The precise meaning of each level differs among the following components:

- Load balancers
- Backend sets
- Backend servers

### Understanding Health Issues

Learn more about how health issues affect a Load Balancer resource.

At the highest level, load balancer health reflects the health of its components. The health status indicators provide information you might need to drill down and investigate an existing issue. Some common issues that the health status indicators can help you detect and correct include:

**A health check is misconfigured.**

In this case, all the backend servers for one or more of the affected listeners report as unhealthy. If your investigation finds that the backend servers do not have problems, then a backend set probably includes a misconfigured health check.

**A listener is misconfigured.**

All the backend server health status indicators report **OK**, but the load balancer does not pass traffic on a listener.

The listener might be configured to:

- Listen on the wrong port.
- Use the wrong protocol.
- Use the wrong policy.

If your investigation shows that the listener is not at fault, check the security list configuration.

**A security rule is misconfigured.**
Health status indicators help you diagnose two cases of misconfigured security rules:

- All entity health status indicators report **OK**, but traffic does not flow (as with misconfigured listeners). If the listener is not at fault, check the security rule configuration.
- All entity health statuses report as unhealthy. You have checked your health check configuration and your services run properly on your backend servers.

In this case, your security rules might not include the IP range for the source of the health check requests. You can find the health check source IP on the Details page for each backend server. You can also use the API to find the IP in the `sourceIpAddress` field of the `HealthCheckResult` object.

### Note:

<table>
<thead>
<tr>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>The source IP for health check requests comes from a Compute instance managed by the Load Balancing service.</td>
</tr>
</tbody>
</table>

**One or more of the backend servers reports as unhealthy.**

A backend server might be unhealthy or the health check might be misconfigured. To see the corresponding error code, check the `status` field on the backend server's Details page. You can also use the API to find the error code in the `healthCheckStatus` field of the `HealthCheckResult` object.

**Other cases in which health status might prove helpful include:**

- VCN network security groups or security lists block traffic.
- Compute instances have misconfigured route tables.

Health status is updated every three minutes. No finer granularity is available.

Health status does not provide historical health data.

**Common Side Effects of Health Check Misconfiguration**

Learn about the different health status indicators for Load Balancer resources.

The following are common side effects of health check misconfiguration, and can be used to troubleshoot issues.

- **Wrong Port**

  In this scenario, all backend servers are reported as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the port. The port must be a port that is listening and has allowed traffic on the backend.

  OCI Logging Error: `errno:EHOSTUNREACH`, `syscall:connect`

- **Wrong Patch**

  In this scenario, all the backend servers are reported as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the path for the HTTP health check it needs to match an actual application on the backend. In this scenario, you can use the curl utility to test from a system in the same network. For example: `$ curl -i http://backend_ip_address/health`

  You receive the configured status code in the response OCI Logging Error: "msg": "invalid statusCode", "statusCode": 404, "expected": "200".

- **Wrong Protocol**

  In this scenario, all the backend servers are reported as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the protocol it needs to match the protocol that is listening on the backend. For example: We only support TCP and HTTP health checks. If your backend is using HTTPS, then you would need to use TCP as the protocol.

  OCI Logging Error: `code:EPROTO`, `errno:EPROTO`
• **Wrong Status Code**

In this scenario, all the backend servers are reported as unhealthy. If the backend servers do not have any problems, for an HTTP health check you might have made a mistake setting the status code to match the actual status code being returned from the backend. A common scenario is when a backend returns a 302 status code but you are expecting a 200 status code. This result is likely the backend sending you to a login page or another location on the server. In this scenario, you can either fix the backend to return the expected code or use 302 in your health check configuration.

OCI Logging Error: msg:invalid statusCode, statusCode:nnn, expected:200 where nnn to be the status code that is returned.

• **Wrong Regex Pattern**

All the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting an incorrect regex pattern consistent with the body, or the backend is not returning the expected body. In this scenario, you can either change the backend to match the pattern or correct the pattern to match the backend. The following are some specific pattern examples.

- Any Content - .*
- A page returning the value Status:OK: - Status:OK:.*
- OCI Logging Error: response match result: failed

• **Misconfigured Network Security Groups, Security Lists, or Local Firewall**

All or some of the backend servers report as unhealthy. If the backend servers do not have any problems, then you might have improperly configured either the network security groups, security lists, or local firewalls (such as firewalld, iptables, or SELinux). In this scenario, you can use either the curl or netcat utilities to test from a system that belongs to the same subnet and network security group as your load balancer instance HTTP. For example:

```bash
$ curl -i http://backend_ip_address/health TCP
```

You can check your local firewall by using the following command: `firewall-cmd --list-all --zone=public`. If your firewall is missing the expected rules, then you can use a command set like this to add the service (this example is for HTTP port 80):

- `firewall-cmd --zone=public --add-service=http`
- `firewall-cmd --zone=public --permanent --add-service=http`

**Health Check Best Practices**

Learn about health check best practices for a Load Balancer resource.

Configure your health check protocol to match your application or service. If you run an HTTP service, then configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, then you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, you might experience transaction failures.

For example:

- The backend HTTP service has issues when communicating with the health check URL and the health check URL returns 5nn messages. An HTTP health check catches the message from the health check URL and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service might not be usable.
- The backend HTTP service responds with 4nn messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

**Creating a Custom Health Check Page**

Create a custom health check page for Load Balancer resources.
In many scenarios, you might want to expose your own custom health check page to do a more thorough check. One example scenario is to use the flask application, as in the following example, rather than relying on your existing application. [https://pypi.org/project/py-healthcheck/](https://pypi.org/project/py-healthcheck/)

```python
import tornado.web
from healthcheck import TornadoHandler, HealthCheck, EnvironmentDump
# add your own check function to the healthcheck
def redis_available():
    client = _redis_client()
    info = client.info()
    return True, "Redis Test Pass"
health = HealthCheck(checkers=[redis_available])
app = tornado.web.Application([
    ("/healthcheck", TornadoHandler, dict(checker=health)),
])
```

In the preceding example, the test page is doing more than just ensuring the HTTP application is listening. This example checks for a redis client and waits for a response to ensure that the full application is healthy before returning a 200 status code. Some other command examples would be to check for disk space or the availability of an upstream dependency. In your health check configuration, specify the following:

- `/healthcheck` as your path
- `flask default 5000` as port
- `200` as status code

**Getting Health Check Policy Details**

Get the details of a health check policy for a Load Balancer resource and backend set.

Use one of the following methods to get the details of a health check policy for a selected load balancer and backend set.

**To get the details of a health check policy using the Console**

Use the OCI Console to get the details of a health check policy for a Load Balancer resource and backend set.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for whose health check policies whose details you want to get.
   - The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   - The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   - The Backend Set Details dialog box appears.
8. Click **Update Health Check**.
   - Alternatively, click the **Actions** icon (-pointer) for the backend set whose health check you want to update, and then click **Update Health Check**.
   - The Update Health Check dialog box appears.

**To get the details of a health check policy using the CLI**

Use the command line interface (CLI) to get the details of a health check policy for a Load Balancer resource and backend set.
Enter the following command:

```
oci lb health-checker get --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb health-checker get --help
```

See **oci lb health-checker get** for a complete description of the command.

**To get the details of a health check policy using the API**

Use the API to get the details of a health check policy for a Load Balancer resource and backend set.

Run the **GetHealthChecker** method to display the details of a health check policy of a backend set for a load balancer. See **GetHealthChecker** for a complete description.

**Editing Health Check Policies**

Update the health check policy for a Load Balancer resource and backend set.

Use one of the following methods to edit and update the health check policy for a selected load balancer and backend set.

**To edit a health check policy using the Console**

Use the OCI Console to update a health check policy of a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for whose health check policies you want to edit.
   
   The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   
   The Backend Set Details dialog box appears.
8. Click **Update Health Check**.
   
   Alternatively, click the **Actions** icon ((gs) for the backend set whose health check you want to update, and then click **Update Health Check**.
   
   The Update Health Check dialog box appears.
9. Update any of the following:
   - **Protocol**: Required. Specify the protocol:
     - HTTP
     - TCP
   
   **Important:**
   Configure your health check protocol to match your application or service. See Health Check Management on page 3236 for more information.

   - **Port**: Optional. Specify the backend server port against which to run the health check.

   **Tip:**
   You can enter the value '0' to have the health check use the backend server's traffic port.

   - **Interval in MS**: Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
   - **Timeout in MS**: Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
   - **Number of retries**: Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.
   - **Status Code**: (HTTP only) Optional. Specify the status code a healthy backend server must return.
   - **URL Path (URI)**: (HTTP only) Required. Specify a URL endpoint against which to run the health check.
   - **Response Body Regex**: (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

10. Click **Save Changes**.

### To edit a health check policy using the CLI

Use the command line interface (CLI) to update a health check policy of a backend set for a Load Balancer resource.

Enter the following command:

```shell
```

See the CLI online help for a list of options:

```shell
oci lb health-checker update --help
```

### To edit a health check policy using the API

Use the API to update a health check policy of a backend set for a network load balancer for a Load Balancer resource.

### Backend Server Management

When you create a Load Balancer resource, you must specify the backend servers (Compute instances) to include in each **backend set**. The load balancer routes incoming traffic to these backend servers based on the policies you specified for the backend set. You can use the Console to add and remove backend servers in a backend set.
To route traffic to a backend server, the Load Balancing service requires the IP address of the compute instance and the relevant application port. If the backend server resides within the same VCN as the load balancer, Oracle recommends that you specify the compute instance’s private IP address. If the backend server resides within a different VCN, you must specify the public IP address of the compute instance. You also must ensure that the VCN's security rules allow Internet traffic.

**Important:**

When you add backend servers to a backend set, you specify either the instance OCID or an IP address for the server to add. An instance with multiple VNICs attached can have multiple IP addresses pointing to it.

- If you identify a backend server by OCID, Load Balancing uses the primary VNIC’s primary private IP address.
- If you identify the backend servers to add to a backend set by their IP addresses, it is possible to point to the same instance more than once.

To enable backend traffic, your backend server subnets must have appropriate ingress and egress security rules. When you add backend servers to a backend set, you can specify the applicable network security groups (NSGs). If you prefer to use security lists for your VCN, the Load Balancing service Console can suggest security list rules for you. You also can configure them yourself through the Networking service. See [Security Lists](#) for more information.

**Note:**

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets. See [Stateful Versus Stateless Rules](#) for more information.

You can add and remove backend servers without disrupting traffic.

**Note:**

You can set up backend servers as compute instance pools. See [Creating an Instance Pool](#) for more information.

**Adding Backend Servers**

Add a backend server to a backend set for a Load Balancer resource.

**Note:**

If the load balancer has no backend sets, you must create one before you can specify a backend server. See [Creating Backend Sets](#) for more information.

Use one of the following methods to add a backend server to a backend set for a selected load balancer.

**To add a backend server using the Console**

Use the OCI Console to add a backend server to a backend set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Click the load balancer whose backend set you want to delete.
6. Click Backend Sets under Resources.
7. The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the name of the backend set to which you want to add one or more backend servers.
   The Backend Set Details page appears.
8. Click Backends under Resources.
   The Backends list appears. All backend servers are listed in tabular form.
9. Click Add Backends.
   The Add Backends dialog box appears.

   **Tip:**
   You cannot add a backend server marked as Backup to a backend set that uses the IP Hash policy.

10. **Choose how to add backend servers:** Specify how you want to add backend servers to the backend set:

    - **Compute Instances:** Choose this option to select from a list of available Compute instances.
    - **Instances in <compartment>:** Select (check) the instances you want to include in the backend set.

      To select instances from a different compartment, use the Change Compartment link and choose a compartment from the list.

      **Tip:**
      You can choose instances from one compartment at a time. After you add instances from one compartment, you must repeat the Add Backends process to add instances from another compartment.

    After you select an instance to add to the backend set, you can specify:

    - **Port:** Required. The backend server port to which the load balancer must direct traffic.
    - **Weight:** The load balancing weight assigned to the server. For more information, see Load Balancing Policies on page 3199.

    Choose to manually configure subnet security list rules that allow the intended traffic or let the Load Balancing service create security list rules for you. To learn more about these rules, see Parts of a Security Rule on page 3714.

    - **Manually configure security list rules after the load balancer is created:** When you choose this option, you must create your own rules after adding the backend servers.
    - **Automatically add security list rules:** When you choose this option, the Load Balancing service creates security list rules for you.

      The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet. You can then choose whether to apply the proposed rules for each affected subnet.

    - **IP Addresses:** Choose this option to enter the IP addresses of the backend servers (Compute instances) to add.
      - **IP Address:** Required. Specify the IP address of a backend server you want to add to the backend set.
      - **Port:** Required. Specify the server port to which the load balancer must direct traffic.
      - **Weight:** Required. Specify the load balancing weight to apply to this server. For more information, see Load Balancing Policies on page 3199.

      You can click the plus + icon to add another server to the list or click the X icon to remove a list item.

11. Click Add.

**To add a backend server using the CLI**

Use the command line interface (CLI) to add a backend server to a backend set for a Load Balancer resource.

Enter the following command:

```
oci lb backend create --backend-set-name backend_set_name --load-balancer-id load_balancer_id --ip-address ip_address --port port [OPTIONS]
```
Load Balancing

See the CLI online help for a list of options:

```
oci lb backend create --help
```

See `oci lb backend create` for a complete description of the command.

### To add a backend server using the API

Use the API to add a backend server to a backend set for a Load Balancer resource.

Run the `CreateBackend` method to add a backend server to a backend set for a load balancer. See `CreateBackend` for a complete description.

### Listing Backend Servers

List the backend servers contained within a backend set for a Load Balancer resource.

Use one of the following methods to display a list of backend servers contained within a backend set for a selected load balancer.

#### To list the backend servers using the Console

Use the OCI Console to list the backend servers contained within a backend set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer containing the backend servers that you want to list.
   
   The Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose backend servers you want to list.
   
   The Backend Set Details dialog box appears.
8. Click Backends under Resources.
   
   The Backends list appears. All backend servers are listed in tabular form.

#### To list the backend servers using the CLI

Use the command line interface (CLI) to list the backend servers contained within a backend set for a Load Balancer resource.

Enter the following command:

```
oci lb backend list --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb backend list --help
```

See `oci lb backend list` for a complete description of the command.

### To list the backend servers using the API

Use the API to list the backend servers contained within a backend set for a Load Balancer resource.

Run the `ListBackends` method to display a list of backend servers for a backend set for a load balancer. See `ListBackends` for a complete description.
Getting Backend Server Details
Get the details of a backend server contained within a backend set for a Load Balancer resource.

Use one of the following methods to display the details of a backend server contained within a backend set for a selected load balancer.

To get the details of a backend server using the Console
Use the OCI Console to get the details of a backend server contained within a backend set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer containing the backend servers that you want to list.
   The Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.
8. Click Backends under Resources.
   The Backends list appears. All backend servers are listed in tabular form.

To get the details of a backend server using the CLI
Use the command line interface (CLI) to get the details of a backend server contained within a backend set for a Load Balancer resource.

Enter the following command:

```
oci lb backend get --backend-name backend_name --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb backend get --help
```

See oci lb backend get for a complete description of the command.

To get the details of a backend server using the API
Use the API to get the details of a backend server contained within a backend set for a Load Balancer resource.

Run the GetBackend method to get the details of a backend contained within a backend set for a load balancer. See GetBackend for a complete description.

Editing Backend Servers
Update a backend server contained within a backend set for a Load Balancer resource.

Use one of the following methods to edit and update the settings of a backend server contained within a backend set for a selected load balancer.

To edit a backend server using the Console
Use the OCI Console to update a backend server contained within a backend set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer containing the backend server that you want to edit.

The Load Balancer Details dialog box appears.

6. Click Backend Sets under Resources.

The Backend Sets list appears. All backend sets are listed in tabular form.

7. Click the backend set whose backend server you want to edit.

The Backend Set Details dialog box appears.

8. Click Backends under Resources.

The Backends list appears. All backend servers are listed in tabular form.

9. Select (check) the row corresponding to the backend server you want to edit.

10. Choose an action from the Actions button list. The available actions include:

- **Edit**: Opens a single dialog box in which you can edit the port, weight, drain, offline, and backup settings.
- **Edit Port**: Opens a dialog box in which you can change the application port setting.
- **Edit Weight**: Opens a dialog box in which you can change the load balancing weight.
- **Edit Drain State**: Opens a dialog box in which you can change the drain state.

If you set the server's drain status to true, the load balancer stops forwarding new TCP connections and new non-sticky HTTP requests to this backend server. This setting allows an administrator to take the server out of rotation for maintenance purposes.

- **Edit Offline State**: Opens a dialog box in which you can change the offline status.

If you set the server's offline status to true, the load balance forwards no ingress traffic to this backend server.

- **Edit Backup State**: Opens a dialog box in which you can change the backup status.

If you set the server's backup status to true, the load balancer forwards ingress traffic to this backend server only when all other backend servers not marked as backup fail the health check policy. This configuration is useful for handling disaster recovery scenarios.

**Note:**

Backend servers marked as Backup are not compatible with a load balancer that uses the IP Hash policy.

- **Delete**: Removes the server from the backend set.

**Tip:**

You can select multiple servers to apply the same action to each one.

11. Click Save Changes.

**To edit a backend server using the CLI**

Use the command line interface (CLI) to update a backend server contained within a backend set for a Load Balancer resource.

Enter the following command:

```bash
oci lb backend update --backend-name backend_name --backend-set-name backend_set_name --load-balancer-id load_balancer_id --backup [true|false] --drain [true|false] --offline [true|false] --weight weight [OPTIONS]
```

The backup parameter indicates whether (true) or not (false) the load balancer treats this server as a backup unit. If the value is true, the load balancer forwards no ingress traffic to this backend server unless all other backend servers not marked as "backup" fail the health check policy. You cannot add a backend server marked as backup to a backend set that uses the IP Hash policy.
Load Balancing

The `drain` parameter indicates whether (`true`) or not (`false`) the load balancer drains this backend server. If the value is `true`, the backend server receives no new incoming traffic.

The `weight` parameter indicates the load balancing policy weight assigned to the server. Backend servers with a higher weight receive a larger proportion of incoming traffic. For example, a server weighted ‘3’ receives three times the number of new connections as a server weighted ‘1.’ For more information on load balancing policies, see How Load Balancing Policies Work.

See the CLI online help for a list of options:

```
oci lb backend update --help
```

See `oci lb backend get` for a complete description of the command.

**To edit a backend server using the API**
Use the API to update a backend server contained within a backend set for a Load Balancer resource.

Run the `UpdateBackend` method to get the details of a backend contained within a backend set for a load balancer. See `UpdateBackend` for a complete description.

**Deleting Backend Servers**
Delete a backend server contained within a backend set for a Load Balancer resource.

Use one of the following methods to delete a backend server contained within a backend set for a selected load balancer.

**To delete a backend server using the Console**
Use the OCI Console to delete a backend server contained within a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer containing the backend server that you want to delete.

   The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.

   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Select (check) the row corresponding to the backend server you want to edit.
8. Click **Actions** and select **Delete** from the list.

   **Tip:**
   You can select multiple servers to delete each one.
9. Confirm the deletion when prompted.

**To delete a backend server using the CLI**
Use the command line interface (CLI) to delete a backend server contained within a backend set for a Load Balancer resource.

Enter the following command:

```
oci lb backend delete --backend-name backend_name --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb backend delete --help
```
See `oci lb backend delete` for a complete description of the command.

**To delete a backend server using the API**

Use the API to delete a backend server contained within a backend set for a Load Balancer resource.

Run the `DeleteBackend` method to delete a backend contained within a backend set for a load balancer. See `DeleteBackend` for a complete description.

**Getting Backend Server Health Details**

Get the health details of a backend server within a backend set for a Load Balancer resource.

The primary and standby load balancers both provide health check results that contribute to the health status.

The following table lists the health status indicators and their meanings.

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>

Use one of the following methods to display the health details of a backend server contained within a backend set for a selected load balancer.

**Getting Backend Server Health Details using the Console**

Use the OCI Console to get the health details of a backend server within a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer containing the backend servers that you want to list.

   The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.

   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.

   The Backend Set Details dialog box appears.
8. Click **Backends** under **Resources**.

   The **Backends** list appears. All backend servers are listed in tabular form.
9. View the health status of the backend server under **Health**.

   See **Health Status Indicators** on page 3236 for descriptions of the load balancer health indicators.
Getting Backend Server Health Details using the CLI
Use the command line interface (CLI) to get the health details of a backend server within a backend set for a Load Balancer resource.

Enter the following command:

```bash
oci lb backend-health get --backend-name backend_name --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb backend-health get --help
```

See `oci lb backend-health get` for a complete description of the command.

Getting Backend Server Health Details using the API
Use the API to get the health details of a backend server within a backend set for a Load Balancer resource.

Run the `GetBackendHealth` method to get the health details a backend set for a load balancer. See `GetBackendHealth` for a complete description.

See Health Status Indicators on page 3236 for descriptions of the load balancer health indicators.

Listener Management
Learn how to use listeners to check for incoming traffic on the load balancer’s IP address.

A listener is a logical entity that checks for incoming traffic on the load balancer’s IP address. To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type. When you create a listener, you must ensure that your VCN’s security rules allow the listener to accept traffic.

**Tip:**
To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

You can have one SSL certificate bundle per listener. You can configure two listeners, one each for ports 443 and 8443, and associate SSL certificate bundles with each listener. For more information about SSL certificates for load balancers, see SSL Certificate Management on page 3308.

Click Listeners under Resources in the Load Balancer Details page to display the Listeners page. This page contains a button for creating listeners.

Creating Listeners
Create a listener for a Load Balancer resource.

Use one of the following methods to create a listener for a selected load balancer.

**To create a listener using the Console**
Use the OCI Console to create a listener for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a listener.

   The Load Balancer Details dialog box appears.
6. Click Listeners under Resources.

   The Listeners list appears. All listeners are listed in tabular form.
7. Click **Create Listener**.

   The Create Listener dialog box appears.

8. Enter the following:

   - **Name**: Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed.
   - **Hostname**: Optional. Select up to 16 virtual hostnames for this listener.

   **Note:**

   To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated hostnames, you can create one on the **Hostnames** page. See **Hostname Management** on page 3283 for more information.

   - **Protocol**: Required. Specify the protocol to use, either HTTP or TCP.
   - **Port**: Required. Specify the port on which to listen for incoming traffic.
   - **Use SSL**: Optional. Check this box to associate an SSL certificate bundle with the listener. The following settings are required to enable SSL handling. See **SSL Certificate Management** on page 3308 for more information.
     - **Certificate Name**: The friendly name of the SSL certificate bundle to use.
     - **Verify Peer Certificate**: Optional. Select this option to enable peer certificate verification.
     - **Verify Depth**: Optional. Specify the maximum depth for certificate chain verification.
   - **Backend Set**: Required. Specify the default backend set to which the listener routes traffic.
   - **Idle Timeout in Seconds**: Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

   **Note:**

   The maximum value is 7200 seconds. For more information, see **Connection Management** on page 3205.

   - Choose either a **Routing Policy** or a **Path Route Set**.
     - **Routing Policy**: Optional. Specify the name of the routing policy that applies to this listener's traffic.
     - **Path Route Set**: Optional. Specify the name of the set of path-based routing rules that applies to this listener's traffic.

   **Note:**

   To apply a path route set to a listener, the set must be part of the load balancer's configuration.
• **Show Advanced Options**: Click to display the following options:
  
  • **TLS Version**: Specify the Transport Layer Security (TLS) version(s):
    
    • 1.0
    • 1.1
    • 1.2 (recommended)

    You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.
  
  • **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

    All choices present in the list have at least one cipher associated with each TLS version you selected.
  
    • Click **Show Cipher Suite Details** to display the individual ciphers the selected cipher suite contains.

  • **Server Order Preference**: Select **Enable** to give preference to the server ciphers over the client.

9. Click **Create Listener**.

When you create a listener, you must also update your VCN's security rules to allow traffic to that listener.

**To create a listener using the CLI**

Use the command line interface (CLI) to create a listener for a Load Balancer resource.

Enter the following command:

```
oci lb listener create --name name --default-backend-set-name default_backend_set_name --load-balancer-id load_balancer_id --port port --protocol protocol [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb listener create --help
```

See [oci lb listener create](#) for a complete description of the command.

**To create a listener using the API**

Use the API to create a listener for a Load Balancer resource.

Run the **CreateListener** method to create a listener for a load balancer. See [CreateListener](#) for a complete description.

**Listing Listeners**

List the listeners for a Load Balancer resource.

Use one of the following methods to display a list of listeners for a selected load balancer.

**To list the listeners using the Console**

Use the OCI Console to list the listeners for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

    All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer containing the listeners that you want to list.

    The Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   
   The **Listeners** list appears. All listeners are listed in tabular form.

**Getting Listener Details**

Get the details of a listener for a Load Balancer resource.

Use one of the following methods to display the details of a listener for a selected load balancer.

**To get the details of a listener using the Console**

Use the OCI Console to get the details of a listener for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer containing the listeners that you want to list.
   
   The Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   
   The **Listeners** list appears. All listeners are listed in tabular form.

   The following details are displayed for each listener:
   
   • Name
   • Protocol
   • Port
   • Cipher Suite
   • Backend Set
   • Routing Policy
   • Path Route Set
   • Hostnames
   • Use SSL

**Editing Listeners**

Update a listener for a Load Balancer resource.

Use one of the following methods to edit and update the settings of a listener for a selected load balancer.

**To edit a listener using the Console**

Use the OCI Console to update a listener for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose listener you want to edit.
   
   The Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   
   The **Listeners** list appears. All listeners are listed in tabular form.
7. Click the **Actions** icon (♦) associated with the listener set you want to edit and click **Edit**.
   
   The Edit Listener dialog box appears.
8. Edit the listener settings. See **Creating Listeners** on page 3250 for details on specific configurations.
9. Click **Update Listener**.

**To edit a listener using the CLI**

Use the command line interface (CLI) to update a listener for a Load Balancer resource.

Enter the following command:

```bash
oci lb lister update --load-balancer-id load-balancer_id --listener-name listener_name --default-backend-set-name default_backend_set_name --port port --protocol protocol [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb listener update --help
```

See [oci lb listener update](#) for a complete description of the command.

**To edit a listener using the API**

Use the API to update a listener for a Load Balancer resource.

Run the `UpdateListener` method to edit a listener for a load balancer. See [UpdateListener](#) for a complete description.

**Deleting Listeners**

Delete a listener from a Load Balancer resource.

Use one of the following methods to delete a listener from a selected load balancer.

**To delete a listener using the Console**

Use the OCI Console to delete a listener from a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose listener you want to delete.
   
   The Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   
   The **Listeners** list appears. All listeners are listed in tabular form.
7. Click the **Actions** icon (🗑️) associated with the listener set you want to delete and click **Delete**.
8. Confirm the deletion when prompted.

**To delete a listener using the CLI**

Use the command line interface (CLI) to delete a listener from a Load Balancer resource.

Enter the following command:

```bash
oci lb lister delete --load-balancer-id load-balancer_id --listener-name listener_name [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb listener delete --help
```

See [oci lb listener delete](#) for a complete description of the command.

**To delete a listener using the API**

Use the API to delete a listener from a Load Balancer resource.
Run the `DeleteListener` method to edit a listener for a load balancer. See `DeleteListener` for a complete description.

**Enabling Listeners to Accept Traffic**

Use one of the following methods to enable a listener to accept traffic for a selected Load Balancer resource.

**To enable a listener to accept traffic using the Console**

Use the OCI Console to enable a listener to accept traffic for a Load Balancer resource.

To enable a listener to accept traffic, update your VCN's security rules:

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   
   The list of VCNs in the current compartment appears.

2. Click the name of the VCN containing your load balancer, and then click **Security Groups** or **Security Lists**.

   A list of the security groups or lists in the cloud network appears.

3. Click the name of the NSG or security list that applies to your load balancer.

4. Add or edit the existing rules to allow access from the appropriate resources.

   An NSG's security rules appear on the **Network Security Group Details** page. From there you can add, edit, or remove rules.

   The **Security List Details** page provides access to separate tables in which you can add or edit **Ingress Rules** or **Egress Rules**.

   For details on rule configuration, see **Security Rules** on page 3710.

**Cipher Suite Management**

Learn how to use cipher suites with a load balancer to determine the security, compatibility, and speed of HTTPS traffic.

A cipher suite is a logical entity for a set of algorithms, or *ciphers*, using Transport Layer Security (TLS) to determine the security, compatibility, and speed of HTTPS traffic. All ciphers are associated with at least one version of TLS 1.0, 1.1, and 1.2.

**Note:**

Any cipher suite you use or create must contain individual ciphers that match the TLS version supported in your environment. Some ciphers can work with multiple TLS versions. If your environment supports at least one of the TLS versions associated with a given cipher, you can use it.

When you create or edit a listener, you add or can change the associated cipher suite. See **Listener Management** on page 3250 for more information.

Click **Cipher Suites** under **Resources** in the Load Balancer Details page to display the Cipher Suites page. This page contains a button for creating cipher suites.

This page also contains a list of all the currently available cipher suites, both ones that came originally preconfigured from Oracle Cloud Infrastructure (`Predefined=Yes`), and ones that you created yourself (`Predefined=No`). You can modify or delete those cipher suites you created yourself (`Predefined=No`). You cannot modify predefined cipher suites.

**Creating Cipher Suites**

Create a cipher suite for a Load Balancer resource.

After you create a hostname, the name becomes available for use with the associated load balance. You can apply the hostname to a listener. See **Listener Management** on page 3250 for more information.

Use one of the following methods to create a cipher suite for a selected load balancer.
To create a cipher suite using the Console

Use the OCI Console to create a cipher suite for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to add a cipher suite.
   The Load Balancer Details dialog box appears.
6. Click Cipher Suites under Resources.
   The Cipher Suites page appears.
7. Click Create Cipher Suite.
   The Create Cipher Suite page appears.
8. Enter a name for the cipher suite you are creating in the Suite Name field.
9. Check those TLS versions under Filters from which you want to select.
   Ciphers associated with the TLS versions you checked (displaying which TLS versions they support) appear. Only select TLS versions that are supported in your environment.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assign at least one cipher to a cipher suite you create. You cannot create a cipher suite that contains no ciphers.</td>
</tr>
</tbody>
</table>

10. Check those ciphers that you want to include in your cipher suite.
   The total number of ciphers available can span multiple pages. Use the Search Ciphers field to find a specific cipher.
   Uncheck a cipher to deselect it from the cipher suite.
11. Click Create Suite.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note the following related to creating cipher suites:</td>
</tr>
<tr>
<td>• Ensure compatibility between specified SSL protocols and configured ciphers in the cipher suite, or else the SSL handshake is not successful.</td>
</tr>
<tr>
<td>• Ensure compatibility between configured ciphers in the cipher suite and configured certificates (for example, RSA-based ciphers require an RSA certificate whereas ECDSA-based ciphers require ECDSA certificates).</td>
</tr>
<tr>
<td>• For all load balancer and listener resources that were created before the cipher suites feature was available, the following apply:</td>
</tr>
<tr>
<td>• When running a GET operation, the cipher suite value returned is by default &quot;oci-default-ssl-cipher-suite-v1&quot; inside the listener's SSL configuration. You can update this value by editing the load balancer or listener.</td>
</tr>
<tr>
<td>• When running a GET operation, the cipher suite value returned is displayed as &quot;oci-customized-ssl-cipher-suite&quot; inside the listener's SSL configuration if the cipher configuration customized after the load balancer creation through Oracle operations.</td>
</tr>
<tr>
<td>• For all existing load balancer backendsets that were created before the cipher suites feature was available, running a GET operation displays the cipher suite value as &quot;oci-wider-compatible-ssl-cipher-suite-v1&quot; inside the backendset's SSL configuration.</td>
</tr>
</tbody>
</table>
Load Balancing

- If running a GET operation on a load balancer listener displays the cipher suite value as "oci-customized-ssl-cipher-suite," then choose the appropriate cipher suite name (either pre-defined or custom defined cipher suites) when updating these load balancers.
- The cipher suite name "oci-customized-ssl-cipher-suite" is reserved for use by Oracle and is not acceptable as an available name for a custom cipher suite.

To create a cipher suite using the CLI

Use the command line interface (CLI) to create a cipher suite for a Load Balancer resource.

Enter the following command:

```shell
oci lb ssl-cipher-suite create --name name --load-balancer-id load-balancer_id --ciphers ciphers [OPTIONS]
```

See the CLI online help for a list of options:

```shell
oci lb ssl-cipher-suite create --help
```

See `oci lb ssl-cipher-suite create` for a complete description of the command.

To create a cipher suite using the API

Use the API to create a cipher suite for a Load Balancer resource.

Run the `CreateSSLCipherSuite` method to edit a listener for a load balancer. See `CreateSSLCipherSuite` for a complete description.

Listing Cipher Suites

List the cipher suites for a Load Balancer resource.

Use one of the following methods to display a list of cipher suites for a selected load balancer.

To list the cipher suites using the Console

Use the OCI Console to list the cipher suites for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to add a cipher suite.
   - The Load Balancer Details dialog box appears.
6. Click Cipher Suites under Resources.
   - The Cipher Suites page appears. All cipher suites are listed in tabular form.

To list the cipher suites using the CLI

Use the command line interface (CLI) to list the cipher suites for a Load Balancer resource.

Enter the following command:

```shell
oci lb ssl-cipher-suite list --load-balancer-id load-balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```shell
oci lb ssl-cipher-suite list --help
```

See `oci lb ssl-cipher-suite list` for a complete description of the command.
To list the cipher suites using the API
Use the API to list the cipher suites for a Load Balancer resource.

Run the `ListSSLCipherSuites` method to list the cipher suites for a load balancer. See `ListSSLCipherSuites` for a complete description.

Getting Cipher Suite Details
Get the details of a cipher suite for a Load Balancer resource.

Use one of the following methods to display the details of a cipher suite for a selected load balancer.

To get the details of a cipher suite using the Console
Use the OCI Console to get the details of a cipher suite for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Click Cipher Suites under Resources.
   - The Cipher Suites page appears. All cipher suites are listed in tabular form.
6. Click the cipher suite whose details you want to get.
   - Alternatively, click the Actions icon (*** ) associated with the cipher suite whose details you want to get and click View Details.
   - The Cipher Suite Details page appears. The Details page displays those ciphers currently included in the cipher suite.

To get the details of a cipher suite using the CLI
Use the command line interface (CLI) to get the details of a cipher suite for a Load Balancer resource.

Enter the following command:

```
oci lb ssl-cipher-suite get --name name --load-balancer-id load-balancer_id
[OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb ssl-cipher-suite get --help
```

See `oci lb ssl-cipher-suite get` for a complete description of the command.

To get the details of a cipher suite using the API
Use the API to get the details of a cipher suite for a Load Balancer resource.

Run the `GetSSLCipherSuite` method to get the details of a cipher suite for a load balancer. See `GetSSLCipherSuite` for a complete description.

Editing Cipher Suites
Update a cipher suite for a Load Balancer resource.

Use one of the following methods to edit and update the settings of a cipher suite for a selected load balancer.

To edit a cipher suite using the Console
Use the OCI Console to update a cipher suite for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Click Cipher Suites under Resources.

The Cipher Suites page appears. All cipher suites are listed in tabular form.

6. Click the Actions icon (⋮) associated with the cipher suite you want to edit and click Edit.

The Manage Ciphers dialog box appears.

7. Modify the ciphers contained in the cipher suite:
   - To add ciphers, click Manage Cipher(s).
     
     The Select Ciphers page appears. Check the ciphers that you want to add. The ciphers you add must be compatible with the TLS version you are using. Use the Filters to limit the available ciphers by the TLS versions they support. Click Select Ciphers. You are returned to the Details page.
   - To remove ciphers, check those ciphers listed in the Details page and click Remove. All the check ciphers are removed.

8. Click Update Ciphers.

   **To edit a cipher suite using the CLI**

   Use the command line interface (CLI) to update a cipher suite for a Load Balancer resource.

   Enter the following command:

   ```bash
   oci lb ssl-cipher-suite update --name name --load-balancer-id load-balancer_id --ciphers ciphers [OPTIONS]
   ```

   See the CLI online help for a list of options:

   ```bash
   oci lb ssl-cipher-suite update --help
   ```

   **To edit a cipher suite using the API**

   Use the API to update a cipher suite for a Load Balancer resource.

   Run the UpdateSSLCipherSuite method to edit a cipher suite for a load balancer. See [UpdateSSLCipherSuite](https://docs.oracle.com/en-us/iaas/api/#/en/oci-lb/20190501/Operations/UpdateSSLCipherSuite) for a complete description.

   **Deleting Cipher Suites**

   Delete a cipher suite from a Load Balancer resource.

   ```
   Note:
   You cannot delete a cipher suite that is in use. Ensure all listeners and backend sets using the cipher suite you want to delete are managed to a different suite first. You might not have access to all compartments containing associated resources.
   ```

   Use one of the following methods to a cipher suite from a selected load balancer.

   **To delete a cipher suite using the Console**

   Use the OCI Console to delete a cipher suite from a Load Balancer resource.
Load Balancing

**Note:**
You can only delete a custom (Predefined=No) cipher suite.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Click Cipher Suites under Resources.
   The Cipher Suites page appears. All cipher suites are listed in tabular form.
6. Click the cipher suite you want to delete.
   The Cipher Suite Details page appears.
7. Click Delete.
   Alternatively, click the Actions icon associated with the cipher suite you want to delete and click Delete.
8. Confirm the deletion when prompted.

**To delete a cipher suite using the CLI**
Use the command line interface (CLI) to delete a cipher suite from a Load Balancer resource.

**Note:**
You can only delete a custom cipher suite.

Enter the following command:

```shell
oci lb ssl-cipher-suite delete --name name --load-balancer-id load-balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```shell
oci lb ssl-cipher-suite delete --help
```

See `oci lb ssl-cipher-suite delete` for a complete description of the command.

**To delete a cipher suite using the API**
Use the API to delete a cipher suite from a Load Balancer resource.

**Note:**
You can only delete a custom cipher suite.

Run the DeleteSSLCipherSuite method to delete a cipher suite from a load balancer. See `DeleteSSLCipherSuite` for a complete description.

**Supported Ciphers**
Learn about the ciphers supported by the Load Balancing service.

Here is a list of supported ciphers by TLS version.

**TLS version 1.2**
Learn the ciphers for TLS 1.2 for a Load Balancer resource.

## Predefined Cipher Suites

Learn about the predefined cipher suites for a Load Balancer resource.

Here is a list of the ciphers suites that are available for use with Load Balancing, along with the individual ciphers they include.

### oci-default-ssl-cipher-suite-v1

Learn about the ciphers contained in the oci-default-ssl-cipher-suite-v1 cipher suite.

This cipher suite contains a restricted set of ciphers that are only supported in TLS version 1.2, and meets stricter compliance requirements.

- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256
- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

### oci-modern-ssl-cipher-suite-v1

Learn about the ciphers contained in the oci-modern-ssl-cipher-suite-v1 cipher suite.

This cipher suite offer wider set of ciphers, but still only supported in TLS version 1.2.

- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- AES128-GCM-SHA256
- AES128-SHA256
- AES256-GCM-SHA384
- AES256-SHA256
- DHE-RSA-AES256-GCM-SHA384

oci-customized-ssl-cipher-suite

This cipher suite reflects customized cipher tasks performed by Oracle on a client-specific basis occurring before the general release of the cipher suite feature.

Managing Cipher Suites in Listeners and Backend Sets

When you create a load balancer, specifying the cipher suite is part of configuring the listener and the backend set. See Creating Load Balancers on page 3207 for more information.

Request Routing Management

Learn how to route incoming requests to various backend sets.
The Load Balancing service enables you to route incoming requests to various backend sets. You can assign virtual hostnames to a listener or create route rules.

Virtual Hostnames

When used in concert with records you create in your DNS system, you can assign virtual hostnames to any listener you create for your load balancer. Hostnames associated with a listener correspond to the backend sets of that listener. These backend sets route traffic to specific backends which host different applications. Some advantages of virtual hostnames include:

- A single associated IP address. Multiple hostnames, backed by DNS entries that you create in your nameservers, can point to the same load balancer IP address.
- A single load balancer. You do not need a separate load balancer for each application.
- A single load balancer shape. Running multiple applications behind a single load balancer helps you manage aggregate bandwidth demands and optimize utilization.
- Simpler backend set management. Managing a set of backend servers under a single resource simplifies network configuration and administration.

You can define exact virtual hostnames, such as "app.example.com," or you can use wildcard names. Wildcard names include an asterisk (*) in place of the first or last part of the name. When searching for a virtual hostname, the service chooses the first matching variant in the following priority order:

1. Exact name match (no asterisk), such as app.example.com.
2. Longest wildcard name that begins with an asterisk, such as *.example.com.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prefix wildcard names might require a wildcard certificate for HTTPS sites.</td>
</tr>
</tbody>
</table>
```

3. Longest wildcard name that ends with an asterisk, such as app.example.*.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suffix wildcard names might require a multi-domain Subject Alternative Name (SAN) certificate for HTTPS sites.</td>
</tr>
</tbody>
</table>
```

You do not need to specify the matching pattern to apply. The pattern is inherent in the asterisk position, that is, starting, ending, or none.

