.ArrayList;
import java.util.List;
import static java.nio.charset.StandardCharsets.UTF_8;

public class Producer {
    public static void main(String[] args) throws Exception {
        final String configurationFilePath = "<config_file_path>";
        final String profile = "<config_file_profile_name>";
        final String ociStreamOcid = "<stream_OCID>";
        final String ociMessageEndpoint = "<stream_message_endpoint>";

        final ConfigFileReader.ConfigFile configFile = ConfigFileReader.parseDefault();
        final AuthenticationDetailsProvider provider = new ConfigFileAuthenticationDetailsProvider(configFile);

        // Streams are assigned a specific endpoint url based on where they are provisioned.
        // Create a stream client using the provided message endpoint.
        StreamClient streamClient = StreamClient.builder().endpoint(ociMessageEndpoint).build(provider);

        // publish some messages to the stream
        publishExampleMessages(streamClient, ociStreamOcid);
    }

    private static void publishExampleMessages(StreamClient streamClient, String streamId) {
        // build up a putRequest and publish some messages to the stream
        List<PutMessagesDetailsEntry> messages = new ArrayList<>();
        for (int i = 0; i < 50; i++) {
            messages.add(PutMessagesDetailsEntry.builder()
                    .key(String.format("messageKey%s", i).getBytes(UTF_8))
                    .value(String.format("messageValue%s", i).getBytes(UTF_8))
                    .build());
        }

        System.out.println(String.format("Publishing %s messages to stream %s.\n", messages.size(), streamId));
        List<PutMessagesDetails> putMessagesDetailsList = messagesDetails(messages).build();
        PutMessagesRequest putRequest = PutMessagesRequest.builder()
                .streamId(streamId)
                .putMessagesDetails(putMessagesDetailsList)
                .build();
        PutMessagesResponse putResponse = streamClient.putMessages(putRequest);
    }
}
Streaming

```java
.putMessagesDetails(messagesDetails)
.build();

PutMessagesResponse putResponse = streamClient.putMessages(putRequest);

// the putResponse can contain some useful metadata for handling failures
for (PutMessagesResultEntry entry : putResponse.getPutMessagesResult().getEntries()) {
    if (StringUtils.isNotBlank(entry.getError())) {
        System.out.println(String.format("Error(%s): %s", entry.getError(), entry.getErrorMessage()));
    } else {
        System.out.println(String.format("Published message to partition %s, offset %s.", entry.getPartition(), entry.getOffset()));
    }
}
```

3. From the `wd` directory, run the following command:

```bash
mvn install exec:java -Dexec.mainClass=oci.sdk.oss.example.Producer
```

4. Use the Console to see the latest messages sent to the stream to verify that production was successful.

**Consuming Messages**

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.

2. Open your favorite editor, such as Visual Studio Code, from the directory `wd`. You should already have `oci-sdk` dependencies for Java as part of the `pom.xml` of your Maven Java project after you’ve met the prerequisites.

3. Create a file named `Consumer.java` in directory `wd` with following code. Replace values of variables `configurationFilePath`, `profile`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

```java
package oci.sdk.oss.example;

import com.google.common.util.concurrent.Uninterruptibles;
import com.oracle.bmc.ConfigFileReader;
import com.oracle.bmc.auth.AuthenticationDetailsProvider;
import com.oracle.bmc.auth.ConfigFileAuthenticationDetailsProvider;
import com.oracle.bmc.streaming.StreamClient;
import com.oracle.bmc.streaming.model.CreateGroupCursorDetails;
import com.oracle.bmc.streaming.requests.CreateGroupCursorRequest;
import com.oracle.bmc.streaming.responses.CreateGroupCursorResponse;
import com.oracle.bmc.streaming.responses.GetMessagesResponse;
import java.util.concurrent.TimeUnit;
import static java.nio.charset.StandardCharsets.UTF_8;
```
public class Consumer {
    public static void main(String[] args) throws Exception {
        final String configurationFilePath = "<config_file_path>";
        final String profile = "<config_file_profile_name>";
        final String ociStreamOcid = "<stream_OCID>";
        final String ociMessageEndpoint = "<stream_message_endpoint>";

        final ConfigFileReader.ConfigFile configFile = ConfigFileReader.parseDefault();
        final AuthenticationDetailsProvider provider =
                new ConfigFileAuthenticationDetailsProvider(configFile);

        // Streams are assigned a specific endpoint url based on where they are provisioned.
        // Create a stream client using the provided message endpoint.
        StreamClient streamClient =
                StreamClient.builder().endpoint(ociMessageEndpoint).build(provider);