The following considerations apply to virtual hostnames:

- You cannot use regular expressions.
- To apply virtual hostnames to a listener, you first create one or more virtual hostnames associated with a load balancer.
- Virtual hostname selection priority is not related to the listener's configuration order.
- You can apply a maximum of 16 virtual hostnames to a listener.
- You can associate a maximum of 16 virtual hostnames with a load balancer.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The virtual hostnames feature supports HTTP and HTTPS listeners only, but does not support TCP listeners.</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Listener</td>
</tr>
<tr>
<td>If a listener has no virtual hostname specified, that listener is the default for the assigned port.</td>
</tr>
<tr>
<td>If all listeners on a port have virtual hostnames, the first virtual hostname configured for that port serves as the default listener.</td>
</tr>
</tbody>
</table>
```
Routing Policies

Request routing policies allow you to route ingress traffic requests based on whether they match certain conditions you define. These rule conditions can use boolean and near-match operations. The rules are evaluated in the order you define and the evaluation stops at the first match. You can attach one such request routing rule set to your HTTP or HTTPS listeners. A well-formed request routing rule is made up of one or more match conditions and a single corresponding route action. You can create multiple routing rules. If an incoming request doesn't match any of the rules you created, the request is routed to a default backend set attached to the listener.

For HTTP headers, query data parameters, and cookies, the following match types are supported:

- Contains: <key> equals <value>
- Does not contain: <key> equals <value>
- Exists: <key>
- Does not exist: <key>

Routing policies also support rules that match against request URL paths. This behavior is similar to path route sets, but offers different match options. The following match types are supported in routing policies for path matching:

- Is: An exact match of the path, such as /videos or /images.
- Is not: Any path that doesn't exactly match the specified path.
- Starts with: A match happens if the path begins with the input value. If the parameter provided was /videos, then a request for /videos/images would still produce a match.
- Does not start with: A match happens if the path begins with anything other than the parameter provided. If the parameter provided was /videos, then a request for /images/stills would still produce a match.
- Ends with: A match happens if the path ends with the parameter. If the parameter provided was /videos, then a request for both /images/videos or /previews/videos would both produce a match.
- Does not end with: A match happens if the path ends with anything other than the parameter provided. So if the parameter provided was /videos, then a request for /videos/images would produce a match.

**Note:**

Path route sets will be retired on Thursday, 24 March 2022. When path route sets are retired, these options take the place of path route sets rules.

The only supported routing rule action is:

- **Route to a specific backend set:** This choice routes the matched requests to a backend set that you specify.

See [Routing Policy Management](#) on page 3287 for more information on creating and managing routing policies.

Path Route Sets

**Note:**

Path route sets will be retired on Thursday, 24 March 2022.

A path route is a string that the load balancer matches against an incoming URI to determine the appropriate destination backend set. Some applications have multiple endpoints or content types, each distinguished by a unique URI path. For example, /admin/, /data/, /video/, or /cgi/. You can use path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.

A path route set includes all path route rules that define the data routing for a particular listener.

Note the following about path route sets:

- You cannot use asterisks in path route strings.
- You cannot use regular expressions.
- Path route string matching is case-insensitive.
- You can specify up to 20 path route rules per path route set.
• You can have one path route set per listener. The maximum number of listeners limits the number of path route sets you can specify for a load balancer.

**Note:**

Browsers often add an ending slash to the path in a request. If you specify a path such as `/admin`, you might want to configure the path both with and without the trailing slash. For example, `/admin` and `/admin/`.

A path route rule consists of a path route string and a pattern match type.

• Pattern match types include:

  • **EXACT_MATCH**
    
    Looks for a path string that exactly matches the incoming URI path.
    
    Applies case-insensitive regex:
    
    ```
    ^<path_string>\$
    ```
  
  • **FORCE_LONGEST_PREFIX_MATCH**
    
    Looks for the path string with the best, longest match of the beginning portion of the incoming URI path.
    
    Applies case-insensitive regex:
    
    ```
    <path_string>.*
    ```
  
  • **PREFIX_MATCH**
    
    Looks for a path string that matches the beginning portion of the incoming URI path.
    
    Applies case-insensitive regex:
    
    ```
    ^<path_string>.*
    ```
  
  • **SUFFIX_MATCH**
    
    Looks for a path string that matches the ending portion of the incoming URI path.
    
    Applies case-insensitive regex:
    
    ```
    .*<path_string>$
    ```

• Path route rules apply only to HTTP and HTTPS requests and have no effect on TCP requests.

See [Path Route Set Management](#) on page 3291 for more information on creating and managing path route sets.

**Rule Priority**

The system applies the following priorities, based on match type, to the path route rules within a set:

• For one path route rule that specifies the EXACT_MATCH type, no cascade of priorities occurs. The listener looks for an exact match only.

• For two path route rules, one that specifies the EXACT_MATCH type and one that specifies any other match type, the exact match rule is evaluated first. If no match is found, then the system looks for the second match type.

• For multiple path route rules specifying various match types, the system applies the following priority cascade:

  1. **EXACT_MATCH**
  2. **FORCE_LONGEST_PREFIX_MATCH**
  3. **PREFIX_MATCH** or **SUFFIX_MATCH**

• The order of the rules within the path route set does not matter for EXACT_MATCH and **FORCE_LONGEST_PREFIX_MATCH**. The system applies the priority cascade no matter where these match types appear in the path route set.
Load Balancing

- If matching cascades down to prefix or suffix matching, the order of the rules within the path route set DOES matter. The system chooses the first prefix or suffix rule that matches the incoming URI path.

See Rule Set Management on page 3296 for more information on creating and managing rule sets.

Virtual Hostname and Path Route Rules Combinations

Virtual hostnames and path route rules route requests to backend sets. Listeners with a virtual hostname receive priority over the default (no hostname) listener. The following example shows the results of a simple routing interaction.

The example system includes three listeners and one path route set:

Listener 1
- Virtual hostname: none
- Default backend set: A
- Path route set: PathRouteSet1

Listener 2
- Virtual hostname: captive.com
- Default backend set: B
- Path route set: PathRouteSet1

Listener 3
- Virtual hostname: wild.com
- Default backend set: C
- Path route set: PathRouteSet1

Path Route Set
- Path route set name: PathRouteSet1
  - Exact match on path string /tame/ routes to backend set B.
  - Exact match on path string /feral/ routes to backend set C.

The following configuration examples show how incoming routes URLs are routed:

- http://animals.com/ is routed to backend set A
  - Virtual hostname animals.com matches Listener 1.
  - Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.
- http://animals.com/tame/ is routed to backend set B
  - Virtual hostname animals.com matches Listener 1.
  - Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.
- http://animals.com/feral/ is routed to backend set C
  - Virtual hostname animals.com matches Listener 1.
  - Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.
- http://captive.com/ is routed to backend set B
  - Virtual hostname captive.com matches Listener 2.
  - Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.
- http://captive.com/tame/ is routed to backend set B
  - Virtual hostname captive.com matches Listener 2.
  - Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.
- http://captive.com/feral/ is routed to backend set C
  - Virtual hostname captive.com matches Listener 2.
  - Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.
Load Balancing

- http://wild.com/ is routed to backend set C
  - Virtual hostname wild.com matches **Listener 3**.
  - Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.
- http://wild.com/tame/ is routed to backend set B
  - Virtual hostname wild.com matches **Listener 3**.
  - Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.
- http://wild.com/feral/ is routed to backend set C
  - Virtual hostname wild.com matches **Listener 3**.
  - Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.

Routing Policy Language

Learn how to write routing policy condition statements that guide load balancer behavior.

To control how incoming requests to resources like web servers are routed, you must create policies. These policies take a general form of "If this, then forward traffic to a backend set." The backend set must be one you have already created.

Routing policies work in the following ways:

- Each HTTP request is evaluated against the rules.
- The rules are run in the order that is defined in the policy.
- Each rule has at least one condition and a backend set.
- If the HTTP request condition matches a rule, the request is forwarded to the backend set defined for the rule. The other rules in the policy are skipped and the request is not evaluated against them.

Example: One Path Rule

Here's an example of a routing policy rule set that contains only one path-based rule:

```json
{
   "name": "BasicPathBasedPolicy",
   "conditionLanguageVersion": "V1",
   "rules": [
      {
         "name": "Documents_rule",
         "condition": "any(http.request.url.path eq (i '/documents'))",
         "actions": [{
            "name": "FORWARD_TO_BACKENDSET",
            "backendSetName": "backendSetForDocuments"
         }]
      }
   ]
}
```

This example shows the following elements:

- The rule set is enclosed in curly brackets {} and contains a name for the rule set, the language version number, and a name for the set of rules.
- The rule set name in the example is "Example_policy". Rules in the set are contained inside square brackets.
- The sole rule in the set is named "Documents_rule".
- The condition for the rule says that if any of the conditions are met, then perform the action in "actions".
- The condition compares the incoming HTTP request URL path with /documents. The comparison is `eq` meaning equals, which could also be written as `=.`
- In the condition statement (i '/documents') declares that '/documents' is case-insensitive.
- When the condition is met, the action taken is to forward the request to a specific backend set, in this case "backendSetForDocuments." This backend set must exist for the rule to be valid.
The rule can be paraphrased as "If the requested URL path is an exact match for /documents then forward the request to the backend set backendSetForDocuments.

Example: Two Simple Path Rules

Here's an example of a routing policy rule set that contains two simple path-based rules. An incoming query is sent to a different backend set based on the request URL path, and forwarding happens if either the first condition or the second condition is met. Multiple rules are evaluated in their order in the policy. If a query happens to match both of these conditions, the action is performed on the first one matched and the second match is skipped.

```json
{
    "name": "PathBasedPolicy",
    "conditionLanguageVersion": "V1",
    "rules": [
        {
            "name": "Documents_rule",
            "condition": "any(http.request.url.path eq (i '/documents'))",
            "actions": [
                {
                    "name": "FORWARD_TO_BACKENDSET",
                    "backendSetName": "backendSetForDocuments"
                }
            ]
        },
        {
            "name": "Videos_rule",
            "condition": "any(http.request.url.path eq (i '/videos'))",
            "actions": [
                {
                    "name": "FORWARD_TO_BACKENDSET",
                    "backendSetName": "backendSetForVideos"
                }
            ]
        }
    ]
}
```

Example: One Rule with Two Conditions

The next policy has one rule with two conditions (each condition is separated by a comma). The first condition examines the request headers, and the second condition examines the request's query string:

```json
{
    "name": "Example_policy",
    "conditionLanguageVersion": "V1",
    "rules": [
        {
            "name": "HR_mobile_user_rule",
            "condition": "all(http.request.headers[(i 'user-agent') eq (i 'mobile'), http.request.url.query['department'] eq 'HR')]",
            "actions": [
                {
                    "name": "FORWARD_TO_BACKENDSET",
                    "backendSetName": "backendSetForHRMobileUsers"
                }
            ]
        }
    ]
}
```

The rule now requires that two conditions are both true to forward a request to a backend set, since it begins with the all keyword. The conditions for the rule can be paraphrased as "If the requested user-agent value in the header is set to mobile and the department value in the header is HR, then forward to the specified backend set."
Example: Two Rules

The final example shows two rules. Each rule has a different action, and both rules have two conditions. Importantly, the second rule begins with the keyword `any`, meaning that only one of the two conditions needs to be true to trigger the action. If more than two conditions specified, if any one of them is true the action is triggered.

```json
{
    "name": "Example_policy",
    "conditionLanguageVersion": "V1",
    "rules": [
      {
        "name": "HR_mobile_user_rule",
        "condition": "all(http.request.headers[(i 'user-agent')] eq (i 'mobile'), http.request.url.query['department'] eq 'HR')",
        "actions": [
          {
            "name": "FORWARD_TO_BACKENDSET",
            "backendSetName": "backendSetForHRMobileUsers"
          }
        ]
      },
      {
        "name": "Documents_rule",
        "condition": "any(http.request.url.path eq (i '/documents'), http.request.headers[(i 'host')] eq 'doc.myapp.com')",
        "actions": [
          {
            "name": "FORWARD_TO_BACKENDSET",
            "backendSetName": "backendSetForDocuments"
          }
        ]
      }
    ]
}
```

Rule Conditions

Learn about the rule conditions of the routing policy language for a Load Balancer resource.

The rule conditions are written in the form of predicates. Multiple predicates can be used in one condition, using combinators. The two combinators: `any()` and `all()` behave like a logical OR or AND. A combinator can also be negated by putting the keyword `not` before it. A simple predicate can be expressed as:

```
<left value> <matcher> <right value>
```

A condition for a rule that must match if the HTTP request URL path starts with `/foo/bar` would be:

```
http.request.url.path sw '/foo/bar'
```

More details about the available matchers are in [Matchers](#) on page 3276.

More details about the available variables are in [Variables](#) on page 3278.

Syntax for multiple predicates

```
not? any|all(<condition>,<condition>,...)
```

Example:

```
all(http.request.url.path sw '/foo', 'bar' in (http.request.url.query))
```

Condition examples

Here are more examples of how conditions can be used. Here are more details on the exact syntax and functionality.
• To match an HTTP request if its URL path starts with "/category/element":

```
http.request.url.path sw '/category/element'
```

• To match an HTTP request if its URL path starts with "/category" or ends with "/id":

```
any(http.request.url.path sw '/category', http.request.url.path ew '/id')
```

• To match an HTTP request if its URL path contains "/category/" and contains "/element/":

```
all(http.request.url.path co '/category/', http.request.url.path co '/element/')
```

• To match an HTTP request if a "User-Agent" request header is present:

```
(i 'User-Agent') in (http.request.headers)
```

• To match an HTTP request if the header "User-Agent" has the value "Some User Agent":

```
http.request.headers[(i 'User-Agent')] eq 'Some User Agent'
```

• To match an HTTP request if the URL query string has a case-sensitive key "search", for example as in the URL https://www.example.com/category/?search=item+foo%20bar&page=1

```
'search' in (http.request.url.query)
```

• To match an HTTP request if the URL query string has a case-sensitive key "search" (case-sensitively) with a case-insensitive value "item+foo%20bar", for example as in the URL https://www.domain.com/category/?search=item+foo%20bar&page=1

```
http.request.url.query['search'] = (i 'item foo bar')
```

Matching for URL query (both keys and values) must be done using URL unescaped versions of their values.

• To case-insensitively match an HTTP request for a cookie named "tastycookie":

```
(i 'tastycookie') in (http.request.cookies)
```

• To case-insensitively match an HTTP request for a cookie named "tastycookie" that contains the case-sensitive value "strawberry":

```
http.request.cookies[(i 'tastycookie')] = 'strawberry'
```

### Matchers

Learn how to use matchers in the routing policy language for a Load Balancer resource.

Multiple matchers are available to use in conditions.

### String Matchers

The next table lists the matchers that operate on string values. Some matchers have alternative variants, meaning any of those variants can be used interchangeably for that matcher.

The examples for each matcher all match the http.request.url.path containing "/category/element/id":

<table>
<thead>
<tr>
<th>Name</th>
<th>Alternatives</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>co</td>
<td></td>
<td>Matches if the value on the left-hand side contains the value on the right-hand side.</td>
<td>http.request.url.path co '/category/element/'</td>
</tr>
<tr>
<td>Name</td>
<td>Alternatives</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>------</td>
<td>--------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>eq</td>
<td>=, ==, equal, equals</td>
<td>Matches if values on the left-hand and right-hand side of the matcher are equal.</td>
<td>http.request.url.path eq &quot;/category/element/id&quot;</td>
</tr>
<tr>
<td>ew</td>
<td></td>
<td>Matches if the value on the left-hand side ends with the value on the right-hand side.</td>
<td>http.request.url.path ew '/id'</td>
</tr>
<tr>
<td>sw</td>
<td></td>
<td>Matches if the value on the left-hand side starts with the value on the right-hand side.</td>
<td>http.request.url.path sw '/category'</td>
</tr>
<tr>
<td>not co</td>
<td></td>
<td>Matches if the value on the left-hand side does not contain the value on the right-hand side.</td>
<td>http.request.url.path not co '/not_element/'</td>
</tr>
<tr>
<td>not eq</td>
<td>!=, not equal, not equals</td>
<td>Matches if values on the left-hand and right-hand side of the matcher are not equal.</td>
<td>http.request.url.path neq '/some/other/path'</td>
</tr>
<tr>
<td>not ew</td>
<td></td>
<td>Matches if the value on the left-hand side does not end with the value on the right-hand side.</td>
<td>http.request.url.path not ew '/not_id'</td>
</tr>
<tr>
<td>not sw</td>
<td></td>
<td>Matches if the value on the left-hand side does not start with the value on the right-hand side.</td>
<td>http.request.url.path not sw '/not_category'</td>
</tr>
</tbody>
</table>

**Partial Matchers**

Some of the variables used in the rules contain arbitrary key-value maps of data when the rules are run. For example `http.request.headers` contains the HTTP request headers. For more details on the available maps, see Variables on page 3278.

The matchers *in* and *not in* can be used to check if a map variable contains a specific key. It depends on the variable what the key actually represents.

The syntax for checking if a map variable contains a specific key is:

```plaintext
<key> in (<map variable>)
```

- `<key>` must be either a case-sensitive or case-insensitive string.
- The right-hand side value must be in parentheses.

For example, this condition matches if the HTTP request has a cookie with the name 'Foo':

```plaintext
'Foo' in (http.request.cookies)
```
Values
Learn how to use values in the routing policy language for a Load Balancer resource.

The values used in predicates can be either constant values or variables which are evaluated at runtime.

Constants
Learn about the constants associated with the values in the routing policy language for a Load Balancer resource.

The rules support string constants written between single-quotes.

Example:

```
http.request.url.path sw '/foo'
```

String case-sensitivity

String matching uses case-sensitive comparisons by default.

For example, if the HTTP request URL path for some request is /foo then the following predicate would not match for that request, because case-sensitive string comparison is used:

```
http.request.url.path eq '/FOO'
```

Case-insensitive matching is done if at least one of the compared values is a case-insensitive string. The syntax for a case insensitive string is:

```
(i '<string content>')
```

For example, these strings are all case-insensitive and are therefore equivalent, when used in predicates:

```
(i 'foo')
(i 'Foo')
(i 'FOO')
```

In comparison to the original example - this predicate does match, because it uses case-insensitive comparison:

```
http.request.url.path eq (i '/FOO')
```

Variables

Learn about the variables associated with the values in the routing policy language for a Load Balancer resource.

Variables are used in conditions to match against some particular value of the HTTP request. The actual values for each variable are determined when the rules are run, that is, during each individual HTTP request.

Map Type Variables

Some of the variables contain arbitrary key-value maps of request data, for example request headers or cookies. For each key, there can be one or more values. For example, there can be multiple request headers with the same name.

Generally map variables can be used in rules these ways:

- To check if a map has a specific key.
- To check if a map has a specific key with a specific value.

Checking if a map has a specific key:

Checking if a map variable has a specific key is done with the in matcher. For more details, refer to Routing Policy Language on page 3273.

For example:

```
'Foo' in (http.request.cookies)
```
This condition matches if the HTTP request has a cookie with the name 'Foo.'

**Checking if a map has a specific key with a specific value:**

Checking if a map has a specific key with a specific value is done using bracket notation to get the values at a specific key. The syntax for using bracket notation is:

```
<variable>[<key>]
```

The `<key>` must be specified as a case-sensitive or case-insensitive string.

The actual check for a specific value is done using the `eq` matcher to check if *any* of the values at that key are equal to that specific value. The predicate matches if at least one of the values at that key match that specific value.

Examples:

- To match if any value of the header "header-name" equals "header-value":
  
  ```
  http.request.headers[(i 'header-name')] eq 'header-value'
  ```

  Header name is compared case-insensitively, but header value is compared case-sensitively.

- To match if any value of the cookie "cookie-name" equals 'cookie-value':
  
  ```
  http.request.cookies['cookie-name'] eq 'cookie-value'
  ```

The `not eq` matcher can be used to check that *none* of the values at that key are equal to a specific value.

Examples:

- To match if no value of the header "header-name" equals "header-value":
  
  ```
  http.request.headers[(i 'header-name')] not eq 'header-value'
  ```

  Header name is compared case-insensitively. Header value is compared case-sensitively.

- To match if no value of the cookie "cookie-name" equals 'cookie-value':
  
  ```
  http.request.cookies['cookie-name'] not eq 'cookie-value'
  ```

### All Available Variables

The variables available to be used in the conditions are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>http.request.headers</code></td>
<td>A map containing HTTP request headers. This map has some special behavior - the keys (header names) must be case-insensitive strings. Using case-sensitive strings for <code>http.request.headers</code> keys in predicates are not allowed.</td>
<td>• Correct usage:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>`(i 'User-Agent') in http.request.headers[(i 'User-Agent')] = 'Mobile'</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>http.request.url.path</td>
<td>HTTP request URL path. This is the request URL, without protocol, domain, port, and query string.</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| http.request.url.query   | A map containing HTTP request URL query elements. If the request URL does not have a query (does not have the ? character) or if the query is empty (the ? character is the last one in the URL), this map is empty. The query is parsed to produce the http.request.url.query map, by taking the query string part of the URL (which is the part after the first ? character) and splitting it into key-value pairs, by treating these characters as special:  
  - & character is the separator between different key-value pairs  
  - = character is the separator between the key and value (inside a key-value pair)  
  The first ? character present in the URL marks the beginning of the query string. If extra ? characters appear after the first one, they are treated the same as any other character, without any special handling.  
  Inside a key-value pair, the first = character present separates the key from the value. If extra = characters are present, they are treated as being part of the value.  
  Keys and values are unescaped according to URL escaping rules. | URL: https://www.domain.com/path?key=value&key=%61&another%20key=another+value  
The http.request.url.query data for a request with this URL would look like this expressed as JSON:  
```json  
{  
  "key": [  
    "value",  
    "a"  
  ],  
  "another key": [  
    "another value"  
  ]  
}  
```

In this example, both key and value are matched case-sensitively. So if instead of key=value the URL contained KEY=value or key=VALUE the condition would not match.  
However, a key-value pair from the URL query string is not added to the http.request.url.query map in these cases:  
- If a = character is not present in a key-value pair  
  Example:  
  URL: https://www.example.com/path?no_key"  
  In this case, the query string element no_key is not present in the http.request.url.query map.  
- If the left-hand side of the = character is empty (the key is not specified)  
  Example: URL: https://www.domain.com/path?no_value  
  In this case - the query string element no_value is not present in the http.request.url.query map.  
  If the right-hand side of the = character is empty - then the value for that key-value pair is an empty string "". |
## Load Balancing

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>http.request.cookies</td>
<td>A map containing HTTP request cookies, parsed from the &quot;Cookie&quot; request header as called out in RFC-6265, where the key is a cookie name and the value is the corresponding cookie value. If the &quot;Cookie&quot; request header is not present in the request - this map is empty.</td>
<td></td>
</tr>
</tbody>
</table>

### Examples

An incoming HTTP/1.1 request looks like this (request line and headers):

```plaintext
GET /category/some_category?action=search&query=search+terms&filters[]=5&features[]=12 HTTP/1.1
Accept-Encoding: gzip, deflate, br
Cookie: cookie_a=1; cookie_b=foo
Host: www.domain.com
User-Agent: Browser Foo/1.0
X-Forwarded-For: 1.2.3.4, 5.6.7.8
X-Forwarded-For: 9.10.11.12
```

Then the variables available for rules would be populated with data from this request as follows:(the data for structured variables is shown in JSON format)

```plaintext
http.request.url.path: "/category/some_category"

http.request.url.query: {
  "action": ["search"],
  "query": ["search terms"],
  "filters[]": ["5", "12"]
}

http.request.headers: {
  "Accept-Encoding": ["gzip, deflate, br"],
  "Cookie": ["some_cookie=1; another_cookie=foo"],
  "Host": ["www.domain.com"],
  "User-Agent": ["Browser Foo/1.0"],
  "X-Forwarded-For": ["1.2.3.4, 5.6.7.8", "9.10.11.12"]
}

http.request.cookies: {
  "cookie_a": ["1"],
  "cookie_b": ["foo"]
}
```

Here are some examples how we could match this request:

- If we wanted to match requests to domain "www.domain.com" and URL paths that start with "/category/", we would use a condition like this:

  ```plaintext
  all(http.request.headers[(i 'Host')] eq 'www.domain.com',
  http.request.url.path sw '/category')
  ```
Load Balancing

- To match requests where the URL path is exactly "/category/some_category" or request query element "action=search"

```java
any(http.request.url.path eq '/category/some_category',
    http.request.url.query['action'] eq 'search')
```

- To match requests that have a query string element named "query" with value "search terms" (after URL unescaping)

```java
http.request.url.query['query'] eq 'search terms'
```

- To match requests that have cookie "cookie_a" but don't have cookie "cookie_c"

```java
all('cookie_a' in (http.request.cookies), 'cookie_c' not in (http.request.cookies))
```

Hostname Management

Learn to use hostnames with a load balancer for one or more listeners.

This topic describes how to manage your load balancer's hostnames for use with one or more listeners.

Creating Hostnames

Create a hostname for a Load Balancer resource.

Use one of the following methods to create a hostname for a selected load balancer.

To create a hostname using the Console

Use the OCI Console to create a hostname for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a hostname.
   
   The Load Balancer Details dialog box appears.
6. Click Hostnames under Resources.
   
   The Hostnames list appears. All hostnames are listed in tabular form.
7. Click Create Hostname.
   
   The Create Hostname dialog box appears.
8. Enter the following:
   
   - Name: Required. Specify a friendly name for the hostname. The name must be unique, and cannot be changed.
   - Hostname: Required. Specify the virtual hostname. See Hostname Management on page 3283 for more information.
9. Click Create. The Work Request Submitted dialog box opens.
10. (optional) Click View All Work Requests to open the Work Requests page and view the status of the work request.
11. Click Close.

To create a hostname using the CLI

Use the command line interface (CLI) to create a hostname for a Load Balancer resource.

Enter the following command:

```bash
oci lb hostname create --hostname hostname --name name --load-balancer-id load_balancer_id [OPTIONS]
```
See the CLI online help for a list of options:

```
oci lb hostname create --help
```

See `oci lb hostname create` for a complete description of the command.

**To create a hostname using the API**

Use the API to create a hostname for a Load Balancer resource.

Run the `CreateHostname` method to create a listener for a load balancer. See `CreateHostname` for a complete description.

**Listing Hostnames**

List the hostnames for a Load Balancer resource.

Use one of the following methods to display a list of hostnames for a selected load balancer.

**To list the hostnames using the Console**

Use the OCI Console to list the hostnames for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a hostname.
   
   The Load Balancer Details dialog box appears.
6. Click **Hostnames** under **Resources**.
   
   The **Hostname** list appears. All hostnames are listed in tabular form.

**To list the hostnames using the CLI**

Use the command line interface (CLI) to list the hostnames for a Load Balancer resource.

Enter the following command:

```
oci lb hostname list --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb hostname list --help
```

See `oci lb hostname list` for a complete description of the command.

**To list the hostnames using the API**

Use the API to list the hostnames for a Load Balancer resource.

Run the `ListHostnames` method to display a list of hostnames for a load balancer. See `ListHostnames` for a complete description.

**Getting Hostname Details**

Get the details of a hostname for a Load Balancer resource.

Use one of the following methods to display the details of a hostname for a selected load balancer.

**To get the details of a hostname using the Console**

Use the OCI Console to get the details of a hostname for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a hostname.

   The Load Balancer Details dialog box appears.

6. Click **Hostnames** under **Resources**.

   The **Hostname** list appears. All hostnames are listed in tabular form.

   The following details are displayed for each hostname:
   
   - **Name**
   - **Hostname**

***To get the details of a hostname using the CLI***

Use the command line interface (CLI) to get the details of a hostname for a Load Balancer resource.

Enter the following command:

```bash
oci lb hostname get --name name --load-balancer-id load_balancer_id
```

See the CLI online help for a list of options:

```bash
oci lb hostname get --help
```

See **oci lb hostname get** for a complete description of the command.

***To get the details of a hostname using the API***

Use the API to get the details of a hostname for a Load Balancer resource.

Run the **GetHostname** method to get the details of a hostname for a load balancer. See **GetHostname** for a complete description.

***Editing Hostnames***

Update a hostname for a Load Balancer resource.

Use one of the following methods to edit and update the settings of a hostname for a selected load balancer.

***To edit a hostname using the Console***

Use the OCI Console to update a hostname for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a hostname.

   The Load Balancer Details dialog box appears.

6. Click **Hostnames** under **Resources**.

   The **Hostnames** list appears. All hostnames are listed in tabular form.

   The following details are displayed for each hostname:
   
   - **Name**
   - **Hostname**

7. For the hostname you want to edit, click the Actions icon (three dots), and then click **Edit**.
8. In the **Edit Hostname** dialog box, enter your updates to the **Hostname** field.

   You cannot edit the **Name** field of an existing virtual hostname.

9. Click **Update**. The **Work Request Submitted** dialog box opens.
10. To close the dialog box, click Close. To open the Work Requests page and view the status of the work request, click View All Work Requests.

To edit a hostname using the CLI
Use the command line interface (CLI) to update a hostname for a Load Balancer resource.

Enter the following command:

```bash
oci lb hostname update --name name --load-balancer-id load_balancer_id
```

[OPTIONS]

See the CLI online help for a list of options:

```bash
oci lb hostname update --help
```

See oci lb hostname get for a complete description of the command.

To edit a hostname using the API
Use the API to update a hostname for a Load Balancer resource.

Run the UpdateHostname method to edit a hostname for a load balancer. See UpdateHostname for a complete description.

Deleting Hostnames
Delete a hostname from a Load Balancer resource.

Use one of the following methods to delete a hostname from a selected load balancer.

To delete a hostname using the Console
Use the OCI Console to delete a hostname from a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for whose hostname you want to delete.
   The Load Balancer Details dialog box appears.
6. Click Hostnames under Resources.
   The Hostnames list appears. All hostnames are listed in tabular form.
7. Click the Actions icon (🗑️) associated with the hostname you want to delete and click Delete.
8. Confirm the deletion when prompted.

To delete a hostname using the CLI
Use the command line interface (CLI) to delete a hostname from a Load Balancer resource.

Enter the following command:

```bash
oci lb hostname delete --name name --load-balancer-id load_balancer_id
```

[OPTIONS]

See the CLI online help for a list of options:

```bash
oci lb hostname delete --help
```

See oci lb hostname delete for a complete description of the command.

To delete a hostname using the API
Use the API to delete a hostname from a Load Balancer resource.
Load Balancing

Run the `DeleteHostname` method to get the details of a hostname for a load balancer. See `DeleteHostname` for a complete description.

Routing Policy Management
Learn to use routing policies to apply a named ordered list of routing rules to a listener.

A routing policy is a named ordered list of routing rules that is applied to a listener.

Creating Routing Policies
Create a routing policy for a Load Balancer resource.

Use one of the following methods to create a routing policy for a selected load balancer.

To create a routing policy using the Console
Use the OCI Console to create a routing policy for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a routing policy.

   The Load Balancer Details dialog box appears.
6. Click Routing Policies under Resources.

   The Routing Policy list appears. All routing policies are listed in tabular form.
7. Click Create Routing Policy.

   The Create Routing Policy dialog box appears.
8. Enter a Name for the routing policy rule set. A name is required. The name must be unique, and cannot be changed. The name cannot begin with a period and cannot contain any of these characters: ; ? # / % \ [ ] . The name must start with an lower- or upper-case letter or an underscore, and the rest of the name can contain numbers, underscores, and upper- or lower-case letters.
9. To create a rule in the rule set:
   a. Choose If All Match (peer conditions use a logical AND) or If Any Match (peer conditions use a logical OR). In rules with multiple conditions, this selection guides whether one or all stated conditions produce an action. There can be up to five rule conditions, and you can have up to five nested conditions within a top-level condition. There can be up to 200 conditions total in a policy. Nested conditions can't have further conditions nested within them.
   b. Each top-level condition has a type, a match style, and a final criteria.
      • Condition Type: The setting can be Path, Request Cookies, Request Header, URL Query, or Nested Match. The available fields for a condition change depending on the condition type.
         A Nested Match also has a Nested conditions match criteria for conditions nested within, allowing you to have a mix of AND and OR in a condition. Click +Another Nested Condition to add another nested condition within the group. You can only nest conditions one level deep.
         • The match style for Path can be: Is, Is not, Starts with, Does not start with, Ends with, or Does not end with. The match style for Request Header, Request Cookies, and URL Query can be: Contains, Does not contain, Exists, or Does not exist.
         • The final criteria depends on the Condition Type selected, and can be a URL String (All Path conditions use this) a Key-Value pair or simply a Key.
   c. Select the Action. If you choose Route to Backend Set, select the destination backend set from the list of available sets.
   d. To create another rule, click + Another Rule.
10. You can also click Show Advanced Controls. An editing window opens where you can directly enter text to define rules using the Routing Policy Language on page 3273.
11. Click Next after you finish defining the rules.

The next step is to confirm the order of the rules.

12. In the right end of the order list row corresponding to that rule. Click the down arrow to see a summary of the conditions and actions set in a rule.

13. Click Reorder to move a rule up or down in the policy order.

Choose from among Move to Top, Move to Bottom, Move Up, or Move Down. The last two options shift that rule up or down by one position in the order.

14. When the routing policy rules are created and in the right order, click Create Routing Policy.

To use a routing policy, you must create a listener that uses the policy.

To create a routing policy using the CLI

Use the command line interface (CLI) to create a routing policy for a Load Balancer resource.

Enter the following command:

```
oci lb routing-policy create --name name --load-balancer-id load_balancer_id --condition-language-version condition_language_version --rules rules [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb routing-policy create --help
```

See `oci lb routing-policy create` for a complete description of the command.

To create a routing policy using the API

Use the API to create a routing policy for a Load Balancer resource.

Run the `CreateRoutingPolicy` method to get the details of a hostname for a load balancer. See `CreateRoutingPolicy` for a complete description.

Listing Routing Policies

List the routing policies for a Load Balancer resource.

Use one of the following methods to display a list of routing policies for a selected load balancer.

To list the routing policies using the Console

Use the OCI Console to list the routing policies for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a routing policy.

   The Load Balancer Details dialog box appears.
6. Click Routing Policies under Resources.

   The Routing Policy list appears. All routing policies are listed in tabular form.

To list the routing policies using the CLI

Use the command line interface (CLI) to list the routing policies for a Load Balancer resource.

Enter the following command:

```
oci lb routing-policy list --load-balancer-id load_balancer_id [OPTIONS]
```
See the CLI online help for a list of options:

```
oci lb routing-policy list --help
```

See `oci lb routing-policy list` for a complete description of the command.

**To list the routing policies using the API**

Use the API to list the routing policies for a Load Balancer resource.

Run the `ListRoutingPolicies` method to display a list of hostnames for a load balancer. See `ListRoutingPolicies` for a complete description.

### Getting Routing Policy Details

Get the details of a routing policy for a Load Balancer resource.

Use one of the following methods to display the details of a routing policy for a selected load balancer.

**To get the details of a routing policy using the Console**

Use the OCI Console to get the details of a routing policy for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a routing policy.
   
   The Load Balancer Details dialog box appears.
6. Click **Routing Policies** under **Resources**.
   
   The **Routing Policy** list appears. All routing policies are listed in tabular form.
7. Click the routing policy whose details you want to get.
   
   The Routing Policy Details page appears.

**To get the details of a routing policy using the CLI**

Use the command line interface (CLI) to get the details of a routing policy for a Load Balancer resource.

Enter the following command:

```
oci lb routing-policy get --routing-policy-name routing_policy_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb routing-policy get --help
```

See `oci lb routing-policy get` for a complete description of the command.

**To get the details of a routing policy using the API**

Use the API to get the details of a routing policy for a Load Balancer resource.

Run the `GetRoutingPolicy` method to get the details of a hostname for a load balancer. See `GetRoutingPolicy` for a complete description.

### Editing Routing Policy Details

Update a routing policy for a Load Balancer resource.

Use one of the following methods to edit and update the settings of a routing policy for a selected load balancer.

**To edit a routing policy using the Console**

Use the OCI Console to update a routing policy for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose routing policy you want to edit.
   The Load Balancer Details dialog box appears.
6. Click **Routing Policies** under **Resources**.
   The **Routing Policy** list appears. All routing policies are listed in tabular form.
7. Click the routing policy whose settings you want to edit.
   The Routing Policy Details page appears.
8. Click **Edit**.
   The Edit Routing Policy dialog box appears.
9. Make your edits.
   See **Creating Routing Policies** on page 3287 for details on the routing policy settings.
10. Click **Save Changes**.

**To edit a routing policy using the CLI**

Use the command line interface (CLI) to update a routing policy for a Load Balancer resource.

Enter the following command:

```
oci lb routing-policy update --routing-policy-name routing_policy_name --load-balancer-id load_balancer_id --rules rules [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb routing-policy update --help
```

See **oci lb routing-policy update** for a complete description of the command.

**To edit a routing policy using the API**

Use the API to update a routing policy for a Load Balancer resource.

Run the **UpdateRoutingPolicy** method to edit a routing policy for a load balancer. See **UpdateRoutingPolicy** for a complete description.

**Deleting Routing Policies**

Delete a routing policy from a Load Balancer resource.

Use one of the following methods to delete a routing policy from a selected load balancer.

**To delete a routing policy using the Console**

Use the OCI Console to delete a routing policy from a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer from which you want to delete a routing policy.
   The Load Balancer Details dialog box appears.
6. Click **Routing Policies** under **Resources**.
   The **Routing Policy** list appears. All routing policies are listed in tabular form.
7. Click the routing policy whose details you want to delete.
   The Routing Policy Details page appears.
8. Click Delete.
9. Confirm the deletion when prompted.

To delete a routing policy using the CLI
Use the command line interface (CLI) to delete a routing policy from a Load Balancer resource.

Enter the following command:

```
oci lb routing-policy delete --routing-policy-name routing_policy_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb routing-policy delete --help
```

See `oci lb routing-policy delete` for a complete description of the command.

To delete a routing policy using the API
Use the API to delete a routing policy from a Load Balancer resource.

Run the `DeleteRoutingPolicy` method to delete a routing policy from a load balancer. See `DeleteRoutingPolicy` for a complete description.

Path Route Set Management
Learn to use path route sets to apply a set of path routes to a Load Balancer resource.

To apply path route rules to a listener, you first create a path route set that contains the rules. The path route set becomes a part of the load balancer's configuration. You then specify the path route set to use when you create or update a listener for the load balancer. To remove a path route set from a listener, edit the listener and choose None as the Path Route Set option.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path route rules will be retired on: Thursday, 24 March 2022. Instead, use routing policies. See Routing Policy Management on page 3287 for more information.</td>
</tr>
</tbody>
</table>

Creating Path Route Sets
Create a path route set for a Load Balancer resource.

Use one of the following methods to create a path route set for a selected load balancer.

To create a path route set using the Console
Use the OCI Console to create a path route set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a path route set.
   The Load Balancer Details dialog box appears.
6. Click Path Route Sets under Resources.
   The Path Route Sets list appears. All routing policies are listed in tabular form.
7. Click Create Path Route Set.
   The Create Path Route Set dialog box appears.
8. Enter the following:

- **Name**: Required. Specify a friendly name for the path route set. The name must be unique, and cannot be changed.

  The path route set name cannot begin with a period and cannot contain the characters ;, ?, #, %, /, \, [, or ]. Avoid entering confidential information.

- **Path Route Rules**
  - **Order**: Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

  **Note:**
  The order of the rules within the path route set usually does not matter. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

  - **Match Style**: Required. The type of matching to apply to incoming URIs. See Request Routing Management on page 3268 for more information.
  - **URL String**: Required. The path string to match against the incoming URI path, for example /admin/.
  - **Backend Set Name**: Required. The name of the target backend set for requests where the incoming URI matches the specified path.
  - Click **+ Additional Rule** to create another path route rule. You can have up to 20 path route rules in a set.
  - Click **X** to delete an existing rule.

9. Click **Create**.

After you create a path route set, the set becomes available for use with the associated load balance. Create or update a listener to apply the path route set.

*To create a path route set using the CLI*

Use the command line interface (CLI) to create a path route set for a Load Balancer resource.

Enter the following command:

```bash
oci lb path-route-set create --name name --load-balancer-id load_balancer_id --path-routes path_routes [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb path-route-set create --help
```

See `oci lb path-route-set create` for a complete description of the command.

*To create a path route set using the API*

Use the API to create a path route set for a Load Balancer resource.

Run the `CreatePathRouteSet` method to create a path route set for a load balancer. See `CreatePathRouteSet` for a complete description.

*Listing Path Route Sets*

List the path route sets for a Load Balancer resource.

Use one of the following methods to display a list of path route sets for a selected load balancer.

*To list the path route sets using the Console*

Use the OCI Console to list the path route sets for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

  All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under Type to only display load balancers.
5. Select the load balancer for which you want to create a path route set.

   The Load Balancer Details dialog box appears.
6. Click **Path Route Sets** under Resources.

   The **Path Route Sets** list appears. All path route sets are listed in tabular form.

**To list the path route sets using the CLI**

Use the command line interface (CLI) to list the path route sets for a Load Balancer resource.

Enter the following command:

```
oci lb path-route-set list --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb path-route-set list --help
```

See [oci lb path-route-set list](#) for a complete description of the command.

**To list the path route sets using the API**

Use the API to list the path route sets for a Load Balancer resource.

Run the ListPathRouteSets method to display a list of path route sets for a load balancer. See ListPathRouteSets for a complete description.

**Getting Path Route Set Details**

Get the details of a path route set for a Load Balancer resource.

Use one of the following methods to display the details of a path route set for a selected load balancer.

**To get the details of a path route set using the Console**

Use the OCI Console to get the details of a path route set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under Type to only display load balancers.
5. Select the load balancer whose path route set details you want to get.

   The Load Balancer Details dialog box appears.
6. Click **Path Route Sets** under Resources.

   The **Path Route Sets** list appears. All path route sets are listed in tabular form.
7. Click the path route set whose details you want to get.

   The Path Route Set Details page appears.

**To get the details of a path route set using the CLI**

Use the command line interface (CLI) to get the details of a path route set for a Load Balancer resource.

Enter the following command:

```
oci lb path-route-set get --path-route-set-name path_route_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb path-route-set get --help
```
See `oci lb path-route-set get` for a complete description of the command.

**To get the details of a path route set using the API**

Use the API to get the details of a path route set for a Load Balancer resource.

Run the `GetPathRouteSet` method to display the details of a path route set for a load balancer. See `GetPathRouteSet` for a complete description.

**Editing Path Route Sets**

Update a path route set for a Load Balancer resource.

Use one of the following methods to edit and update a path route set for a selected load balancer.

**To edit a path route rule using the Console**

Use the OCI Console to update a path route set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for whose path route set you want to update.
   
   The Load Balancer Details dialog box appears.
6. Click Path Route Sets under Resources.
   
   The Path Route Sets list appears. All path route sets are listed in tabular form.
7. Click the path route set whose settings you want to edit.
   
   The Path Route Set Details page appears.
8. Click Edit.
   
   Alternatively, click the Actions icon (.collider) associated with the path route set you want to edit and click Edit.
   
   The Edit Path Route Set dialog box appears.
9. Edit the following as needed for each rule you want to change:
   
   - **Order**: Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.
   
     **Note:**
     
     The order of the rules within the path route set usually does not matter. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.
   
   - **Match Style**: Required. The type of matching to apply to incoming URIs. See Request Routing Management on page 3268 for more information.
   
   - **URL String**: Required. The path string to match against the incoming URI path, for example `/admin/`.
   
   - **Backend Set Name**: Required. The name of the target backend set for requests where the incoming URI matches the specified path.
   
     - Click + Additional Rule to create another path route rule. You can have up to 20 path route rules in a set.
     
     - Click X to delete an existing rule.
10. Click Save Changes.

**To edit a path route set using the CLI**

Use the command line interface (CLI) to update a path route set for a Load Balancer resource.
Enter the following command:

```
oci lb path-route-set update --path-route-set-name path_route_set_name --load-balancer-id load_balancer_id --path-routes path_routes [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb path-route-set update --help
```

See `oci lb path-route-set update` for a complete description of the command.

**To edit a path route set using the API**

Use the API to update a path route set for a Load Balancer resource.

Run the `UpdatePathRouteSet` method to edit a path route set for a load balancer. See `UpdatePathRouteSet` for a complete description.

**Deleting Path Route Sets**

Delete a path route set from a Load Balancer resource.

Use one of the following methods to delete a path route set from a selected load balancer.

**To delete a path route set using the Console**

Use the OCI Console to delete a path route set from a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for whose path route set you want to update.
   - The Load Balancer Details dialog box appears.
6. Click Path Route Sets under Resources.
   - The Path Route Sets list appears. All path route sets are listed in tabular form.
7. Click the path route set whose settings you want to delete.
   - The Path Route Set Details page appears.
8. Click Delete.
   - Alternatively, click the Actions icon ( ) associated with the path route set you want to delete and click Delete.
9. Confirm the deletion when prompted.

**To delete a path route set using the CLI**

Use the command line interface (CLI) to delete a path route set from a Load Balancer resource.

Enter the following command:

```
oci lb path-route-set delete --path-route-set-name path_route_set_name --load-balancer-id load_balancer_id --path-routes path_routes [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb path-route-set delete --help
```

See `oci lb path-route-set delete` for a complete description of the command.

**To delete a path route set using the API**

Use the API to delete a path route set from a Load Balancer resource.
Run the `DeletePathRouteSet` method to delete a path route set for a load balancer. See `DeletePathRouteSet` for a complete description.

**Rule Set Management**
Learn to use rule sets composed of actions that are applied to traffic at a Load Balancer resource's listener.

A rule set is a named set of rules associated with a load balancer and applied to one or more listeners on that load balancer. To apply a rule set to a listener, you first create the rule set that contains the rules. Rules are objects that represent actions applied to traffic at a load balancer listener. The rule set becomes a part of the load balancer's configuration. You can specify the rule set to use when you create or update a listener for the load balancer.

You can include the following types of rules in a rule set:

- **Access control rules**, which restrict access to application resources based on the source of the request.
- **Access method rules**, which specify the permitted HTTP methods.
- **URL redirect rules**, which route incoming HTTP requests to a different destination URL.
- **Request and response header rules**, which add, alter, or remove HTTP request or response headers.
- **HTTP header rules**, which specify the size of the HTTP header and whether period and underscore characters are permitted within the headers.

**Note:**
Rule sets apply only to HTTP listeners.

You can apply an existing rule set when you edit a listener. You can apply the same rule set to multiple listeners on the same load balancer.

Rule sets are not shared between load balancers. To use the same set of rules on another load balancer, you must create a new, identical rule set under that load balancer.

You can have up to 20 rules in a rule set. You can associate a maximum of 50 rules with a load balancer.

**Access Control Rules**
Learn about access control rules for Load Balancer resources.

Access control rules permit access to application resources based on user-specified IP address or address range match conditions. If you do not specify any access control rules, the default rule is to allow all traffic. If you add access control rules, the load balancer denies any traffic that does not match the rules.

The service accepts only classless inter-domain routing (CIDR) format (`x.x.x.x/y` or `x:x::x/y`) strings for the match condition.

Specify `0.0.0.0/0` or `::/0` to match all incoming traffic.

**Note:**
Only US Government Cloud regions currently permit IPv6 values.

**Access Method Rules**
Learn about access method rules for Load Balancer resources.

Access method rules specify the HTTP methods allowed at the associated listener. The load balancer does not forward a disallowed request to the backend servers and returns a 405 Method Not Allowed response with a list of the allowed methods. You can associate only one list of allowed methods with a given listener.

By default, you can specify only the standard HTTP methods defined in the HTTP Method Registry. The list of HTTP methods is extensible. If you need to configure custom HTTP methods, contact My Oracle Support to remove the restriction from your tenancy. Your backend application must be able to handle the specified methods.

The following list shows the default HTTP methods:

<table>
<thead>
<tr>
<th>ACL</th>
<th>LABEL</th>
<th>OPTIONS</th>
<th>SEARCH</th>
</tr>
</thead>
</table>

Oracle Cloud Infrastructure User Guide
URL Redirect Rules
Learn about URL redirect rules for Load Balancer resources.

URL redirect rules specify how to route incoming HTTP requests to a different destination URL. URL redirect rules apply only to HTTP listeners. You configure each redirect rule for a particular listener and a designated path. A listener can have only one redirect rule for a given incoming URL path.

When you create a URL redirect rule, you specify the path string and match condition the service uses to evaluate an incoming URL for redirection. You also define the redirect URL and response code.

Incoming Path String Evaluation
You specify the path string, or pattern, to evaluate in the incoming URL. For example:

```
/video
```

You also specify the match condition to apply when evaluating the incoming URL for redirection. The available match types are:

- **FORCE_LONGEST_PREFIX_MATCH**
  The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
- **EXACT_MATCH**
  The incoming URL path must exactly and completely match the specified path string.
- **PREFIX_MATCH**
  The beginning portion of the incoming URL path must exactly match the specified path string.
- **SUFFIX_MATCH**
  The ending portion of the incoming URL path must exactly match the specified path string.

Redirection URL Construction
You define the redirect URL applied to the original request. URL redirect rules recognize the following URL components:

```
<protocol>://<host>[:<port>]/<path>?<query>
```
You can specify a literal string or provide a token for any component. Tokens extract values from the incoming HTTP request URL. Tokens are case-sensitive. For example, `{host}` is a valid token, but `{HOST}` is not.

- **Protocol**
  
  The HTTP protocol to use in the redirect URL. Valid values are HTTP and HTTPS.
  
  The `{protocol}` token extracts the protocol from the incoming HTTP request URL. It is the only valid token for this property.

- **Host**
  
  The valid domain name or IP address to use in the redirect URL.
  
  The `{host}` token extracts the host from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

  Curly braces `{}` are valid in this property only to surround tokens.

- **Port**
  
  The communication port to use in the redirect URL. Valid values include integers from 1 to 65535.
  
  The `{port}` token extracts the port from the incoming HTTP request URL. It is the only valid token for this property.

- **Path**
  
  The HTTP URL path to use in the redirect URL. To omit the path from the redirect URL, set this value to an empty string.
  
  The `{path}` token extracts the path string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

  If the path string does not begin with the `{path}` token, it must begin with a forward slash `/`.

- **Query**
  
  The query string to use in the redirect URL. To omit all incoming query parameters from the redirect URL, set this value to an empty string.
  
  The `{query}` token extracts the query string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

  If the query string does not begin with the `{query}` token, it must begin with a question mark `?`.

  You can specify multiple query parameters as a single string. Separate each query parameter with an ampersand `&`.

  If the specified query string results in a redirect URL ending with `?` or `&`, the last character is truncated. For example, if the incoming URL is `http://host.com:8080/documents` and the query property value is `?lang=en&{query}`, the redirect URL is `http://host.com:8080/documents?lang=en`. The system truncates the final ampersand `&` because the incoming URL included no value to replace the `{query}` token.

**Important:**

Failure to specify a value for at least one URL component field can result in a redirect loop.

**Manual Redirect URL Construction**

The Console provides text entry fields for each URL component. Alternatively, you can manually specify the full redirect URL.

You can retain the literal characters of a token when you specify values for the path and query properties of the redirect URL. Use a backslash `\` as the escape character for the `\`, ``, and `{}` characters. For example, if the incoming HTTP request URL is `/video`, the path property value `/example(path)123\{path\}` appears in the constructed redirect URL as `/example/video123(path)`. 
Some path and query string examples:

- `/example/video/123` appears as `/example/video/123` in the redirect URL.
- `/example{path}` appears as `/example/video/123` in the redirect URL when `/video/123` is the path in the incoming HTTP request URL.
- `{path}/123` appears as `/example/video123` in the redirect URL when `/example/video` is the path in the incoming HTTP request URL.
- `/{host}/123` appears as `/example.com/123` in the redirect URL when `example.com` is the hostname in the incoming HTTP request URL.
- `/{host}/{port}` appears as `/example.com/123` in the redirect URL when `example.com` is the hostname and `123` is the port in the incoming HTTP request URL.
- `/{query}` appears as `/lang=en` in the redirect URL when the query is `lang=en` in the incoming HTTP request URL.
- `lang=en&time_zone=PST` appears as `lang=en&time_zone=PST` in the redirect URL.
- `{query}` appears as `lang=en&time_zone=PST` in the redirect URL when `lang=en&time_zone=PST` is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, the `{query}` token renders as an empty string.
- `lang=en&{query}&time_zone=PST` appears as `lang=en&country=us&time_zone=PST` in the redirect URL when `country=us` is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, this value renders as `lang=en&time_zone=PST`.
- `protocol={protocol}&hostname={host}` appears as `protocol=http&hostname=example.com` in the redirect URL when the protocol is `http` and the hostname is `example.com` in the incoming HTTP request.
- `port={port}&hostname={host}` appears as `port=8080&hostname=example.com` in the redirect URL when the port is `8080` and the hostname is `example.com` in the incoming HTTP request URL.

**Response Code**

You can specify the HTTP status code to return when the incoming request is redirected. Valid response codes for redirection from the standard HTTP specification are:

- 301 Moved Permanently
- 302 Found
- 303 See Other
- 307 Temporary Redirect
- 308 Permanent Redirect

The default value is 302 Found.

**Request and Response Header Rules**

Learn about request and response header rules for Load Balancer resources.

Request and response header rules add, alter, or remove HTTP request or response headers. These rules can help you pass metadata to your backend servers to do things like:

- Identify which listener sent a request.
- Notify a backend server about SSL termination.

Examples of how rule sets can help you enhance site security include:

- Adding headers to prevent external domains from iframing your site.
- Removing debug headers, such as "Server," sent by backend servers. This action helps you hide the implementation details of your backend.
- Adding the "strict-transport-security" header, with a proper value, to responses. This header helps guarantee that access to your site is HTTPS only.
- Adding the "x-xss-protection" header with a proper value. This header helps you enforce the cross-site scripting (XSS) protection built into modern browsers.
• Adding the "x-content-type" header with a proper value. This header helps you prevent attacks based on content type shifting.

**Note:**
Adding or removing the built-in Host header or one of the X-Headers as described in HTTP "X-" Headers does not remove or override the header value. Instead, performing these actions can append other values or duplicate the header.

**Example: Notify WebLogic that the Load Balancer Terminated SSL**
You can configure your load balancer to perform SSL termination. Often, your backend applications require notification of this action. For example, HTTPS WebLogic e-commerce online transaction processing looks for the WL-Proxy-SSL header to confirm that a request came in over SSL. You can use rule sets to add this header at the load balancer listener.

**Note:**
For security reasons, WebLogic ignores this header unless you check the WebLogic Plugin Enabled box in WebLogic's Administration Console.

1. Create a rule set with the following settings. See Creating Rule Sets on page 3300 for more information.
   • Choose the Add Request Header option from the Action list.
   • Enter WL-Proxy-SSL as the Header name.
   • Set the header Value:
     • If your load balancer is configured to perform SSL termination, set this value to "true."
     • If the SSL termination point is in the web server where the plugin operates, set this value to "false."

2. Create a listener, or edit an existing listener, and add the new rule set. See Listener Management on page 3250 for more information.

**HTTP Header Rules**
Learn about HTTP header rules for Load Balancer resources.

HTTP header rules specify the size of the HTTP header and the kinds of characters that are permitted within the header. Because some applications require a URL header size greater than the default 8k to support their features, HTTP header rules allow you to set header buffers of up to 64k to avoid "414" (large URI requests) errors.

HTTP header rules allow periods (".") and underscores ("_"), providing you more flexibility in your naming structures.

**Creating Rule Sets**
Create a rule set for a Load Balancer resource.

Use one of the following methods to create a rule set for a selected load balancer.

To create a rule set using the Console
Use the OCI Console to create a rule set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Rule Sets under Resources.
   The Rule Sets list appears. All rule sets are listed in tabular form.
7. Click **Create Rule Set**.
   
The Create Rule Set dialog box appears.
8. Enter the following:

- **Name**: Required. Specify a friendly name for the rule set. The name must be unique, and cannot be changed. Avoid entering confidential information.
- **Specify Access Control Rules**: Optional. Check this box to add access control rules.
  - **IP Address CIDR**: Enter the IP address CIDR block from which access is allowed.
  - **+ Another Access Control Rule**: Optional. Click this button to enter another IP address CIDR or click the corresponding X to remove an existing entry.
- **Specify Access Method Rules**: Optional. Check this box to add access method rules.
  - **Allowed Methods**: From the list, select the HTTP methods to allow. You can select multiple methods. Click the label's X to remove an existing method.
- **Specify URL Redirect Rules**: Optional. Check this box to add URL redirect rules.
  - **Source Path**: Specify the incoming path string that triggers the redirect rule. For example, /video.
  - **Match Type**: Choose the match condition to apply when evaluating an incoming path string. The available match types are:
    - **FORCE_LONGEST_PREFIX_MATCH**
      The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
    - **EXACT_MATCH**
      The incoming URL path must exactly and completely match the specified path string.
    - **PREFIX_MATCH**
      The beginning portion of the incoming URL path must exactly match the specified path string.
    - **SUFFIX_MATCH**
      The ending portion of the incoming URL path must exactly match the specified path string.
  - **Redirect to**: Specify a value for at least one URL component field. Any component fields that you do not modify retain the incoming URL’s values. Optionally, click the **Switch to full URL** link to enter the redirect URL manually.
    - **Caution**: Failure to specify a value for at least one URL component field can result in a redirect loop.
  - **Protocol**: Specify the HTTP protocol to use in the redirect URL. Valid values are:
    - {protocol}
    - HTTPS
    - HTTP
  - **Host**: Specify a valid domain name (hostname) or IP address for the redirect URL. All redirect URL tokens are valid for this property.
  - **Port**: Specify the communication port to use in the redirect URL. Valid values include integers from 1 to 65535.
  - **Path**: The HTTP URL path to use in the redirect URL. All redirect URL tokens are valid for this property.
    - **Important**: If the path string does not begin with the {path} token, it must begin with the forward slash character /.
  - **Query**: Specify the query string to use in the redirect URL. All redirect URL tokens are valid for this property.
Important:
If the query string does not begin with the \{query\} token, it must begin with the question mark ? character.

- **Response Code:** Specify the HTTP status code to return when the incoming request is redirected. The default response code is 302 Found.

Valid response codes for redirection from the standard HTTP specification are:
- 301 Moved Permanently
- 302 Found
- 303 See Other
- 307 Temporary Redirect
- 308 Permanent Redirect

- + **Another URL Redirect Rule** Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.

- **Specify Request Header Rules:** Optional. Check this box to add request header rules.

- **Order:** Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.

- **Action:** Select the action that the rule applies. Available actions include:

  - **Add Request Header**
    Adds the specified header and value to the incoming request.
    
    If the specified header is already present, the system replaces it.
    
    If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.

  - **Extend Request Header**
    Adds the specified prefix or suffix to the incoming request.
    
    Provide a prefix value, a suffix value, or both when you choose this action.
    
    The system does not support this rule for headers with multiple values.

  - **Remove Request Header**
    Removes the specified header.
    
    If the same header appears more than once in the request, the load balancer removes all occurrences of the specified header.

```
Note:
These rules apply only to HTTP or HTTP2 headers.
```

- **Header:** A header name that conforms to RFC 7230.

```
Caution:
The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do
```
Load Balancing

- **Value**: (Add rules only.) A header value that conforms to RFC 7230.
- **Prefix**: (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
- **Suffix**: (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
- **Another Request Header Rule**: Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.
- **Specify Response Header Rules**: Optional. Check this box to add response header rules.
- **Order**: Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.
- **Action**: Select the action that the rule applies. Available actions include:
  - **Add Response Header**
    Adds the specified header and value to the outgoing response.
    If the specified header is already present, the system replaces it.
    If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.
  - **Extend Response Header**
    Adds the specified prefix or suffix to the incoming request.
    Provide a prefix value, a suffix value, or both when you choose this action.
    The system does not support this rule for headers with multiple values.
  - **Remove Response Header**
    Removes the specified header.
    If the same header appears more than once in the response, the load balancer removes all occurrences of the specified header.

**Note:**
These rules apply only to HTTP or HTTP2 headers.

- **Header**: A header name that conforms to RFC 7230.

**Caution:**
The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do not rely on underscore or dash characters to uniquely distinguish header names.
• **Value:** (Add rules only.) A header value that conforms to RFC 7230.
• **Prefix:** (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
• **Suffix:** (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
• **Another Response Header Rule** Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.

• **Specify HTTP Rules:** Optional. Check this box to specify HTTP header options for a listener.
  • **HTTP Header Buffer Size:** Select one of the following buffer sizes for the HTTP header from the list: None, 8k, 16k, 32k, 64k.
  • **Allow Invalid Characters in HTTP Header:** Check this box to allow periods (".") and underscores ("_") in the HTTP header.

• **Specify HTTP Header Options:** Optional. Check this box to specify HTTP header options for a listener.
  • **HTTP Header Buffer Size:** Select one of the following buffer sizes for the HTTP header from the list: None, 8k, 16k, 32k, 64k.
  • **Allow Invalid Characters in HTTP Header:** Optional. Check this box to allow invalid characters in the HTTP header.

9. **Click Create.**

After you create a rule set, the set becomes available for use with the associated load balancer. **Update a listener** to apply the rule set.

**To create a rule set using the CLI**

Use the command line interface (CLI) to create a rule set for a Load Balancer resource.

Enter the following command:

```
oci lb rule-set create --name name --load-balancer-id load_balancer_id --items items [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb rule-set create --help
```

See `oci lb rule-set create` for a complete description of the command.

**To create a rule set using the API**

Use the API to create a rule set for a Load Balancer resource.

Run the `CreateRuleSet` method to create a rule set for a load balancer. See `CreateRuleSet` for a complete description.

**Listing Rule Sets**

List the rule sets for a Load Balancer resource.

Use one of the following methods to display a list of rule sets for a selected load balancer.

**To list the Rule Sets using the Console**

Use the OCI Console to list the rule sets for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.

   The Load Balancer Details dialog box appears.

6. Click **Rule Sets** under **Resources**.

   The **Rule Sets** list appears. All rule sets are listed in tabular form.

*To list the Rule Sets using the CLI*

Use the command line interface (CLI) to list the rule sets for a Load Balancer resource.

Enter the following command:

```
oci lb rule-set list --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb rule-set list --help
```

See [oci lb rule-set list](https://docs.oracle.com/en-us/iaas/api/ht/generic.html#oci-lb-rule-set-list) for a complete description of the command.

*To list the Rule Sets using the API*

Use the API to list the rule sets for a Load Balancer resource.

Run the **ListRuleSets** method to list the rule sets for a load balancer. See [ListRuleSets](https://docs.oracle.com/en-us/iaas/api/ht/generic.html#oci-lb-rule-set-get) for a complete description.

**Getting Rule Set Details**

Get the details of a rule set for a Load Balancer resource.

Use one of the following methods to get the details of a rule set for a selected load balancer.

*To get the details of a rule set using the Console*

Use the OCI Console to get the details of a rule set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.

2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.

5. Select the load balancer for which you want to create a rule set.

   The Load Balancer Details dialog box appears.

6. Click **Rule Sets** under **Resources**.

   The **Rule Sets** list appears. All rule sets are listed in tabular form.

7. Click the rule set whose details you want to get.

   The Rule Set Details page appears.

*To get the details of a rule set using the CLI*

Use the command line interface (CLI) to list the rule sets for a Load Balancer resource.

Enter the following command:

```
oci lb rule-set get --rule-set-name rule_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb rule-set get --help
```

See [oci lb rule-set get](https://docs.oracle.com/en-us/iaas/api/ht/generic.html#oci-lb-rule-set-get) for a complete description of the command.
To get the details of a rule set using the API
Use the API to get the details of a rule set for a Load Balancer resource.

Run the `GetRuleSet` method to get the details of a rule set for a load balancer. See `GetRuleSet` for a complete description.

Editing Rule Sets
Update a rule set for a Load Balancer resource.

Use one of the following methods to edit and update a rule set for a selected load balancer.

To edit a rule set using the Console
Use the OCI Console to update a rule set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   - The Load Balancer Details dialog box appears.
6. Click Rule Sets under Resources.
   - The Rule Sets list appears. All rule sets are listed in tabular form.
7. Click the rule set whose settings you want to edit.
   - The Rule Set Details page appears.
8. Click Edit.
   - The Edit Path Route Set dialog box appears.
9. Make your edits.
   - See Creating Rule Sets on page 3300 for details on the rule set settings.
10. Click Save Changes.

To edit a rule set using the CLI
Use the command line interface (CLI) to update a rule set for a Load Balancer resource.

Enter the following command:
```
oci lb rule-set update --rule-set-name rule_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:
```
oci lb rule-set update --help
```

See `oci lb rule-set get` for a complete description of the command.

To edit a rule set using the API
Use the API to update a rule set for a Load Balancer resource.

Run the `UpdateRuleSet` method to edit a rule set for a load balancer. See `UpdateRuleSet` for a complete description.

Deleting Rule Sets
Delete a rule set from a Load Balancer resource.

Run the `DeleteRuleSet` method to delete a rule set from a load balancer. See `DeleteRuleSet` for a complete description.
Load Balancing

To delete a rule set using the Console
Use the OCI Console to delete a rule set from a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   The Load Balancer Details dialog box appears.
6. Click Rule Sets under Resources.
   The Rule Sets list appears. All rule sets are listed in tabular form.
7. Click the rule set whose settings you want to edit.
   The Rule Set Details page appears.
8. Click Delete.
   Alternatively, click the Actions icon ( ) associated with the path route set you want to delete and click Delete.
9. Confirm the deletion when prompted.

To delete a rule set using the CLI
Use the command line interface (CLI) to delete a rule set from a Load Balancer resource.

Enter the following command:

```
oci lb rule-set delete --rule-set-name rule_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb rule-set delete --help
```

See oci lb rule-set delete for a complete description of the command.

To delete a rule set using the API
Use the API to delete a rule set from a Load Balancer resource.

Run the DeleteRuleSets method to delete a rule set from a load balancer. See DeleteRuleSets for a complete description.

SSL Certificate Management
Learn to use single socket layer (SSL) certificates with your Load Balancer resource.

To use SSL with your load balancer, you must add one or more certificate bundles to your system. The certificate bundle you upload includes the public certificate, the corresponding private key, and any associated Certificate Authority (CA) certificates. For the easiest workflow, upload the certificate bundles you want to use before you create the listeners or backend sets you want to associate them with.

Load balancers commonly use single domain certificates. However, load balancers with listeners that include request routing configuration (see Request Routing Management on page 3268) might require a subject alternative name (SAN) certificate (also called multi-domain certificate) or a wildcard certificate. The Load Balancing service supports each of these certificate types.

Note:

- The Load Balancing service does not generate SSL certificates. It can only import an existing certificate that you already own. The certificate can be one issued by a vendor, such as Verisign or GoDaddy. You can
Load Balancing

also use a self-signed certificate that you generate with an open source tool, such as OpenSSL or Let's Encrypt. Refer to the corresponding tool's documentation for instructions on how to generate a self-signed certificate.

- If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

Oracle Cloud Infrastructure accepts x.509 type certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Converting to PEM Format

If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format. The following example commands provide guidance.

**Certificate or Certificate Chain from DER to PEM**

```
openssl x509 -inform DER -in <certificate_name>.der -outform PEM -out <certificate_name>.pem
```

**Private Key from DER to PEM**

```
openssl rsa -inform DER -in <private_key_name>.der -outform PEM -out <private_key_name>.pem
```

**Certificate Bundle from PKCS#12 (PFX) to PEM**

```
openssl pkcs12 -in <certificate_bundle_name>.p12 -out <certificate_bundle_name>.pem -nodes
```

**Certificate bundle from PKCS#7 to PEM**

```
openssl pkcs7 -in <certificate_bundle_name>.p7b -print_certs -out <certificate_bundle_name>.pem
```

Configuring Peer Certificate Verification

Peer certificate verification is used for client authentication. Peer certificate verification depth is the number of certificates in the chain that need to be verified for client authentication.

The following are expected values to be set:

- One intermediate certificate, client certificate, root certificate - 2
- Client certificate, root certificate - 1s

To determine if your peer certificate verification is configured incorrectly, note the following:

- The client indicates that it is unable to verify the certificate and results in a client SSL handshake failure. This error message varies based on the client type.
- In the load balancer logs, the following error appears: Client %s has SSL certificate verify error
• Use the OpenSSL utility to run the following command:
  
  ```bash
  openssl verify -verbose -CAfile RootCert.pem Intermediate.pem
  ```

  An error occurs that shows at what depth the validation failure is occurring:
  ```
  error 20 at 0 depth lookup:unable to get local issuer certificate
  ```

  To resolve this situation, provide the correct certificate depth and confirm that the client certificate and certificate authority certificate match and are in the correct order.

### Uploading Certificate Chains

If you have multiple certificates that form a single certification chain (for example, any intermediate certificate authority certificates), then include all relevant certificates in one file in the correct order before you upload them to the system. The correct order begins with the certificate directly signed by the trusted root certificate authority at the bottom of the list. Any additional certificates are pasted above the signed certificate.

Combine the server certificate (SSL_Certificate.crt) and the intermediate certificate authority certificate (intermediateCA.crt) files into a single, concatenated file.

To get a single, concatenated file from the SSL certificate and the intermediate certificate authority certificate, open a command prompt and run the following command:

```bash
cat ssl_certificate.crt IntermediateCA.crt >> certbundle.pem
```

The following example of a concatenated certificate chain file includes four certificates:

```plaintext
-----BEGIN CERTIFICATE-----
Base64-encoded_certificate
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
Base64-encoded_certificate
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
Base64-encoded_certificate
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
Base64-encoded_certificate
-----END CERTIFICATE-----
```

### Submitting Private Keys

**Note:**

Oracle recommends a minimum length of 2048 bits for your RSA private key.

If your private key submission returns an error, the three most common reasons are:

- You provided an incorrect passphrase.
- Your private key is malformed.
- The system does not recognize the encryption method used for your key.

### Key Pair Mismatch

If you receive an error related to the private key and public key being mismatched, then before uploading, use the following OpenSSL commands to confirm that they are part of the same pair:

```bash
openssl x509 -in certificate_name.crt -noout -modulus | openssl sha1
openssl rsa -in private_key.key -noout -modulus | openssl sha1
```
Confirm that the returned sha1 hash values match exactly. If they are different, then the private key provided is not used to sign the public certificate and cannot be used.

**Private Key Consistency**

If you receive an error related to the private key, then you can use OpenSSL to check its consistency:

```bash
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

**Decryption a Private Key**

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```bash
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

**Updating an Expiring Certificate**

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The steps to update your client or backend server are unique to your system.</td>
</tr>
</tbody>
</table>
2. Upload the new SSL certificate bundle to the load balancer:
   
a. Open the navigation menu, click Networking, and then click Load Balancers.
   
b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
   
c. Click the load balancer you want to configure.
   
d. In the Resources menu, click Certificates, and then click Add Certificate.
   
e. In the Add Certificate dialog box, enter the following:
      
      • **Certificate Name**: Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
      
      • **Choose SSL Certificate File**: Required. Drag and drop the certificate file, in PEM format, into the SSL Certificate field.
      
      Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.
      
      • **Specify CA Certificate**: Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
      
      • **Choose CA Certificate File**: Drag and drop the CA certificate file, in PEM format, into the CA Certificate field.
      
      Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.
      
      • **Specify Private Key**: Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
      
      • **Choose Private Key File**: Drag and drop the private key, in PEM format, into the Private Key field.
      
      Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.
      
      • **Enter Private Key Passphrase**: Optional. Specify the private key passphrase.
      
   
f. Click Add Certificate.
3. Edit listeners or backend sets (as needed) so they use the new certificate bundle

Editing a listener:
- a. Open the navigation menu, click Networking, and then click Load Balancers.
- b. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
- c. In the Resources menu, click Listeners.
- d. For the listener you want to edit, click the Actions icon (three dots), and then click Edit Listener.
- e. In the Certificate Name list, choose the new certificate bundle.
- f. Click Submit.

Editing a backend set:

```
Important:
Updating the backend set temporarily interrupts traffic and can drop active connections.
```

- a. Open the navigation menu, click Networking, and then click Load Balancers.
- b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
- c. In the Resources menu, click Backend Sets, and then click the name of the backend set you want to edit.
- d. Click Edit Backend Set.
- e. In the Edit Backend Set dialog box, select (check) Use SSL.
- f. In the Certificate Name list, choose the new certificate bundle.
- g. Click Save Changes.

4. (Optional) Remove the expiring SSL certificate bundle

```
Important:
You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.
```

- a. Open the navigation menu, click Networking, and then click Load Balancers.
- b. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
- c. Click the load balancer you want to configure.
- d. In the Resources menu, click Certificates.
- e. For the certificate you want to delete, click the Actions icon (three dots), and then click Delete.
- f. Confirm when prompted.

Configuring SSL Handling

Learn about configuring SSL handling for a Load Balancer resource.

You can perform the following SSL handling tasks for a load balancer:

- Terminate SSL at the load balancer. This configuration is frontend SSL. Your load balancer can accept encrypted traffic from a client. No encryption of traffic exists between the load balancer and the backend servers.
- Implement SSL between the load balancer and your backend servers. This configuration is backend SSL. Your load balancer does not accept encrypted traffic from client servers. Traffic between the load balancer and the backend servers is encrypted.
- Implement point-to-point SSL. Your load balancer can accept SSL encrypted traffic from clients and encrypts traffic to the backend servers.
**Terminating SSL at the Load Balancer**

To terminate SSL at the load balancer, you must create a listener at a port such as 443, and then associate an uploaded certificate bundle with the listener. See Creating Listeners on page 3250 for more information.

**Implementing Backend SSL**

To implement SSL between the load balancer and your backend servers, you must associate an uploaded certificate bundle with the backend set. See Creating Backend Sets on page 3228 for more information.

**Note:**

- If you want to have more than one backend server in the backend set, sign your backend servers with an intermediate CA certificate. The intermediate CA certificate must be included as part of the certificate bundle.
- Your backend services must be able to accept and terminate SSL.

**Implementing Point-to-Point SSL**

To implement point-to-point SSL, you must associate uploaded certificate bundles with both the listener and the backend set. See Creating Listeners on page 3250 and Creating Backend Sets on page 3228 for more information.

**Adding Certificates**

Add a certificate to a Load Balancer resource.

Use one of the following methods to add a certificate to a selected load balancer.

**To add a certificate using the Console**

Use the OCI Console to add a certificate to a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   - The Load Balancer Details dialog box appears.
6. Click Certificates under Resources.
   - The Certificates list appears. All certificates are listed in tabular form.
7. Click Add Certificate.
   - The Add Certificate dialog box appears.
8. Enter the following:

- **Certificate Name:** Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.)
- **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.

   Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

   **Important:**
   
   If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
- **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.

   Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.

- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
- **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.

   Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.

- **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

9. Click **Add Certificate**.

**To add a certificate using the CLI**

Use the command line interface (CLI) to list the certificates to a Load Balancer resource.

Enter the following command:

```
oci lb certificate create --certificate-name certificate_name --load-balancer-id load_balancer_id --items items [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb certificate create --help
```

See [oci lb certificate create](http://docs.oracle.com) for a complete description of the command.

**To add a certificate using the API**

Use the API to add a certificate to a Load Balancer resource.

Run the `CreateCertificate` method to create a certificate for a load balancer. See [CreateCertificate](http://docs.oracle.com) for a complete description.

**Listing Certificates**

List the certificates for a Load Balancer resource.

Use one of the following methods to display a list of certificates for a selected load balancer.

**To list the certificates using the Console**

Use the OCI Console to list the certificates for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   The Load Balancer Details dialog box appears.
6. Click **Certificates** under **Resources**.
   The **Certificates** list appears. All certificates are listed in tabular form.

**To list the certificates using the CLI**

Use the command line interface (CLI) to list the certificates for a Load Balancer resource.

Enter the following command:

```
oci lb certificate list --certificate-name certificate_name --load-balancer-id load_balancer_id --items items [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb certificate list --help
```

See [oci lb certificate list](#) for a complete description of the command.

**To list the certificates using the API**

Use the API to list the certificates for a Load Balancer resource.

Run the `ListCertificates` method to list the certificates for a load balancer. See [ListCertificates](#) for a complete description.

### Deleting Certificates

Delete a certificate from a Load Balancer resource.

**Important:**

You cannot delete an SSL certificate that is associated with a listener or backend set. Remove the bundle from any listeners or backend sets before deleting.

Use one of the following methods to delete a certificate from a selected load balancer.

**To delete a certificate using the Console**

Use the OCI Console to delete a certificate from a Load Balancer resource.

**Important:**

You cannot delete an SSL certificate that is associated with a listener or backend set. Remove the bundle from any listeners or backend sets before deleting.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   The Load Balancer Details dialog box appears.
6. Click **Certificates** under **Resources**.
   The **Certificates** list appears. All certificates are listed in tabular form.
7. Click the **Actions** icon (⋯) associated with the certificate you want to delete and click **Delete**.
8. Confirm the deletion when prompted.
**To delete a certificate using the CLI**

Use the command line interface (CLI) to delete a certificate from a Load Balancer resource.

Enter the following command:

```
oci lb certificate delete --certificate-name certificate_name --load-balancer-id load_balancer_id --items items [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb certificate delete --help
```

See `oci lb certificate delete` for a complete description of the command.

**To delete a certificate using the API**

Use the API to delete a certificate from a Load Balancer resource.

Run the `DeleteCertificate` method to create a certificate for a load balancer. See `DeleteCertificate` for a complete description.

**Work Request Management**

This topic describes how to view the state of work requests associated with a given load balancer.

**Note:**

The Load Balancing service does not use the common Work Requests API to support work request operations. Instead, the Load Balancing API supports Load Balancing work requests. See Using the Console to View Work Requests on page 303 for information on viewing work requests for other services.

**Work Request Status**

Many of the Oracle Cloud Infrastructure Load Balancing service requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment. To provide visibility for in-progress workflows, the Load Balancing service creates a work request object.

Because some operations depend on the completion of other operations, you must monitor each operation’s work request and confirm it has succeeded before proceeding to the next operation. For example, if you want to create a backend set and add a backend server to the new set, you first must create the backend set. After that operation completes, you can add the backend server. If you try to add a backend server before the backend set creation completes, the system cannot ensure that the request to add the server succeeds.

You can monitor the request to add a backend set to determine when that workflow is complete, and then add the backend server.

The following table lists the work request states:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accepted</td>
<td>The request is in the work request queue to be processed.</td>
</tr>
<tr>
<td>In Progress</td>
<td>A work request record exists for the specified request, but no associated WORK_COMPLETED record exists.</td>
</tr>
<tr>
<td>Succeeded</td>
<td>A work request record exists for this request and an associated WORK_COMPLETED record has the state Succeeded.</td>
</tr>
<tr>
<td>Status</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>Failed</td>
<td>A work request record exists for this request and an associated WORK_COMPLETED record has the state <strong>Failed</strong>.</td>
</tr>
</tbody>
</table>

**Listing Work Requests**
List the work requests for a Load Balancer resource.

Use one of the following methods to display a list of work requests for a selected load balancer.

**To list the work requests using the Console**
Use the OCI Console to list the work requests for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   
   The Load Balancer Details dialog box appears.
6. Click **Work Requests** under **Resources**.

   The **Work Requests** list appears. All work requests are listed in tabular form.

**To list the work requests using the CLI**
Use the command line interface (CLI) to list the work requests for a Load Balancer resource.

Enter the following command:

```
oci lb work-request list --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb work-request list --help
```

See **oci lb work-request list** for a complete description of the command.

**To list the work requests using the API**
Use the API to list the work requests for a Load Balancer resource.

Run the **ListWorkRequests** method to delete a rule set from a load balancer. See **ListWorkRequests** for a complete description.

**Getting Work Request Details**
Get the details of a work request for a Load Balancer resource.

Use one of the following methods to get the details of a work request for a selected load balancer.

**To get the details of a work request using the Console**
Get the details of a work request for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose rule set you want to delete.
   The Load Balancer Details dialog box appears.
6. Click **Work Requests** under **Resources**.
   The **Work Requests** list appears. All work requests are listed in tabular form.
7. Find the work request whose details you want to get from the list. The following details for each work request are displayed:
   - **Status**: See **Work Request Status** on page 3317 for a list of statuses and their descriptions.
   - **Type**: API method used for run the work request.
   - **OCID**: Oracle Cloud identifier of the work request.
   - **Error Details**: Details of any errors associated with the work.
   - **Started**: UTC-based date-time group when the work request was started.
   - **Finished**: UTC-based date-time group when the work request was finished.

**To get the details of a work request using the CLI**

Use the command line interface (CLI) to get the details of a work request for a Load Balancer resource.

Enter the following command:

```
oci lb work-request get --work-request-id work_request_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb work-request get --help
```

**To get the details of a work request using the API**

Use the API to get the details of a work request for a Load Balancer resource.

Run the **GetWorkRequest** method to get the details of a work request for a load balancer. See **GetWorkRequests** for a complete description.

**Diagnosing Load Balancer using Smart Check**

Use Smart Check to diagnose and fix Load Balancer configuration and environment issues.

Your load balancer includes Smart Check, which runs in the background to detect issues with the load balancer configuration and operating environment. Access the results of Smart Check activities through the Oracle Cloud Infrastructure Console as a resource of the load balancer.

Smart Check evaluates the load balancer approximately every 10 seconds. Each check reviews configuration issues such as the following:

- Load balancer's backend servers are in a drain or offline state.
- Protocol mismatches exist on the HTTP listener.
- Port mismatches exist on the HTTP backend servers.

Smart Check results are presented in tabular format within the load balancer's Details page. Each category of issues has an assigned status of High, Medium, Low, and OK. You can display details of each check, including recommendations for corrective actions where necessary. An Informational tab is also available to provide best practices and recommendations on how to make your load balancer work optimally.

**To run Smart Check Diagnostics from the Console**

Use the OCI Console to run Smart Check on a Load Balancer resource to detect any configuration issues.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Click the load balancer on which you want to run Smart Check diagnostics.
   The Load Balancer Details page appears.
6. Click Smart Check under Resources.
   The Smart Check tab appears, containing the Smart Check list. All Smart Check diagnostic entries are listed in tabular form.
   The Last Checked indicator displays the UTC-based date-time group the load balancer was last diagnosed.
   Checks occur every 10 seconds.
   Each entry contains the following columns and associated values:
   - Risk Level: Displays the risk of each entry using one of the following levels:
     - (red indicator) High: Smart Check detected a high-level severity configuration recommendation.
     - (yellow indicator) Medium: Smart Check detected a medium-level severity configuration recommendation.
     - (black indicator) Low: Smart Check detected a low-level severity configuration recommendation.
     - (green indicator) OK: Smart Check completed without any configuration recommendations.
   - Category: Displays the area of the load balancer to which the Smart Check entry pertains, for example:
     - Logging
   - Risk Details: Displays details on the issue, for example:
     - Not all logging is enabled.
   - Recommended Action: Describes corrective action you can take for the issue, for example:
     - Enable all logging.
     - Click the “down” arrow at the end of the entry to display details, including links to where you can perform corrective or preemptive actions.
7. Click the Informational tab to display a list of best practices and recommendations to follow. Click the "down" arrow at the end of the entry to display details, including recommended fixes to any warnings or critical issues detected by Smart Check.
   Each entry contains the following columns and associated values:
   - Category: Displays the area of the load balancer to which the Smart Check entry pertains, for example:
     - Backend Timeout
   - Details: Displays details on the issue, for example:
     - Set the listener idle timeout to at least 10 seconds less than backend's keep-alive timeout.
   - Recommended Action: Describes corrective action you can take for the issue, for example:
     - Edit the listener and change the idle timeout.
     - Click the "down" arrow at the end of the entry to display details, including links to where you can perform corrective or preemptive actions.

Log Management
Learn how to manage access and error logs for Load Balancer resources using the Oracle Oracle Cloud Infrastructure Console.

The Load Balancer service uses the OCI Logging service to managing logging. See Logging Overview on page 3348 for general information on logging, including how to name log files and create log groups.

See Details for Load Balancer Logs on page 3390 for information on how to understand load balancer log entries.

Creating Logs
Create access and error logs for a Load Balancer resource.
Use one of the following methods to create access and error logs for a selected load balancer.

**To create an error log using the Console**

Use the OCI Console to enable error logging for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   
   The Load Balancer Details dialog box appears.
6. Click **Logs** under **Resources**.
   
   The **Logs** list appears. Entries for access and error logs are listed in tabular form.
7. Click the **Enable Log** switch for the error category to enable error logging.

   Alternatively, click the **Actions** icon (⁎) associated with the error category and click **Enable**.
   
   The Enable Log dialog box appears.
8. Enter the following:

   - **Compartment**: Select the compartment within which the log file resides from the list.
   - **Log Group**: Select an existing log group from the list or click **Create New Group** where you can enter the name and description of a new logging group within which your log resides.
   - **Log Name**: Enter the name of the log.
   - **Log Retention**: Select the time period in months each error logging entry is to be retained from the list.

   See **Managing Logs and Log Groups** on page 3350 for more information on log and log groups, including naming syntax guidelines.
9. Click **Enable Log**.
   
   The Logs list is updated to show the error log that you created. The error log is enabled by default.

**To create an access log using the Console**

Use the OCI Console to enable access logging for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   
   The Load Balancer Details dialog box appears.
6. Click **Logs** under **Resources**.
   
   The **Logs** list appears. Entries for access and error logs are listed in tabular form.
7. Click the **Enable Log** switch for the access category to enable access logging.

   Alternatively, click the **Actions** icon (⁎) associated with the access category and click **Enable**.
   
   The Enable Log dialog box appears.
8. Enter the following:
   
   • **Compartment**: Select the compartment within which the log file resides from the list.
   • **Log Group**: Select an existing log group from the list or click **Create New Group** where you can enter the name and description of a new logging group within which your log resides.
   • **Log Name**: Enter the name of the log.
   • **Log Retention**: Select the time period in months each access logging entry is to be retained from the list.

   See [Managing Logs and Log Groups](#) on page 3350 for more information on log and log groups, including naming syntax guidelines.

9. Click **Enable Log**.

The Logs list is updated to show the access log that you created. The access log is enabled by default.

### Enabling Logging

Enable disabled access or error logging for a Load Balance resource.

Use one of the following methods to enable disabled access or error logging for a selected load balancer.

#### To enable error logging using the Console

Use the OCI Console to enable disable error logging for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a rule set.

   The Load Balancer Details dialog box appears.
6. Click **Logs** under **Resources**.

   The **Logs** list appears. Entries for access and error logs are listed in tabular form.
7. Click the **Enable Log** switch for the error category to **Enabled**.

   Alternatively, click the **Actions** icon (●) associated with the error category and click **Enable**.
8. Confirm the enabling when prompted.

#### To enable access logging using the Console

Use the OCI Console to enable disabled access logging for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a rule set.

   The Load Balancer Details dialog box appears.
6. Click **Logs** under **Resources**.

   The **Logs** list appears. Entries for access and error logs are listed in tabular form.
7. Click the **Enable Log** switch for the access category to **Enable**.

   Alternatively, click the **Actions** icon (●) associated with the access category and click **Enable**.
8. Confirm the enabling when prompted.
Getting Log Details
Get the details of an access or error log for a Load Balance resource.

Use one of the following methods to get the details of an access or error log for a selected load balancer.

To get the details of an error log using the Console
Get the details of an error log for a Load Balance resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the error log link under Log Name.
   Alternatively, click the Actions icon (.Actions) associated with the error category and click Edit Log.
   The Log Details dialog box appears.

To get the details of an access log using the Console
Get the details of an access log for a Load Balance resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the access log link under Log Name.
   Alternatively, click the Actions icon (Actions) associated with the access category and click Edit Log.
   The Log Details dialog box appears.

Renaming Logs
Rename an access or error log for a Load Balance resource.

Use one of the following methods to rename an access or error log for a selected load balancer.

To rename an error log using the Console
Use the OCI Console to rename an error log for a Load Balance resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the access log link under Log Name.
   Alternatively, click the Actions icon (▲) associated with the access category and click Edit Log.
   The Log Details dialog box appears.
8. Click Edit.
   The Edit Log dialog box appears.
9. Rename the log.
10. Click Save Changes.

To rename an access log using the Console
Use the OCI Console to rename an access log for a Load Balance resource.
1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the access log link under Log Name.
   Alternatively, click the Actions icon (▲) associated with the access category and click Edit Log.
   The Log Details dialog box appears.
8. Click Edit.
   The Edit Log dialog box appears.
9. Rename the log.
10. Click Save Changes.

Deleting Logs
Delete an access or error log from a Load Balance resource.

Use one of the following methods to delete an access or error log from a selected load balancer.

To delete an error log using the Console
Use the OCI Console to delete an error log from a Load Balance resource.
1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the error log link under Log Name.
   The Log Details dialog box appears.
8. Click Delete.
   Alternatively, click the Actions icon ( Antony ) associated with the error category and click Delete.
9. Confirm the deletion when prompted.

To delete an access log using the Console
Use the OCI Console to delete an access log from a Load Balance resource.
1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the access log link under Log Name.
   The Log Details dialog box appears.
8. Click Delete.
   Alternatively, click the Actions icon ( Antony ) associated with the access category and click Delete.
9. Confirm the deletion when prompted.

Disabling Logging
Disable access or error logging for a Load Balancer resource.
Use one of the following methods to disable access or error logging for a selected load balancer.

To disable error logging using the Console
Use the OCI Console to disable error logging for a Load Balancer resource.
1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click Logs under Resources.
   The Logs list appears. Entries for access and error logs are listed in tabular form.
7. Click the Enable Log switch for the error category to Disabled.
   Alternatively, click the Actions icon ( Antony ) associated with the error category and click Disable.
8. Confirm the disabling when prompted.

To disable access logging using the Console
Use the OCI Console to disable access logging for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer for which you want to create a rule set.
   The Load Balancer Details dialog box appears.
6. Click **Logs** under **Resources**.
   The **Logs** list appears. Entries for access and error logs are listed in tabular form.
7. Click the **Enable Log** switch for the access category to **Disabled**.
   Alternatively, click the **Actions** icon ( [… ] ) associated with the access category and click **Disable**.
8. Confirm the disabling when prompted.

### Load Balancing Metrics

You can monitor the health, capacity, and performance of your load balancers by using **metrics**, **alarms**, and **notifications**.

This topic describes the metrics emitted by the Load Balancing service in the **oci_lbaas** metric namespace.

**Resources:** Load balancers, listeners, and backend sets.

Your load balancer acts as an intermediary for data traffic between clients and your application servers. Clients send requests to your load balancer and the load balancer distributes the requests to your backend servers according to rules you establish. See the diagram in **Overview of Load Balancing** on page 3192 for a high-level view of a simple public load balancing system configuration.

The Load Balancing service metrics help you measure the number and type of connections, and quantity of data managed by your load balancer. You can use metrics data to diagnose and troubleshoot load balancer and client issues. The metrics also help you analyze the HTTP responses returned by the servers in your backend set.

To view a default set of metrics charts in the Console, navigate to the load balancer or backend set you're interested in, and then click **Metrics**. You also can use the Monitoring service to create **custom queries**.

### Prerequisites

- **IAM policies:** To monitor resources, you must be given the required type of access in a **policy** written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which **compartment** you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- The metrics listed on this page are automatically available for any load balancer, listener, and backend set you create. You do not need to enable monitoring on the resource to get these metrics.

### Available Metrics: oci_lbaas

Learn about the available metrics for the Load Balancing service.

The Load Balancing service metrics include the following **dimensions**:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITYDOMAIN</td>
<td>The <em>availability domain</em> in which the load balancer resides.</td>
</tr>
</tbody>
</table>
Load Balancing

Metric | Description
---|---
BACKENDSETNAME | The name of the backend set to which the metrics apply.
LBCOMPONENT | The load balancer component to which the metrics apply. Valid metrics for the Load Balancing service vary among the three lbComponent dimension values:
- Backendset
- Listener
- Loadbalancer

The tables on this page describe which data is valid for each of these dimension values. If you choose a metric that does not apply to the specified dimension value, the metric returns no data.

LBHOSTID | A unique ID that represents the current load balancer host. This ID is subject to change.
LISTENERNAME | The name of the listener to which the metrics apply.
REGION | The region in which the load balancer resides.
RESOURCEID | The OCID of the resource to which the metrics apply.

**Metrics for the lbComponent Dimension Value "Backendset"**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveConnections</td>
<td>Active Connections</td>
<td>count</td>
<td>The number of active connections from the load balancer to all backend servers.</td>
<td>availabilityDomain backendSetName lbComponent lbHostId region resourceId</td>
</tr>
<tr>
<td>BackendServers</td>
<td>Backend Servers</td>
<td>count</td>
<td>The number of backend servers in the backend set.</td>
<td></td>
</tr>
<tr>
<td>BackendTimeouts</td>
<td>Backend Timeouts</td>
<td>count</td>
<td>The number of timeouts across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>BytesReceived</td>
<td>Bytes Received</td>
<td>bytes</td>
<td>The number of bytes received across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>BytesSent</td>
<td>Bytes Sent</td>
<td>bytes</td>
<td>The number of bytes sent across all backend servers.</td>

**Viewing Load Balancer Metrics**

View metrics for a Load Balancer resource.

Use one of the following methods to view load balancer metrics.

**To view metrics for a single balancer**

Use the OCI Console to view metrics for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display load balancers.
5. Select the load balancer whose metrics you want to view.

   The Load Balancer Details dialog box appears.
6. Click **Metrics** under **Resources**.

   The **Metrics** list appears. All routing policies are listed in tabular form.
7. In the **Resources** menu, click **Metrics** (if necessary).

   The **Metrics** page displays a default set of charts for the current load balancer.
8. Specify the following:
   - **Start Time**: The date-time group for when the metric period starts.
   - **End Time**: The date-time group for when the metric period ends.
   - **Quick Selects**: Select a pre-determined time period for the metric period from the list.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 3458. For information about notifications for alarms, see **Notifications Overview** on page 4248.

**To view metrics for all load balancers in a compartment**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.

   The Service Metrics page appears.
2. Select the **Compartment** from the list.
3. Select "oci_lbass" from the Metric Namespace list.

A default set of charts for the selected metric namespace appears in the Service Metrics page. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

Troubleshooting Load Balancing

Learn about troubleshooting methods for addressing Load Balancing service issues.

Enable Oracle Cloud Infrastructure load balancing access and error logs to troubleshoot common errors. See Log Management on page 3320 for more information.

Troubleshooting an HTTP 502 Bad Gateway Error

Learn how to troubleshoot an HTTP 502 bad gateway error for a Load Balancer resource.

In addition to monitoring and management, load balancing logging helps you to identify, isolate, and troubleshoot issues with your load balancer infrastructure. The following procedure illustrates how to troubleshoot a 502 Bad Gateway error encountered when deploying a new web application, example.com. The example uses an Oracle Cloud Infrastructure public load balancer as the front end in a development environment. The task fails with a 502 Bad Gateway error on the browser. Troubleshoot the issue using load balancer access and error logs, as follows:

1. Confirm the error using the curl utility, as follows:

```bash
curl -v http://example.com
```

```
> GET / HTTP/1.1
> Host: 192.0.2.99
> User-Agent: curl/7.54.0
> Accept: */*
>
< HTTP/1.1 502 Bad Gateway
< Content-Type: text/html
< Content-Length: 161
< Connection: keep-alive
```
2. Search the load balancer access and error logs for "lbStatusCode" and "backendStatusCode."

   • If the results include backendStatusCode: 502, then:

     Possible causes:
     • Issue is an improperly configured backend.
     • Backend is likely another reverse proxy or LB.

     Possible resolutions:
     • Examine upstream proxy logs to determine why the 502 error is being returned.
     • Resolve any issues on the ultimate backend that is causing the upstream proxy to return a 502 error.

   • If the results include backendStatusCode: 504, then:

     Possible causes:
     • When a 504 error occurs from the backend, it typically indicates that the backend is another proxy or load balancer service instance. The error typically occurs when a proxy is unable to connect to an upstream server in a specified amount of time.
     • Examine the logs of the upstream system to determine what is causing the upstream proxy from connecting to the backend.

     Possible resolutions:
     • Increase the amount of time for the connection timeout.
     • Determine why the backend is taking longer to respond than usual using a utility, such as tcpdump, and built-in application tools.

   • If the results include backendStatusCode: 500, then:

     Possible causes:
     • When a 500 error occurs from the backend, it typically indicates a server-side error, commonly known as an "Internal Server Error." Backend applications typically cause this error.
     • Inability to connect to upstream resources, such as databases, APIs, and services.

     Possible resolutions:
     Resolve application-level issue that is causing the error.

   • If the results include backendStatusCode: with no error code, then:

     • Typically, when no backend status code accompanies lbStatusCode: 502, no backend is available to send the connections.
     • You might also notice a No healthy backends available in associated backendSet message in the load balancer error Logs.
     • Ensure that the backends are healthy. If the backends are healthy, then confirm that the health check is properly configured.

---

**Debugging a Backend Server Timeout**

Learn how to debug a timeout error associated with a backend server used by a Load Balancer resource.

When the backend server exceeds the response time when responding to a request, a 504 error occurs indicating that the backend server is either down or not responding to the request forwarded by the load balancer. The client application receives the following response code: HTTP/1.1 504 Gateway Timeout.

Errors can occur for the following reasons:

• The load balancer failed to establish a connection to the backend server before the connection timeout expired.
• The load balancer established a connection to the backend server but the backend did not respond before the idle timeout period elapsed.
• The security lists or network security groups for the subnet or the VNIC did not allow traffic from the backends to the load balancer.
• The backend server or application server failed.
Follow these steps to troubleshoot the backend server timeout errors:

1. Use the curl utility to directly test the backend server from a host in the same network.

```
curl -i http://backend_ip_address
```

If this test takes longer than one second to respond, an application-level issue is causing latency. Oracle recommends that you check any upstream dependencies that might cause latency, including:

- Network attached storage such as iSCSI or NFS
- Database latency
- An off-premise API
- An application tier

2. Check the application by accessing it directly from the backend server. Check its access logs to determine if the application can be accessed and is functioning properly.

3. If the load balancer and the backend server are in different subnets, then check whether the security lists contain rules to allow traffic. If no rules exist, then traffic is not allowed.

4. Enter the following commands to determine whether firewall rules exist on the backend servers that block traffic:

```
iptables -L lists all firewall rules enforced by iptables
sudo firewall-cmd --list-all lists all firewall rules enforced by firewalld
```

5. Enable logging on the load balancer to determine whether the load balancer or the backend server is causing the latency.

### Testing TCP and HTTP Backend Servers

Learn how to test the TCP and HTTP backend servers used by a Load Balancer resource.

This topic describes how to troubleshoot a load balancer connection. The topology used in this procedure has a public load balancer in a public subnet and the backends are in the same subnet.

Oracle recommends that you use the Oracle Cloud Infrastructure Logging service to troubleshoot issues. (See Details for Load Balancer Logs on page 3390.)

In addition to using Oracle Cloud Infrastructure logging, however, you can use other utilities listed in this section to troubleshoot the traffic that is processed by the load balancer and sent to a backend. To perform these tests, Oracle recommends that you create an instance in the same network as your load balancer and allow the traffic in the same network security groups and security lists. Use the following tools to troubleshoot:

- **ping**

Before using the more advanced utilities listed here, Oracle recommends that you perform a basic ping test. For this test to succeed, you must allow ICMP traffic between the test instance and the backend.

```
$ ping backend_ip_address
```

The response should look similar to:

```
PING 192.0.2.2 (192.0.2.2) 56(84) bytes of data.
64 bytes from 192.0.2.2: icmp_seq=1 ttl=64 time=0.028 ms
64 bytes from 192.0.2.2: icmp_seq=2 ttl=64 time=0.044 ms
```

If you receive a message that contains "64 bytes from...", then the ping succeeded.

Receiving a message that contains "Destination Host Unreachable" indicates that the system does not exist.

Receiving no message indicates that the system exists but the ICMP protocol is not allowed. Check all firewalls, security lists, and network security groups to ensure ICMP is allowed.
• **curl**

Use the **curl** utility to send HTTP requests to a specific host, port, or URL.

- The following example shows using **curl** to connect to a backend that is sending a 403 Forbidden error:

```bash
$ curl -I http://backend_ip_address/health
HTTP/1.1 403 Forbidden
Date: Tue, 17 Mar 2021 17:47:10 GMT
Content-Type: text/html; charset=UTF-8
Content-Length: 3539
Connection: keep-alive
Last-Modified: Tue, 10 Mar 2021 20:33:28 GMT
ETag: "dd3-5b3c6975e7600"
Accept-Ranges: bytes
```

In the preceding example, the health check fails, returning a 403 error, indicating that the backend does not have local file permissions configured properly for the health check page.

- The following example shows using **curl** to connect to a backend that is sending a 404 Not Found error:

```bash
$ curl -I http://backend_ip_address/health
HTTP/1.1 404 Not Found
Date: Tue, 17 Mar 2021 17:47:10 GMT
Content-Type: text/html; charset=UTF-8
Content-Length: 3539
Connection: keep-alive
Last-Modified: Tue, 10 Mar 2021 20:33:28 GMT
ETag: "dd3-5b3c6975e7600"
Accept-Ranges: bytes
```

In the preceding example, the health check fails, returning a 404 error, indicating that the health check page does not exist in the expected location.

- The following example shows a backend that exists and either a network security group, the security lists, or a local firewall is blocking the traffic:

```bash
$ curl -I backend_ip_address
```

```bash
curl: (7) Failed connect to backend_ip_address:port; Connection refused
```

- The following example shows a backend that does not exist:

```bash
$ curl -I backend_ip_address
```

```bash
curl: (7) Failed connect to backend_ip_address:port; No route to host
```

• **Netcat**

Netcat is a networking utility for reading from and writing to network connections using TCP or UDP.

- The following example shows using the **netcat** utility at the TCP level to ensure that the destination backend server can receive a connection:

```bash
$ nc -vz backend_ip_address port
Ncat: Connected to backend_ip_address:port.
```

In the preceding example, **port** is open for connections.

- $ nc -vn backend_ip_address port

```
Ncat: Connection timed out.
```

In the preceding example, **port** is closed.
• **Tcpdump**

  Use the `tcpdump` utility to capture all traffic to a backend to ensure which traffic is coming from a load balancer and what is being returned to the load balancer.

  ```
  sudo tcpdump -i any -A port src load_balancer_ip_address
  11:25:54.799014 IP 192.0.2.224.39224 > 192.0.2.224.80: Flags [P.], seq 1458768667:1458770008, ack 2440130792, win 704, options [nop,nop,TS val 461552632 ecr 208900561], length 1341: HTTP: POST /health HTTP/1.1
  ```

• **OpenSSL**

  When troubleshooting SSL issues between the load balancer instance and the backend servers, Oracle recommends using the `openssl` utility. This utility opens an SSL connection to a specific host name and port, and prints the SSL certificate and other parameters.

  Other options for troubleshooting issues are:
  
  • `-showcerts`
    
    This option prints all certificates in the certificate chain presented by the backend server. Use this option to identify issues, such as a missing intermediate certificate authority certificate.
  
  • `-cipher cipher_name`
    
    This option forces the client and server use a specific cipher suite and helps to rule out whether the backend is allowing specific ciphers.

• **Netstat**

  Use the `netstat -natp` command to ensure that the application running on the backend server is up and running. For TCP or HTTP traffic, the backend application, IP address, and port must all be in `listen` mode. If the application port on the backend server is not in `listen` mode, then the TCP port of the application is not up.

  To resolve this issue, ensure that the application is up and running by either restarting the application or the backend server.

**Common Load Balancer Errors**

Learn about common load balancer errors associated with the Load Balancing service.

Common load balancer errors include, series 500 and series 400 errors, health check errors, client errors, and SSL errors. The subsequent topics in this section describe these common errors and detail troubleshooting procedures for each, where applicable.

**Server Errors (500-599)**

Learn about common load balancer server errors (500-599) associated with the Load Balancing service.

**504**

**Error messages:**

• `lbStatusCode: "504"`
• `backendStatusCode: ""`

**Oracle Cloud Infrastructure log category:** Access log

**Symptoms:**

The client fails with a 504 error.

**Possible causes:**

The load balancer is not able to establish connections with any of the backends, even though the health check is marking the backends as available.

**Possible solutions:**

Configure the health check correctly.
The troubleshooting documentation: Editing Health Check Policies on page 3241

502, 502

Error messages:
- `lbStatusCode: "502"
- `backendStatusCode: "502"

Oracle Cloud Infrastructure log category: Access log and error log

Symptoms:
- The client fails with a 502 Bad Gateway error.
- The backend health check succeeds.
- The backend returns a 502 error.

Possible causes:
- An application on the backend is returning a 502 error.
- The backend is configured incorrectly.
- The backend is likely another reverse proxy or load balancer.

Possible solutions:
Examine the backend application logs to determine why a 502 error is returned.

Troubleshooting documentation: Troubleshooting an HTTP 502 Bad Gateway Error on page 3332 and Testing TCP and HTTP Backend Servers on page 3334.

502

Error messages:
- `lbStatusCode: "502"
- `backendStatusCode: ""
- No healthy backends available in associated backend set

Oracle Cloud Infrastructure log category: Access log and error log

Symptoms:
- The client fails with a 502 Bad Gateway error.
- The backend health check fails.
- No traffic observed to a specific backend or all backends.

Possible causes:
- A backend application is not responding to the health check with the expected response.
- If no error occurs from the backend, then a TCP health check is configured.
- A single backend or all backends are configured in `drain` mode.

Possible solutions:
- Determine why TCP health check is failing.
- Convert to HTTP health check.
- Change the `drain` mode to false (undrain) for a given backend or all backends.

Troubleshooting documentation: Troubleshooting an HTTP 502 Bad Gateway Error on page 3332 and Testing TCP and HTTP Backend Servers on page 3334.

Backend Connection Issue

Error:
Backend ip_address abruptly closes connection.

Oracle Cloud Infrastructure log category: Error log

Symptoms:
- The client fails with a 502 Bad Gateway error.
- The client reports IO error in load balancer metrics.

Possible causes
The backend connection timeout is configured incorrectly, with a lower timeout value than the load balancer.

Possible solutions:
- Determine why backend application is timing out.
- If the backend timeout value needs to be adjusted, then adjust it to be greater than the load balancer timeout value.

Troubleshooting documentation: Testing TCP and HTTP Backend Servers on page 3334

Session Persistence Issue

Error message:
Persistence selected backend ip_address which failed and no_fallback is selected

Oracle Cloud Infrastructure log category: Error log

Symptoms:
- The client fails with a 502 Bad Gateway error.
- Session persistence is failing.

Possible causes
- Backend set is configured with session persistence and the expected backend is not available because the connection failed or timed out.
- Fallback option is disabled.

Possible solutions:
- Determine why backend application is not reachable.
- Enable fallback option in case the selected server is unavailable.

Troubleshooting documentation: Fallback on page 3204

For all other 5nn errors, the most likely causes are issues with the backend server.

Client Errors (400-499)
Learn about common load balancer client errors (400-499) associated with the Load Balancing service.

400

Error messages:
- lbStatusCode: "400"
- backendStatusCode: ""
- 400 bad request header or cookie too large

Oracle Cloud Infrastructure log category: Access log

Symptoms:
- The load balancer returns a status code 400.
- The backend does not return a status code.
Possible causes:
The client is sending a request that exceeds the configured buffer size.

Possible solutions:
Increase the HTTP request header size on the load balancer. By default, the size limit is 8 KB but raising it to 64 KB resolves the issue.

Troubleshooting documentation: HTTP Header Rules on page 3300

404, 404

Error messages:
- lbStatusCode: "404"
- backendStatusCode: "404"

Oracle Cloud Infrastructure log category: Access log

Symptoms:
- The load balancer returns a 404 status code.
- The backend returns a 404 status code.

Possible causes:
The expected page does not exist on the backend.

Possible solutions:
- Create the missing page.
- Configure the client to call the correct page.

403, 403

Error messages:
- lbStatusCode: "403"
- backendStatusCode: "403"

Oracle Cloud Infrastructure log category: Access log

Symptoms:
- The load balancer returns a 403 status code.
- The backend returns a 403 status code.

Possible causes:
- Expected page does not have sufficient permission on the backend.
- Expected authentication token is missing or not being forwarded.

Possible solutions:
- Create missing permissions on backend.
- Adjust client configuration to ensure that tokens are sent properly.
- Ensure that all tokens being sent are arriving at the backend.
- If the header is missing:
  - Adjust header size on the load balancer or the client.
  - Allow headers with special characters.

Troubleshooting documentation: HTTP Header Rules on page 3300

Health Check Errors
Learn about health check errors associated with Load Balancer resources.
Load Balancing

**No Healthy Backends**

Error message:

```
No healthy backends available in associated backendSet
```

**Oracle Cloud Infrastructure log category**: Error log

**Symptoms**: The client fails with a 502 Bad Gateway error.

**Possible causes**:
- No backends in the backend set.
- No backends responding to health check.

**Possible solutions**:
- Determine why backends are not responding to health check.
- Check and adjust any health check settings, including status code, regular expressions, interval timeout, port, and protocol.

**Troubleshooting documentation**: Editing Health Check Policies on page 3241

**Status Code Issues**

**Backend health status failure reason**: Status code Mismatch

**Oracle Cloud Infrastructure log category**: Backend Health Status

**Error message**:

```
"msg" : "invalid statusCode", "statusCode" : XXX, "expected" : "200"
```

**Oracle Cloud Infrastructure log category**: Error log

**Symptoms**:
- The backend fails the health check.
- The client fails with a 502 Bad Gateway error.
- invalid statusCode appears in the error logs.

**Possible causes**:
- The backend is responding with an incorrect response code.
- The backend health check fails because of response code mismatch.
- The health check failures are because of an unexpected status code in the regular expression body.

**Possible solutions**:
- Determine why the backend is sending the incorrect response code.
- Adjust the path or status code of the health check to match the backend.

**Troubleshooting documentation**: Editing Health Check Policies on page 3241

**Response Match Failed**

**Backend Health Status Failure Reason**: Regular expression mismatch

**Oracle Cloud Infrastructure log category**: Backend Health Status

**Error message**:

```
"response match result: failed"
```
Oracle Cloud Infrastructure log category: Error log

Symptoms:
• The backend fails the health check.
• The client fails with a 502 Bad Gateway error.
• "response match result: failed" appears in the error logs.

Possible causes:
The backend health check fails because of regular expression mismatch, incorrect value returned, or incorrect value provided to the health check.

Possible solutions:
• Determine why the backend is sending the incorrect body.
• Adjust the path or regular expression pattern of the health check to match the backend.

Troubleshooting documentation: Editing Health Check Policies on page 3241

Unreachable Host
Backend Health Status Failure Reason: Connection failed
Oracle Cloud Infrastructure category: Backend Health Status

Error messages:

"errno":"EHOSTUNREACH","syscall":"connect"

"ECONNREFUSED","errno":"ECONNREFUSED"

Oracle Cloud Infrastructure log category: Error log

Symptoms:
• The backend fails the health check.
• The client fails with a 502 Bad Gateway error.
• "EHOSTUNREACH" appears in error logs.

Possible causes:
• The backend health check fails because of an unreachable host.
• The backend health check fails because of a connection reset.
• An application or firewall is actively refusing the connection.

Possible solutions:
• Check the local instance firewall to confirm that traffic is being allowed.
• Check the local instance to confirm that the application is running.
• Check the network security group and security lists to confirm that traffic is allowed.

Troubleshooting documentation: Access and Security on page 3707

Health Status Issues

Error messages:

"healthStatus":"Unhealthy to Healthy"

"healthStatus":"Healthy to Unhealthy"

Oracle Cloud Infrastructure log category: Error log
Load Balancing

Symptoms:
- The client behaves as expected but fails periodically.
- The backend switches between passing and failing the health check.
- "Unhealthy to Healthy" or "Healthy to Unhealthy" appears in error logs.

Possible causes:
- An unhealthy backend becomes healthy.
- If the health status of the backend changes often, it can indicate a chronic problem.

Possible solutions:
- Ensure that the instance is not changing health status abnormally.
- Check application logs on the backend server for any application-specific issues.

Connection Issues

Backend Health Status Failure Reason: Timed out

Oracle Cloud Infrastructure category: Backend Health Status

Error messages:

"msg":"connect timed out","elapsed":3000"

Oracle Cloud Infrastructure log category: Error log

Symptoms:
- The client fails with a 502 Bad Gateway error.
- The backend is periodically or chronically failing health checks.
- "connect timed out" appears in the error logs.

Possible causes:
- The backend server is not responding to health checks in the expected time period.
- Slow upstream dependency including database, application service or API, or slow storage services, such as Oracle Cloud Infrastructure File Storage service, Elastic Block Store, or Object Storage.

Possible solutions:
- Perform a local test to the backend to eliminate the load balancer as a cause.
- Check the performance of all upstream dependencies.
- Check application logs on the backend server for any dependencies reporting any sort of timeout.

Troubleshooting documentation: Testing TCP and HTTP Backend Servers on page 3334.

SSL Errors
Learn about single socket layer (SSL) errors associated with Load Balancer resources.

SSL Virtual Listener Issues

Error message:

Not all SSL virtual listeners on port 443 have the same set of SSL protocols defined

Symptoms:
You cannot create backends for an existing load balancer nor can you add new servers to the backend created previously within the same load balancer.

Possible causes:
Mismatch of transport layer security (TLS) versions.

Possible solutions:
Match TLS versions on the listeners.

Troubleshooting documentation: SSL Certificate Management on page 3308

SSL Handshake Issues

Error message:

```
(SSL: error:140770FC:SSL routines:SSL23_GET_SERVER_HELLO:unknown protocol)
while SSL handshake error
```

Oracle Cloud Infrastructure log category: Client log

Symptoms:
The client experiences SSL handshake failures in Oracle Cloud Infrastructure metrics (see Load Balancing Metrics on page 3326).

Possible causes:
The backend is not configured to accept SSL.

Possible solutions:
• Confirm that the backend certificate matches the certificate authority that is provided.
• Ensure that all certificates in the chain are provided in the correct order in the Certificate field.
• Ensure that you provide the correct certificate depth.

Troubleshooting documentation: SSL Certificate Management on page 3308

Backend SSL Handshake Issues

Error messages:

```
Peer backend_ip_address closed connection in SSL handshake
```

Oracle Cloud Infrastructure log category: Error log

Symptoms:
• The client fails with a 502 Bad Gateway error.
• The client experiences SSL handshake failures in Oracle Cloud Infrastructure metrics (see Load Balancing Metrics on page 3326).

Possible causes:
• The backend is not configured to accept SSL.
• The backend certificate is invalid.

Possible solutions:
• Confirm that the backend certificate matches the certificate authority that is provided.
• Ensure that all certificates in the chain are provided in the correct order in the Certificate field.
• Ensure that you provide the correct certificate depth.

Troubleshooting documentation: SSL Certificate Management on page 3308

SSL Certificate Issues

Error:
Client *backend_ip_address* has SSL certificate verify error.

**Oracle Cloud Infrastructure log category:** Error log

**Symptoms:**
The client experiences SSL handshake failures in Oracle Cloud Infrastructure metrics (see Load Balancing Metrics on page 3326).

**Possible causes:**
- The client certificate is invalid.
- The client certificate is not trusted.
- Invalid peer certification verify depth.

**Possible solutions:**
- Ensure that the client certificate is valid.
- Remove Peer Cert Verify feature on the listener.

**Troubleshooting documentation:** Key Pair Mismatch on page 3310 and Private Key Consistency on page 3311.

### Client SSL Certificate Issues

**Error message:**

```
Client backend_ip_address sent no required SSL certificate
```

**Oracle Cloud Infrastructure log category:** Error log

**Symptoms:**
- The client experiences a 400 Response error.
- no required SSL certificate appears in error logs.

**Possible causes:**
The client is not sending a client certificate.

**Possible solutions:**
- Update the client to send the correct client certificate.
- Remove Peer Cert Verify feature on the listener.
- Adjust the certificate verification depth.

**Troubleshooting documentation:** Configuring Peer Certificate Verification on page 3309.

### SSL Error Causes Backend Health Check Failure

**Error message:**

```
"code":"EPROTO","errno":"EPROTO"
```

**Oracle Cloud Infrastructure log category:** Error log

**Symptoms:**
The backend health check fails because of the SSL error.

**Possible causes:**
The backend is configured to accept SSL but the health check protocol selected does not match that of the backend.

**Possible solutions:**
Confirm that you are using non-TLS health check on a backend that has TLS enabled.
SSL Host Name Verification Fails

Error message:

SSL host name verification failed for host_name

Oracle Cloud Infrastructure log category: Error log

Symptoms:

- The client fails with a 502 Bad Gateway error.
- Error message contains SSL host name verification failed.

Possible causes:

Host name provided does not match what is expected.

Possible solutions:

- Configure client to use the expected host name.
- Configure certificate to match the host name sent by the client.

Client Access Denied

Error:

Access for client_ip_address denied by HTTP ACL rule.

Oracle Cloud Infrastructure log category: Error log

Symptoms:

- The client fails with a 502 Bad Gateway error.
- The backend does not pass health check.
- forbidden by HTTP ACL rule appears in the error log.

Possible causes:

Access control rule set is enabled but does not include the source IP address.

Possible solutions:

Check and apply respective rule set to include the source IP address.

Client Timeout Issue

Error:

Client client_name timed out

Oracle Cloud Infrastructure log category: Error log

Symptoms:

- The client fails with a 502 Bad Gateway error.
- The client experiences SSL handshake failures in Oracle Cloud Infrastructure metrics (see Load Balancing Metrics on page 3326).
**Possible causes:**
The client terminated the connection sooner than the configured timeout for the load balancer.

**Possible solutions:**
- Configure client timeout to match expected application configuration.
- Determine why the backend did not respond in the configured amount of time.

*Troubleshooting documentation:* Testing TCP and HTTP Backend Servers on page 3334.

**Load Balancer Troubleshooting FAQs**
Learn more about troubleshooting load balancers using these frequently asked questions (FAQs).

Q: Does a cipher suite get negated or removed while adding a new one?

A: There can only be one cipher suite attached to a listener at a time, which controls all allowable ciphers. The cipher suite attached to the listener must have all ciphers for which you require support.
# Load Balancing

## Features

### Public and private load balancers

**Public load balancer**: Offers a public IP address to front-end internet traffic within a single availability domain, or across multiple availability domains. **Private load balancer**: Isolates your load balancer from the internet and simplifies your security posture. The Load Balancing service assigns it a private IP address that serves as the entry point for incoming traffic.

### High availability

Highly available load balancers ensure the entry point to your network and application traffic does not have a single point of failure.

### Flexibility

Manage your load balancer via API or web console to dynamically add and remove application nodes to the traffic flow. Load balance traditional or cloud native enterprise applications with your choice of TCP or HTTP protocols. Full end-to-end API capability to automate load balancer administration tasks.

### SSL

**SSL offload**: Offload costly and CPU-intensive SSL handshakes to your load balancer. **End-to-end SSL**: Supports end-to-end SSL encryption.

### Content-based routing

**Host-based routing**: Host multiple web applications using a single load balancer and common set of backend servers. **Path-based routing**: Optimize resource utilization by routing to independent backend sets based on the URL paths.

### Session persistence

Supports session persistence and enables sticky sessions, whereby requests from a client are directed to the same backend server on the load balancer throughout the life of a session.

**Application cookie persistence**: Load Balancing service activates session persistence when a backend server(application) sends a set-cookie response header containing a recognized cookie name. **Load balancer cookie persistence**: Enables administrators to generate HTTP session cookie at the Load balancer and share the cookie with associated backend servers.

This chapter explains how to use Oracle Cloud Infrastructure Logging.

Logging Overview

The Oracle Cloud Infrastructure Logging service is a highly scalable and fully managed single pane of glass for all the logs in your tenancy. Logging provides access to logs from Oracle Cloud Infrastructure resources. These logs include critical diagnostic information that describes how resources are performing and being accessed.

How Logging Works

Use Logging to enable, manage, and search logs. The three kinds of logs are the following:

- **Audit logs**: Logs related to events emitted by the Oracle Cloud Infrastructure Audit service. These logs are available from the Logging Audit page, or are searchable on the Search page alongside the rest of your logs.
- **Service logs**: Emitted by OCI native services, such as API Gateway, Events, Functions, Load Balancing, Object Storage, and VCN Flow Logs. Each of these supported services has pre-defined logging categories that you can enable or disable on your respective resources.
- **Custom logs**: Logs that contain diagnostic information from custom applications, other cloud providers, or an on-premise environment. Custom logs can be ingested through the API, or by configuring the Unified Monitoring Agent. You can configure an OCI Compute instance/resource to directly upload Custom Logs through the Unified Monitoring Agent. Custom logs are supported in both a virtual machine and bare metal scenario.

A log is a first-class Oracle Cloud Infrastructure resource that stores and captures log events collected in a given context. For example, if you enable Flow Logs on a subnet, it has its own dedicated log. Each log has an OCID and is stored in a log group. A log group is a collection of logs stored in a compartment. Logs and log groups are searchable, actionable, and transportable.

To get started, enable a log for a resource. Services provide log categories for the different types of logs available for resources. For example, the Object Storage service supports the following log categories for storage buckets: read and write access events. Read access events capture download events, while write access events capture write events. Each service can have different log categories for resources. The log categories for one service have no relationship to the log categories of another service. As a result, the Functions service uses different log categories than the Object Storage service.

When you enable a log, you must add it to a log group that you create. Log groups are logical containers for logs. Use log groups to organize and streamline management of logs by applying IAM policy or grouping logs for analysis. For more information, see Managing Logs and Log Groups on page 3350.

Logs are indexed in the system, and searchable through the Console, API, and CLI. You can view and search logs on the Logging Search page. When searching logs, you can correlate across many logs simultaneously. For example, you can view results from multiple logs, multiple log groups, or even an entire compartment with one query. You can filter, aggregate, and visualize your logs. For more information, see Searching Logs on page 3420.

After you enable a log, log entries begin to appear on the detail page for the log (see Enabling Logging for a Resource on page 3363 for more information). If you need more archiving support, you can use Service Connector Hub.
Logging

(archiving to object storage, write to stream, and so on). For more information on service logs, see Service Log Reference on page 3365, and Service Connector Hub on page 4752.

Logging Workshop

See the OCI Logging Workshop for step-by-step, lab-based instructions on setting up your environment, enabling service logs, creating custom application logs, searching logs, and exporting log content to Object Storage.

Logging APIs

Oracle Cloud Infrastructure Logging has the following APIs available:

- Logging Management API
- Logging Ingestion API
- Logging Search API

Also see Using the (Logging Management) API, Using the (Logging Ingestion) API for custom logs, and Using the (Logging Search) API for more information on logging operations specific to each API.

Logging Concepts

The following concepts are essential to working with Logging.

Service Logs

Critical diagnostic information from supported Oracle Cloud Infrastructure services. See Supported Services on page 3363.

Custom Logs

Diagnostic information from custom applications, other cloud providers, or an on-premise environment. To ingest custom logs, call the API directly or configure the unified monitoring agent.

Audit Logs

Read-only logs from the Audit service, provided for you to analyze and search. Audit logs capture the information about API calls made to public endpoints throughout your tenancy. These include API calls made by the Console, Command Line Interface (CLI), Software Development Kits (SDK), your own custom clients, or other Oracle Cloud Infrastructure services.

Log Groups

Log groups are logical containers for logs. Use log groups to streamline log management, including applying IAM policy or searching sets of logs. You can move log groups from one compartment to another and all the logs contained in the log group moves with it.

Service Log Category

Services provide log categories for the different types of logs available for resources. For example, the Object Storage service supports the following log categories for storage buckets: read and write access events. Read access events capture download events, while write access events capture write events. Each service can have different log categories for resources. The log categories for one service have no relationship to the log categories of another service.

Service Connector Hub

Service Connector Hub moves logging data to other services in Oracle Cloud Infrastructure. For example, use Service Connector Hub to alarm on log data, send log data to databases, and archive log data to Object Storage. For more information, see Service Connector Hub on page 4752.
Unified Monitoring Agent

The fluentd-based agent that runs on customer machines (OCI instances), to help customers ingest custom logs.

Agent Configuration

A configuration of the Unified Monitoring Agent that specifies how custom logs are ingested.

Log Encryption

OCI logs are encrypted according to the following:

- Logs are encrypted in-flight, that is, while they are in the process of being ingested into Oracle Cloud Infrastructure Logging;
- After the logs are in the system, they are encrypted with disk-level encryption for commercial environments; and
- Logs are also encrypted when they are archived, and while in storage.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators: Use the following topics to find examples of IAM policy for Logging:

- Required Permissions for Working with Logs and Log Groups on page 3351
- Required Permissions for Searching Logs on page 3420

Managing Logs and Log Groups

This topic describes how to manage logs and log groups.
Overview of Logs and Log Groups

Logs contain critical diagnostic information that tells you how your resources are performing and being accessed. You can enable logging on supported resources. To see a list of supported resources grouped by service, see Supported Services on page 3363.

Log groups are logical containers for organizing logs. Logs must always be inside log groups. You must create a log group to enable a log.

Use log groups to limit access to sensitive logs with IAM policy. With log groups, you don't have to rely on complex compartment hierarchies to secure your logs. For example, say the default log group in a single compartment is where you store logs for the entire tenancy. You grant access to the compartment for log administrators with IAM policy as you normally would. However, let's say some projects contain personally identifiable information (PII) and those logs can only be viewed by a select group of log administrators. Log groups allow you to put logs that contain PII into a separate log group, and then use IAM policy to restrict access to all but a few log administrators.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

Administrators: for policy samples specific to logs and log groups, see Required Permissions for Working with Logs and Log Groups on page 3351.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to know more about writing policies for Logging, see Details for Logging on page 2986.

Required Permissions for Working with Logs and Log Groups

To enable service logs in a resource, a user must be granted manage access on the log group and access to the resource. In general, inspect access on the resource is enough, but check for specific resources. Inspect access provides permission to update the resource and permission for the log group that contains the log.

Logs and log groups use the log-group resource-type, but to search the contents of logs you must use a different resource-type.

Managing log groups and log objects

To manage groups or objects, use verbs for log-groups:

- Allow group A to use log-groups in compartment C
- Allow group B to manage log-groups in compartment C
Allow group D to read log-groups in compartment C

This allows users in group A to create, update, or delete log groups and log objects in compartment C.

**To provision agent configurations**

Three different types of access are needed:

1. Access to operate on configurations.
2. Access to operate on log groups.
3. Inspect capabilities on dynamic groups or groups.

To have access to configurations, the policy must be:

Allow group B to use unified-configuration in compartment X

**To create, update, or delete custom logs used as a destination in a configuration**

This policy allows users in compartment B to create, update, or delete configurations in compartment X.

To provide a destination for the logs incoming from the configuration, you need log-groups access:

Allow group B to use log-groups in compartment X

**To assign a configuration to a set of instances**

To assign a configuration to a set of instances, you need inspect access to the dynamic group or group that identifies the instances:

Allow group B (IDENTITY_DYNAMIC_GROUP_INSPECT) in tenancy / Allow group B (IDENTITY_GROUP_INSPECT) in tenancy

**Enable instances to push logs into the Logging service**

To allow instances to push logs, the instances need to have access to get a configuration and push the logs. log-content controls this permission (where X is the compartment where the configurations are located):

Allow dynamic-group production-fleet to use log-content in compartment X

**To view logs**

To view logs in the Console (Search), the following is required:

Allow group Searchers to read log-content in compartment X

**Example log search policy**

To allow a group to read the contents of indexed logs:

allow group GroupA to read log-groups in tenancy
allow group GroupA to read log-content in tenancy

**Example policies for logs and log groups**

In these examples, policy statements use GroupA as the name of the group.

To allow a group to view the log groups in the tenancy (or in a compartment), requires inspect access:

allow group GroupA to inspect log-groups in tenancy
To allow a group to read metadata for logs or log groups, requires read access:

allow group GroupA to read log-groups in tenancy

To allow a group to update log groups, or the logs in them, requires use access:

allow group GroupA to use log-groups in tenancy

To enable a log on a resource (or to create and delete log groups and the logs in them), requires manage access:

allow group GroupA to manage log-groups in tenancy

To allow usage of a specific log group or groups, use a where clause with the target.loggroup.id variable. For example:

Allow group GroupA to manage loggroups in tenancy where target.loggroup.id='ocid1.loggroup.oc1.phx.<uniqueID>'

To specify multiple log groups:

Allow group GroupA to manage log-groups in tenancy where any {target.loggroup.id='ocid1.loggroup'}

Custom logs

For custom logs the following is required. This policy is needed to allow the user to search logs through the Console Search page:

allow group userGroup1 to read log-content in compartment c

Note:
Even though this policy is described for usage with custom logs, the policy is also true for all logs. LOG_CONTENT_READ allows reading logs from both custom and OCI service logs. It is identical in behavior to this policy:

allow group GroupA to read log-content in tenancy

The following is needed for the agent that uses the instance principal on the virtual machine to send logs:

allow dynamicgroup1 to use log-content in compartment c

Note:
If a user group is being used instead of a dynamic group for pushing custom logs, replace the dynamic group name with the user group name in these policies.

For custom logs, if you use allow group dynamicGroup1 to use log-content in compartment c, the instances in that dynamic group get permission to download the configuration, send logs, and can search logs.

IAM Policy Requirements for Resources

In addition to the permissions to work with the log group, to add service logs to a resource you must have the update permission for the resource. For many resources, the update permission is granted with the use verb. For example, users who can use buckets in CompartmentA, can also enable logging on a bucket in CompartmentA.

However, some resources don't include permission to update a resource with the use verb. For example, to update a rule for the Events service, you must have the full manage permission. To enable a log on an Events rule (or any other resource that doesn't include the update permission with the use verb), you must have the manage permission.
To allow a group to enable logging for these resources, without granting the full permissions of manage, you can add a policy statement to grant only the `<RESOURCE>_UPDATE` permission (or, in the case of the Events service, `<RESOURCE>_MODIFY`) from the manage verb. For example, to allow a group EventUsers to enable logs on Events rules in CompartmentA, you could write a policy like the following:

```
Allow group EventUsers to read cloudevents-rules in compartment CompartmentA
Allow group EventUsers to manage cloudevents-rules in compartment CompartmentA
  where request.permission='EVENTRULE_MODIFY'
```

For information about resource permissions, see Policy Reference on page 2837.

**VCN Flow Logs IAM Policy**

In addition to Required Permissions for Working with Logs and Log Groups on page 3351, subnet read and update permissions are required for managing VCN Flow Logs.

To provide subnet permissions, use one of the following policies, listed in order from broader to narrowed privileges:

```
Allow group FlowLogsEnablers to manage virtual-network-family in tenancy
Or:
Allow group FlowLogsEnablers to manage subnets in tenancy
Or:
Allow group FlowLogsEnablers to {SUBNET_READ, SUBNET_UPDATE} in tenancy
```

This group is similar to what is described for EventUsers in IAM Policy Requirements for Resources on page 3353.

**Example Scenario**

Your company has an Operations department. Within the Operations department are several costs centers. You want to be able to tag resources that belong to the Operations department with the appropriate cost center.

1. Create a log group called "confidential". Avoid entering confidential information.
2. Add logs with sensitive data to the "confidential" log group.

An employee named Alice already belongs to the group BucketManagers. Alice can manage buckets in CompartmentA. You want Alice and other members of BucketManagers group to be able to enable logs on buckets in CompartmentA.

To grant the BucketManagers group access to the sensitive data log group (and only the sensitive data log group), add the following statements to the BucketManagers policy:

```
Allow group BucketManagers to manage log-groups in compartment CompartmentA
  where
  target.loggroups.id='ocid1.lumloggroup.oc1.phx.<uniqueID>'
```

Alice can now enable logs to bucket resources in CompartmentA.

**Move Log Groups to a Different Compartment**

You can move log groups from one compartment to another. When you move a log group to a new compartment, all the logs in the log group move with the log group to the new compartment. After you move the log group to the new compartment, the policies in the new compartment apply immediately, and affect access to the log group and any logs the log group contains.

For more information, see Moving Resources to a Different Compartment on page 3128.
Log and Log Group Names

For log group names, the first character must start with a letter. Otherwise, the following guidelines apply to both log and log group names:

- Use from 1 to 256 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.
- Log and log group names are case-sensitive. Logging handles write-log and WRITE-log as separate logs.
- Avoid entering confidential information.

Legacy Archival

Legacy automatic log archival was previously available before general release. This is a toggle configurable for every log. If enabled, it automatically creates a bucket in your compartment, and places a copy of your log there. New and improved functionality is now available in Service Connector Hub on page 4752.

Using the Console

The Logs table lists both custom logs and service logs (indicated by the Log type field). The table is organized in terms of the following fields:

- Log name
- Log type
- Status
- Details
- Created

From this page you can click the Log name entry to go to the Log details page, or click the linked resource in Details to go directly to the resource. For example, if the log is for the Load Balancer service, clicking the link opens the Load Balancer Details page. From the action menu, you can edit the log, disable logging, change the log group, view tags, or delete the log.

To view the contents of logs

1. Open the navigation menu and click Observability & Management. Under Logging, click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Under Log name, click the name of the log you want to view. The log detail page opens. This page displays the following on the Log Information tab:
   - OCID
   - Compartment
   - Log Group (click to view the log group contents)
   - Created date and time in UTC format
   - Retention Period

   **Note:**
   Retention period can be set in 30-day increments, up to a maximum of 180 days.

- Legacy Archival mode
- Status (Creating, Active, Updating, Inactive, Deleting, Deleted)
- The Tags tab shows associated tags for this log.
- Under Log Details, following is displayed: the Log Type (whether Service or Custom), Service (for service logs), Log Category, and Resource (click to view the linked resource).

   In the Explore Log resource, log data is displayed in a similar manner as the Log Data on the Search page. You can apply some simple filters, such as sorting by newest or oldest from the Sort field, or filtering by time from the corresponding Filter by Time field.
4. Click **Explore with Log Search**, which allows you to view this log on the **Search** page directly. After clicking this link, the **Search** page opens with the **Select Logs to Search** field populated with the log in the filter settings. At this point, you can perform more analysis and investigation related to this log directly on the **Search** page. For more information, see **Searching Logs** on page 3420.

In addition to these functions in the **Explore Log** resource, you can also click the **Metrics** resource to view interactive charts for either a chosen time period (**Start Time** and **End Time**), or pre-selected ranges from **Quick Selects**. The charts display the **Bytes Ingested** (total bytes of log entries ingested) and the **Search Success** (number of successful search queries issued by the user).

Clicking anywhere in a chart displays a larger version of the chart. You can perform several chart actions from the **Options** menu (both in the **Metrics** resource and in the zoomed-in view):

- **View Query in Metrics Explorer**: Opens the chart in the Monitoring Metrics Explorer. See **Metrics Explorer page** on page 3484 for more information.
- **Copy Chart URL**
- **Copy Query (MQL)**
- **Create an Alarm on this Query**: Opens the Monitoring **Create Alarm** page. See **To create an alarm** on page 3523 for more information.
- **Table View**: Displays a tabular summary of the chart data. Select **Chart View** to switch back to the chart.

**To edit the name of a log**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens.
4. Click **Edit**. The **Edit Log** panel is displayed. This panel indicates the resource, and allows you to change the log name in the associated field under **Configure Log**. You can also enable or disable the **Enable Legacy Archival Logs** setting (see **Legacy Archival** on page 3355). Avoid entering confidential information.

From the main **Logs** page, for the log you want to edit, you can also click the the Actions icon (three dots), and then click **Edit** to access the **Edit Log** panel.

5. Make your changes and click **Save Changes**.

**To delete a log**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens.
4. Click **Delete**. A confirmation dialog is displayed regarding the delete operation.
5. Confirm by clicking **Delete**.

From the main **Logs** page, for the log you want to delete, you can also click the the Actions icon (three dots), and then click **Delete**.

**To move a log to a new log group**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens.
4. Click **Change Log Group**. The **Move to a Different Log Group** dialog is displayed.
5. From the **Choose New Group** list, select the new group from the list, and click **Change Log Group**. The new log group membership is reflected on the **Log Information** tab's **Log Group** field.

From the main **Logs** page, for the log you want to move to a new group, you can also click the the Actions icon (three dots), and then click **Change Log Group**.
**To enable or disable an existing log**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens.
4. Click **Disable Log/Enable Log**. A confirmation dialog is displayed regarding the disabling or enabling of the log.
5. Confirm by clicking **Disable Log/Enable Log**. The log detail page changes its status and displays **Inactive** (for a disabled log) or **Active** (for an enabled log) in the status field, both on the log detail page and the **Logs** page.

From the main **Logs** page, for the log you want to enable or disable, you can also click the the Actions icon (three dots), and then click **Disable Logging/Enable Logging**.

**To create a log group**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Log Groups**.
2. Choose a compartment you have permission to work in and click **Create Log Group**. The **Create Log Group** panel is displayed.
3. Enter the following:
   - **Compartment**: The compartment in which you want to create the log group. This field is pre-filled based on your compartment choice.
   - **Name**: A name for this log group. The first character of a log group name must be a letter. For more, see Log and Log Group Names on page 3355. Avoid entering confidential information.
   - **Description**: A friendly description.
   - Optionally, enter tagging information.
4. Click **Create**. The log group detail page is then displayed. From this page you can:
   - Edit the group
   - Move resources
   - Add tags
   - Delete the log group
   - View log group information and tags
   - View log group resources (explore the log group, view the logs included in the log group, create custom or service logs, and view metrics)

The **Metrics** resource in a log group detail page functions the same as in a log detail page. See To view the contents of logs on page 3355 for more information.

**To edit a log group**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.
3. Click **Edit**. The **Edit Log Group** panel is displayed. From here, you can change the log group name and its description in the associated fields. Avoid entering confidential information. See Log and Log Group Names on page 3355 for more information on naming.

From the main **Log Groups** page, for the log group you want to edit, you can also click the the Actions icon (three dots), and then click **Edit**.
4. Make your changes and click **Update**.

*Note:*  
You cannot move, edit, or delete the default log group.

**To delete a log group**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.

   **Tip:**
   You cannot delete a log group that contains logs.

3. Click **Delete**. A confirmation dialog is displayed regarding the delete operation.
4. Confirm by clicking **Delete**. The log group is removed from the **Log Groups** page.

   From the main **Log Groups** page, for the log group you want to delete, you can also click the the Actions icon (three dots), and then click **Delete**.

   **Note:**
   You cannot move, edit, or delete the default log group.

**To move a log group to a different compartment**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.
3. Click **Move Resource**. The **Move Resource to a Different Compartment** dialog is displayed.
4. Choose the new compartment and then click **Move Resource**.

   From the main **Log Groups** page, for the log group you want to move to a new compartment, you can also click the the Actions icon (three dots), and then click **Move Resource**.

   **Note:**
   You cannot move, edit, or delete the default log group.

**To list the logs in a log group**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Log Groups**.
2. Choose a compartment you have permission to work in.
3. For the log group you want to inspect for logs, click the name of the log group under **Log Group** in the table. The log group detail page is displayed.
4. In **Resources**, click **Logs** to display a list of all the logs contained in the log group. This resource table of logs functions in the same manner as the main **Logs** page.

**Using the Command Line Interface (CLI)**

For more information on installing the CLI, see Quickstart on page 5320, and logging-ingestion, logging, and logging-search for command documentation.

**Agent Configuration Commands**

The following are Unified Monitoring Agent configuration-related commands.

**To create a unified agent configuration registration**

```bash
oci logging agent-configuration create --compartment-id | -c <compartment_OCID>, --is-enabled <boolean>, --service-configuration <service_configure>
```

**To create a unified agent log configuration registration**

```bash
oci logging agent-configuration create-log-configuration --compartment-id | -c <compartment_OCID>, --is-enabled <boolean>
```
To get a unified agent configuration for an ID

```
oci logging agent-configuration get --config-id <agent_configuration_OCID>
```

To list all agent configurations in the specified compartment

```
oci logging agent-configuration list --compartment-id <compartment_OCID>
```

To update an existing unified agent configuration

```
oci logging agent-configuration update --config-id <agent_configuration_OCID>,
--display-name <configuration_name>, --is-enabled <Boolean>, --service-configuration <service_configure>
```

This call fails if the log group does not exist.

To update an existing unified agent log configuration

```
oci logging agent-configuration update-log-configuration --config-id <agent_configuration_OCID>,
--display-name <configuration_name>, --is-enabled <Boolean>
```

This call fails if the log group does not exist.

To move a unified agent configuration into a different compartment within the same tenancy

```
oci logging agent-configuration change-compartment --config-id <agent_configuration_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource. For information about moving resources between compartments, see Moving Resources to a Different Compartment on page 3128.

To delete a unified agent configuration

```
oci logging agent-configuration delete --config-id <agent_configuration_OCID>
```

Log Commands

The following are log commands.

Create a log within a specified log group

```
oci logging log create --display-name <log_name>, --log-group-id <log_group_OCID>,
--log-type <SERVICE_or_CUSTOM>
```

This call fails if the log group has already been created with the same displayName or (service, resource, category) triplet.

Get the log object configuration for the log object OCID

```
oci logging log get --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

List the specified log group’s log objects

```
oci logging log list --log-group-id <log_group_OCID>
```
Move a log into a different log group within the same tenancy

```
oci logging log change-log-group --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource.

To delete a log object in a log group

If you have an issue with deleting a log object, open a command prompt and run the following command to delete it:

```
oci logging log delete --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

To ingest logs associated with a logId

```
oci logging-ingestion put-logs --log-entry-batches, --log-id, --specversion
```

List all services supporting logging

```
oci logging service list
```

Update an existing log object with the associated configuration

```
oci logging log update --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

This call fails if the log object does not exist.

**Log Group Commands**

The following are log group-related commands.

Create a new log group with a unique display name

```
oci logging log-group create --compartment-id | -c <compartment_OCID>, --display-name <log_group_name>
```

This call fails if the log group is already created with same displayName in the compartment.

Get a specified log group's information

```
oci logging log-group get --log-group-id <log_group_OCID>
```

List all log groups for the specified compartment or tenancy

```
oci logging log-group list --compartment-id | -c <compartment_OCID>
```

Updates an existing log group with the associated configuration

```
oci logging log-group update --log-group-id <log_group_OCID>
```

This call fails if the log group does not exist.

Move a log group into a different compartment within the same tenancy

```
oci logging log-group change-compartment --log-group-id <log_group_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource. For information about moving resources between compartments, see **Moving Resources to a Different Compartment** on page 3128.

To delete a specified log group

```
oci logging log-group delete --log-group-id <log_group_OCID>
```
Work Request Commands
The following are work request-related logging commands.

Get the details of a work request with a given ID

```
oci logging work-request get --work-request-id <work_request_OCID>
```

List the work requests in a compartment

```
oci logging work-request list --compartment-id | -c <compartment_OCID>
```

List the errors for a given work request

```
oci logging work-request-error list --work-request-id <work_request_OCID>
```

List the logs for a given work request

```
oci logging work-request-log list --work-request-id <work_request_OCID>
```

Delete a work request that has not yet started

```
oci logging work-request delete --work-request-id <work_request_OCID>
```

Object Storage Example
The following is a logging command example related to Object Storage.

To create a log group and create a log in Object Storage

```
oci logging log-group create --compartment-id <compartment_OCID> --display-name CLITestLogGroup
oci logging log create --display-name object_log_write --log-group-id <log_group_OCID> --log-type SERVICE --is-enabled true --configuration file://~/oci/objectstorage_configuration.json
```

goctstorage_configuration.json:

```json
{
  "archiving": {
    "isEnabled": true
  },
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "source": [
    {
      "category": "write",
      "parameters": null,
      "resource": "bucket-cli-sample",
      "service": "objectstorage",
      "sourceType": "OCISERVICE"
    }
  ]
}
```

VCN Flow Logs Example
The following are sample logging commands related to VCN Flow Logs.

To create a log group

```
oci logging log-group create --compartment-id <compartment_OCID> --display-name <log_group_name>
```
To create a **flowlogs** log object (enable Flow Logs)

```bash
oci logging log create --display-name <log_display_name> --log-group-id <log_group_OCID>
--description <description> --log-type SERVICE --is-enabled <Boolean>
--configuration file://input.json
```

Sample configuration file:

```json
{
    "compartment-id": "...",
    "source": {
        "resource": "ocid1.subnet.....", # OCID of subnet for which flowlogs is enabled.
        "service": "flowlogs", # "flowlogs" is the official service name and it should be all lowercase.
        "source-type": "OCISERVICE", # OCISERVICE is the name of the Logging source-type.
        "category": "all"
    }
}
```

To disable a **flowlogs** log object (disable Flow Logs)

```bash
oci logging log update --log-group-id <log_group_OCID> --log-id <log_OCID>
--is-enabled false
```

To delete the log object

```bash
oci logging log delete --log-id <log_OCID>
```

**Functions Example**
The following is a sample Functions-related logging command.

**To enable Functions logging**

```bash
oci logging log create --display-name cli_test --log-group-id ocid1.loggroup.oc1.phx.<log_group_OCID>
--log-type SERVICE --is-enabled true --configuration file://fnconfig.json
```

Sample fnconfig.json configuration file:

```json
{
    "compartment-id": "ocid1.compartment.oc1..<compartment_OCID>"
    "source": {
        "resource": "ocid1.fnapp.oc1.phx.<unique_ID>",
        "service": "functions",
        "source-type": "OCISERVICE",
        "category": "invoke"
    }
}
```

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the following operations to manage logs:
Logging

- ListLogs
- GetLog
- CreateLog
- UpdateLog
- ChangeLogLogGroup
- DeleteLog

Use the following operations to manage log groups:

- ListLogGroups
- GetLogGroup
- CreateLogGroup
- UpdateLogGroup
- ChangeLogGroupCompartment
- DeleteLogGroup

Service Logs

Oracle Cloud Infrastructure services, such as API Gateway, DevOps, Email Delivery, Events, Functions, Load Balancing, Object Storage, VCN Flow Logs, and Site-to-Site VPN emit service logs. Each of these supported services has a Logs resource that allows you to enable or disable logging for that service.

Supported Services

You can enable service logs for the following Oracle Cloud Infrastructure services:

- API Gateway
- DevOps
- Email Delivery
- Events
- Functions
- Load Balancers
- Object Storage
- VCN Flow Logs
- Site-to-Site VPN

**Note:**

Site-to-Site VPN logs are only supported with v2 IPSec connections. v1 connections are not supported.

**Note:**

This list of Oracle Cloud Infrastructure services is updated as supported services are added.

Enabling Logging for a Resource

Logs can be enabled in two places: directly on the resource itself, or on the central Logs page. When you enable a log on a specific resource, you specify the category. Different resources can have different categories. For example, rules in the Events Service have the Logs resource available for logging management. The rule can issue a log according to the category listed in the corresponding Category field. On this page, the logs are listed that the resource can create.

**Note:**

For Site-to-Site VPN logs, an error is displayed on the log details page if you attempt to enable logs for a v1 Site-to-Site VPN connection. Only v2 connections are supported.
**Note:**

When a log object is in an invalid state after failing (CREATING, DELETING, UPDATING), the only action available will be to delete the object. You can use the CLI to retrieve the logs of the work flow, to identify the nature of the failure (for example, a resource not found, an operation was not allowed on the resource, an internal failure, and so on). See Using the Command Line Interface (CLI) on page 3358 for more information on logging CLI commands.

---

**Enabling Logging from the Resource page**

For Oracle Cloud Infrastructure services that are compatible with Logging, the **Logs** resource allows you to manage the logs issued by the resource. You can view the following information:

- Category
- Status
- Log name
- Log group

In addition, you can enable or disable logging, edit the log, or delete it (the last two options are available in the action menu). When enabling logging, you also create the log object itself.

For a newly created resource, logging is automatically enabled. For a resource you want to enable logging on, under **Resources** click **Logs**, and then toggle **Enable Logging**. The Create Log panel is displayed, and the entry fields are pre-populated:

- **Compartment** (the same as your resource)
- **Log Group**: The first log group in your compartment. You can select another log group, or create a new group by clicking **Create New Group**.
- **Log Name**: Pre-populated as the name of your resource and the category, which are combined with an underscore (`<resource>_<category>`). For example, if the resource is named "resource" and the category is "ruleexecutionlog", the log name is "resource_ruleexecutionlog".

After logging is enabled, you can click the link under **Log name** or **Log group** to view the log details or log group details pages, respectively.

To disable logging, toggle the **Enable log** control, which displays a disable logging confirmation dialog. Click **Disable Log** to confirm. The **Status** field is set to INACTIVE to indicate the inactive status.

When creating a log, a log object is established. To delete the log, select **Delete** from the action menu. A confirmation is displayed confirming whether you want to delete the log. After clicking **Delete**, this removes the log object, as opposed to disabling it (which means the log object still exists but does not record new data into it).

---

**Enabling Logging on the Logs page**

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**. The **Logs** page is displayed.
2. Click **Enable Service Log**. The Enable Resource Log panel is displayed.
3. Under **Select Resource**, **Resource Compartment**, choose a compartment you have permission to work in.
4. Select a service from the **Service** list (see **Supported Services** on page 3363 for the available services).
5. **Select a resource:**
   - In **Service**, select the service of the resource for which you want to enable the log.
   - In **Resource Compartment**, select the compartment of the resource.
   - **Tip:**
     You can type in the list box to perform a filtered search of all compartments in the tenancy.
   - In **Resource** select a resource.

6. **Configure the log:**
   - In **Log Category** select a log category to specify the type of log to create. For example, Object Storage buckets have categories for read and write. Select read to enable a log with only read events. Select write for a log with only write events.
   - **Tip:** You can only have one log for any combination of service, resource, and log category. For example, Object Storage buckets have two categories: read and write. Therefore:
     - You can enable a single read log and a single write log for every bucket in your tenancy.
     - You cannot enable more than two logs (one read and one write) for any one bucket.
   - In **Log Name**, type a name for the log. See Log and Log Group Names on page 3355 for more information. Avoid entering confidential information. Select **Enable Legacy Archival Logs** to automatically create a bucket in your compartment, and place a copy of your log there. See Legacy Archival on page 3355 for more information.

7. **To specify the log location** (click **Show Advanced Options** if necessary):
   - In **Compartment**, select the compartment for the log.
   - **Tip:** You can type in the list box to perform a filtered search of all compartments in the tenancy.
   - In **Log Group**, select a log group for the log.
   - **Tip:** To create a new log group, click **Create New Group**.

8. **In Log Retention**, select a value from the list:
   - 1 month (the default)
   - 2 months
   - 3 months
   - 4 months
   - 5 months
   - 6 months

9. **Apply any tagging-related information** in the **Tag Namespace**, **Tag Key**, and **Value** fields.

10. **Click Enable Log.**

    The Log detail page is displayed, and the log is in the process of being created (a "Creating log" message is displayed). See Using the Console on page 3355 for more information on viewing and using this page.

**Service Log Reference**

The overarching logging schema is described in Logging Format Overview on page 3366, while each service that enables logging has its own specific logging details. This reference includes:

- Details for API Gateway on page 3369
- Details for DevOps Logging on page 3373
- Details For Email Delivery on page 3375
Logging Format Overview

Every log line is normalized into a common event format for ease of correlation. This format is based on the JSON implementation of CloudEvents v1.0 specification. A log line has three key sections:

- Unified envelope
- Oracle-specific metadata (oracle.*)
- Contents of the log line (data)

Outer Envelope Format

All messages sent to the ingestion front end use the outer envelope format, and only change the message body based on the log type. The outer envelope format conforms to the CloudEvents v1.0 spec, with extension fields defined for logging purposes. The following table describes this format.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Position</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specification Version</td>
<td>Yes</td>
<td>Body: specversion</td>
<td>String</td>
<td>The version of the CloudEvents specification this message conforms to.</td>
</tr>
<tr>
<td>Id</td>
<td>Yes</td>
<td>Body: id</td>
<td>String</td>
<td>A source-unique identifier for this message. Duplicate messages can have the same ID. Consumers can assume events with the same IDs are unique.</td>
</tr>
<tr>
<td>Type</td>
<td>Yes</td>
<td>Body: type</td>
<td>String</td>
<td>The type of the message. Consumers use the type and specversion to determine how to interpret the body. Pattern: com.oraclecloud.{service}.{resource-type}.{category}. For example: com.oraclecloud.compute.instance.terminated</td>
</tr>
<tr>
<td>Name</td>
<td>Required</td>
<td>Position</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------</td>
<td>-----------</td>
<td>-------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Source</td>
<td>Yes</td>
<td>Body: source</td>
<td>URI-reference</td>
<td>The message source. When emitted by a service, refers to the name of the resource that generated the message, for example, the Object Storage bucket name, Instance Name. When emitted by an agent, based on the source/input used to read events. For example, the instance name (not the OCID) or the hostname of the asset in an on-premise environment.</td>
</tr>
<tr>
<td>Subject</td>
<td>No</td>
<td>Body: subject</td>
<td>String</td>
<td>A specific subresource that generated the event, if applicable to the source. This is useful for sources with subresources. Examples:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Object Storage example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Source: my-bucket</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Subject: image.png</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Custom Logging example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Source: hostname</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Subject: /var/log/some.log</td>
</tr>
<tr>
<td>Name</td>
<td>Required</td>
<td>Position</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------</td>
<td>----------------</td>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Time</td>
<td>No</td>
<td>Body: time</td>
<td>Timestamp</td>
<td>The time the message was generated. If present, must adhere to the format specified in RFC 3339. If not provided, the wall clock of the ingestion host that receives the request is used.</td>
</tr>
<tr>
<td>Data Schema</td>
<td>No</td>
<td>Body: dataschema</td>
<td>String</td>
<td>The schema version for the data field. This is not required, and if not provided, is assumed to be the initial version.</td>
</tr>
<tr>
<td>Data Content Type</td>
<td>No</td>
<td>Body: datacontenttype</td>
<td>String</td>
<td>The format in which the message body is encoded. If not provided, the default is JSON (equivalent to datacontenttype: application/json).</td>
</tr>
<tr>
<td>Message Body</td>
<td>Yes</td>
<td>Body: data</td>
<td>Object</td>
<td>The message body encoded in the format defined by datacontenttype. If datacontenttype is not specified, this is expected to be JSON (equivalent to datacontenttype: application/json).</td>
</tr>
<tr>
<td>Oracle Cloud Metadata</td>
<td>Yes</td>
<td>Body: oracle</td>
<td>Object</td>
<td>More Oracle-specific metadata is provided in a map of attributes at the top level of the envelope. This conforms to CloudEvents v1 Attribute Extensions specification. See the following table for supported Oracle Cloud Infrastructure metadata attributes.</td>
</tr>
</tbody>
</table>
Oracle Metadata Attributes

The following attributes are supported in the oci extension field of the message format. Naming for these attributes conforms to the CloudEvents v1 Attribute Naming Convention, that is, they are lowercase alpha-numeric identifiers fewer than 20 characters long.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required for Ingestion</th>
<th>Enriched for Retrieval</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logid</td>
<td>Yes</td>
<td>-</td>
<td>String</td>
<td>The OCID of the log object the message was sent to.</td>
</tr>
<tr>
<td>loggroupid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the log group the object resides in.</td>
</tr>
<tr>
<td>tenantid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the tenant that owns the log object.</td>
</tr>
<tr>
<td>compartmentid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the compartment the log object resided in at the time the message was ingested.</td>
</tr>
</tbody>
</table>

Details for API Gateway

This topic provides details for API Gateway logs.

Resources

- API deployment

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Access Logs</td>
<td>Access logs for an API deployment.</td>
</tr>
<tr>
<td>Execution</td>
<td>Execution Logs</td>
<td>Execution logs for an API deployment.</td>
</tr>
</tbody>
</table>

Availability

API Gateway Access/Execution logging is available in all the regions of the commercial realm.

API Deployment Access Log

API deployment access logs record a summary of every request and response that goes through the API gateway, matching a route on the API deployment. Each access log entry contains information about the request and response (time the request was received, server protocol, response status, and so on). For the complete list of fields, see Contents of an Access Log on page 3369.

Contents of an Access Log

Access logs appear as a value in the Log Data field. This value is JSON-formatted data with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpMethod</td>
<td>GET</td>
<td>HTTP method derived from the request line.</td>
</tr>
<tr>
<td>requestUri</td>
<td>/example/</td>
<td>Request URI derived from the request line.</td>
</tr>
<tr>
<td>serverProtocol</td>
<td>HTTP/1.1</td>
<td>HTTP protocol derived from the request line.</td>
</tr>
</tbody>
</table>
**Field** | **Example** | **Description**
---|---|---
bodyBytesSent | 45 | Total size of the response (in bytes) sent to the client.
gatewayId | ocid1.apigateway.oc1.iad.<unique_ID> | OCID of the API Gateway for the API deployment servicing the request.
httpUserAgent | Apache-HttpClient/4.5.9 (Java/1.8.0_252) | HTTP user agent for the request.
message | GET /example/ HTTP/1.1 | Request line received from the client.
opcRequestId | FF7F0B8A32246FC7526AE45A2FA8D5CE/A408784281BF81B0EE23596CE57CA93C7/C06F7DDDFC7C505FAA0566D8F2FE0BB2 | Value of the opc-request-id HTTP header, or an internally generated request ID if none was specified in the request.
remoteAddr | 138.1.55.172 | IP address of the requesting client.
httpReferrer | https://www.example.com | The URL of the referral, if present.
requestDuration | 0.016 | Total time taken (in seconds, with millisecond precision), from when the gateway starts receiving request from the client, until it completes sending a response to the client.
status | 404 | Status code of the response from the gateway.

**Sample Access Log**

```json
{
    "httpMethod": "GET",
    "requestUri": "/example/",
    "serverProtocol": "HTTP/1.1",
    "bodyBytesSent": 45,
    "gatewayId": "ocid1.apigateway.oc1.iad.<unique_ID>",
    "httpUserAgent": "Apache-HttpClient/4.5.9 (Java/1.8.0_252)",
    "message": "GET /example/ HTTP/1.1",
    "opcRequestId": "FF7F0B8A32246FC7526AE45A2FA8D5CE/A408784281BF81B0EE23596CE57CA93C7/C06F7DDDFC7C505FAA0566D8F2FE0BB2",
    "remoteAddr": "138.2.05.172",
    "requestDuration": 0.016,
    "status": 404
}
```

**API Deployment Execution Log**

API deployment execution logs record information about processing within the API gateway for an individual route, to help with troubleshooting and monitoring. Each execution log entry contains information (time the request was received, level to denote the severity of the log message, a message code, and so on). For the complete list of fields, see **Contents of an Execution Log** on page 3370.

**Contents of an Execution Log**

By default Log Level info is enabled. This value is JSON-formatted data with the following fields:
### Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>code</td>
<td>request.loopDetected</td>
<td>Short code for the logging event encountered while running the request. For the complete list of message codes, see the &quot;Log Codes&quot; table <a href="#">Log Codes</a> on page 3371.</td>
</tr>
<tr>
<td>gatewayId</td>
<td>ocid1.apigateway.oc1.iad.&lt;unique_ID&gt;</td>
<td>API gateway OCID for the API deployment servicing the request.</td>
</tr>
<tr>
<td>functionId</td>
<td>ocid1.fnfunc.oc1.iad.&lt;unique_ID&gt;</td>
<td>OCID of function that the API gateway invoked. This field is only present for function backends.</td>
</tr>
<tr>
<td>level</td>
<td>WARN</td>
<td>Log level for the execution log entry, whether INFO, WARN, or ERROR.</td>
</tr>
<tr>
<td>message</td>
<td>A request loop has been detected - requests for this gateway are being directed back to this gateway.</td>
<td>Execution message emitted while processing the request.</td>
</tr>
<tr>
<td>opcRequestId</td>
<td>FF7F0B8A32246FC7526AE45A2FA8A408784281BF81B0EE23596CE57C06F7DDDFFC7C505FAA0566D8F2EB08B3</td>
<td>Discussions of the opc-request-id HTTP header, or an internally generated request ID if none was specified in the request.</td>
</tr>
<tr>
<td>functionCode</td>
<td>FunctionInvokeSyslogUnavailable</td>
<td>A code provided by Oracle Functions to uniquely define the function's error. This field is only present for function backends.</td>
</tr>
<tr>
<td>functionMessage</td>
<td>Syslog endpoint unavailable</td>
<td>A message provided by Oracle Functions to describe the function's error. This field is only present for function backends.</td>
</tr>
<tr>
<td>functionStatusCode</td>
<td>502</td>
<td>The HTTP status code returned by Oracle Functions. This field is only present for function backends.</td>
</tr>
</tbody>
</table>

#### Log Codes

<table>
<thead>
<tr>
<th>Log Code</th>
<th>Description</th>
<th>Related Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpBackend.timeout</td>
<td>Request to the HTTP backend timed out.</td>
<td>HTTP Backend</td>
</tr>
<tr>
<td>httpBackend.dnsResolutionFailed</td>
<td>Failed to resolve the HTTP backend URL.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.sslHandshakeFailed</td>
<td>SSL Handshake failed with the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.successfulRequest</td>
<td>Successful request to the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.responseReceived</td>
<td>Response received from the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.requestSent</td>
<td>Request sent to the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>Log Code</td>
<td>Description</td>
<td>Related Feature</td>
</tr>
<tr>
<td>---------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>functionBackend.successfulRequest</td>
<td>Successful invocation of the Oracle Function.</td>
<td>Oracle Functions Backend</td>
</tr>
<tr>
<td>functionBackend.notFoundOrNotAuthorized</td>
<td>Failed to invoke the Oracle Function due to 404 from Oracle Functions service.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.rateLimited</td>
<td>Rate limited when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.serviceUnavailable</td>
<td>Oracle Functions service unavailable.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.badGateway</td>
<td>Received &quot;Bad Gateway&quot; when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.timeout</td>
<td>Oracle Function invocation timed out.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.internalServiceError</td>
<td>Internal service error when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>specification.badVariableReference</td>
<td>The context variable couldn't be resolved.</td>
<td>Incorrect Specification at run-time</td>
</tr>
<tr>
<td>specification.invalidAuthenticationPolicy</td>
<td>Invalid authentication policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badTransformationPolicy</td>
<td>Bad transformation policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badHeaderTransformationPolicy</td>
<td>Bad Header Transformation policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badQueryParameterTransformationPolicy</td>
<td>Bad Query Parameter Transformation policy.</td>
<td></td>
</tr>
<tr>
<td>request.internalServiceError</td>
<td>Internal service error.</td>
<td>Request processing</td>
</tr>
<tr>
<td>request.loopDetected</td>
<td>A request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.</td>
<td></td>
</tr>
<tr>
<td>request.possibleLoopDetected</td>
<td>A possible request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.</td>
<td></td>
</tr>
<tr>
<td>request.headersTruncated</td>
<td>Request headers were truncated.</td>
<td></td>
</tr>
<tr>
<td>request.queryParametersTruncated</td>
<td>Request query parameters were truncated.</td>
<td></td>
</tr>
<tr>
<td>authorization.unauthorizedRequest</td>
<td>Authorization failed for the request.</td>
<td>Request Authorization</td>
</tr>
<tr>
<td>authorization.scopeCheckFailed</td>
<td>Failed to check the scope for the request.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.successfulFunctionInvocation</td>
<td>Successfully invoked the Oracle Function.</td>
<td>Custom Authentication</td>
</tr>
<tr>
<td>customAuthentication.failedFunctionInvocation</td>
<td>Failed to invoke the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.authenticationSuccessful</td>
<td>Authorization successful.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.authenticationFailed</td>
<td>Authentication failed.</td>
<td></td>
</tr>
</tbody>
</table>
### Sample Execution Logs

- **Type:** Request
- **Scenario:** Request Loop Detected
- **Description:** A request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.
- **Example:**

```json
{
    "code": "request.loopDetected",
    "gatewayId": "ocid1.apigateway.oc1.iad.<unique_ID>"
    "level": "WARN",
    "message": "A request loop has been detected - requests for this gateway are being directed back to this gateway.",

### Details for DevOps Logging

This topic provides details for DevOps logs.

### Resources

- devopsproject
Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>DevOps Logs</td>
<td>Includes all DevOps service-related logs.</td>
</tr>
</tbody>
</table>

Availability

DevOps logging is available in all the regions of the commercial realm.

Comments

You can enable DevOps logs for a given project, which means deployments are logged for all the pipelines inside that project. For more information, see DevOps Logs.

Contents of a DevOps Log

A DevOps log record contains the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>specversion</td>
<td>Oracle Cloud Infrastructure Logging schema version.</td>
<td>1.0</td>
</tr>
<tr>
<td>type</td>
<td>Category of the log. Possible values:</td>
<td>com.oraclecloud.devops.deployment</td>
</tr>
<tr>
<td></td>
<td>• deployment</td>
<td></td>
</tr>
<tr>
<td>source</td>
<td>Name of the Project the log is associated with.</td>
<td>myDemoProject</td>
</tr>
<tr>
<td>subject</td>
<td>OCID of the target resource where the deployment is getting executed.</td>
<td>ocid1.instance.oc1.&lt;region_ID&gt;.&lt;unique_ID&gt;</td>
</tr>
<tr>
<td></td>
<td>Possible values for target resource:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• instance</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• fnfunc</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• cluster</td>
<td></td>
</tr>
<tr>
<td>id</td>
<td>Random UUID, unique to each log entry.</td>
<td>e3002eaa-d717-472e-8474-d024943a0f27</td>
</tr>
<tr>
<td>time</td>
<td>Time the log was generated in the DevOps Service.</td>
<td>2021-02-18T18:21:52.024Z</td>
</tr>
<tr>
<td>oracle.loggroupid</td>
<td>OCID of the log group.</td>
<td>ocid1.&lt;loggroup&gt;.oc1.&lt;region_ID&gt;.&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>oracle.logid</td>
<td>OCID of the service log object.</td>
<td>ocid1.log.oc1.&lt;region_id&gt;.&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>oracle.tenantid</td>
<td>OCID of the tenancy.</td>
<td>ocid1.&lt;tenancy&gt;.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>oracle.compartmentid</td>
<td>OCID of the compartment that the log group belongs to.</td>
<td>ocid1.&lt;compartment&gt;.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>oracle.ingestedtime</td>
<td>The time the log was ingested by OCILogging.</td>
<td>2021-02-18T18:22:01.453Z</td>
</tr>
<tr>
<td>data.deploymentId</td>
<td>OCID of the deployment with which log message is associated.</td>
<td>ocid1.devopsdeployment.oc1.&lt;region_ID&gt;.&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>data.deployPipelineId</td>
<td>OCID of the deployment pipeline ID with which the log message is associated.</td>
<td>ocid1.devopsdeploypipeline.oc1.&lt;region_ID&gt;.&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>data.deployStageId</td>
<td>OCID of the deploy stage ID with which the log message is associated.</td>
<td>ocid1.devopsdeploystage.oc1.&lt;region_ID&gt;.&lt;unique_ID&gt;</td>
</tr>
</tbody>
</table>
| data.producer                | Producer of the log message. Some of the logs are produced by the DevOps service code, while other logs are produced by scripts from the customer. For example, the deployment service can run scripts provided by the customer during the deployment to instance groups. Such customer-provided scripts could produce STDOUT and STDERR messages, which are also included in the log. The producer field can distinguish them accordingly. Possible Values:  
  • DEVOPS_SERVICE  
  • USER_SCRIPT | DEVOPS_SERVICE                                                               |

**Sample DevOps Log**

```json
{
  "specversion": "1.0",
  "type": "com.oraclecloud.devops.deployment",
  "source": "Project name",
  "subject": "ocid1.instance.oc1.<region_ID>.<unique_ID>",
  "id": "e3002eaa-d717-472e-8474-d024943a0f27",
  "time": "2020-10-18T21:02:40.58Z",
  "oracle": {
    "logid": "ocid1.log.oc1.<region_ID>.<unique_ID>",
    "loggroupid": "ocid1.<loggroup>.oc1.<region_ID>.<unique_ID>",
    "tenantid": "ocid1.<tenancy>.oc1.<unique_ID>",
    "compartmentid": "ocid1.<compartment>.oc1.<unique_ID>",
    "ingestedtime": "2020-10-18T21:02:40.58Z"
  },
  "data": {
    "deploymentId": "ocid1.devopsdeployment.oc1.<region_ID>.<unique_ID>",
    "deployPipelineId": "ocid1.devopsdeploypipeline.oc1.<region_ID>.<unique_ID>",
    "deployStageId": "ocid1.devopsdeploystage.oc1.<region_ID>.<unique_ID>",
    "message": "Manual Approval stage: Waiting for required approvals",
    "producer": "DEVOPS_SERVICE"
  }
}
```

**Details For Email Delivery**

This topic provides details for Email Delivery logs.
Resources

- emaildomain

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>emaildelivery.emaildomain.outbound</td>
<td>emaildelivery.emaildomain.outbound</td>
<td>Inbound email successful and failed submissions logs.</td>
</tr>
<tr>
<td>emaildelivery.emaildomain.outboundrelayed</td>
<td>emaildelivery.emaildomain.outboundrelayed</td>
<td>Logs for successful and failed email submissions for outbound delivery.</td>
</tr>
</tbody>
</table>

Policies

EMAIL_DOMAIN_UPDATE permission is required, along with Logging policies, to perform Logging-related operations. For details on Email Delivery policies, see Details for the Email Delivery Service on page 2958.