        // A cursor can be created as part of a consumer group.
        // Committed offsets are managed for the group, and partitions
        // are dynamically balanced amongst consumers in the group.
        System.out.println("Starting a simple message loop with a group cursor");
        String groupCursor =
                getCursorByGroup(streamClient, ociStreamOcid, "exampleGroup", "exampleInstance-1");
        simpleMessageLoop(streamClient, ociStreamOcid, groupCursor);
    }

    private static void simpleMessageLoop(
            StreamClient streamClient, String streamId, String initialCursor) {
        String cursor = initialCursor;
        for (int i = 0; i < 10; i++) {
            GetMessagesRequest getRequest =
                    GetMessagesRequest.builder()
                            .streamId(streamId)
                            .cursor(cursor)
                            .limit(25)
                            .build();

            GetMessagesResponse getResponse =
                    streamClient.getMessages(getRequest);

            // process the messages
            System.out.println(String.format("Read %s messages.",
                    getResponse.getItems().size()));
            for (Message message : ((GetMessagesResponse) getResponse).getItems()) {
                System.out.println(String.format("%s: %s",
                        message.getKey() == null ? "Null" : new String(message.getKey(), UTF_8),
                        new String(message.getValue(), UTF_8)));
            }

            // getMessages is a throttled method; clients should retrieve sufficiently large message
            // batches, as to avoid too many http requests.
            Uninterruptibles.sleepUninterruptibly(1, TimeUnit.SECONDS);
        }
    }
}
```java
// use the next-cursor for iteration
cursor = getResponse.getOpcNextCursor();
}
}

private static String getCursorByGroup(
    StreamClient streamClient, String streamId, String groupName,
    String instanceName) {
  System.out.println(
    String.format(
      "Creating a cursor for group %s, instance %s."
    ,
      groupName, instanceName));

  CreateGroupCursorDetails cursorDetails =
    CreateGroupCursorDetails.builder()
      .groupName(groupName)
      .instanceName(instanceName)
      .type(CreateGroupCursorDetails.Type.TrimHorizon)
      .commitOnGet(true)
      .build();

  CreateGroupCursorRequest createCursorRequest =
    CreateGroupCursorRequest.builder()
      .streamId(streamId)
      .createGroupCursorDetails(cursorDetails)
      .build();

  CreateGroupCursorResponse groupCursorResponse =
    streamClient.createGroupCursor(createCursorRequest);
  return groupCursorResponse.getCursor().getValue();
}
}

4. From the wd directory, run the following command:

    mvn install exec:java -Dexec.mainClass=oci.sdk.oss.example.Consumer

5. You should see messages similar to the following:

    Starting a simple message loop with a group cursor
    Creating a cursor for group exampleGroup, instance exampleInstance-1.
    Read 25 messages.
    Null: Example Test Message 0
    Null: Example Test Message 0
    Read 2 messages
    Null: Example Test Message 0
    Null: Example Test Message 0
    Read 1 messages
    Null: Example Test Message 0
    Read 10 messages
    key 0: value 0
    key 1: value 1

    Note:
    If you used the Console to produce a test message, the key for each
    message is Null

Next Steps
See the following resources for more information:

1. OCI SDK for Java on GitHub
```
2. **OCI SDK for Java Streaming examples**

**SDK for Python Streaming Quickstart**

This quickstart shows you how to use the Oracle Cloud Infrastructure (OCI) SDK for Python on page 5373 and Oracle Cloud Infrastructure Streaming to publish and consume messages.

Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the SDK Guides.

**Prerequisites**

1. To use the SDK for Python, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. This user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key.

   **Note:** For more information, see Configuring the SDK.

2. Collect the Messages endpoint and OCID of a stream. See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint and let Oracle manage encryption. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream.

3. Python 3.6 or later, with PIP installed and updated.

4. Visual Code Studio (recommended) or any other integrated development environment (IDE).

5. Install oci-sdk packages for Python using the following command:

   ```python
   pip install oci
   ```

   **Note:** We recommend that you use a Python virtual environment when installing oci. See Downloading and Installing the SDK for more information.

6. Ensure that you have a valid SDK configuration file. For production environments, you should use instance principal authorization.

**Producing Messages**

1. Open your favorite editor, such as Visual Studio Code, from the directory `wd`. You should already have oci-sdk packages for Python installed for your current Python environment after you've met the prerequisites.