Contents of an OutboundAccepted Email Log

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>recipient</td>
<td>Email address of the recipient. This may not be present in logs with error type Authorization failure, Reset, or Disconnected.</td>
<td><a href="mailto:user@example.com">user@example.com</a></td>
</tr>
<tr>
<td>sender</td>
<td>The first email address in the &quot;From:&quot; header in the email message.</td>
<td><a href="mailto:support@example.com">support@example.com</a></td>
</tr>
</tbody>
</table>
| action   | Provides context for the data in the log. Supported values for Acceptance Logs:  
- Accept: Log provides information around acceptance status for an email.  
Automated processors must tolerate logs with unrecognized action values. | accept |
<table>
<thead>
<tr>
<th><strong>Property</strong></th>
<th><strong>Description</strong></th>
<th><strong>Example</strong></th>
</tr>
</thead>
</table>
| errorType     | Provides information for troubleshooting issues. This is omitted for successfully accepted emails. Supported values for acceptance logs:  
* Suppressed: Email was suppressed and not relayed.  
* Authorization failure: Email was not accepted due to authorization failures.  
* Recipient Address Rejected: Email could not be accepted due to invalid recipient address.  
* Daily Limit reached: Email could not be accepted due to limits.  
* Sender Rate Limit reached: Email could not be accepted due to limits.  
* Message size limit exceeded: Email could not be accepted due to message size limit exceeded.  
* Reset: The client cancelled the mail transaction (via SMTP RSET).  
* Disconnected: The client connection to the service was lost before the mail transaction was complete.  
* Message parse error: Email could not be accepted due to invalid message format. Only authorization failures are logged. Oracle reserves the right to add new values to this field as needed, so parsers must be able to tolerate unrecognized values. | Daily limit reached |
<p>| smtpStatus    | SMTP status in acceptance logs will contain the SMTP error, or status returned to the SMTP submission client for this recipient. | 250 2.1.5 <a href="mailto:user@example.com">user@example.com</a> and options Ok |
| messageId     | MessageId is a unique ID that represents an email send operation. It is used to track an email end-to-end. MessageId is either provided by the customer, or will be generated by the MTA while processing email. This will not be present in acceptance logs that fail before receiving message data. | <a href="mailto:06a9aa8e-0542-4ddf-8255-ec9c2f5e02a3@smtp-ad3-fd1-303-us-phoenix-1.imtaad3.vendpphox.oraclevnc">06a9aa8e-0542-4ddf-8255-ec9c2f5e02a3@smtp-ad3-fd1-303-us-phoenix-1.imtaad3.vendpphox.oraclevnc</a> | See <a href="https://datatracker.ietf.org/doc/html/rfc5322#section-3.6.4">https://datatracker.ietf.org/doc/html/rfc5322#section-3.6.4</a> for more information. |
| envelopeSender| The initial envelope sender (MAIL FROM) address provided when the email was submitted, which is used to authorize email sending. Unlike Body:data.sender (aka header From), this is provided for acceptance failure cases, as this is available for failures prior to transfer of message content. | <a href="mailto:support@example.com">support@example.com</a> |
| senderId      | Approved sender OCID. This will be the OCID associated with the Body:data.sender if that is present, otherwise, it will be the OCID associated with Body:data.envelopeSender. This may not be present on authorization failures. | ocid1.emailsender.oc1.phx.&lt;unique_ID&gt; |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>senderCompartmentId</td>
<td>Compartment OCID of the approved sender. This will be the compartment OCID associated with the Body: data.senderId. This may not be present on authorization failures.</td>
<td>ocid1.compartment.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>headers</td>
<td>(Available in future) Configurable headers at approved sender level. Set up through a support request, and is a maximum of four headers.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;X-Campaign-ID&quot;: &quot;campaign1&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;Recipient-Group-ID&quot;: &quot;group1&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;Sub-Account-ID&quot;: &quot;account1&quot;</td>
</tr>
<tr>
<td>receivingDomain</td>
<td>Email domain of the recipient. Although this is redundant with the domain name portion of the recipient field, this can be useful for aggregation views of the logs.</td>
<td>example.com</td>
</tr>
<tr>
<td>messageSizeInKiB</td>
<td>Message size in kibibytes (rounded to an integer with rounding mode ceiling).</td>
<td>5</td>
</tr>
<tr>
<td>authzOpcRequestId</td>
<td>OPC request ID for the authorization call made from the Email Delivery Service to Identity, to authorize an approved sender.</td>
<td>6D6E701D166D72B8BCB7881647CBBF34D8</td>
</tr>
<tr>
<td>message</td>
<td>A summary of the log event.</td>
<td>Accepted email <a href="mailto:support@example.com">support@example.com</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td># <a href="mailto:user@example.com">user@example.com</a></td>
</tr>
</tbody>
</table>

### Contents of an OutboundRelayed Email Log

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>recipient</td>
<td>Email address of the recipient.</td>
<td><a href="mailto:user@example.com">user@example.com</a></td>
</tr>
<tr>
<td>sender</td>
<td>&quot;From:&quot; header in the email message.</td>
<td><a href="mailto:support@example.com">support@example.com</a></td>
</tr>
<tr>
<td>action</td>
<td>Provides context for the data in the log. Supported values for relayed, bounce, and complaint logs:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Relay: Successfully relayed to the receiving mail server.</td>
<td>• relay</td>
</tr>
<tr>
<td></td>
<td>• Bounce: Bounced back from receiving mail server.</td>
<td>• bounce</td>
</tr>
<tr>
<td></td>
<td>• Complaint: Recipient marked email as spam, and mailbox provider supports a complaint feedback loop.</td>
<td>• complaint</td>
</tr>
</tbody>
</table>

**Note:**

Automated processors must tolerate logs with unrecognized action values.

<table>
<thead>
<tr>
<th>errorType</th>
<th>Provides information for troubleshooting issues. Only present in &quot;Bounce&quot; logs.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Supported values for relayed, bounce, and compliant logs are the following:</td>
</tr>
<tr>
<td></td>
<td>• Soft bounce: A transient error from the receiving server resulting in an undelivered message.</td>
</tr>
<tr>
<td></td>
<td>• Hard bounce: A permanent error from the receiving server, resulting in an undelivered message, and the recipient's address being added to the suppression list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>bounceCategory</th>
<th>Category of bounce. Only present in &quot;Bounce&quot; logs.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>bad-mailbox</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>reportGeneratedTime</td>
<td>Time when action is generated. Only present in some &quot;Bounce&quot; and &quot;Complaint&quot; logs.</td>
</tr>
<tr>
<td>originalMessageAcceptedTime</td>
<td>Time when the original message is accepted by the Email Delivery service. Refers to the original time stamp for bounced messages only, so this is not present in all relayed logs.</td>
</tr>
<tr>
<td>bounceCode</td>
<td>An SMTP response code, such as 5.5.0, 4.7.1. Only present in &quot;Bounce&quot; logs. See <a href="https://www.ietf.org/rfc/rfc1893.txt">https://www.ietf.org/rfc/rfc1893.txt</a> for more information.</td>
</tr>
</tbody>
</table>
| smtpStatus             | SMTP status includes the information generated by a remote SMTP server on the internet, and is usually not controlled by Email Delivery.                                                                 | "250 2.1.5 Recipient ok""550 5.1.1
\langle user@example.com\rangle recipient does not exist here."

<td>The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.</td>
</tr>
<tr>
<td>message</td>
<td>The event message.</td>
</tr>
<tr>
<td>target</td>
<td>The rule action. For example:</td>
</tr>
<tr>
<td></td>
<td>• For streaming, it means that the event was delivered to the stream.</td>
</tr>
<tr>
<td></td>
<td>• For a notification, it means it was delivered to the email subscribed to the topic.</td>
</tr>
<tr>
<td></td>
<td>• For a function, it means it triggered the function with the event data.</td>
</tr>
</tbody>
</table>

An Example Events Log

For events there are two types of messages:

```json
{
  "specversion": "1.0",
  "type": "com.oraclecloud.eventsservice.eventrule.ruleexecutionlog",
  "source": "Flowlogs",
  "id": "6e6dbfd3-4bce-4848-af53f19bd6c9",
  "time": "2020-08-24T23:31:44Z",
  "oracle": {
    "logid": "ocid1.log.oc1.iad.<unique_ID>",
    "loggroupid": "ocid1.loggroup.oc1.iad.<unique_ID>",
    "compartmentid": "ocid1.compartment.oc1..<unique_ID>",
    "tenantid": "ocid1.tenancy.oc1..<unique_ID>",
    "ingestedtime": "2020-08-19T15:33:30.832Z"
  },
  "data": {
    "ruleId": "ocid1.eventrule.oc1.iad.<unique_ID>",
    "eventId": "24bc7219-efec-4ccd-350b-be2d833439d2",
    "message": "Event failed to deliver to FAAS. Exception from FAAS endpoint
    https://ptktjbkp22a.us-ashburn-1.functions.oci.oraclecloud.com,
    exception message:
    (502, FunctionInvokeImageNotAvailable, false) Failed to pull function image
    (opc-request-id: AA3D3CEE50107C103AA662B8646A0EEE/01EGHCZXXNW1BT0750ZJ0058HCQ)
    opc-request-id AA3D3CEE50107C103AA662B8646A0EEE/01EGHCZXXNW1BT0750ZJ0058HCQ,
    statuscode 502", "target": "ocid1.fnfunc.oc1.iad.<unique_ID>"
  }
}
```

```json
{
  "specversion": "1.0",
  "type": "com.oraclecloud.eventsservice.eventrule.ruleexecutionlog",
  "source": "cmi-push-vcn-splunk-phoenix",
  "id": "52007b4c-225e-4d6c-9dea-077b884a94e9",
  "time": "2020-08-24T23:35:16Z",
  "oracle": {
    "logid": "ocid1.log.oc1.iad.<unique_ID>",
    "loggroupid": "ocid1.loggroup.oc1.iad.<unique_ID>",
    "compartmentid": "ocid1.compartment.oc1..<unique_ID>",
    "tenantid": "ocid1.tenancy.oc1..<unique_ID>",
    "ingestedtime": "2020-08-19T15:33:30.832Z"
  },
  "data": {
    "ruleId": "ocid1.eventrule.oc1.iad.<unique_ID>",
    "eventId": "24bc7219-efec-4ccd-350b-be2d833439d2",
    "message": "Event failed to deliver to FAAS. Exception from FAAS endpoint
    https://ptktjbkp22a.us-ashburn-1.functions.oci.oraclecloud.com,
    exception message:
    (502, FunctionInvokeImageNotAvailable, false) Failed to pull function image

    opc-request-id AA3D3CEE50107C103AA662B8646A0EEE/01EGHCZXXNW1BT0750ZJ0058HCQ,
    statuscode 502", "target": "ocid1.fnfunc.oc1.iad.<unique_ID>"
  }
}
```
Logging

"tenantid": "ocid1.tenancy.oc1..<unique_ID>!
"ingestedtime": "2020-08-19T15:33:30.832Z"
}
"data": {
"ruleId": "ocid1.eventrule.oc1.phx.<unique_ID>
"eventId": "30bde0fa-af8a-f50c-aa01-4fc42f28acb9",
"message": "Rule has matched event"
}
}

Events Log Object Name

Objects that store Events log data use the following naming format:

Rule_Execution_Log/<event_rule_OCID>/<YYYY-MM-DDTHH_MMZ>[_<seqNum>].log.gz

For example:

Rule_Execution_Log/
ocid1.eventrule.oc1.phx.<unique_ID>/2019-03-21T00_00Z.log.gz
Rule_Execution_Log/
ocid1.eventrule.oc1.phx.<unique_ID>/2019-03-21T00_00Z_2.log.gz

Details for Functions

This topic provides details for Functions logs.

Resources

• applications

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>invoke</td>
<td>Function Invocation Logs</td>
<td>Logs entries each time a function in an application is invoked.</td>
</tr>
</tbody>
</table>

Availability

Functions logging is available in all the regions of the commercial realm.

Comments

To use Functions logging, you must add a print statement to your function.

Examples:

For node js:

```javascript
console.log('Entering Hello Node.js function');
```

For java:

```java
System.out.println("Entering Java Hello World Function");
```

For go:

```go
fmt.Println("Entering Hello Go function")
```
## Contents of a Functions Log

<table>

</table>

## An Example Functions Log

```json
{
    "specversion": "1.0",
    "type": "com.oraclecloud.functions.application.functioninvoke",
    "source": "Application display name",
    "subject": "Function display name",
    "id": "487c8669-f384-4c79-950a-d6df47246093",
    "time": "2020-08-19T15:33:29.000Z",
    "oracle": {
        "logid": "ocid1.log.oc1.iad.<unique_ID>",
        "loggroupid": "ocid1.loggroup.oc1.iad.<unique_ID>",
        "compartmentid": "ocid1.compartment.oc1..<unique_ID>",
        "tenantid": "ocid1.tenancy.oc1..<unique_ID>",
        "ingestedtime": "2020-08-19T15:33:30.832Z"
    },
    "data": {
        "applicationId": "ocid1.fnapp.oc1.iad.<unique_ID>",
        "containerId": "01EG3NN3C11BT19PGZJ00000WZ/01EG3NN3C11BT19PGZJ00000W0",
        "functionId": "ocid1.fnfunc.oc1.iad.<unique_ID>",
        "requestId": "/01EG3NN3C11BT19PGZJ00000VZ/01EG3NN3C11BT19PGZJ00000W0",
        "src": "STDERR",
```
Functions Log Object Name

Objects that store Functions log data use the following naming format:

\[ \text{log/}<\text{function-OCID}>/\langle YYY-MM-DD \rangle_/\langle \text{seqNum}\rangle].\text{log.gz} \]

For example:

\[ \text{log/ocid1.function.oc1.phx.}<\text{unique_ID}>/2019-03-21T00_00Z.log.gz \]
\[ \text{log/ocid1.function.oc1.phx.}<\text{unique_ID}>/2019-03-21T00_00Z_2.log.gz \]

Using the Command Line Interface (CLI)

See Functions Example on page 3362 for an example command to enable Functions logging.

Details for Load Balancer Logs

This topic provides details for load balancer access logs. See Log Management on page 3320 for more information on Load Balancer logging.

Resources

- load balancer

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Access Logs</td>
<td>Load balancer access logs.</td>
</tr>
<tr>
<td>Error</td>
<td>Error Logs</td>
<td>Load balancer error logs.</td>
</tr>
</tbody>
</table>

Availability

LBaaS access logs are available in all the regions of the commercial realm.

Load Balancer Access Log

Load balancer access logs capture detailed information about requests sent to the load balancer. Each access log entry contains:

- The time the request was received.
- Client and intermediate HTTP proxy IP addresses.
- Time taken at the load balancer and backend to process the request.

Limitations and Considerations

Some traffic might not be logged during a capture window because of capacity issues or system errors. In such cases, the following error log message is logged.

```
{"timestamp":"2020-08-05T00:12:39+00:00","errorLog":
{"type":"General","errorDetails": "Missed 100 access logs" }}
```

For traffic destined to the public IP of a load balancer, access logs record the corresponding private IP.
**Contents of an Access Log**

Access logs appear as a value in the **Log Data** field. This value is a JSON-formatted data with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>2020-04-20T00:56:18+00:00</td>
<td>Log entry generation time in ISO-8601 format.</td>
</tr>
<tr>
<td>clientAdd</td>
<td>192.168.0.33:7870</td>
<td>IP address and port number of the requesting client.</td>
</tr>
<tr>
<td>forwardedForAddr</td>
<td>192.168.0.33</td>
<td>IP address of the client and http proxies between client and load balancer.</td>
</tr>
<tr>
<td>host</td>
<td>a.com</td>
<td>Domain name which resolves to VIP address assigned to the load balancer.</td>
</tr>
<tr>
<td>backendAddr</td>
<td>192.168.0.34:8080</td>
<td>IP address and port number of the backend server, which processed the client request.</td>
</tr>
<tr>
<td>requestProcessingTime</td>
<td>0.003</td>
<td>Total time taken (in seconds, with millisecond precision), from when the load balancer starts receiving request from the client, until it completes sending responses to the client.</td>
</tr>
<tr>
<td>backendConnectTime</td>
<td>0.00</td>
<td>Time spent (in seconds, with millisecond precision), to establish backend server connection.</td>
</tr>
<tr>
<td>backendProcessingTime</td>
<td>0.002</td>
<td>Total time taken from the load balancer establishing a connection to a backend, until it completes receiving the response from the backend.</td>
</tr>
<tr>
<td>lbStatusCode</td>
<td>200</td>
<td>Status code of the response from the load balancer.</td>
</tr>
<tr>
<td>backendStatusCode</td>
<td>200</td>
<td>Status code of the response from the target.</td>
</tr>
<tr>
<td>receivedBytes</td>
<td>150</td>
<td>Total size of the request (in bytes), received from the client.</td>
</tr>
<tr>
<td>sentBytes</td>
<td>450</td>

## Logging

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingRulesEngineErrors</td>
<td>0</td>
<td>Routing rule engine error during policy evaluation for the request. Either 0 (no error) or 1 when any error occurs. If an error occurs, requests are forwarded to the default backend set attached to the listener.</td>
</tr>
</tbody>
</table>

### Load Balancer Error Log

Load balancer error logs capture detailed information about requests related to troubleshooting and monitoring. Each Error Log entry contains information such as the time the request was received, error type, and extra details related to the specific error.

### Contents of an Error Log

This value is JSON-formatted data with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>2020-08-04T21:25:27+00:00</td>
<td>Log entry generation time in ISO-8601 format.</td>
</tr>
<tr>
<td>type</td>
<td>frontDoor</td>
<td>Error log Category.</td>
</tr>
<tr>
<td>errorDetails</td>
<td>Access for client 160.34.88.6 forbidden by ACL rule</td>
<td>Detailed description of the error message.</td>
</tr>
</tbody>
</table>

### Sample Error Logs

### Details for Object Storage

This topic provides details for Object Storage logs.

### Resources

- buckets

### Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>write</td>
<td>Write Access Events</td>
<td>Includes logs for write events.</td>
</tr>
</tbody>
</table>
API value (ID): | Console (Display Name) | Description |
---|---|---|
read | Read Access Events | Includes logs for read events. |

**Availability**

Object Storage logging is available in all the regions of the commercial realm.

**Comments**

Choose the log category for the type of information that you want to log. For example, if you enable a write log, the `requestAction` property would contain values of PUT, POST, or DELETE. If you enable a read log, `requestAction` would contain values of GET, LIST, or HEAD.

**Note:**

Service logs for Object Storage are delivered on a best effort basis. In limited situations, a small number of log entries may not be delivered successfully.

**Contents of an Object Storage Log**

"principalId": "ocid1.user.oc1..<unique_ID>"
}
```
Object Storage Log Object Name

Objects that store Object Storage data use the following naming format:

```
public_log/<bucket_name>/<YYYY-MM-DDTHH_MMZ>[<seqNum>].log.gz
```

For example:

- `public_log/example_bucket/2019-03-21T00_00Z.log.gz`
- `public_log/example_bucket/2019-03-21T00_00Z_2.log.gz`

Using the Command Line Interface (CLI)

See Object Storage Example on page 3361 for example commands.

Details for VCN Flow Logs

This topic provides details for VCN Flow logs.

Resources

- subnet

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>Flow Logs (All records)</td>
<td>Includes both accept and reject records in VCN flow logs.</td>
</tr>
</tbody>
</table>

Availability

VCN Flow Logs are available in all the regions of the commercial realm.

Comments

Each instance in a VCN has one or more virtual network interface cards (VNICs). The Networking service uses security rules to determine what traffic is allowed through a given VNIC. Security rules can be defined using Security lists or Network security groups.

To help troubleshoot the traffic in and out of your VNICs, you can set up VCN flow logs. Flow logs record details about traffic that has been accepted or rejected based on the security rules set up for your VCN.

You can enable flow logs for a given subnet, which means traffic is logged for all existing and future VNICs in that subnet. Each flow log contains information about traffic for a single VNIC.
Note:
Certain traffic to core Oracle infrastructure services hosted on link-local (169.254.0.0/16) IP addresses do not appear in flow logs. This includes items such as VCN DNS, DHCP, and block storage. Also excluded is network management traffic, such as ARP.

Contents of a VCN Flow Log
A flow log record contains the following fields:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.action</td>
<td>Type of record. Possible values:</td>
<td>ACCEPT</td>
</tr>
<tr>
<td></td>
<td>• ACCEPT: This record's traffic was accepted by the security lists.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REJECT: This record's traffic was rejected by the security lists.</td>
<td></td>
</tr>
<tr>
<td>data.bytesOut</td>
<td>Number of bytes recorded in the capture window.</td>
<td>17114</td>
</tr>
<tr>
<td>data.destinationAddress</td>
<td>IP address of the destination, either in IPv4 dot, or IPv6 colon notation.</td>
<td>10.0.99.4, 8222:91f5:88bb:2bf0:94a:e71b:65d3:4bd7</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> When IPv6 traffic is encountered in a customer's virtual cloud network, a flow log entry with IPV6 address values is generated, in place of the current location of IPV4 values. The source and destination addresses could be either IPv4 or IPv6, based on the configuration and traffic present in the customer’s VCN. This data is only available in regions where IPv6 support is generally available, and configured by the customer.</td>
<td></td>
</tr>
<tr>
<td>data.destinationPort</td>
<td>IANA port number of the destination.</td>
<td>36266</td>
</tr>
<tr>
<td>data.endTime</td>
<td>End time of the capture window in UNIX epoch seconds.</td>
<td>1598917970</td>
</tr>
<tr>
<td>data.flowid</td>
<td>Hash of key fields (source and destination addresses, ports, and protocol).</td>
<td>a6a73770</td>
</tr>
<tr>
<td>data.packets</td>
<td>Number of packets recorded in the capture window.</td>
<td>250</td>
</tr>
<tr>
<td>data.protocol</td>
<td>IANA protocol number.</td>
<td>6</td>
</tr>
<tr>
<td>data.protocolName</td>
<td>IANA name for protocol.</td>
<td>TCP</td>
</tr>
<tr>
<td>data.sourceAddress</td>
<td>IP address of the source, either in IPv4 dot, or IPv6 colon notation.</td>
<td>123.0.0.1, 1fde:9f1c:2433:4038:68fe:e0b:73f3:3b3b</td>
</tr>
<tr>
<td></td>
<td>See the note in the data.destinationAddress description.</td>
<td></td>
</tr>
<tr>
<td>data.sourcePort</td>
<td>IANA port number of the source.</td>
<td>443</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Sample Value</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
</tbody>
</table>
| data.startTime   | Start time of the capture window in Unix epoch seconds. UNIX epoch time uses a fixed point in the past to reference the current time. That means that every second of the current time can be expressed as a number, such as 1576090259 (which is Wednesday, December 11, 2019 6:50:59 PM GMT). Each flow log record records a one-minute interval (0 to 59 seconds) of data flow, using epoch start and end times to indicate the time that data appears during the 60-second interval for that record. Let's consider the epoch time entries that would appear for data flow during a fixed interval of 140 seconds. At five seconds past a particular minute, you open a connection to your host and begin to continuously send data over that connection for the next 140 seconds (< three minutes, three records). Epoch start and end times would appear in the log according to the following:  
- The first record would show an epoch start time at the five seconds past the minute mark and an epoch end time at the end of that minute (54 seconds later).  
- The next record would show an epoch start time at the zero-seconds mark, and epoch end time at the end of that minute (59 seconds later). This assumes you sent the data continuously. If your transmission had been intermittent, the epoch times would reflect the first and last second data flow that occurred during that 60-second interval (the absolute time).  
- The final record would show an epoch start time at the zero-seconds mark, and an epoch end time for 20 seconds later (since the total flow life was only 140 seconds, or 20 seconds into the third one-minute logging interval recorded by each record). | 1598917969 |
| data.status      | Status of data capture window. Possible values:  
- OK: Normal packet log.  
- NODATA: No traffic was recorded during the capture window, in which case, only the following data fields are set: endTime, startTime, status, and version. The remaining data fields are set to null: action, bytesOut, destinationAddress, destinationPort, flowid, packets, protocol, protocolName, sourceAddress, and sourcePort.  
- SKIPDATA: Some traffic was not logged during the capture window because of system errors or capacity issues, in which case, only data fields endTime, startTime, status, and version are set, and the remaining data fields are set to null. The flow log can contain other records for accepted or rejected traffic in the capture window. | OK          |
<p>| data.version     | Version of the flow log record schema.                                                                                                                                                                      | 2            |
| datetime         | Timestamp in milliseconds. Same as the oracle.ingestedtime field but in milliseconds.                                                                                                                                 | 159891795000 |
| id               | Random UUID, unique to each log entry.                                                                                                                                                                      | abcdeadbed-abed-abed-abcdabcdabcd |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.compartmentid</td>
<td>OCID of the compartment the log group is in.</td>
<td>ocid1.compartment.oc1.&lt;region-id&gt;.&lt;unique-id&gt;</td>
</tr>
<tr>
<td>oracle.ingestedtime</td>
<td>Time the log was ingested by OCI Logging.</td>
<td>2020-08-31T23:53:54Z</td>
</tr>

<td>1.0</td>
</tr>
<tr>
<td>time</td>
<td>Same as startTime.</td>
<td>2020-08-31T23:52:35Z</td>
</tr>
<tr>
<td>type</td>
<td>Category of log: DataEvent, QualityEvent.NoData, or QualityEvent.SkipData.</td>
<td>com.oraclecloud.vcn.flowlogs.DataEvent</td>
</tr>
</tbody>
</table>

**Limitations and Considerations**

- Some traffic might not be logged during a capture window because of capacity issues or system errors. In such cases, NODATA, or SKIPDATA log status is recorded.
- Some services manage VNICS. For example, the Load Balancing service manages VNICS attached to load balancers. Flow logs for managed VNICS are captured, and identified by VNIC ID. Flow logs, however, currently do not include a field to indicate what service such VNICS belong to.
- For traffic over the public IP of a Compute instance, flow logs records the corresponding private IP.

**Using the Command Line Interface (CLI)**

See [VCN Flow Logs Example](#) on page 3361 for example commands.

**Details for Site-to-Site VPN**

This topic provides details for Site-to-Site VPN logs.

**Resources**

- IPSecConnection

**Log Categories**

</tbody>
</table>
Logging

Availability

See Site-to-Site VPN v2 availability on page 4034 for up-to-date information on Site-to-Site VPN logging availability.

Comments

Site-to-Site VPN logs contain all status-related information of the IPSec tunnels associated with the site-to-site type of IPSec connections. This includes bringing of tunnels up or down, and accompanying negotiation information. Each IPSec connection has two IPSec tunnels created, thus the Site-to-Site VPN logs will contain status on both tunnels. Amongst other types of filtering, IPSec tunnels can be distinguished and thus filtered on their data.TunnelId (see Contents of a Site-to-Site VPN Log on page 3401 below for details).

Most Site-to-Site VPN log messages begin with a connection name. The connection name is unique for each IPSec tunnel. Its base form is comprised of ten numeric digits (see the sample value for the data.message property in the table below). In total, a connection name has three additional variants, and which variant(s) are used is based on the following:

1. Each IPSec tunnel has a unique ten-digit key assigned to (for example, 9123456789) which is contained in the beginning of many of the IPSec log messages. This is the form for IPv4 tunnels.
2. If the given IPSec tunnel is also configured for IPv6, IPSec log messages can also contain the same ten-digit key with a _v6 appended to it (for example, 9123456789_v6).
3. If the tunnel is policy-based (that is, MED is enabled) there can be multiple SAs depending on the configuration. The form of the ten-digit key for IPv4 tunnels with multiple SAs is a sequence of _1, _2, _3, and accordingly depending on the number of SAs (for example, 9123456789_1, 9123456789_2, 9123456789_3).
4. If the given policy-based tunnel is also configured for IPv6, IPSec log messages can also contain the same ten-digit key and SA index, along with v6 (for example, 9123456789_v6_1).

Contents of a Site-to-Site VPN Log

A Site-to-Site VPN log contains the following fields:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.message</td>
<td>The Site-to-Site VPN log message.</td>
<td>&quot;2062988354&quot;: terminating SAs using this connection</td>
</tr>
<tr>
<td>data.tunneld</td>
<td>The IPSec tunnel OCID of one of the IPSec connection's IPSec tunnels.</td>
<td>ocid1.ipsectunnel.region1.sea.&lt;uniqueId&gt;</td>
</tr>
<tr>
<td>id</td>
<td>Random UUID, unique to each log entry.</td>
<td>e3002eaa-d717-472e-8474-d024943a0f27</td>

<td>--------------</td>
</tr>
<tr>
<td>time</td>
<td>Time the log was generated in the IPSec tunnel.</td>
<td>2021-02-18T18:21:52.024Z</td>
</tr>
<tr>
<td>type</td>
<td>Category of the log. Set of possible values: read</td>
<td>com.oraclecloud.vpn.ipseclog.read</td>
</tr>
</tbody>
</table>

**An Example Site-to-Site VPN Log**

```json
{
  "message": "2062988354": terminating SAs using this connection",
  "tunnelId": "ocid1.ipsectunnel.region1.sea.uniqueId",
  "id": "e3002eaa-d717-472e-8474-d024943a0f27",
  "oracle": {
    "tenantId": "ocid1.tenancy.region1..uniqueId",
    "ingestedtime": "2021-02-18T18:22:01.453Z",
    "loggroupid": "ocid1.loggroup.region1.sea.uniqueId",
    "logid": "ocid1.log.region1.sea.uniqueId",
    "tenantId": "ocid1.tenancy.region1..uniqueId"
  },
  "source": "ocid1.ipsecconnection.region1.sea.uniqueId",
  "specversion": "1.0",
  "time": "2021-02-18T18:21:52.024Z",
  "type": "com.oraclecloud.vpn.ipseclog.read"
}
```

**Troubleshooting**

An error is displayed on the log details page if you attempt to enable logs for a v1 Site-to-Site VPN connection. Only v2 connections are supported.

**Audit Logs**

On the Audit page, you can explore audit logs. Audit logs are also searchable on the Search page, and you can view Audit logs in every compartment by selecting the Audit log group on the Search page. For an overview of Audit, see Overview of Audit on page 598.

**Required Permissions for Audit Logs**

To view and search Audit logs, you must have the corresponding Audit-related permissions. See Details for the Audit Service on page 2850 and Required Permissions for Searching Logs on page 3420 for more information.

**Filtering Audit Logs**

To filter audit logs:
1. Open the navigation menu and click Observability & Management. Under Logging, click Audit. The list of audit logs in the current compartment is displayed.

2. Choose a compartment you have permission to work in.

3. In User, add user filters. Multiple users can be added.

4. In Resource, add resource filters. Multiple resources can be filtered on.

5. In Request Action Types, select an action operation:

   - GET
   - POST
   - PUT
   - PATCH
   - DELETE

   Multiple request action types can be filtered on.

6. In Event Type, add event filters. Multiple event filters can be added.

7. In Custom Filters, start typing to automatically display filter settings, along with operators. For example, entering `d` displays filters starting with that letter. Use the up or down arrow keys to select from the list, or continue typing to enter what you want to filter on. This functions the same as this field on the Logging Search page.

   **Note:**

   If you want to find log events with a specific status code, include quotes ("), around the code to avoid results that have those numbers embedded in a longer string.

8. In Filter by Time, select from one of the preset time periods:

   - Past 5 Minutes (the default)
   - Past 15 Minutes
   - Past Hour
   - Past 3 Hours
   - Today
   - Custom (choose your own using the Start Date and End Date fields)

9. After entering your search text or filters, click Apply.

   **Note:**

   Since the Audit page automatically refreshes after applying filters, you do not need to click the Apply button as you select different filters. You will, however, need to click Apply again after some time has passed and new logs have appeared.

The Convert to search option allows viewing your Audit Log results in the Search page, to further search and perform analysis across other logs in the system. When you use this option, the Advanced Search version of the Search page is filled with the chosen filter parameters (available in the Query field).

Click View query syntax to view the actual syntax query statement(s) associated with your filter settings. If you have applied multiple filters for a field, you can view how the query is constructed in terms of the combined OR and AND statements.

**Exploring the Details of Events**

On the Explore Events tab, each log entry is organized in terms of the Event Time, User, Resource, Type, Action, and Status. Click and expand an audit log entry. Each entry displays the log data in a JSON field view, similar to the Search page, where you can collapse and expand nodes, or click the copy icon to copy the log entry to the clipboard.

**To export log data**

At the top right portion of Explore Events, click Export Log Data (JSON). This feature allows you to export the log data to a JSON file that you can save to your system.
Logging

Viewing the Activity Stream

Click the **Activity Stream** tab to view the audit logs as a visual sequential list (by date, from newest to oldest log event). You click and expand an event to display the event in JSON format, and you can click the copy icon to copy the audit event to the clipboard.

Exporting Audit Events

Audit events can be exported using Service Connector Hub on page 4752.

Audit Schema

See Version 2 Audit Log Schema on page 598 for more information on the audit logging schema.

Custom Logs

Custom logs are logs that contain diagnostic information from custom applications, other cloud providers, or an on-premise environment. Custom logs can be ingested in the following ways:

- By using PutLogs to ingest custom logs directly. See the Logging Ingestion API and REST APIs on page 5528 for more information. Also see Using the API on page 3419 for an example log entry payload that can be used with PutLogs.
- By configuring the Unified Monitoring Agent. See Installing the Agent on page 3406 for instructions.

Note:

When managing Oracle Cloud Agent plugins, the Unified Monitoring Agent is referred to as "Custom Logs Monitoring".

Custom logs can be viewed in the Oracle Cloud Infrastructure Compute instance page, and have an associated Logs resource. They can also be viewed on the Logging Search page, Logs page, or within an associated Log Groups detail page. Custom logs are also supported in bare metal instances.

The agent can be installed on many machines, and it pulls logs from local directories, where your apps or systems emit logs. The agent can also parse your logs for you. All of this is configured in Agent Configurations. You can create an agent configuration separately, and then associate a custom log with it, or create a custom log and then later create its agent configuration.

An agent configuration is the central mechanism for defining:

- What hosts you want logs from.
- What specific logs you want from the hosts.
- Additional parsers.
- The custom log destination.

Creating a custom log is a two-step process, in that you create the custom log object first, and then second, create its associated agent configuration. See Creating Custom Logs on page 3404 for more information on creating custom logs and agent configurations, and Agent Management on page 3406 for more information on setting up and managing the agent.

Note:

For the agent to run correctly, ensure that your firewall settings allow the following URI endpoints:

- https://auth.<your region>.oraclecloud.com

Creating Custom Logs

To create custom logs:
1. Open the navigation menu and click Observability & Management. Under Logging, click Logs.

2. Under List Scope, Compartment, choose a compartment you have permission to work in.

3. In Custom Log Name, enter a name for the custom log. Avoid entering confidential information.

4. From Compartment, choose a compartment you have permission to work in.

5. From Log Group, select a log group to place the custom log into.

6. Optionally, select a log retention value from Log Retention, and add any applicable tags in Add Tags.

7. Click Create Log Object. The Create Agent Configuration panel is displayed. You can next create a new configuration, to define the parameters for the associated log data (the default), or add it later.

8. In Name and compartment, enter a Configuration Name in the corresponding field, and select a Compartment you have permissions to work in.

9. In Choose Host Groups, which allows you to define which VMs apply to this configuration, select a Group Type from the list, whether Dynamic Group or User Group.

   For the Dynamic Group case, Dynamic Group refers to a group of instances, which you can create in the IAM feature of the Console. See About Dynamic Groups on page 3118 for more information. These Dynamic Groups can be selected from the Groups field when setting up Dynamic Group settings.

   For the User Group case, select the group from the Groups field. User Groups also refer to the IAM Groups feature of the Console. See Managing Groups on page 3115 for more information.

   Click Add Host Group to add more groups. You can add a combination of Group Types for the agent configuration, that is, both Dynamic Groups and User Groups can be set up in the configuration.

   **Note:**
   A maximum of five groups per configuration are allowed, and a host can be in a maximum of five different groups.

10. Next, in the configuration, you need to define the format of the logs (that is, what logs do you want to watch for) in Configure Log Inputs. Select an Input Type from the list, whether Windows Event Log or Log Directory.

    - For Windows Event Log, enter an Input Name and select an Event Channels option from the list.
    - For Log Directory, enter an Input Name and a Path in the corresponding fields. For example, /<log_path>/</log_name>. Multiple paths can be entered.

   Click Advanced Parser Options, which opens the Advanced Parser Options panel. This allows you to specify how to parse the log, according to the following parsers. Some of the parsers require further input and have more options, depending on the type chosen.

   - AUDITD
   - JSON
   - TSV
   - CSV
   - NONE (the default)
   - SYSLOG
   - APACHE2
   - APACHE_ERROR
   - MSGPACK
   - REGEXP
   - MULTILINE

   For example for JSON, you must select a Time Type value from the list, while optionally, you can specify event time and null field settings. Meanwhile for REGEXP, you specify the regular expression for matching logs, along with the time format. See Log Inputs and Parsers on page 3411 for more information.

11. After configuring the log inputs and the parser, you can optionally specify any tag settings. Click Submit to save your changes, and create the custom log and its associated agent configuration.

   In summary, the agent configuration defines what instances the configuration applies to (Choose Host Groups), which log files are obtained and what parser (if any) is used (Configure Log Inputs), and to what log object in the
Oracle Cloud Infrastructure system that the records are pushed to (Select log destination). The latter is already set up since this was set during the custom log creation step.

The custom log object is now created, as well as the agent configuration, which pulls data from instances, and pushes into the custom log object.

Agent Management

To ingest events from your applications into your custom log, you can install the Oracle fluentd-based agent. This agent allows you to control exactly which logs you want to collect, how to parse them, and more.

**Note:**

The Unified Monitoring Agent is a fully managed agent, and custom client configuration is not officially supported. For example, gathering logs from remote sources is not recommended, since doing so can have serious security implications (because the log source cannot be verified).

Oracle Cloud Infrastructure Logging provides an easy mechanism (Agent Configurations) to enable and manage the agent for a set of supported operating systems. Agent Configurations give you a central experience to easily configure what custom logs you want to ingest across your fleet of hosts. The following are the supported operating systems for agent configurations:

- Oracle Linux 7, Oracle Linux 8
- CentOS 7, CentOS 8
- Ubuntu 16.04, Ubuntu 18.04, Ubuntu 20.04

**Note:**

For Linux, only register Linux-specific input types, such as "Log Path", for a dynamic group that includes only a Linux instance. For Windows, only register Windows-specific input types, such as "Windows event log", for a dynamic group that includes only a Windows instance. Otherwise, the Unified Monitoring Agent malfunctions if you register a Windows input type for a Linux instance, and vice versa.

Installing the Agent

**New Oracle Cloud Infrastructure Instances**

For supported operating systems, you can enable the agent directly during creation time. The Custom Logs Monitoring plugin must be enabled, and all plugins must be running. See Managing Plugins with Oracle Cloud Agent on page 1089 for more information.

**Existing Oracle Cloud Infrastructure Instances**

For existing instances with supported operating systems, the Custom Logs Monitoring plugin must be enabled, and all plugins must be running. See Managing Plugins with Oracle Cloud Agent on page 1089 for more information.

If you already have the monitoring plugin enabled, then your instance will be automatically patched to install the agent by September 18, 2020. Otherwise, you can follow the manual installation instructions:

**Linux:**

1. **Connect to the instance.**
2. You can obtain the agent by using this script, and then run the script to download the agent. For example:

```bash
./downloadAgent.sh centos7
./downloadAgent.sh centos8
./downloadAgent.sh oel7
./downloadAgent.sh oel8
```
Otherwise, you can download the agent for the following individual operating systems:

- Oracle Linux 7 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ol7-repo/o/unified-monitoring-agent-0.0.8.rpm
- Oracle Linux 8 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ol8-repo/o/unified-monitoring-agent-0.0.8.rpm
- CentOS 7 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-centos7-repo/o/unified-monitoring-agent-0.0.8.rpm
- CentOS 8 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-centos8-repo/o/unified-monitoring-agent-0.0.8.rpm
- Ubuntu 16 DEB: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ubuntu16-repo/o/unified-monitoring-agent-0.0.8.deb
- Ubuntu 18 DEB: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ubuntu18-repo/o/unified-monitoring-agent-0.0.8.deb
- Ubuntu 20 DEB: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ubuntu20-repo/o/unified-monitoring-agent-0.0.8.deb

For the FIPS-enabled agent:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance is impacted when using the FIPS-enabled agent.</td>
</tr>
</tbody>
</table>

- CentOS 7 RPM: https://objectstorage.us-langley-1.oraclegovcloud.com/n/iaashydra/b/agent-manual-download-centos7-repo/o/unified-monitoring-agent.rpm

3. Run the following command to install the RPM:

   yum install -y <rpm-name>

   For Ubuntu:

   apt install -y <deb-package-name>

Windows:

1. Connect to the instance.
2. Download the agent from: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-windows-repo/o/unified-monitoring-agent-0.0.7.msi
3. Open an elevated command prompt (running as Administrator), and run the MSI command (installation can take up to five minutes to complete):

   C:\path\to\file\unified-monitoring-agent-0.0.2.msi

4. For a more advanced version of the preceding command (to debug MSI installation issues), run:

   msiexec /i "C:\path\to\file\unified-monitoring-agent-0.0.2.msi" /l*v "C:\unified-monitoring-agent_msi.log"
Instances Created from Custom Images and Non-Oracle Cloud Infrastructure Instances

1. Install the agent according to the same steps in Existing Oracle Cloud Infrastructure Instances on page 3406.
2. Configure User API keys for the instance you are running on. To generate the user API key, follow the instructions described in How to Generate an API Signing Key on page 5304.
   - (Linux) Step 2a. Place the ".oci" directory and its contents under /etc/unified-monitoring-agent.
   - (Windows) Step 2a. For Windows, there are a few steps that differ, so ensure to follow the appropriate steps. Create the ".oci" folder and its contents in the directory C:\oracle_unified_agent.
3. Follow the instructions described in Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768, to create the configuration file with the modifications in the next step.
4. After following the steps in Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768, ensure to name the profile (<profile-name>) for this section as "UNIFIED_MONITORING_AGENT".

The following is an example of what the configuration looks like for the Unified Monitoring Agent to use for authentication with the service:

```
[UNIFIED_MONITORING_AGENT]
user=ocid1.user.region..aaa...
fingerprint=<cert fingerprint>
key_file=/path/to/ocifolder/.oci/private.pem
tenancy=ocid1.tenancy.region..aaa...
region=<instances region>
pass_phrase="pashphrase1234"
```

Verify Agent Installation

Windows:

1. Connect to the instance.
2. Open Services.msc (Start menu and type services.msc). Scroll until you see the "Oracle Unified Monitoring Agent" and that the agent is in a "Running" state.
3. In the Task Scheduler under Task Scheduler Library, verify that the UnifiedAgentConfigUpdater exists, and has (or will) run successfully. After the initial install, it can take up to 20 minutes for the first run. If preferred, this can be run manually.
4. After the UnifiedAgentConfigUpdater task has run, verify that a "unified-monitoring-agent.conf" file in exists in C:\oracle_unified_agent.
5. After a few minutes, supervisor (unified-monitoring-agent-supervisor-0.log) logs and worker (unified-monitoring-agent-0.log) logs appear in the C:\oracle_unified_agent directory.
6. The preceding logs contain the Fluentd parser and plugin output.

Oracle Linux 7, Oracle Linux 8, CentOS 7, CentOS 8, Ubuntu 16, Ubuntu 18, and Ubuntu 20:

1. Connect to the instance.
2. Check that the agent is running by running the following command:

```
systemctl status unified-monitoring-agent
```
3. The status looks like the following:

```
Loaded: loaded (/usr/lib/systemd/system/unified-monitoring-agent.service; enabled; vendor preset: disabled)
Active: active (running) since Thu 2020-09-10 18:11:45 GMT; 2h 14min ago
Docs: https://docs.cloud.oracle.com/
```

Managing Agent Configurations

To use agent configurations, you must be running an Oracle Cloud Infrastructure instance with the supported operating system (see Agent Management on page 3406). Agent configurations give you a central experience to easily configure what custom logs you want to ingest across your fleet of hosts. A configuration allows you to select:
Logging

- Which hosts you want to collect logs from.
- Exactly which logs you want to ingest from those hosts.
- A log group/log destination.

Configurations are managed through the Console and Logging API. In addition, since you can choose to create an agent configuration later after creating a custom log, you can use the Agent Configurations page to set up the agent configuration and point it to your custom log.

The Agent Configurations page is organized in terms of the following:

- Name
- Config OCID
- Status
- Created

To create a new agent configuration

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click Create Agent Config. The Agent Configurations panel is displayed.
4. In Name and compartment, enter a Configuration Name in the corresponding field, and select a Compartment you have permissions to work in. Avoid entering confidential information.
5. In Choose Host Groups, select a Group Type from the list, whether Dynamic Group or User Group. Click Add Host Group to add more groups.
6. In Configure Log Inputs, select an Input Type from the list, whether Windows Event Log or Log Directory.
   - For Windows Event Log, enter an Input Name and select an Event Channels option from the list.
   - For Log Directory, enter an Input Name and a Path in the corresponding fields.
7. In Select log destination, the User Group or Dynamic Group in the configuration that you select in Compartment needs to have permission to work in the compartment. Select the Log Group, and the Log Name from the corresponding drop-down lists. The Log Name can only point to a custom log and the custom log must exist in the chosen log group for the configuration to work.
8. Optionally, after clicking Show Additional Options, specify any preferred tag settings.
9. Click Create. The agent configuration is created and appears in the Agent Configurations page.

To view an agent configuration

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under Name in the table. The agent configuration detail page is displayed. This page displays the following on the Log Information tab:
   - OCID
   - Compartment
   - Created date and time in UTC format
   - Status (Creating, Active, Updating, Inactive, Deleting, Deleted)
   - The Tags tab shows associated tags for this log.
   - Under Log Details the following is displayed: the compartment, the linked log group and log name.

In the Configuration resource, the Host Group and Log Input configuration settings are listed in corresponding tables. Under Host Group you can view the Group Type, Group Name, and the OCID. Click the linked Group Type (whether a User Group or Dynamic Group), which opens the IAM Groups or Dynamic
Groups section of the Console, respectively. See Managing Groups on page 3115 and About Dynamic Groups on page 3118 for more information.

Under Log Input you can view the Input Type, Input Name, File Paths, Parser, and Parser Parameters (if applicable for the chosen parser).

In the Explore Log resource, log data is displayed in a similar manner as the Log Data on the Search page. You can apply some simple filters, such as sorting by newest or oldest from the Sort field, or filtering by time from the corresponding Filter by Time field.

Clicking Explore with Log Search allows you to view this log on the Search page directly. After clicking this link, the Search page opens with the Select Logs to Search field populated with the log in the filter settings. At this point, you can perform more analysis and investigation related to this log directly on the Search page. For more information, see Searching Logs on page 3420.

**To edit an agent configuration**

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under Name in the table. The agent configuration detail page is displayed.
4. Click Edit. The Agent Configurations panel is displayed.

   From the main Agent Configurations page, for the agent configuration you want to edit, you can also click the the Actions icon (three dots), and then click Edit to access the Agent Configurations panel.
5. Make your changes and click Update.

**To enable or disable an existing agent configuration**

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under Name in the table. The agent configuration detail page is displayed.
4. Click Disable/Enable. A confirmation dialog is displayed regarding the disabling or enabling of the agent configuration.

   Confirm by clicking Disable/Enable. The agent configuration detail page changes its status and displays Inactive (for a disabled configuration), or Active (for an enabled configuration) in the status field, both on the agent configuration detail page and the Agent Configurations page.

   From the main Agent Configurations page, for the agent configuration you want to disable/enable, you can also click the the Actions icon (three dots), and then click Disable/Enable.

**To delete an agent configuration**

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under Name in the table. The agent configuration detail page is displayed.
4. Click Delete. A confirmation dialog is displayed regarding the delete operation.

   Confirm by clicking Delete. The agent configuration is removed from the Agent Configurations page.

**To move an agent configuration to a different compartment**

1. Open the navigation menu and click Observability & Management. Under Logging, click Agent Configurations. The Agent Configurations page is displayed.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under **Name** in the table. The agent configuration detail page is displayed.
4. Click **Move Resource**. The **Move Resource to a Different Compartment** dialog is displayed.
5. Choose the new compartment and then click **Move Resource**.
   
   From the main **Agent Configurations** page, for the agent configuration you want to move to a new compartment, you can also click the the Actions icon (three dots), and then click **Move Resource**.

**Selecting Target Hosts with Dynamic Groups**

To set up a configuration for multiple hosts, you can use the **Dynamic Group** feature from IAM. The overall process first involves creating a compartment, then placing all the instances in the compartment you want to collect logs from. Next, you can create the Dynamic Group. The Dynamic Group policy statement would then point to the compartment that contains the instances. Lastly, create a log group, custom log, and its associated agent configuration.

Set the following policy statement:

```
allow dynamic-group <dynamic_group_name> to use log-content in tenancy
```

This policy statement allows the agent configuration to push logs to the Logging service backend, which you can later see in the Logging Service's **Search** page.

In the Dynamic Groups configuration, set up your Dynamic Group to have a rule that includes all the agents that you want to use to send logs to the Logging service. For example, in a Rule inside the Dynamic Group it can state:

```
ANY {instance.id = 'ocid1.instance.<region>.<location>.<unique_ID>', instance.compartment.id = 'ocid1.compartment.<region>..<unique_ID>'}
```

If you remove `instance.id = 'ocid1.instance.<region>.<location>.<unique_ID>'` and just have:

```
ANY {instance.compartment.id = 'ocid1.compartment.<region>..<unique_ID>'}
```

this means use all the instances under this compartment to send logs. For more information on Dynamic Groups, see **About Dynamic Groups** on page 3118.

Next, create the log group (see **To create a log group** on page 3357). After the log group is created, you can then create the custom log and the agent configuration (see **Creating Custom Logs** on page 3404 for steps to create the custom log and agent configuration). During the agent configuration, you can use the Dynamic Group you created earlier and select it in the **Choose Host Groups** section of the **Agent Configurations** panel. This links the log configuration with the instance you want to send logs to. Once the agent configuration is active, the logs you see are sent by the instance, inside the Dynamic Group you earlier set up. You can later click **Explore with Log Search** in the agent configuration to view the logs through the **Search** page (see **Searching Logs** on page 3420).

**Log Inputs and Parsers**

Agent configurations allow you to easily select which types of logs you want to ingest, and how to parse them. The following are the supported log inputs in agent configurations:

- Windows Event Logs
- Log Directory (Tail)

For **Log Directory** inputs, you can specify parsers to structure your logs. The following are the list of supported parsers:

- None
- Auditd (https://github.com/linux-audit/audit-documentation/wiki)
- JSON (https://docs.fluentd.org/parser/json)
- CSV (https://docs.fluentd.org/parser/csv)
- TSV (https://docs.fluentd.org/parser/tsv)
Logging

- Syslog (https://docs.fluentd.org/parser/syslog)
- Apache2 (https://docs.fluentd.org/parser/apache2)
- Apache_Error (https://docs.fluentd.org/parser/apache_error)
- Msgpack (https://docs.fluentd.org/parser/msgpack)
- Regexp (https://docs.fluentd.org/parser/regexp)
- Multiline (https://docs.fluentd.org/parser/multiline)

Log Destination

You can choose the exact log group and log object where you want your log events to be indexed. All incoming log events from your hosts are ingested and indexed in your selected log object. After they are ingested, you can view and search your log events on the Search page (see Searching Logs on page 3420). All existing Oracle Cloud Infrastructure Identity and Access Management policies in both the log group and compartment apply both during ingestion and search. So, only authorized users can view and ingest logs in your tenancy.

Viewing Custom Logs in a Compute Instance

The Logs resource on a Compute Instance page allows you to view logging details for the instance in the selected compartment. Logging Search APIs are called and any available logs are pulled for the instance. Instances can have a customer application running on them (for example, a gaming server), and they can configure logs from the gaming server to be collected by the Unified Monitoring Agent, and then be pushed into the Logging service and be indexed there. Logs are pulled and displayed on the Logs resource. As such, when a customer views their Compute instance, they can see that their application is pushing logs to the Logging service. Logs, however, cannot be enabled or created from this interface.

Under Explore Logs, you can sort log entries (Newest, the default or Oldest), or filter by time (the default Past 5 minutes, Past 15 minutes, Past hour, Past 24 hours, Today, Custom). Otherwise the functionality is the same as when you are viewing logs under Log Data in the central logging Search page (see Using the Console on page 3421).

Click Explore with Log Search to open the central logging Search page, where you can add or remove filters and so on. The Search page loads with instanceid of the instance already set as a filter under Filters.

Click Create Custom Log to open the central Logs page, where you can create custom logs for the instance. Custom logs are sent from Oracle Cloud Infrastructure Compute VM instances.

For the Logs resource to be available on such an instance, the following is required:

- The Custom Logs Monitoring plugin must be enabled, and all plugins must be running. For more information, see Managing Plugins with Oracle Cloud Agent on page 1089.
- The instance must have one of the supported operating systems:
  - Oracle Linux 7, Oracle Linux 8
  - CentOS 7, CentOS 8
  - Windows 2012 R2, 2016, 2019
  - Ubuntu 16.04, Ubuntu 18.04, Ubuntu 20.04

If the operating system is not supported, then this Logs resource is not displayed. If the operating system is supported by the Oracle Cloud Agent and is not enabled, a warning is displayed that you must enable the agent to create logs.

Agent Troubleshooting

The following topics describe troubleshooting tips related to the Unified Monitoring Agent, for both Linux and Windows.

Hardware Requirements

Depending on your logging requirements and configuration (number of logs, type of buffering, and so on), the hardware requirements and performance of the Unified Monitoring Agent can vary widely. When no operational pressure is present (less than 1.000 log events per minute), the agent should not consume more than 200 MB of RAM,
Logging

and 20% of a CPU core. The Unified Monitoring Agent service hard-coded limits are 5 GB RAM, and 40% of a core.
1 GB of RAM is also recommended.

Enabling Monitoring

Monitoring can aid with troubleshooting. See Enabling Monitoring for Compute Instances on page 1154 for more
information on how you can enable monitoring (metrics and logging) in your Oracle Cloud Infrastructure Compute
instances.

Linux

systemd Units

The Unified Monitoring Agent is based on systemd units, and is composed of the following components:

1. unified-monitoring-agent.service: The main Unified Monitoring Agent service.
2. unified-monitoring-agent_config_downloader.service: The configuration automatic updater service.
3. unified-monitoring-agent_config_downloader.timer: The timer unit, which triggers the automatic downloder
   service on specified, randomized, intervals.
4. unified-monitoring-agent_restarter.path: The path unit, which triggers the reload of the configuration by the
   Unified Monitoring Agent, if a change is detected (because of a new configuration being downloaded by the
   automatic updater service).

Note:

Remember that most of the systemctl or journalctl commands must be run with super user privileges (either as root, or through sudo).

To verify the correct operation of these systemd units, you can use the systemctl command like the following:

systemctl status <unit_name>

Where <unit_name> must be replaced with one of the following values:

1. unified-monitoring-agent.service
2. unified-monitoring-agent_config_downloader.service
3. unified-monitoring-agent_config_downloader.timer
4. unified-monitoring-agent_restarter.path

Typically these systemctl commands show output similar to the following:

```bash
systemctl status unified-monitoring-agent.service
# unified-monitoring-agent.service - unified-monitoring-agent: Fluentd based data
collector for Oracle Cloud Infrastructure
   Loaded: loaded (/usr/lib/systemd/system/unified-monitoring-agent.service; enabled; vendor preset: disabled)
   Active: active (running) since Tue 2020-09-29 13:54:03 UTC; 1min 37s ago
     Docs: https://docs.cloud.oracle.com
   Process: 2337 ExecReload=/bin/kill -USR2 ${MAINPID} (code=exited, status=0/SUCCESS)
   Main PID: 2327 (fluentd)
   Memory: 66.3M (limit: 5.0G)
   CGroup: /system.slice/unified-monitoring-agent.service
```
The most important parts of the systemctl command output are the Loaded and Active fields. The Loaded field has the value loaded for all system units. The Active field has the following values:

- active (running) for the unified-monitoring-agent.service unit.
- active (waiting) or active (running) for the unified-monitoring-agent_restarter.path and the unified-monitoring-agent_config_downloader.timer units.
- active (running) or inactive (dead) for the unified-monitoring-agent_config_downloader.service unit. For the latter value, the field Main PID includes the value code=exited, status=0/SUCCESS).

Processes

Another way to further verify the correct operation of the Unified Monitoring Agent, is to check the system’s running processes. When operating correctly, the Unified Monitoring Agent runs two processes: one supervisor process, and one worker process. You can verify their existence by running the following command in a terminal (sample output included):

```
ps aux | grep unified-monitoring-agent[0-9]
```

```bash
```
As shown in the preceding sample, there are two processes running, with the same arguments, except for the extra `--under-supervisor` added to the second one. This denotes the worker process, thus making the process without this parameter the supervisor.

**Logs**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remember that most of the systemctl or journalctl commands must be run with super user privileges (either as root, or through sudo).</td>
</tr>
</tbody>
</table>

The Unified Monitoring Agent logs are available at `/var/log/unified-monitoring-agent/unified-monitoring-agent.log`. This file includes logs from the Unified Monitoring Agent itself.

Besides the agent's logs, which do not contain system-related events (for example, service start, service stop, and so on), you can also view the logs from journald, systemd's system logging service. To view the system logs specific to a unit, you can use the journalctl command like the following:

```
journalctl -u <unit_name>
```

Where `<unit_name>` must be replaced with one of the following values:

1. unified-monitoring-agent.service
2. unified-monitoring-agent_config_downloader.service
3. unified-monitoring-agent_config_downloader.timer
4. unified-monitoring-agent_restarter.path

When querying journald logs through journalctl, you can also define specific time ranges:

```
journalctl --since "2020-12-30 00:00:01" --until "2020-12-31 23:59:59"
```

The date format used is YYYY-MM-DD HH:MM:SS.

You can also tail the journal logs, by adding the `-f` parameter:

```
journalctl -f
```

**Troubleshooting Scenarios**

**Problem:** The Unified Monitoring Agent is not installed.

**Solution:** For newly created instances, it can take up to 25 minutes for the automatic installation of the agent. If it is not installed after this time period, check the following:

1. The network connectivity of the instance.
2. Whether monitoring is enabled in the Console.

You can also check the log file `/var/log/oracle-cloud-agent/plugins/unifiedmonitoring/unifiedmonitoring.log` for information regarding the installation of the Unified Monitoring Agent by the Oracle Cloud Agent.

**Problem:** The Unified Monitoring Agent is not running. Its status is not loaded/active, nor are both supervisor and worker processes running.

**Solution:** Restart the Unified Monitoring Agent and check the logs for any problems:

```
systemctl restart unified-monitoring-agent
```

**Problem:** Configuration is not automatically downloaded.
**Solution:** Ensure you have followed the steps in *Installing the Agent* on page 3406 and *Verify Agent Installation* on page 3408. Consult the journal of the automatic configuration updater service by running:

```
journalctl -u unified-monitoring-agent_config_downloader.service
```

**Problem:** Configuration is not automatically reloaded.

**Solution:** Ensure you have followed the steps in *Installing the Agent* on page 3406 and *Verify Agent Installation* on page 3408. Consult the journal of all the units:

1. The timer unit must have run at least one time.
2. The automatic configuration download service must have run after the relevant time unit has triggered it. You can verify from its logs that the configuration has been downloaded and extracted to the Unified Monitoring Agent's configuration directory. You can also verify this by listing the files in that directory:
   ```
   ls -lhatR /etc/unified-monitoring-agent
   `` `
3. Verify that the path unit is active by checking its status:
   ```
   systemctl status unified-monitoring-agent_restarter.path
   ```
4. Verify that a reload signal has been received by the Unified Monitoring Agent, by inspecting its journal:
   ```
   journalctl -u unified-monitoring-agent_config_downloader.service
   `` "Reloading unified-monitoring-agent" appears in the output of this command.

**Problem:** You are testing your parsing pattern and need to force the agent to download the configuration right away.

**Solution:** Run the following command:

```
systemctl restart unified-monitoring-agent_config_downloader
```

**Note:**
Automatic update of the configuration on the agent side can take up to 30 minutes.

**Data Collection**

If you want to open a ticket so an engineer can help you with your problem regarding the Unified Monitoring Agent, include the output of the following commands. Super user privileges might be required for some of them.

```
yum info unified-monitoring-agent
rpm -ql unified-monitoring-agent | xargs sha512sum
systemctl status --full unified-monitoring-agent.service
systemctl status --full unified-monitoring-agent_config_downloader.service
systemctl status --full unified-monitoring-agent_config_downloader.timer
systemctl status --full unified-monitoring-agent_restarter.path
journalctl -a --no-pager -u unified-monitoring-agent.service
journalctl -a --no-pager -u unified-monitoring-agent_config_downloader.service
journalctl -a --no-pager -u unified-monitoring-agent_config_downloader.timer
journalctl -a --no-pager -u unified-monitoring-agent_restarter.path
```

For Ubuntu use a command like the following:

```
apt show unified-monitoring-agent
dpkg -L unified-monitoring-agent | xargs sha512sum
```

Also include an archive of the files under `/var/log/unified-monitoring-agent/` and `/var/log/oracle-cloud-agent/`. You can create a gzipped tar archive of these directories with the command:

```
tar cvzf agent_logs_$(date +%s).tar.gz /var/log/unified-monitoring-agent/ /var/log/oracle-cloud-agent/
```
If the Unified Monitoring Agent is running but has erratic behavior, you can also include backtrace and memory profile information, by running the following command and including the files /tmp/sigdump-<integer>.log in your report (where <integer> is an integer with 1–6 digits, even though in rare cases it might have more than that).

```
ps aux | grep unified-monitoring-agent[t] | grep ruby | awk '{print $2}' | xargs kill -SIGCONT
```

What this command does is to find the Unified Monitoring Agent process PIDs, and send them the SIGCONT signal, which causes a dump to be generated in /tmp/sigdump-<integer>.log.

### Uninstall and Reinstall

You can remove the Unified Monitoring Agent, without removing the agent's configuration, by running the following command:

```
yum -y remove unified-monitoring-agent
```

For Ubuntu:

```
apt -y remove unified-monitoring-agent
```

The agent's configuration remains under the /etc/unified-monitoring-agent/ directory. If you do not want to keep the configuration for a future (re)installation of the Unified Monitoring Agent package, you need to remove it manually:

```
# use the following command to print the contents of the agent's configuration directory
find /etc/unified-monitoring-agent/
# use the following command to remove the directory and all of its contents (this step cannot be undone)
rm -rf /etc/unified-monitoring-agent/
```

The agent is automatically reinstalled by the Oracle Cloud Agent, at most 25 minutes. You need to have monitoring enabled for your instance in the Console for this to occur. See Managing Plugins with Oracle Cloud Agent on page 1089 for more information.

### Windows

#### Unified Monitoring Agent Troubleshooting Steps

**Check the service status:**

1. The agent runs as part of a Windows service, to see its status, open the start menu and type Services.msc and open it. Go to the service Oracle Cloud Unified Monitoring Service to see the status.
2. Right-click the service and select Properties for more information. Start/stop/restart are available here.
3. From the Start menu type cmd, right-click on Command Prompt and select Run as Administrator. Run the following commands:
   - To view Unified Monitoring Agent service status:
     
     ```
     sc query unified-monitoring-agent
     ```
   - Restart the Unified Monitoring Agent service:
     
     ```
     sc stop unified-monitoring-agent
     sc start unified-monitoring-agent
     ```
Find Windows Service errors:

1. From the Start menu, type Event Viewer and select it.
2. Open Windows Logs, then System. Every time a service starts or stops, fails to do either, or crashes suddenly, it is recorded here.

Fluentd logs:

1. Open explorer.exe (file icon on the task bar)
2. Go to C:\oracle_unified_agent.
3. If there is only one file, it means that there isn’t a valid configuration file on the machine.
4. If there are two files, then there is a supervisor log that will have all the setup/start-up logs, and a worker log with all the parsing/output logs. unified-monitoring-agent.conf is the name of the configuration file if it has been downloaded properly.
5. Run Fluentd manually. Try the preceding steps to identify the issue, but if needed, you can debug an issue by manually running Fluentd.

Automatic Configuration Updater Troubleshooting Steps

1. Verify Task Scheduler is running as expected.
2. From the Start menu, and type Task Scheduler.
3. Go to Task Scheduler (Local), then Task Scheduler Library. Find the task named UnifiedAgentConfigUpdater.
4. Verify the Last Run Time. If it was at an invalid date, or it says not run, then the Next Run time will be when it should run for the first time. For debugging, select the task and select Run if you need it to run immediately.
5. Last Run Result specifies the outcome of downloading the configuration from the control plane. If there is an error result, you need to run it manually to determine what happened. Task Scheduler does not keep output logs.
6. Run the configuration updater manually.
Oracle Cloud Agent Troubleshooting Steps

Check the Oracle Cloud Agent logs. For Windows Server 2012r2 or 2016, the log file locations are:

- C:\Users\OCA\AppData\Local\Local\OracleCloudAgent\agent.log
- C:\Users\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring\unifiedmonitoring.log (runtime logs)
- C:\Users\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring\unifiedmonitoring_msi.log (install logs)
- C:\oracle_unified_agent\unified-monitoring-agent-0.log (agent worker log, which might not exist depending on state)
- C:\oracle_unified_agent\unified-monitoring-agent-supervisor-0.log (agent supervisor log, which might not exist depending on state)

Windows Server 2019 log file locations:

- C:\Windows\ServiceProfiles\OCA\AppData\Local\OracleCloudAgent\agent.log
- C:\Windows\ServiceProfiles\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring\unifiedmonitoring.log (runtime logs)
- C:\Windows\ServiceProfiles\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring\unifiedmonitoring_msi.log (install logs)
- C:\oracle_unified_agent\unified-monitoring-agent-0.log (agent worker log, which might not exist depending on state)
- C:\oracle_unified_agent\unified-monitoring-agent-supervisor-0.log (agent supervisor log, which may not exist depending on state)

Intermittent Failed MSI Install

An intermittent failed MSI install can occur for one of two reasons:

1. An MSI installation was interrupted (system reboot, process stop, and so on), and on the second run, the msiexec.exe process is still holding a file handle to a folder that it created.
2. During an upgrade where the MSI fails to get access to the main agent folder, because Ruby.exe doesn’t end like it should (a Fluentd issue). This causes the MSI to fail and to clean up the system, removing much of the agent (not the position or buffer files though).

In both instances, a second install or letting Oracle Cloud Agent run through the install a second time resolves this issue. If it still is stuck in this state do the following:

1. Stop all msiexec and ruby processes in Task Manager, Details.
2. Rename C:\oracle_unified_agent to C:\oracle_unified_agent_old.
3. Install the agent again, or wait for Oracle Cloud Agent to install it.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operation to ingest custom logs directly:

- PutLogs

The following is a sample log entry payload that can be used with PutLogs:

```json
{
    "specversion":"1.0",
    "logEntryBatches": [ 
    { 
        "entries": [ 
        { 
            "data": "Random test",
```
Searching Logs

This topic describes how to search your logs using the Search page.

Overview of Log Search

Logging provides a powerful tool to search indexed logs. Use the Console to perform any of the following tasks:

• Search logs, whether in a basic user interface mode, or by typing custom queries in an advanced mode.
• Filter on values in logs, whether by log fields, text search, or time intervals, all in terms of chosen compartments or log groups.
• Visualize log data in a bar chart view, along with accompanying tabular data.
• Explore each log line in more detail. View the raw JSON payload, and view before/after information.
• Export search results to a JSON file.

Logs are indexed by default, which allows them to be searched using the Console.

Note:

For logs to be available and to be searchable from a certain time frame, they must first be enabled, and you can only search for logs after they start ingesting.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

Administrators: For specific examples of policy, see Required Permissions for Searching Logs on page 3420.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to know more about writing policies for Logging, see Details for Logging on page 2986.

Required Permissions for Searching Logs

To search indexed logs, a user must have the read permission on the log content and read access to the log group.

allow group GroupA to read log-groups in tenancy
allow group GroupA to read log-content in tenancy

To search indexed logs, you must have access to the log group that contains the indexed logs. For more information, see Required Permissions for Working with Logs and Log Groups on page 3351.

To view and search Audit Logs on page 3402, you must also have the corresponding Audit-related permissions. See Details for the Audit Service on page 2850 for more information. For example:
Logging

• search "compartment" requires AUDIT_EVENT_READ, and if there are any log objects, it would also require LOG_CONTENT_READ
• search "compartment/_Audit" requires just AUDIT_EVENT_READ.
• search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid" requires LOG_CONTENT_READ only.
• search "compartmentOcid1/_Audit" "compartmentOcid2/logGroupNameOrOcid/logNameOrOcid" requires LOG_CONTENT_READ on logGroupNamOrOcid and AUDIT_EVENT_READ on compartmentOcid1.

Using the Console

You can perform log searches by using either the Basic mode filter controls in the interface, or the Advanced mode custom query language interface. See Basic Search Queries on page 3421 and Advanced Search Queries on page 3422 for more information.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only a 14-day range is available when performing log search queries.</td>
</tr>
</tbody>
</table>

Basic Search Queries

To search and filter logs:

1. Open the navigation menu and click Observability & Management. Under Logging, click Search.
2. In Custom filters, you can start typing to automatically display filter settings, along with operators. For example, entering d displays filters starting with that letter. Use the up or down arrow keys to select from the list, or continue typing to enter what you want to filter on. For example, data.compartmentName='<tenancy_name>'.
3. In Select logs to search, the root compartment is already selected by default for filtering. Click this field to open the Select Logs to Search panel, where you can filter by compartments you have permission to work in, in addition to filtering by Log Groups and Logs. You can filter by multiple compartments and log groups. For any filters you create in this panel that you want to remove, click the filter X icon in the Select Logs to Search field.
4. The log data in the Explore and Visualize tabs is reloaded according to your filter settings, or you can click Search to apply the filter.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Since the Search page automatically refreshes after applying filters and selecting logs, you do not need to click the Search button as you select different filters. You will, however, need to click Search again after some time has passed and new logs have appeared. When performing Advanced Mode queries however, you do need to always click this button to submit a query.</td>
</tr>
</tbody>
</table>

To remove a filter(s) from the Search page, under Filters, click the X icon next to the filter.

To search with Quick Start Queries

You can quickly search according to several predetermined queries. From Quick Start Queries, select a query from the list. The Search page displays the results for the chosen query.

To limit results to a specific time range

In Filter By Time, select a time range from the list, or select Custom to specify a date range in the calendar Start Date and End Date. You can also specify a time value in the box next to the calendar. Use an end time to refine the time window.

Didn't get the result you expected?
Logging

Try specifying a time range:

- Under **Filter by time**, select a predetermined time range or specify a custom date range. Use an end time to refine the time window.

**Advanced Search Queries**

When performing a search on the Logging **Search** page, you can click **Show Advanced Mode** to enter your own custom log search queries. In addition, **Advanced Mode** searching provides more comprehensive search options that are not available in **Basic Mode**.

Be default, the following is displayed in the **Query** field after clicking **Show Advanced Mode**:

```
search "ocid1.tenancy.oc1..<unique_id>" | sort by datetime desc
```

For example, you can modify this default search by entering:

```
search "ocid1.tenancy.oc1..<unique_id>" | sort by datetime desc
| summarize count() as cnt by rounddown(datetime, '15m') as interval
```

This returns `{"interval": 1600364700000,"cnt": 31}` and `{"interval": 1600365600000,"cnt": 220}` under **Log Data** in the **Explore** tab.

When entering search queries, **auto-complete hints** are providing as you type (which you can select from a pop-up menu as you type), and **syntax validation** is performed in real time in the background as you type a query.

**Note:**

When you switch from **Advanced Mode** to **Basic Mode**, the query is lost and is not available in **Basic Mode**. A warning is displayed for this scenario to confirm your preference.

The **Advanced Mode** search uses a specific syntax, using the Logging query language, which is described in **Logging Query Language Specification** on page 3431.

**To search with Quick Start Queries**

You can quickly search according to several predetermined queries. From **Quick Start Queries**, select a query from the list. The **Search** page displays the results for the chosen query.

**Saved Searches**

You can save the search parameters that you use for any searches performed in both **Basic Mode** and **Advanced Mode**.

To save a search:

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Saved Searches**.
2. Under **List Scope**, **Compartment**, choose a compartment you have permission to work in. The **Saved Searches** page is displayed.
3. You can start the save operation using one of these two methods:
   - From the **Saved Searches** page, click **New Search**, which opens the Logging **Search** page, where you can begin a search.
   - From the **Search** page directly, whether in **Basic Mode** and **Advanced Mode**.
4. Apply filter and search settings as described in **Basic Search Queries** on page 3421 and **Advanced Search Queries** on page 3422.
5. Click **Save Search**. The **New Saved Search** panel is displayed.
6. In **Search Name**, enter a name to associate with your saved search. Avoid entering confidential information.
7. In **Compartment**, select a compartment you have permissions to work in.
8. In **Description**, enter a description for the saved search.
9. Click **Save Search** to save your search.

**Note:**

The **Search Query** field cannot be edited and is view-only. It only displays the contents of your search parameters.

10. The search is saved and a message appears with the linked name of your saved search. Clicking the linked saved search name opens the details page for the saved search, where you can view more information about it. This page displays the following on the **Saved Search Information** tab:

- **OCID**
- **Region**
- **Compartment**
- **Description**
- **Created** date and time in UTC format.
- **Last Modified** date and time in UTC format.
- **Search Query** view-only description of the search parameters in the saved search.
- The **Tags** tab shows associated tags for this log.
- Under **Latest Results**, log data is displayed under **Saved Search Data**, in a similar manner as the **Log Data** on the **Search** page. You can apply some simple filters, such as sorting by newest or oldest from the **Sort** field, or filtering by time from the corresponding **Filter by Time** field.

11. Click **Explore with Log Search**, which allows you to view this saved search on the **Search** page directly. After clicking this link, the **Search** page opens with the saved search loaded, whether it is a basic or advanced mode search. At this point, you can perform more analysis and investigation related to this search directly on the **Search** page. For more information, see **Searching Logs** on page 3420.

While on the **Search** page, you can also switch between any of the saved searches by selecting them from the **Saved Searches** list.

**Note:**

When editing a saved search from the **Saved Searches** page, you can only change the **Search Name**, **Compartment**, and **Description** fields in the **Edit Saved Search** panel. If you need to change the search parameters, create a new saved search.

**Viewing and Working with Search Results**

After you get an initial set of results, you can view more details, whether in terms of the log fields, JSON, or before and after states, and visually as a chart. On the **Explore** tab under **Log Data**, a **Number of Log Events Per Minute** bar graph displays the number of log events, according to your filter settings.

**Note:**

You will need to click **Click Enter to search** after time has passed, to see the latest logs.

**Note:**

For any actions taken on the **Explore** and **Visualize** tabs, you can define how often to refresh the data on the **Search** page, by selecting a value from the **Autorefresh** list (choose from **OFF**, **5 Minutes**, or **15 Minutes**). The default is **OFF**.

**To examine a single log entry**

- In the **Explore** tab under **Log Data**, click the down arrow ( ) to expand the log entry in **JSON** view.

  The **JSON** view is displayed. In JSON view you can view the log data fields and values, collapse and expand nodes, or click the copy icon to copy the log entry to the clipboard.
To switch between JSON and Before & After view

- In the Explore tab under Log Data, click the down arrow (¶) to expand the log entry and click JSON.

  The JSON view is displayed. Click the Before & After tab to switch to its view.

To examine Before & After view

- In the Explore tab under Log Data, click the down arrow (¶) to expand the log entry and click Before & After.

  The Before & After view is displayed. In contrast to the entry labeled as Current, this view displays the exact preceding and successive logging lines in the log object.

Right-click to view more log options

- In the Explore tab, each entry has three interactive header columns, which correspond to: the log time stamp, the plugin where the log occurred, and the log message.

  Right-click one of the log entry columns to open a context-sensitive menu for that entry and the column header. These options are available whether the log entry is collapsed or expanded. The following right-click options are available:

  - Copy value

    **Note:**
    
    This is the only option available for the third column's right-click menu.

  - Filter matching
  - Filter not matching
  - Remove from summary view

To export log data

At the top-left portion of Log Data, click Export Log Data (JSON). This feature allows you to export the log data to a JSON file that you can save to your system.

To visualize log data as a chart

You can view log data graphically as a chart, along with accompanying tabular data.

Select from the following chart settings:

- **Visualization Type**: Select Bar. The Bar charts are organized in terms of time (UTC) on the X-axis, with time on the Y-axis. You can hover the mouse over bars when stacked bars appear, which displays the number of log records in a tool tip.

  - **Interval**: Select from 1 minute (the default), 5 minutes, 15 minutes, 30 minutes, or 1 hour.

  - **Group By**: Select a logging field to group the results by.

  For any chart type being viewed, you can click to expand the `<number of> records found` list below the chart, which lists the total record sum, and the number of records at each time interval.

Using the Command Line Interface (CLI)

For more information on installing the CLI, see Quickstart on page 5320, and logging-search for command documentation.

Submit a query to search logs

```
oci logging-search search-logs --search-query, --time-end, --time-start
```
To search within a compartment

```
oci logging-search search-logs --search-query 'search "ocid1.tenancy.oc1..<unique_ID>"' --time-start 2021-06-22T00:30:00Z --time-end 2021-06-22T00:35:00Z
```

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the following operation to search logs:

- **SearchLogs**

Use the following for saved searches:

- **LogSavedSearch**

**SearchLogs SDK Examples**

See the following [SearchLogs](#) SDK examples for:

- Java
- Python
- Go
- TypeScript
- .NET C#
- Ruby

**Java example:**

```java
/**
 * To make this code sample work in your Oracle Cloud tenancy,
 * please replace the values for the following placeholders:
 * <compartment_OCID> - the ocid of your compartment where the logs are stored;
 * <log_group_OCID> - the ocid of your log group under the above compartment;
 * <log_OCID> - the ocid of your log object under the above log group.
 */

import com.oracle.bmc.ConfigFileReader;
import com.oracle.bmc.auth.AuthenticationDetailsProvider;
import com.oracle.bmc.auth.ConfigFileAuthenticationDetailsProvider;
import com.oracle.bmc.loggingsearch.LogSearchClient;
import com.oracle.bmc.loggingsearch.model.*;
import com.oracle.bmc.loggingsearch.requests.*;
import com.oracle.bmc.loggingsearch.responses.*;
import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.HashMap;
import java.util.Date;
import java.util.Arrays;

public class SearchLogsExample {
    public static void main(String[] args) throws Exception {
        
        // Create a default authentication provider that uses the DEFAULT profile in the configuration file.
```
* Refer to <see href="https://docs.cloud.oracle.com/en-us/iaas/Content/API/Concepts/sdkconfig.htm#SDK_and_CLI_Configuration_File">the public documentation</see> on how to prepare a configuration file.

```java
final ConfigFileReader.ConfigFile configFile = ConfigFileReader.parseDefault();
final AuthenticationDetailsProvider provider = new ConfigFileAuthenticationDetailsProvider(configFile);

/* Create a service client */
LogSearchClient client = new LogSearchClient(provider);

/* Create a request and dependent object(s). */
SearchLogsDetails searchLogsDetails = SearchLogsDetails.builder()
    .timeStart(new Date("Mon May 10 01:02:29 UTC 2021"))
    .timeEnd(new Date("Mon May 10 02:02:29 UTC 2021"))
    .searchQuery("search "<compartment_OCID>/<log_group_OCID>/<log_OCID>")
    // where level = 'INFO'
    .isReturnFieldInfo(false).build();

SearchLogsRequest searchLogsRequest = SearchLogsRequest.builder()
    .searchLogsDetails(searchLogsDetails)
    .opcRequestId("RIJJ870XLQBPBRN6ZWO/OpcRequestIdExample/UniqueRequestId")
    .limit(10).build();

/* Send request to the Client */
SearchLogsResponse response = client.searchLogs(searchLogsRequest);

System.out.println("opc-request-id: " + response.getOpcRequestId());
System.out.println("Got results: " + response.getSearchResponse().getResults().stream().count());
```

**Python example:**

```python
# To make this code sample work in your Oracle Cloud tenancy,
# please replace the values for the following placeholders:
# <compartment_OCID> - the ocid of your compartment where the logs are stored;
# <log_group_OCID> - the ocid of your log group under the above compartment;
# <log_OCID> - the ocid of your log object under the above log group.

        limit: 10
    )

# Get the data from response
puts "#{search_logs_response.data}"
**Logging Query Language Specification**

This topic describes the query syntax components that can be used with Advanced Search Queries on page 3422 and Saved Searches on page 3422.

**Query Components**

The logging query language processing is based on a data flow model. Each query can reference one or more logs, and produces a table dataset as a result. The query language provides several operators for searching, filtering, and aggregating structured and unstructured logs.

A logging query includes the following components:

- Log streams
- Fields
- Data types
- Stream expressions
- Pipe expressions
- Operators

**Log Streams**

To begin your search, you must first define the set of logs you want to search. You can choose to search specific log objects, log groups, or compartments. You can mix and match as many logs as you need. The search scope is defined using the following pattern:

```
search <log_stream> (,? <log_stream>)*
```

The query language fetches log entries from the scope you provide, and constructs a *log stream* that you can filter, aggregate, and visualize.

Log stream:

```
<log_stream> := "<compartment_ocid> ( /<log_goup_ocid> ( /<log_object_ocid> ? )? )?"
```

Examples:

```
search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid"
search "compartmentOcid/logGroupNameOrOcid"
search "compartmentOcid"
search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid", "compartmentOcid_2/logGroupNameOrOcid_2", "compartmentOcid_3"
```

**Fields**

All fields in log streams are case-sensitive. Although actual logs have indexed fields in lower case only, you can also create new fields in the query with mixed case:

```
search "..."
 | select event as EventName
```
Logging

Fields are in JSON notation, therefore, special characters must be in quotes.

```
Fields: <field_name> := <identifier> (DOT <identifier>)*
```

For **Identifier**:

```
<identifier> := a-zA-Z[a-zA-Z_0-9]* | ("" (\\" | ")")* ")"
```

Examples:
- type
- data.message
- data.request.URL
- "type"
- "data"."message"
- "data.message" (not the same as "data"."message")
- data."event"
- data."first name"
- data."an example of escaped ("\") double quotes"

**Data Types**
The following key data types are supported by the query language. These are (long and double) 8 bytes.

For details about the representation of the values of the corresponding types, see **Literals** on page 3438.

- Strings
- Numbers (integer, float-point)
- Arrays
- Booleans
- Timestamps
- Intervals

**Stream Expressions**
All expressions which produce a stream are stream expressions. Stream expressions can be formed using the following operators:

- **Tabular operators**
- **Aggregate operators**

**Pipe Expressions**
A pipe (|) applies an operator on the left side to a stream expression on the right side. The pipe expression is a stream expression.

The operator on the right side of a pipe must consume only one stream (for example, aggregate operations, filters).

The left side becomes the "current stream" for the right side expression, making all fields in the current stream available according to short names. For example:

```
search "application"
  | where level = 'ERROR'

>>
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1", 
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2", 
"message":"reached 90% file size limit... ", "impact":4}
```
Operators

The following are supported when performing advanced queries:

- Tabular operators
- Scalar operators
- Aggregate operators

Tabular Operators

A tabular operator creates or modifies a log stream by filtering out or changing log entries. Also refer to BNF syntax notation. The following are tabular operators:

- search
- where
- top
- sort
- dedup
- select
- extend

search

Constructs a log stream from actual log objects. Also see Log Streams on page 3431 for details, and Using the Command Line Interface (CLI) on page 3424 for additional examples.

search "compartmentOCID/loggroup1/logname1" "compartmentOCID/loggroup2/logname2" "compartmentOCID/loggroup3/logname3"

where

Filters the current log stream using a Boolean expression.

search "application"
| where level = 'ERROR'

where is optional:

search "application"
| level = 'ERROR'

Some example comparisons with numbers and Boolean field comparisons are the following:

| data.statusCode = 200

| data.isPar
You can perform a full text search by specifying a filter on the entire content of the log. A search on `logContent` returns any log line where a value matches your string. This functionality supports wildcards. For example:

```
search "application"
   | where logContent = 'ERROR'  -- returns log lines with a value matching "ERROR"
```

```
search "application"
   | where logContent = '*ERROR*' -- returns log lines with a value containing "ERROR"
```

top
Fetched only a specified number of rows from the current log stream, sorted based on some expression.

```
<top> := top [0-9]+ by <expr>
```

Examples:

- top 3 by datetime
- top 3 by *
- top 3 by (a + b)

A number of rows must be a constant positive integer, and a sorting expression must be provided.

```
search "application"
   | top 3 by impact

["timestamp": "2019-01-03T00:06:59", "level": "ERROR", "host": "host2",
  "message": "reached 95% file size limit...", "impact": 5]
["timestamp": "2019-01-03T00:06:39", "level": "ERROR", "host": "host2",
  "message": "reached 90% file size limit...", "impact": 4]
["timestamp": "2019-01-03T00:04:01", "level": "ERROR", "host": "host1",
  "message": "download failed...", "impact": 2]
```

sort
Sorts the current log stream by the specified columns, in either ascending (default) or descending order. The operator uses the "DESC" and "ASC" keywords to specify the type of the order. The default sort order is asc.

```
<sort> := sort by <sort_expr> (, <sort_expr>)*
<sort_expr> := <expr> (asc | desc)?
```

Example:

```
search "application"
   | sort by impact desc

["timestamp": "2019-01-03T00:06:59", "level": "ERROR", "host": "host2",
  "message": "reached 95% file size limit...", "impact": 5]
["timestamp": "2019-01-03T00:06:39", "level": "ERROR", "host": "host2",
  "message": "reached 90% file size limit...", "impact": 4]
["timestamp": "2019-01-03T00:04:01", "level": "ERROR", "host": "host1",
  "message": "download failed...", "impact": 2]
["timestamp": "2019-01-03T00:05:33", "level": "WARNING", "host": "host2",
  "message": "reached 70% file size limit...", "impact": 1]
["timestamp": "2019-01-03T00:04:05", "level": "INFO", "host": "host1",
  "message": "host list updated..."
["timestamp": "2019-01-03T00:06:59", "level": "INFO", "host": "host2",
  "message": "fs clean up started..."]
```
Logging

More than one column can be used to specify the order:
search "application"
| sort by host, impact desc
>>
{"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host":"host2",
"message":"reached 95% file size limit... ", "impact":5}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2",
"message":"reached 90% file size limit... ", "impact":4}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1}
{"timestamp": "2019-01-03T00:06:59", "level":"INFO", "host":" host2",
"message":"fs clean up started..."}
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:04:05", "level":"INFO", "host":" host1",
"message":"host list updated..."}
dedup
Processes the current log stream by filtering out all duplicates by specified columns. If more than one column is
specified, all columns have to be delimited by commas.
<dedup> := dedup <expr> (, <expr>)
Examples:
search "application"
| dedup host
>>
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1}
search "application"
| dedup host, impact
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2",
"message":"reached 90% file size limit... ", "impact":4}
{"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host":"host2",
"message":"reached 95% file size limit... ", "impact":5}
select
Applies a series of named scalar expressions to the current log stream. See summarize for an aggregation version of
select.
<select> := select <select_expr> (, <select_expr>)*
<select_expr> := ( * | <expr> (as <identifier>)? )
Example:
search "application"
| select level, host, impact+10 as impact, timestamp
>>
{"level":"ERROR", "host":"host1", "impact": 12, "timestamp":
"2019-01-03T00:04:01"}

Oracle Cloud Infrastructure User Guide

Logging

{"level":"INFO", "host":" host1", "timestamp": "2019-01-03T00:04:05"}
{"level":"WARNING", "host":"host2", "impact": 11, "timestamp":
"2019-01-03T00:05:33"}
{"level":"ERROR", "host":"host2", "impact": 14, "timestamp":
"2019-01-03T00:06:39"}
{"level":"ERROR", "host":"host2", "impact": 15, "timestamp":
"2019-01-03T00:06:59"}
{"level":"INFO", "host":" host2", "timestamp": "2019-01-03T00:06:59"}
extend
Extends the current log stream with a computed column.
<extend> := extend <expr> (as <identifier>)?
Example:
search "application"
| extend concat(host, 'us.oracle.com') as fqn
>>
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2, "fqn": "host1.us.oracle.com"}
{"timestamp": "2019-01-03T00:04:05", "level":"INFO", "host":" host1",
"message":"host list updated...", "fqn": "host1.us.oracle.com"}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1, "fqn":
"host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2",
"message":"reached 90% file size limit... ", "impact":4, "fqn":
"host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host":"host2",
"message":"reached 95% file size limit... ", "impact":5, "fqn":
"host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:59", "level":"INFO", "host":" host2",
"message":"fs clean up started...", "fqn": "host2.us.oracle.com"}
Scalar Operators
Scalar operators are applicable to individual values.
Arithmetic operations are the following:
•
•
•
•

+
*
/

Boolean operators are the following:
•
•

and
or

Unary operator:
•

-(<expr>)

Comparison operators are the following (numeric expressions only):
•
•
•
•

<expr>
<expr>
<expr>
<expr>

> <expr>
>= <expr>
<= <expr>
< <expr>

Oracle Cloud Infrastructure User Guide

3436


• `<expr> = <expr>`
• `<expr> != <expr>`

String comparison:
• `<expr> = <expr>`

Functions:
• `not (<expr>)`
• `contains_ci/contains_cs (<expr>, <expr>, (true | false))`
  The last parameter is case-sensitive.
• `rounddown (<expr>, '[0-9]+(d | h | m | s)')`
  The last parameter is the time interval in days, hours, minutes, or seconds.
• `concat (<axpr>, <expr>)`
• `upper (<expr>)`
• `lower (<expr>)`
• `substr (<expr>, [0-9]+ (, [0-9]+)?)`
  The second argument is the start index, while the third argument is optional, namely, how many characters to take.
• `isnull (<expr>)`
• `isnotnull (<expr>)`

Aggregate Operators
**count**
Calculates a number of rows in the current log stream:

```
search "application"
 | count
>>
{"count": 6}
```

**summarize**
Groups the current log stream by the specified columns and time interval, and aggregates using named expressions. If grouping columns are not specified, `summarize` aggregates over the whole stream.

```
search "application"
 | summarize count(impact) as impact by level, rounddown(datetime, '1m') as timestamp
```

Special Columns
**logContent**
`logContent` is a special column which represents the text of the whole original message. For example:

```
search "application"
 | where logContent = '*ERROR*' -- returns log lines with a value containing "ERROR"
```

Comments
Both single line and multi-line comments are supported, for example:

```
search "application"
```
Identifiers

Identifiers are the names of all available entities in the query. An identifier can reference a field in the current log stream, or a parameter defined in the beginning of the query. Identifiers have the following format:

name: \$?[a-zA-Z_]\[a-zA-Z_0-9]*

For example: level, app_severity, $level.