2. Create a file named `Producer.py` in the `wd` directory with following code. Replace values of variables `ociConfigFilePath`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

   ```python
   import oci
   from base64 import b64encode

  ociMessageEndpoint = "<stream_message_endpoint>"
  ociStreamOcid = "<stream_OCID>"
   ociConfigFilePath = "<config_file_path>"
   ociProfileName = "<config_file_profile_name>"

   def produce_messages(client, stream_id):
   ```
# Build up a PutMessagesDetails and publish some messages to the stream
message_list = []
for i in range(100):
    key = "messageKey" + str(i)
    value = "messageValue " + str(i)
    encoded_key = b64encode(key.encode()).decode()
    encoded_value = b64encode(value.encode()).decode()
    message_list.append(oci.streaming.models.PutMessagesDetailsEntry(key=encoded_key,
                                                                      value=encoded_value))

message_list.append(oci.streaming.models.PutMessagesDetailsEntry(key=encoded_key,
                                                                  value=encoded_value))

print("Publishing {} messages to the stream {}" .format(len(message_list), stream_id))
messages = oci.streaming.models.PutMessagesDetails(messages=message_list)
put_message_result = client.put_messages(stream_id, messages)

# The put_message_result can contain some useful metadata for handling failures
for entry in put_message_result.data.entries:
    if entry.error:
        print("Error ({}): {}" .format(entry.error, entry.error_message))
    else:
        print("Published message to partition {}, offset {}" .format(entry.partition, entry.offset))

config = oci.config.from_file(ociConfigFilePath, ociProfileName)
stream_client = oci.streaming.StreamClient(config, service_endpoint=ociMessageEndpoint)

# Publish some messages to the stream
produce_messages(stream_client, ociStreamOcid)

3. From the wd directory, run the following command:

    python Producer.py

4. Use the Console to see the latest messages sent to the stream to verify that production was successful.

**Consuming Messages**

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.

2. Open your favorite editor, such as Visual Studio Code, from the directory wd. You should already have oci-sdk packages for Python installed for your current Python environment after ensuring you have the prerequisites.

3. Create a file named `Consumer.py` in directory `wd` with following code. Replace values of variables `ociConfigFilePath`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

```python
import oci
import time
from base64 import b64decode

ociMessageEndpoint = "<stream_message_endpoint>"
ociStreamOcid = "<stream_OCID>"
ociConfigFilePath = "<config_file_path>"
ociProfileName = "<config_file_profile_name>"
```
def get_cursor_by_group(sc, sid, group_name, instance_name):
    print(" Creating a cursor for group {}, instance {}".format(group_name, instance_name))
    cursor_details =
    oci.streaming.models.CreateGroupCursorDetails(group_name=group_name, instance_name=instance_name,
        type=oci.streaming.models.
        CreateGroupCursorDetails.TYPE_TRIM_HORIZON,
        commit_on_get=True)
    response = sc.create_group_cursor(sid, cursor_details)
    return response.data.value

def simple_message_loop(client, stream_id, initial_cursor):
    cursor = initial_cursor
    while True:
        get_response = client.get_messages(stream_id, cursor, limit=10)
        # No messages to process. return.
        if not get_response.data:
            return
        # Process the messages
        print(" Read {} messages".format(len(get_response.data)))
        for message in get_response.data:
            if message.key is None:
                key = "Null"
            else:
                key = b64decode(message.key.encode()).decode()
            print("{}: {}".format(key,
                b64decode(message.value.encode()).decode()))

        # get_messages is a throttled method; clients should retrieve
        sufficiently large message
        # batches, as to avoid too many http requests.
        time.sleep(1)
        # use the next-cursor for iteration
        cursor = get_response.headers["opc-next-cursor"]

    config = oci.config.from_file(ociConfigFilePath, ociProfileName)
    stream_client = oci.streaming.StreamClient(config,
        service_endpoint=ociMessageEndpoint)

    # A cursor can be created as part of a consumer group.
    # Committed offsets are managed for the group, and partitions
    # are dynamically balanced amongst consumers in the group.
    group_cursor = get_cursor_by_group(stream_client, ociStreamOcid, "example-
        group", "example-instance-1")
    simple_message_loop(stream_client, ociStreamOcid, group_cursor)

4. From the wd directory, run the following command:

    python Consumer.py

5. You should see messages similar to the following:

    Starting a simple message loop with a group cursor
    Creating a cursor for group example-group, instance example-instance-1
    Read 2 messages
    Null: Example Test Message 0
    Null: Example Test Message 0
Streamed messages:
Null: Example Test Message 0
Null: Example Test Message 0
Read 1 messages
Null: Example Test Message 0
Read 10 messages
key 0: value 0
key 1: value 1

**Note:**
If you used the Console to produce a test message, the key for each message is Null

**Next Steps**

See the following resources for more information:

1. [OCI SDK for Python on GitHub](https://github.com/oracle/oci-sdk)
2. [OCI SDK for Python Streaming examples](https://github.com/oracle/oci-sdk/tree/main/examples/python
cstreaming)

**SDK for JavaScript Streaming Quickstart**

This quickstart shows how to use the Oracle Cloud Infrastructure (OCI) SDK for TypeScript and JavaScript on page 5377 and Oracle Cloud Infrastructure Streaming to publish and consume messages.

Refer to the [Streaming Service Overview](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/overview.html) on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the [SDK Guides](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html).

**Prerequisites**

1. To use the SDK for TypeScript and JavaScript, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. This user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/overview.html#GUID-79D050B3-F96A-4D86-BB2F-36EB03C6C87C) on page 81. For a list of typical policies you may want to use, see [Common Policies](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html#GUID-D7A8B803-8F46-4CDD-AE2A-374F415928F1) on page 2806.
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. For more information, see [Getting Started](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html#GUID-E6E50198-051A-482C-AA24-2A309F9DE6C1) on page 5379.
2. Collect the Messages endpoint and OCID of a stream. See [Listing Streams and Stream Pools](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html#GUID-6F406882-8298-4D6B-AB10-3D523F2B3319) on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint and let Oracle manage encryption. Refer to [Creating Streams](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html#GUID-97152E4E-60A2-440B-882F-252C3E5F58A2) on page 4868 and [Creating Stream Pools](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/streaming/directory.html#GUID-6F406882-8298-4D6B-AB10-3D523F2B3319) on page 4870 if you do not have an existing stream.
4. [Visual Code Studio](https://code.visualstudio.com/) (recommended) or any other integrated development environment (IDE).
5. Open a command prompt that has npm in its path, change to the directory where you want to keep your code for this quickstart (wd, for example), and then run the following command to install the OCI SDK for JavaScript:
   ```bash
   npm install oci-sdk
   ```

**Producing Messages**

1. Open your favorite editor, such as Visual Studio Code, from the directory wd. You should already have `oci-sdk` packages for JavaScript installed in this directory after you've met the prerequisites.
2. Create a file named `Producer.js` in the `wd` directory with following code. Replace values of variables `ociConfigFile`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpointForStream` in the following code snippet with the values applicable for your tenancy.

```javascript
const common = require("oci-common");
const st = require("oci-streaming"); // OCI SDK package for OSS
const ociConfigFile = "<config_file_path>";
const ociProfileName = "<config_file_profile_name>";
const ociMessageEndpointForStream = "<stream_message_endpoint>";
const ociStreamOcid = "<stream_OCID>";

// provide authentication for OCI and OSS
const provider = new common.ConfigFileAuthenticationDetailsProvider(ociConfigFile, ociProfileName);

async function main() {
  // OSS client to produce and consume messages from a Stream in OSS
  const client = new st.StreamClient({ authenticationDetailsProvider: provider });

  client.endpoint = ociMessageEndpointForStream;

  // build up a putRequest and publish some messages to the stream
  let messages = [];
  for (let i = 1; i <= 3; i++) {
    let entry = {
      key: Buffer.from("messageKey" + i).toString("base64"),
      value: Buffer.from("messageValue" + i).toString("base64")
    };
    messages.push(entry);
  }

  console.log("Publishing %s messages to stream %s.", messages.length, ociStreamOcid);
  const putMessageDetails = { messages: messages };
  const putMessagesRequest = {
    putMessagesDetails: putMessageDetails,
    streamId: ociStreamOcid
  };
  const putMessageResponse = await client.putMessages(putMessagesRequest);
  for (var entry of putMessageResponse.putMessagesResult.entries)
    console.log("Published messages to partition %s, offset %s", entry.partition, entry.offset);
}

main().catch((err) => {
  console.log("Error occurred: ", err);
});
```

3. From the `wd` directory, run the following command:

```bash
node run Producer.js
```

4. Use the Console to see the latest messages sent to the stream to verify that production was successful.

**Consuming Messages**

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.
2. Open your favorite editor, such as Visual Studio Code, from the directory `wd`. You should already have the `oci-sdk` packages for JavaScript installed in this directory after you’ve met the prerequisites.

3. Create a file named `Consumer.js` in directory `wd` with following code. Replace values of variables `ociConfigFile`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpointForStream` in the following code snippet with the values applicable for your tenancy.

```javascript
const common = require("oci-common");
const st = require("oci-streaming"); // OCI SDK package for OSS

const ociConfigFile = "<config_file_path>";
const ociProfileName = "<config_file_profile_name>";
const ociMessageEndpointForStream = "<stream_message_endpoint>";
const ociStreamOcid = "<stream_OCID>";

// provide authentication for OCI and OSS
const provider = new common.ConfigFileAuthenticationDetailsProvider(ociConfigFile,
  ociProfileName);

const consumerGroupName = "exampleGroup";
const consumerGroupInstanceName = "exampleInstance-1";

async function main() {
  // OSS client to produce and consume messages from a Stream in OSS
  const client = new st.StreamClient({
    authenticationDetailsProvider: provider
  });
  client.endpoint = ociMessageEndpointForStream;

  // A cursor can be created as part of a consumer group.
  // Committed offsets are managed for the group, and partitions
  // are dynamically balanced amongst consumers in the group.
  console.log("Starting a simple message loop with a group cursor");
  const groupCursor = await getCursorByGroup(client, ociStreamOcid,
    consumerGroupName, consumerGroupInstanceName);
  await consumerMsgLoop(client, ociStreamOcid, groupCursor);
}

main().catch((err) => {
  console.log("Error occurred: ", err);
});

async function consumerMsgLoop(client, streamId, initialCursor) {
  let cursor = initialCursor;
  for (var i = 0; i < 10; i++) {
    const getRequest = {
      streamId: streamId,
      cursor: cursor,
      limit: 2
    };
    const response = await client.getMessages(getRequest);
    console.log("Read %s messages.", response.items.length);
    for (var message of response.items) {
      if (message.key !== null) {
        console.log("%s: %s",
          Buffer.from(message.key, "base64").toString(),
          Buffer.from(message.value, "base64").toString());
      } else {
        console.log("Null: %s",
          Buffer.from(message.value, "base64").toString());
      }
    }
  }
}
```
async function getCursorByGroup(client, streamId, groupName, instanceName) {
    console.log("Creating a cursor for group %s, instance %s.", groupName, instanceName);
    const cursorDetails = {
        groupName: groupName,
        instanceName: instanceName,
        type: st.models.CreateGroupCursorDetails.Type.TrimHorizon,
        commitOnGet: true
    };
    const createCursorRequest = {
        createGroupCursorDetails: cursorDetails,
        streamId: streamId
    };
    const response = await client.createGroupCursor(createCursorRequest);
    return response.cursor.value;
}

async function delay(s) {
    return new Promise(resolve => setTimeout(resolve, s * 1000));
}

4. From the wd directory, run the following command:

    node run Consumer.js

5. You should see messages similar to the following:

    Starting a simple message loop with a group cursor
    Creating a cursor for group exampleGroup, instance exampleInstance-1.
    Read 1 messages.
    Null: Example Test Message 0
    Read 1 messages.
    Null: Example Test Message 0
    Read 1 messages.
    Null: Example Test Message 0
    Read 2 messages.
    Null: Example Test Message 0
    Null: Example Test Message 0
    Read 2 messages.
    Null: Example Test Message 0
    Null: Example Test Message 0

    **Note:**
    If you used the Console to produce a test message, the key for each message is Null

**Next Steps**

See the following resources for more information:

1. OCI SDK for JavaScript on GitHub
2. OCI SDK for JavaScript examples
 SDK for TypeScript Streaming Quickstart

This quickstart shows you how to use the Oracle Cloud Infrastructure (OCI) SDK for TypeScript and JavaScript on page 5377 and Oracle Cloud Infrastructure Streaming to publish and consume messages.

Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the SDK Guides.

Prerequisites

1. To use the SDK for TypeScript and JavaScript, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. This user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. For more information, see Getting Started on page 5379.
2. Collect the Messages endpoint and OCID of a stream. See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint and let Oracle manage encryption. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream.
3. Node.js version 8.x or later. Download the latest long-term support (LTS) version.
4. Install the TypeScript interpreter for NodeJS globally:
   ```
   npm install -g typescript
   ```
5. Visual Code Studio (recommended) or any other integrated development environment (IDE).
6. Open a command prompt that has npm in its path, change to the directory where you want to keep your code for this quickstart (wd, for example), and then run the following command to install the OCI SDK for TypeScript:
   ```
   npm install oci-sdk
   ```
   Alternatively, you can be more efficient with dependencies by installing just the OCI TypeScript SDK packages for authentication and Streaming:
   ```
   npm install oci-common
   npm install oci-streaming
   ```
7. Ensure that you have a valid SDK configuration file. For production environments, you should use instance principal authorization.

Producing Messages

1. Open your favorite editor, such as Visual Studio Code, from the directory wd. You should already have oci-sdk packages for TypeScript installed in this directory after you've met the prerequisites.
2. Create a file named Producer.ts in the wd directory with following code. Replace values of variables ociConfigFile, ociProfileName, ociStreamOcid, and ociMessageEndpointForStream in the following code snippet with the values applicable for your tenancy.
   ```
   const common = require("oci-common");
   const st = require("oci-streaming"); // OCI SDK package for OSS
   const ociConfigFile = "<config_file_path>";
   const ociProfileName = "<config_file_profile_name>";
   const ociMessageEndpointForStream = "<stream_message_endpoint>"; // example value "https://cell-1.streaming.region.oci.oraclecloud.com"
   const ociStreamOcid = "<stream_OCID>";
   // provide authentication for OCI and OSS
   ```
const provider = new common.ConfigFileAuthenticationDetailsProvider(ociConfigFile, ociProfileName);

async function main() {
  // OSS client to produce and consume messages from a Stream in OSS
  const client = new st.StreamClient({ authenticationDetailsProvider: provider });

  client.endpoint = ociMessageEndpointForStream;

  // build up a putRequest and publish some messages to the stream
  let messages = [];
  for (let i = 1; i <= 3; i++) {
    let entry = {
      key: Buffer.from("messageKey" + i).toString("base64"),
      value: Buffer.from("messageValue" + i).toString("base64")
    };
    messages.push(entry);
  }

  console.log("Publishing %s messages to stream %s.", messages.length, ociStreamOcid);
  const putMessageDetails = { messages: messages };
  const putMessagesRequest = {
    putMessagesDetails: putMessageDetails,
    streamId: ociStreamOcid
  };
  const putMessageResponse = await client.putMessages(putMessagesRequest);
  for (var entry of putMessageResponse.putMessagesResult.entries)
    console.log("Published messages to partition %s, offset %s", entry.partition, entry.offset);

}

main().catch((err) => {
  console.log("Error occurred: ", err);
});

3. From the terminal in the wd directory, run the following command to compile Producer.ts and generate Producer.js:

tsc Producer.ts

4. From the same directory, run the following command:

node run Producer.js

You should see terminal output similar to the following:

$:/path/to/directory/wd>node Producer.js
Publishing 3 messages to stream ocid1.stream.oc1.exampleuniqueID.
Published messages to partition 0, offset 1314
Published messages to partition 0, offset 1315
Published messages to partition 0, offset 1316

5. Use the Console to see the latest messages sent to the stream to verify that production was successful.

Consuming Messages

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.
2. Open your favorite editor, such as Visual Studio Code, from the directory `wd`. You should already have the `oci-sdk` packages for TypeScript installed in this directory after you've met the prerequisites.

3. Create a file named `Consumer.ts` in directory `wd` with following code. Replace values of variables `ociConfigFile`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpointForStream` in the following code snippet with the values applicable for your tenancy.

```typescript
const common = require("oci-common");
const st = require("oci-streaming"); // OCI SDK package for OSS

const ociConfigFile = "<config_file_path>";
const ociProfileName = "<config_file_profile_name>";
const ociMessageEndpointForStream = "<stream_message_endpoint>"; // example value "https://cell-1.streaming.region.oci.oraclecloud.com"
const ociStreamOcid = "<stream_OCID>";

// provide authentication for OCI and OSS
const provider = new common.ConfigFileAuthenticationDetailsProvider(ociConfigFile,
  ociProfileName);

async function main() {
  // OSS client to produce and consume messages from a Stream in OSS
  const client = new st.StreamClient({ authenticationDetailsProvider:
    provider });

  client.endpoint = ociMessageEndpointForStream;

  // Use a cursor for getting messages; each getMessages call will return a next-cursor for iteration.
  // There are a couple kinds of cursors, we will use group cursors

  // Committed offsets are managed for the group, and partitions
  // are dynamically balanced amongst consumers in the group.

  console.log("Starting a simple message loop with a group cursor");
  const groupCursor = await getCursorByGroup(client, ociStreamOcid,
    "exampleGroup01000", "exampleInstance-1");
  await simpleMessageLoop(client, ociStreamOcid, groupCursor);
}

async function getCursorByGroup(client, streamId, groupName, instanceName) {
  console.log("Creating a cursor for group %s, instance %s.", groupName,
    instanceName);
  const cursorDetails = {
    groupName: groupName,
    instanceName: instanceName,
    type: st.models.CreateGroupCursorDetails.Type.TrimHorizon,
    commitOnGet: true
  };
  const createCursorRequest = {
    createGroupCursorDetails: cursorDetails,
    streamId: streamId
  };
  const response = await client.createGroupCursor(createCursorRequest);
  return response.cursor.value;
}

async function simpleMessageLoop(client, streamId, initialCursor) {
  let cursor = initialCursor;
  for (var i = 0; i < 5; i++) {
    const getRequest = {
      ... // more code
    }
    ... // more code
  }
}
```
const response = await client.getMessages(getRequest);
console.log("Read %s messages.", response.items.length);
for (var message of response.items) {
  if (message.key !== null) {
    console.log("Key: %s, Value: %s, Partition: %s",
    Buffer.from(message.key, "base64").toString(),
    Buffer.from(message.value, "base64").toString(),
    Buffer.from(message.partition, "utf8").toString());
  } else{
    console.log("Key: Null, Value: %s, Partition: %s",
    Buffer.from(message.value, "base64").toString(),
    Buffer.from(message.partition, "utf8").toString());
  }
}

async function delay(s) {
  return new Promise(resolve => setTimeout(resolve, s * 1000));
}

main().catch((err) => {
  console.log("Error occurred: ", err);
});

// getMessages is a throttled method; clients should retrieve
// sufficiently large message
// batches, as to avoid too many http requests.
await delay(2);
cursor = response.opcNextCursor;
}

4. From the terminal in the wd directory, run the following command to compile Consumer.ts and generate Consumer.js:

tsc Consumer.ts

5. From the wd directory, run the following command:

node run Consumer.js

6. You should see messages similar to the following:

Starting a simple message loop with a group cursor
Creating a cursor for group exampleGroup01000, instance exampleInstance-1.
Read 6 messages.
Key: messageKey1, Value: messageValue1, Partition: 0
Key: messageKey2, Value: messageValue2, Partition: 0
Key: messageKey3, Value: messageValue3, Partition: 0
Key: Null, Value: message value and key null, Partition: 0
Key: Null, Value: message value and key null, Partition: 0
Key: Null, Value: message value and key null, Partition: 0
Read 0 messages.
Read 0 messages.
Read 0 messages.
Next Steps

See the following resources for more information:

1. OCI SDK for TypeScript on GitHub
2. OCI SDK for TypeScript examples

SDK for .NET Streaming Quickstart

This quickstart shows you how to use the Oracle Cloud Infrastructure (OCI) SDK for .NET on page 5387 and Oracle Cloud Infrastructure Streaming to publish and consume messages. These examples use C# language.

Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the SDK Guides.

Prerequisites

In this quickstart, we create and run a simple .NET console application by using Visual Studio Code and the .NET CLI. Project tasks, such as creating, compiling, and running a project are done by using the .NET CLI. If you prefer, you can follow this tutorial with a different IDE and run commands in a terminal.

1. To use the SDK for .NET, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. This user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. For more information, see SDK configuration file.

2. Collect the Messages endpoint and OCID of a stream. See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint and let Oracle manage encryption. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream.

3. Install .NET 5.0 SDK or later. Ensure that dotnet is set in your PATH environment variable.

4. Visual Studio Code (recommended) with the C# extension installed. For information about how to install extensions on Visual Studio Code, see VS Code Extension Marketplace.

5. Ensure that you have a valid SDK configuration file. For production environments, you should use instance principal authorization.

Producing Messages

1. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd.
2. Open the terminal and cd into the wd directory.
3. Create a C# .NET console application by running the following command in the terminal:

```
dotnet new console
```

You should see a message indicating that the application was created:

```
The template "Console Application" was created successfully.
```

This creates a `Program.cs` file with C# code for a simple "HelloWorld" application.

4. Add OCI SDK packages for basic IAM authentication and Streaming to your C# project as follows:

```
dotnet add package OCI.DotNetSDK.Common

dotnet add package OCI.DotNetSDK.Streaming
```

5. Replace the code in `Program.cs` in the `wd` directory with following code. Replace values of variables `configurationFilePath`, `profile`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

```csharp
using System;
using System.Collections.Generic;
using System.Text;
using System.Threading.Tasks;
using Oci.Common.Auth;
using Oci.Common.Waiters;
using Oci.StreamingService;
using Oci.StreamingService.Models;
using Oci.StreamingService.Requests;
using Oci.StreamingService.Responses;

namespace OssProducer
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            Console.WriteLine("Starting example for OSS Producer");
            string configurationFilePath = "<config_file_path>";
            string profile = "<config_file_profile_name>";
            string ociStreamOcid = "<stream_OCID>";
            string ociMessageEndpoint = "<stream_message_endpoint>";

            try
            {
                var provider = new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);
                StreamClient streamClient = new StreamClient(provider);
                streamClient.SetEndpoint(ociMessageEndpoint);
                await PublishExampleMessages(streamClient, ociStreamOcid);
            }
            catch (Exception e)
            {
                Console.WriteLine($"Streaming example failed: {e}");
            }
        }

        private static async Task PublishExampleMessages(StreamClient streamClient, string streamId)
        {
```
Streaming

// build up a putRequest and publish some messages to the
stream
List<PutMessagesDetailsEntry> messages = new
List<PutMessagesDetailsEntry>();
for (int i = 0; i < 100; i++)
{
PutMessagesDetailsEntry detailsEntry = new
PutMessagesDetailsEntry
{
Key = Encoding.UTF8.GetBytes($"messagekey-{i}"),
Value = Encoding.UTF8.GetBytes($"messageValue-{i}")
};
messages.Add(detailsEntry);
}
Console.WriteLine($"Publishing {messages.Count} messages to
stream {streamId}");
PutMessagesDetails messagesDetails = new PutMessagesDetails
{
Messages = messages
};
PutMessagesRequest putRequest = new PutMessagesRequest
{
StreamId = streamId,
PutMessagesDetails = messagesDetails
};
PutMessagesResponse putResponse = await
streamClient.PutMessages(putRequest);
// the putResponse can contain some useful metadata for
handling failures
foreach (PutMessagesResultEntry entry in
{
if (entry.Error != null)
{
Console.WriteLine($"Error({entry.Error}):
{entry.ErrorMessage}");
}
else
{
Console.WriteLine($"Published message to partition
{entry.Partition}, offset {entry.Offset}");
}
}
}
}
}
6. From the wd directory, run the following command:
dotnet run
7. Use the Console to see the latest messages sent to the stream to verify that production was successful.
Consuming Messages
1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console
to produce a test message, or use the stream and messages we created in this quickstart.
2. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd.

3. Create a C# .NET console application by running the following command on the terminal:

```
dotnet new console
```

You should see a message indicating that the application was created:

```
The template "Console Application" was created successfully.
```

This creates a `Program.cs` file with C# code for a simple "HelloWorld" application.

4. Add OCI SDK packages for basic IAM authentication and Streaming to your C# project as follows:

```
dotnet add package OCI.DotNetSDK.Common
```

```
dotnet add package OCI.DotNetSDK.Streaming
```

5. Replace the code in `Program.cs` in the `wd` directory with following code. Replace values of variables `configurationFilePath`, `profile`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

```csharp
using System;
using System.Collections.Generic;
using System.Text;
using System.Threading.Tasks;
using Oci.Common.Auth;
using Oci.Common.Waiters;
using Oci.StreamingService;
using Oci.StreamingService.Models;
using Oci.StreamingService.Requests;
using Oci.StreamingService.Responses;

namespace OssConsumer
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            Console.WriteLine("Starting example for OSS Consumer");
            string configurationFilePath = "<config_file_path>";
            string profile = "<config_file_profile_name>";
            string ociStreamOcid = "<stream_OCID>";
            string ociMessageEndpoint = "<stream_message_endpoint>";

            try
            {
                var provider = new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);

                StreamClient streamClient = new StreamClient(provider);
                streamClient.SetEndpoint(ociMessageEndpoint);

                // A cursor can be created as part of a consumer group.
                // Committed offsets are managed for the group, and
                // partitions are dynamically balanced amongst consumers in the
                // group.
                Console.WriteLine("Starting a simple message loop with a group cursor");
                string groupCursor = await GetCursorByGroup(streamClient, ociStreamOcid, "exampleGroup", "exampleInstance-1");
                await SimpleMessageLoop(streamClient, ociStreamOcid, groupCursor);
            }
        }
    }
}