The quoted form allows special symbols in the names (except double quotes):

name: "[^"]"+

For example: "opc-request-id", "-level".

All parameter references start with a dollar sign ($), for example: $level.

Functions

Scalar functions are the following:

- isnull(expr1)
- concat(expr1, ...)

Aggregate functions are the following:

- sum(expr1)
- min(expr1)
- max(expr1)
- count(): Counts a number of rows.
- count(expr): Counts a number of non-null expr values.

System parameters

All parameters with the prefix "query." are reserved. The following parameters are supported:
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query.from</td>
<td>String with date time in ISO 8601 format.</td>
<td>'2007-04-05T14:30'</td>
<td>Specifies starting time of the query window.</td>
</tr>
<tr>
<td>query.to</td>
<td>String with date time in ISO 8601.</td>
<td>'2007-04-05T14:30+05:00'</td>
<td>Specifies end time of the query window.</td>
</tr>
</tbody>
</table>
Chapter 31

Marketplace

This chapter explains how to work with listings in the Oracle Cloud Infrastructure Marketplace.

Overview of Marketplace

Oracle Cloud Infrastructure Marketplace is an online store that offers solutions specifically for customers of Oracle Cloud Infrastructure. In the Oracle Cloud Infrastructure Marketplace catalog, you can find listings for two types of solutions from Oracle and trusted partners: images and stacks. These listing types include different categories of applications. Also, some listings are free and others require payment.

Images are templates of virtual hard drives that determine the operating system and software to run on an instance. You can deploy image listings on an Oracle Cloud Infrastructure Compute instance. Marketplace also offers stack listings. Stacks represent definitions of groups of Oracle Cloud Infrastructure resources that you can act on as a group. Each stack has a configuration consisting of one or more declarative configuration files. With an image or a stack, you have a customized, more streamlined way of getting started with a publisher’s software.

Besides being an online store, Oracle Cloud Infrastructure Marketplace offers a way for members of the Oracle Cloud Infrastructure community to share custom images with other community members. You can take a custom image that you imported to Oracle Cloud Infrastructure Compute and make it available as a community application. The application appears alongside other images that users can choose from during the process of creating an instance.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

While the resources created from Marketplace images and stacks have an OCID to identify them, the listings themselves have a listing ID and a package version ID for every package version in the listing. Listing IDs are numeric values. Package version IDs are string values. These identifiers are unique to Marketplace and unrelated to OCIDs.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later
Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For the actual policy statements required to perform tasks related to Marketplace, see the topic specific to the task.

Working with Listings

This topic describes how to work with listings in the Oracle Cloud Infrastructure Marketplace catalog. You can do the following:

• Search for listings to find what you want to deploy
• Filter listings to refine application results
• View a listing to learn about the product that it offers
• Launch an instance from an image listing
• Launch stack resources from a stack listing
• Download Terraform configuration files from stack listings to update deployed applications

By default, Marketplace displays all listings in its catalog. However, an individual's ability to see or launch particular listings varies by tenancy, according to what permissions the individual has, and the pricing model for the listing.

Listings are either image listings or stack listings. Image listings have a Launch Instance button. Stack listings have a Launch Stack button.

For information about pricing and how it affects whether you can see a listing, see Pricing for Listings on page 3441.

Pricing for Listings

Marketplace listings belong to one of several pricing models available to and set by the publisher when the publisher creates the listing. Pricing models include:

• **Free:** usage incurs no charge
• **BYOL:** usage relies on software licenses that you already own
• **Paid:** usage incurs charges based on hourly rates, either according to OCPU hours consumed or according to the number of instances (irrespective of OCPU hours consumed by each)

The listing price does not include any additional fees that you might incur for the use of infrastructure resources.

For a cloud account to access paid listings, it must have a United States mailing address and the form of payment provided when the account was created must support payment in United States dollars. United States-based customers can deploy most paid listings in any commercial region data center, but some paid listings can only be deployed in United States commercial regions. These listings have a region restriction label that marks them as **US-only**.

Customers in US Government Cloud realms can see all paid listings from Oracle and third-party publishers. Users in United Kingdom government tenancies do not have access to any paid listings.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the policies you need to create to provide users with access to Marketplace depend on whether the tenancy is in a commercial region, the United Kingdom Government Cloud region, or the United States Government Cloud realm.

**Note:**
In commercial regions and the United Kingdom Government Cloud region, administrators do not need to write policies to grant users the ability to list or read listings. In these regions, you can see individual listings and lists of listings by default. Furthermore, to reduce the scope of access to a particular compartment, specify the specific compartment instead of the tenancy in the policy statement.

### For a Tenancy in a Commercial Region or the United Kingdom Government Cloud

- The following policy gives the specified example group, MarketplaceUsers, the ability to list accepted terms of use agreements. However, it does not include the ability to accept a terms of use agreement. The terms of use agreement for a given listing must be viewed and accepted prior to launch. For a policy that includes the ability to use listings, see the policy statements later in this section that grant access to the type of listing you want to launch, whether an image listing or a stack listing.

  - Allow group MarketplaceUsers to inspect compartments in tenancy
  - Allow group MarketplaceUsers to read app-catalog-listing in tenancy

- The following policy gives the specified example group, MarketplaceUsers, the ability to not only list and read, but also use Marketplace listings. It does not include the ability to create instances using images from listings. (For that, see the next set of policy statements.)

  - Allow group MarketplaceUsers to inspect compartments in tenancy
  - Allow group MarketplaceUsers to manage app-catalog-listing in tenancy

- The following policy gives the specified example group, MarketplaceUsers, general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. Use this policy in conjunction with the preceding policy for users who need to launch instances from image listings. For users who need to launch stacks from stack listings, use this policy in conjunction with the next set of policy statements.

  - Allow group MarketplaceUsers to manage instance-family in compartment ABC
  - Allow group MarketplaceUsers to read app-catalog-listing in tenancy
  - Allow group MarketplaceUsers to use volume-family in compartment ABC
  - Allow group MarketplaceUsers to use virtual-network-family in compartment XYZ

- The policies described in Policies for Managing Resources Used with Resource Manager on page 3170 grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

  If you need to write more restrictive policies, see the policy references on which these policies were based, Details for the Core Services on page 2855 and Details for Resource Manager on page 3033, as needed.
For a Tenancy in the US Government Cloud Realm

**Note:**
The following policies assume you already have existing policies for the specified groups to address the ability to inspect anything in the tenancy, including all compartments.

- The following policy gives the specified example group, MarketplaceUsers, the ability to view all listings in the specified example compartment:

  ```
  Allow group MarketplaceUsers to read marketplace-listings in compartment ABC
  ```

- The following policy gives the specified example group, MarketplaceUsers, the ability to work with all listings in the specified example compartment in any way possible. The statements include the ability to accept terms of use agreements, view listings, and create images and stacks from listings:

  ```
  Allow group MarketplaceUsers to manage app-catalog-listings in compartment ABC
  Allow group MarketplaceUsers to use marketplace-listings in compartment ABC
  Allow group MarketplaceUsers to manage instance-family in compartment ABC
  Allow group MarketplaceUsers to use volume-family in compartment ABC
  Allow group MarketplaceUsers to manage virtual-network-family in compartment ABC
  Allow group MarketplaceUsers to manage orm-stack in compartment ABC
  Allow group MarketplaceUsers to manage orm-job in compartment ABC
  ```

- The following policy gives the specified example group, MarketplaceUsers, the ability to work with specific listings in the specified example compartment in any way possible. The statements include the ability to list and subscribe to images and the ability to create images and stacks from listings:

  ```
  Allow group MarketplaceUsers to manage app-catalog-listings in compartment ABC
  Allow group MarketplaceUsers to use marketplace-listings in compartment ABC where any {listing.id='123456', listing.id='987654'}
  Allow group MarketplaceUsers to manage instance-family in compartment ABC
  Allow group MarketplaceUsers to use volume-family in compartment ABC
  Allow group MarketplaceUsers to manage virtual-network-family in compartment ABC
  Allow group MarketplaceUsers to manage orm-stack in compartment ABC
  Allow group MarketplaceUsers to manage orm-job in compartment ABC
  ```

- The following policy gives the specified example group, AgreementAcceptors, the ability to accept the terms of use agreement for any listing in the specified example compartment. The statements make it possible for anyone with the appropriate permissions to launch an image or stack from a listing without having the permission to accept the terms of use agreement themselves:

  ```
  Allow group AgreementAcceptors to read marketplace-listings in compartment ABC
  Allow group AgreementAcceptors to manage app-catalog-listings in compartment ABC
  ```

If you need to write more restrictive policies, see the policy reference on which policies for tenancies in the US Government Cloud realm were based, Details for the Marketplace Service on page 3011.

**Using the Console**

**To find a listing**

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications.
2. Click the Search for listings by entering a name, ID, category, or publisher name text box.
3. Provide a search string, and then press ENTER. (If you provide a listing ID, it must contain the full, exact listing ID to match. Marketplace supports partial matching for other listing search types.)

Marketplace displays all current listings that contain the search string in either the name, listing ID, application category, or publisher name. To refine the results, you can filter them.

To filter listings
1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications.
2. Under Filters, do one or more of the following:
   - To display listings of a certain deployment type, click Type, and then click either Image or Stack.
   - To display listings from a specific publisher, click Publisher, and then click a publisher name.
   - To display listings from a particular product category, click Category, and then click a category name.
   - To display listings according to price, click Price, and then click a pricing model.

You can combine multiple filters to further narrow down listings. You can also clear filters to expand the list of listings that you see.

To view a listing's details
1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications.
2. Click the listing that you're interested in.
3. Marketplace displays the listing overview by default. To view other details, do the following:
   - To view information about the publisher, click Provider.
   - To view other listings from the same publisher, click More Apps.
   - To view instructions for using the instance that you create from the listing, click Usage Information.

To launch an instance based on an image

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you create an instance, several other resources are involved (for example, an image, a cloud network, or a subnet). Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications.
2. Click the listing that you're interested in.
3. Review the Usage Instructions tab to ensure you understand what you will need to deploy and to access the instance after you launch it. Both Linux and Windows instances require a cloud network to launch the instance into. For more information, see Networking Overview on page 3604. Depending on the type of instance, to access it, you might need an SSH key pair or a security list that enables Remote Desktop Protocol. For more information, see Managing Key Pairs on Linux Instances on page 1021 and Creating a Windows Instance on page 1032.
4. Under Version, click the package version of the image that you want to install. By default, the menu displays the latest version.
5. Under Compartment, click the name of the compartment where you want to launch the instance. (If you don't have permissions to launch the instance in the selected compartment, it will be launched in the root compartment instead.)
6. Select the check box to accept the terms of use, and then click Launch Instance.
7. To finish launching the instance, follow the instructions in Creating an Instance.

The information you need to connect to an instance after you create it might be in the Usage Information or the Related Documents sections of the listing.
To launch a stack

**Tip:**

When you create a stack, potentially many other resources are involved (for example, an instance, a cloud network, or a subnet), aside from the stacks and jobs resources. You must have the required access to all involved resources to create a stack. Those other resources can be in the same *compartment* with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

1. Open the navigation menu and click **Marketplace**. Under **Marketplace**, click **All Applications**.
2. Click the listing that you're interested in.
3. Review the **Usage Instructions** tab and ensure you understand what you will need to deploy and to access the instance after the stack finishes deployment.
4. Under **Version**, click the package version of the stack that you want to install. By default, the menu displays the latest version.
5. Under **Compartment**, click the name of the compartment where you want to launch the instance. (If you don't have permissions to launch the instance in the selected compartment, it will be launched in the root compartment instead.)
6. Select the check box to accept the terms of use, and then click **Launch Stack**.
7. On the **Stack Information** page, configure the following:
   - **Name**. Optionally, provide a name by which you can refer to the stack after it's deployed. Avoid entering confidential information.
   - **Description**. Optionally, provide a description of the stack. For example, you can specify the name of the application that will run on the instance after the stack is deployed.
   - **Create in Compartment**. This is the compartment where the stack will be created in the tenancy. (Stacks are attached to a specific region. However, where necessary, the resources on a given stack can be deployed across multiple regions.)
   - **Tags**. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

When you are ready, click **Next**.

8. On the **Configure Variables** page, verify that the values for variables extracted from the Terraform configuration file are as you want them. Some variables might be required, but don't have a default value and must be configured before you can proceed. These vary from listing to listing, but often include the following: availability domain and compartment. Optionally, you can change default values, such as any display names automatically given to resources, to help differentiate them. For some stacks, you can customize additional variables by selecting the **Additional Customization** or **WLS Instance Advanced Configuration** check box. The variables in these sections otherwise use default values. When you are ready, click **Next**.

9. On the **Review** page, confirm that variables have been configured properly. (Marketplace does not display variables that have default values or variables that you didn't change.) Then, click **Create**.

Resource Manager runs the plan job and the apply job to create stack resources accordingly. The information you need to connect to the instance created as part of the stack can appear in the **Application Information** tab or in the **Usage Information** or **Related Documents** sections of the listing.

**To download a Terraform configuration file**

1. Open the navigation menu and click **Marketplace**. Under **Marketplace**, click **All Applications**.
2. Click the listing that you're interested in.
3. Under **Version**, click the package version of the stack that you want. By default, the menu displays the latest version.
4. Under **Compartment**, click the name of any compartment. (You must select a compartment in order to accept the terms of use in the next step.)
5. Select the check box to accept the terms of use, and then click **Download**.
6. Follow the prompts to save the configuration file locally.

For information about how to use the file to edit a stack or create a stack, see *Managing Stacks and Jobs* on page 4508.

### Using the Command Line Interface (CLI)

For information about using the CLI, see *Command Line Interface (CLI)*. For a complete list of flags and options available for CLI commands, see the *Command Line Reference*.

#### To filter listings

Open a command prompt and run `oci marketplace listing list` to view listings that meet specified filter criteria:

```
oci marketplace listing list --package-type <package_type> --publisher-id <unique_publisher_ID> --category <product_category> --pricing <pricing_model>
```

For example, the following command lists only image listings:

```
oci marketplace listing list --package-type image
```

The following command lists only listings from the specified publisher:

```
oci marketplace listing list --publisher-id 29367738
```

The following command lists only listings from the specified product category:

```
oci marketplace listing list --category "database management"
```

The following command lists only listings that have the specified pricing model:

```
oci marketplace listing list --pricing byol
```

#### To view a listing's details

Open a command prompt and run `oci marketplace listing get` to view detailed information about a listing:

```
oci marketplace listing get --listing-id <listing_ID>
```

For example:

```
oci marketplace listing get --listing-id 29367738
```

#### To launch an instance

Open a command prompt and run `oci compute instance launch` to launch an instance:

```
oci compute instance launch --availability-domain <availability_domain> --compartment-id <compartment_OCID> --shape <instance_shape> --subnet-id <subnet_OCID> --image-id <image_OCID>
```
For example:

```bash
oci compute instance launch --availability-domain oc1:phx:ad-1 --compartment-id ocld1.compartment.oc1..example1example25qr1po4agcmothkbqgmu2zzum45ibplooqtabwk3zz --shape VM.Standard1.2 --subnet-id ocld1subnet.oc1.phx.exampleahetdvobxd5cqbqfcm2ddryahoqrp4t2fauxvbdeirpa2gpt2a --image-id ocld1.image.oc1.phx.exampleae44ah3byet6tvl123cvtbetuyfckfwgg6fwrkk3fauxscyq
```

### Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with listings:

- GetListing
- GetPackage
- ListCategories
- ListListings
- ListPackages
- ListPublishers

### Publishing Listings

Applications listed in Oracle Cloud Infrastructure Marketplace are provided by publishers. Publishers belong to the Oracle PartnerNetwork. Oracle reviews and approves the applications submitted by publishers. If you would like to become a publisher, see How do I become a marketplace publisher? in the Oracle Cloud Marketplace Partner Portal documentation.

If you simply want to share a custom image that you imported to Oracle Cloud Infrastructure through Compute, see Publishing Community Applications on page 3447.

### Publishing Community Applications

This topic describes how to share and manage a custom image as a community application.

With Marketplace, you can take custom images that you imported to Oracle Cloud Infrastructure Compute and publish them to make them available to others in the Oracle Cloud Infrastructure community. Community applications are custom images provided to the community by the community. Community members can select from community applications when launching an instance, similarly to how they might select an Oracle image, partner image, or other image.

Anyone who uses community applications does so at their own risk. As with all images, terms of use exist between the publisher of the image and the customer, and you must accept any terms of use agreement associated with an image if you want to use the image.

Community applications appear alongside other images, such as platform images or partner images, to users of Compute during the instance creation workflow. Compute users can select from community images when they select an image to launch an instance. Community applications do not appear in Marketplace alongside applications from publishers in the Oracle PartnerNetwork.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies enable the creation of community applications in Marketplace for community use and provide access to community applications to users. For any policies, if you want to reduce the scope of access to a particular compartment, specify the compartment instead of the tenancy.

- The following policy gives the specified example group the ability to list, view, create, update, delete, or move community applications.

  ```
  Allow group PublicationAdmins to manage marketplace-publications in tenancy where listing.type='Community'
  ```

- The following policy gives the Marketplace service the ability to do everything with Compute custom images, including listing, viewing, creating, updating, deleting, and moving them.

  ```
  Allow service Marketplace to manage instance-images in tenancy
  ```

- The following policy gives the specified example group the ability to list community applications when selecting an image while launching an instance and to see the terms of use agreements associated with the images:

  ```
  Allow group CommunityApplicationLaunchers to read marketplace-community-listings in tenancy
  Allow group CommunityApplicationLaunchers to inspect compartments in tenancy
  Allow group CommunityApplicationLaunchers to read app-catalog-listing in tenancy
  ```

If you need to write more restrictive policies, see the policy reference on which these policies were based, Details for the Marketplace Service on page 3011 and Details for the Core Services on page 2855, as needed.

**Using the Console**

**To create a community application**

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications. Then, click Community Applications.

2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a community application.

3. Click Create.

4. In the Create Community Application dialog box, click Name, and then enter a name for the community application. The same name is used in the listing that Marketplace makes available for use.

5. Click Short Description, and then enter a short description of the community application. The short description accompanies the listing and is shown wherever the listing displays in a condensed format.

6. Optionally, click Long Description, and then enter a longer description of the community application. The long description accompanies the listing and is shown wherever the listing displays in full.

7. Under Contact Information, enter the name and email address that you want others to use to contact you if they need support with the community application. Avoid entering any confidential information.

8. Next, under Specify Listing, do one of the following to choose the custom image that you want to share:

   ```
   Note:
   You cannot publish a Windows custom image as a community application.
   ```

   - To select from a list of custom images available to you, click Choose Image, choose the compartment where the image exists, and then select the check box of the image that you want to publish.

   - To specify a custom image by its OCID, click Provide OCID, click the text box, and then enter the OCID of the image that you want to publish.

9. Click Community Application’s Terms of Use, and then enter the terms of use that you want community members to agree to if they want to use the image.
10. To confirm that you have the authority to create the community application and share the image with community members, select the I represent that I have the right and authority to share this Community Application in accordance with my agreement with Oracle applicable to the Services and with the related Service Specifications check box. You must select the check box to proceed.

11. When you are finished, click Create.

To view a community application's details

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications. Then, click Community Applications.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the community application you want to view.
3. From the list of community applications in the compartment, click the community application name.
4. The console displays the following information:
   - OCID: The unique, Oracle-assigned ID of the community application.
   - Created: The date and time when you initially created the community application.
   - Compartment: The unique, Oracle-assigned ID of the compartment that contains the community application.
   - Original Source: The custom image that formed the basis of the community application.
   - Contact Information: The name and email address that users of the community application can contact when they need support.
   - Short Description: A short description of the community application that displays to users when the listing is condensed.
   - Long Description: A longer description of the community application that displays to users when the listing is expanded.

To view all community applications in a compartment

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications. Then, click Community Applications.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the community applications you want to view.

The console displays a list of all community applications in the compartment that you have permission to view.

To update a community application

Note:

You can update the name of a community application, its descriptions, or its contact information. You cannot update the image or terms of use for an existing community application. To publish a different custom image, create a new community application.

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications. Then, click Community Applications.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the community application that you want to update.
3. Click the name of the community application, and then click Edit Details.
4. In the Edit Community Application dialog box, update information as needed. Avoid entering any confidential information.
5. When you are finished, click Save.

To delete a community application

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications. Then, click Community Applications.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the community application that you want to delete.
3. Click the name of the community application, and then click Delete.
4. To confirm, click **Delete** again.

**To move a community application to another compartment**

1. Open the navigation menu and click **Marketplace**. Under **Marketplace**, click **All Applications**. Then, click **Community Applications**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the community application that you want to move.
3. Click the name of the community application, and then click **Move Resource**.
4. Choose the compartment to which you want to move the community application, and then click **Move Resource**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**To create a community application**

Open a command prompt and run `oci marketplace publication create` to create a new community application:

```
oci marketplace publication create --compartment-id <target_compartment_id> --name '<publication_name>' --short-description '<short_application_description>' --contact-name '<name_of_support_contact>' --contact-email '<email_of_support_contact>' --image-id <custom_image_OCID> --terms-of-use '<text_of_application_terms_of_use>'
```

For example:

```
oci marketplace publication create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmu2zzum45ibplooqtabwk3zz --name 'My Best Application' --short-description 'This application will change your life.' --contact-name 'John Doe' --contact-email 'john@example.com' --image-id ocid1.image.oc1.phx.exampleanquwmne2sptdemm32pmp4fau7yah44sndcjoccyfctbzwf77a --terms-of-use 'I agree to use this software at my own risk.'
```

Avoid entering confidential information.

**To view a community application's details**

Open a command prompt and run `oci marketplace publication get` to view a community application's details:

```
oci marketplace publication get --publication-id <target_publication_id>
```

For example:

```
oci marketplace publication get --publication-id ocid1.marketplacecommunitylisting.oc1..examplea3o7jtytz3lsfauxeq6sp5ye3ex624rgsw2o14csvb3jrv3v76l3v6xx
```

**To view all community applications in a compartment**

Open a command prompt and run `oci marketplace publication get` to view all community applications in a compartment:

```
oci marketplace publication get --publication-id <target_publication_id>
```
For example:

```bash
oci marketplace publication get --publication-id
ocid1.marketplacecommunitylisting.oc1..examplea3o7jtytz3lsfauxeq6sp5ye3ex624rgsw2ol4cvbpy2qtm57dgja
```

**To update a community application**

Note:

You can update the name of a community application, its descriptions, or its contact information. You cannot update the image or terms of use for an existing community application. To publish a different custom image, create a new community application.

Open a command prompt and run `oci marketplace publication update` to update an existing community application:

```bash
oci marketplace publication update --publication-id <target_publication_id>
--name '<publication_name>'
```

For example:

```bash
oci marketplace publication update --publication-id
ocid1.marketplacecommunitylisting.oc1..examplea3o7jtytz3lsfauxeq6sp5ye3ex624rgsw2ol4cvbpy2qtm57dgja
--name 'New Application Name'
```

Avoid entering confidential information.

**To delete a community application**

Open a command prompt and run `oci marketplace publication delete` to delete a community application:

```bash
oci marketplace publication delete --publication-id <target_publication_id>
```

For example:

```bash
oci marketplace publication delete --publication-id
ocid1.marketplacecommunitylisting.oc1..examplea3o7jtytz3lsfauxeq6sp5ye3ex624rgsw2ol4cvbpy2qtm57dgja
```

**To move a community application to another compartment**

Open a command prompt and run `oci marketplace publication change-compartment` to move a community application from one compartment to another:

```bash
oci marketplace publication change-compartment --compartment-id <target_compartment_id> --publication-id <target_publication_id>
```

For example:

```bash
oci marketplace publication change-compartment --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz
--publication-id
ocid1.marketplacecommunitylisting.oc1..examplea3o7jtytz3lsfauxeq6sp5ye3ex624rgsw2ol4cvbpy2qtm57dgja
```
Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with community applications:

- ListPublications
- GetPublication
- CreatePublication
- UpdatePublication
- DeletePublication
- ChangePublicationCompartment
- ListPublicationPackages
- GetPublicationPackage

Service Catalog

A Service Catalog enables your organization to create and manage catalogs of applications that are approved for use in your tenancy. These applications are offered through marketplace in the form of image and stack listings. Applications can be a public application available on marketplace or a private application offered within the organization. The Service Catalog allows organizations to centrally manage applications and helps achieve consistent governance and compliance requirements. Approved or restricted sets of applications can reduce risks of misuse or overspending by end users, giving administrators peace of mind. End users can quickly deploy only approved applications that follow constraints set by the organization.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies enable the creation of applications in a Service Catalog and provide access to those applications to users. For any policies, if you want to reduce the scope of access to a particular compartment, specify the compartment instead of the tenancy.

- The following policy gives the specified example group the ability to list, view, create, update, delete, or move Private Applications in all compartments.

```
allow group CatalogAdmins to manage private-applications in tenancy
```

- The following policy gives the specified example group the ability to list, view, create, update, delete, or move Service Catalogs in all compartments.

```
allow group CatalogAdmins to manage service-catalogs in tenancy
```

- The following policy gives the specified example group the ability to browse and launch Service Catalog applications in all compartments:

```
allow group CatalogUsers to inspect service-catalog-contents in tenancy
```

- The following policy gives the specified example group the ability to browse and launch applications only from within a specific service catalog:

```
allow group CatalogUsers to inspect service-catalog-contents in tenancy where service-catalog.id='ocid1.servicecatalog.oc1.iad.aaaaaaaaexampleocid'
```
• The following policy gives the specified example group the ability to browse and launch applications only from within those service catalog which are hosted in the compartment Project-A:

```allow group CatalogUsers to inspect service-catalog-contents in compartment Project-A```

If you need to write more restrictive policies, see the policy reference on which these policies were based: Details for the Marketplace Service on page 3011 and Details for the Core Services on page 2855, as needed.

**Working with Service Catalogs**

This section describes how to create, edit, view, and delete Service Catalogs.

**Using the Console**

*To create a Service Catalog*

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Catalog Manager**. The **Catalog Manager** page appears, showing the list of Service Catalogs.
2. You can select a compartment with the **Compartment** drop-down list in the **List Scope** section on the left side of the page.
3. Click the **Create Service Catalog** button at the top of the list of Service Catalogs. The **Create Service Catalog** dialog appears.
4. Enter the name of the Service Catalog in the **Name** text box.
5. Select the compartment using the **Create in Compartment** drop-down list.
6. You can optionally select one or more Marketplace or Private applications to share in this catalog from the Applications list:
   a. Select an application by clicking the check box next to it.
   b. You can type in a search term in the **Search for applications** text box at the top of the list.
   c. You can filter the list by selecting a filter from the available drop-down lists in the **Filter** section to the left of the list of applications.
7. Click the **Create** button.

*To view a Service Catalog's details*

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Catalog Manager**. The **Catalog Manager** page appears, showing the list of Service Catalogs.
2. You can select the compartment scope of the displayed Service Catalogs with the **Compartment** drop-down list.
3. Click on the name of the Service Catalog in the list. The Service Catalog's details page displays.

*To update a Service Catalog*

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Catalog Manager**. The **Catalog Manager** page appears, showing the list of Service Catalogs.
2. Click on the name of the Service Catalog in the list. The Service Catalog's details page displays.
3. Click the **Edit** button.
4. You can update the name of the Service Catalog by modifying the value in the **Name** text box.
5. You can add or remove applications in the **Applications** list.
   a. You can search by name or filter the list by selecting one or more filters in **Filter** section to the left of the list of applications.
   b. Check or uncheck the box next to the application name that you want to include or remove.
6. When you are finished, click **Save Changes**.

*To delete a Service Catalog*

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Catalog Manager**. The **Catalog Manager** page appears, showing the list of Service Catalogs.
2. There are two ways to delete a Service Catalog:
   a. From the list of Service Catalogs on the Catalog Manager page:
      1. Click the context menu icon to the right of the Service Catalog you want to delete, then click *Delete*.
      2. To confirm, click *Delete* again.
   b. From the Edit Service Catalog page:
      1. Click the *Delete* button.
      2. To confirm, click *Delete* again.

To view all Service Catalogs in a compartment

1. Open the navigation menu. Under the Solutions and Platform group, go to Service Catalog. Then, click Catalog Manager. The Catalog Manager page appears, showing the list of Service Catalogs.
2. You can select a compartment with the Compartment drop-down list in the List Scope section on the left side of the page.

To move a Service Catalog application to another compartment

1. Open the navigation menu. Under the Solutions and Platform group, go to Service Catalog. Then, click Catalog Manager. The Catalog Manager page appears, showing the list of Service Catalogs.
2. Click on the name of the Service Catalog you want to move. The details page for that Service Catalog appears.
3. Click the Move Resource button.
4. Select the destination compartment from the Choose New Compartment list, then click Move Resource.

Browsing and Launching Service Catalog Applications

1. Open the navigation menu. Under the Solutions and Platform group, go to Service Catalog. Then, click Applications. The Applications page appears, showing all of the marketplace listings and private applications available in the compartment.
2. Click on the name of the application you want to launch. The Application Details page appears.
3. Click the Launch button.
4. For more information, see Working with Listings on page 3441.

Working with Private Applications

This section describes how to create, edit, view, and delete Private Applications.

Using the Console

To create a Private Application

1. Open the navigation menu. Under the Solutions and Platform group, go to Service Catalog. Then, click Private Applications. The Private Applications page appears, showing the list of Private Applications.
2. You can select a compartment with the Compartment drop-down list in the List Scope section on the left side of the page.
3. Click the Create button at the top of the list. The Create Private Application dialog appears.
4. Enter the name of the Private Application in the Name text box.
5. You can add an icon by dragging and dropping the JPG or PNG file into the Application Icon box or by clicking the Browse link and selecting a file. If you don't provide an icon, a default icon is provided.
6. Enter a short description in the Short Description text box.
7. Enter a more detailed description in the Long Description text box. This description will be displayed to the user at launch time.
8. Enter the version of the application into the Application Version field.
9. Upload a Terraform configuration file by dragging and dropping the file into the **Upload File Containing Terraform Configuration** box or by clicking the **Browse** link and selecting a file.

   **Note:**

10. Click the **Create** button.

**To view a Private Application's details**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Private Applications**. The **Private Applications** page appears, showing the list of Private Applications.
2. Click the name of the Private Application that you want to view. The **Private Application Details** page appears.

**To update a Private Application**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Private Applications**. The **Private Applications** page appears, showing the list of Private Applications.
2. Click on the **Edit** button.
3. Update the name of the Private Application in the **Name** text box.
4. Change the icon by dragging and dropping the JPG or PNG file into the **Application Icon** box or by clicking the **Browse** link and selecting a file.
5. Update the short description in the **Short Description** text box.
6. Update the detailed description in the **Long Description** text box. This description will be displayed to the user at launch time.
7. Click the **Save** button.

**To delete a Private Application**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Private Applications**. The **Private Applications** page appears, showing the list of Private Applications.
2. There are two ways to delete a Private Application:
   a. From the list of Private Applications on the **Private Applications** page:
      1. Click the context menu icon to the right of the Private Application you want to delete, then click **Delete**.
      2. To confirm, click **Delete** again.
   b. From the **Edit Private Application** screen:
      1. Click the **Delete** button.
      2. To confirm, click **Delete** again.

**To view all Private Applications in a compartment**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Private Applications**. The **Private Applications** page appears, showing the list of Private Applications.
2. You can select a compartment with the **Compartment** drop-down list in the **List Scope** section on the left side of the page.

**To move a Private Application to another compartment**

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Service Catalog**. Then, click **Private Applications**. The **Private Applications** page appears, showing the list of Private Applications.
2. Click on the name of the Private Application you want to move. The details page for that Private Application appears.
3. Click the **Move Resource** button.
4. Select the destination compartment from the **Choose New Compartment** list, then click **Move Resource**.
Viewing Accepted Terms of Use Agreements

Before you can launch an image or a stack from a Marketplace listing, you must first read and accept all software terms of use agreements associated with the package version that you choose. This topic describes how to see what terms of use agreements you have accepted through Oracle Cloud Infrastructure Marketplace. Your organization might need or want to review the specific terms of use associated with a particular package version after you deploy one or more Marketplace listings.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For administrators, the following policies provide access to Marketplace.

- The following policy gives the specified group the ability to list accepted terms of use agreements. The terms of use agreement for a given listing must be viewed and accepted prior to launch. The policy does not include the ability to list, read, or use listings themselves. For that, see the policy statements that grant access to the type of listing you want to launch, whether an image listing or a stack listing.

  ```
  Allow group <IAM_group_name> to inspect compartments in tenancy
  ```

- The following policy gives the specified group the ability to list, read, and use Marketplace image listings. It does not include the ability to create instances using images from listings. (For that, see the next policy.) Furthermore, to reduce the scope of access to just creating subscriptions in a particular compartment, specify that compartment instead of the tenancy.

  ```
  Allow group <IAM_group_name> to manage app-catalog-listing in tenancy
  ```

- The following policy gives the specified group general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. Use this policy in conjunction with the preceding policy for users who need to launch instances from image listings. For users who need to launch stacks from stack listings, use this policy in conjunction with the next set of policies.

  ```
  Allow group <IAM_group_name> to manage instance-family in compartment ABC
  Allow group <IAM_group_name> to read app-catalog-listing in tenancy
  Allow group <IAM_group_name> to use volume-family in compartment ABC
  Allow group <IAM_group_name> to use virtual-network-family in compartment XYZ
  ```

- The policies described in Policies for Managing Resources Used with Resource Manager on page 3170 grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

If you need to write more restrictive policies, see the policy references on which these policies were based, Details for the Core Services on page 2855 and Details for Resource Manager on page 3033, as needed.

Using the Console

To view the accepted terms of use agreements for a given compartment

1. Open the navigation menu and click Marketplace. Under Marketplace, click All Applications.
2. Click Accepted Agreements.
3. Under **List Scope**, click **Compartment**, and then click the name of the compartment where you accepted a terms of use agreement that you now want to view.

4. In the list, next to the listing that you're interested in, click the Actions menu (⋮). (Marketplace independently lists package versions with their distinct terms of use agreements. Also, Marketplace tracks what agreements you accept regardless of whether you actually complete the software deployment. Therefore, the list might show the names of listings that you didn't actually finish deploying in your tenancy.)

5. To review any of the terms of use agreements you accepted for the specified listing and package version, click its name.

### Using the Command Line Interface (CLI)

For information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en-us/m湎2/). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](https://docs.oracle.com/en-us/m湎2/).

**To view the accepted terms of use agreements for a given compartment**

Open a command prompt and run `oci marketplace accepted-agreement list` to view a list of terms of use agreements that you previously accepted:

```bash
oci marketplace accepted-agreement list --compartment-id <compartment_id>
```

For example:

```bash
oci marketplace accepted-agreement list --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibploogtawbk3zz
```

### Using the API

For information about using the API and signing requests, see [REST APIs](https://docs.oracle.com/en-us/m paylaş/2/) and [Security Credentials](https://docs.oracle.com/en-us/m paylaş/). For information about SDKs, see [Software Development Kits and Command Line Interface](https://docs.oracle.com/en-us/m paylaş/).

Use the following operations to work with a listing's terms of use agreement:

- CreateAcceptedAgreement
- DeleteAcceptedAgreement
- GetAcceptedAgreement
- GetAgreement
- ListAcceptedAgreements
- ListAgreements
- UpdateAcceptedAgreement

### Oracle Cloud Microsoft Workloads Competency Partners

Oracle Cloud helps you build, deploy, scale, and manage Windows-based applications quickly, easily, securely, and cost-effectively.

The Oracle Partner Finder helps customers select the qualified partners for deploying Microsoft workloads on Oracle Cloud Infrastructure (OCI).

- **Find OCI Microsoft partners**

The Oracle Cloud Marketplace helps customers find qualified Microsoft solutions from the Oracle Partner Network (OPN) program.

- **Find Microsoft solutions in the OCI Marketplace**
Chapter 32

Monitoring

This chapter explains how to actively and passively monitor performance and usage metrics for your resources.

Monitoring

Use Monitoring to query metrics and manage alarms. Metrics and alarms help monitor the health, capacity, and performance of your cloud resources.

Get Started
- Learn about metrics
- View service dashboards
- Services that emit metrics
- Learn about alarms

Query Metrics
- Create a query
- Filter by dimensions
- Aggregate results
- Learn about Monitoring Query Language (MQL)

Publish Custom Metrics
- Steps to publish custom metrics

Troubleshooting
- Investigate missing resources or metrics
- Troubleshoot query limits
- Confirm validity of alarm intervals

Manage Alarms
- Alarms best practices
- View firing alarms
- Create a threshold alarm
- Suppress an alarm

- Cloud infrastructure community forum

Overview of Monitoring

The Oracle Cloud Infrastructure Monitoring service enables you to actively and passively monitor your cloud resources using the Metrics and Alarms features.
How Monitoring Works

The Monitoring service uses metrics to monitor resources and alarms to notify you when these metrics meet alarm-specified triggers.

Metrics are emitted to the Monitoring service as raw data points, or timestamp-value pairs, along with dimensions and metadata. Metrics come from a variety of sources:

- Resource metrics automatically posted by Oracle Cloud Infrastructure resources. For example, the Compute service posts metrics for monitoring-enabled Compute instances through the oci_computeagent namespace. One such metric is CpuUtilization. See Supported Services on page 3468 and Viewing Default Metric Charts on page 3470.
- Custom metrics published using the Monitoring API.
- Data sent to new or existing metrics using Service Connector Hub on page 4752.

Metric data posted to the Monitoring service is only presented to you or consumed by the Oracle Cloud Infrastructure features that you enable to use metric data.

When you query a metric, the Monitoring service returns aggregated data according to the specified parameters. You can specify a range (such as the last 24 hours), statistic, and interval. The Console displays one monitoring chart per metric for selected resources. The aggregated data in each chart reflects your selected statistic and interval. API requests can optionally filter by dimension and specify a resolution. API responses include the metric name along with its source compartment and metric namespace. You can feed the aggregated data into a visualization or graphing library.

Metric and alarm data is accessible via the Console, CLI, and API. For retention periods, see Storage Limits on page 3470.

The Alarms feature of the Monitoring service publishes alarm messages to configured destinations managed by the Notifications service. Each destination is a topic with a set of subscribers. For more information about the Notifications service, see Notifications Overview on page 4248.

Message types

The message type indicates the reason that the message was sent.

- OK_TO_FIRING: The alarm changed from OK status to FIRING status.
- FIRING_TO_OK: The alarm changed from FIRING status to OK status.
- REPEAT: The alarm is maintaining a FIRING status and repeat notifications are configured.
Monitoring

- **RESET**: The alarm is not detecting the metric firing; the metric is no longer being emitted. The resource that was emitting the metric might have been moved or terminated.

**Important:**
When a RESET status change occurs, determine the health of the resource.

**Message format and examples**

Alarm message format:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dedupekey</td>
<td><strong>string</strong> Unique identifier for all the alarm messages of the alarm. Use for de-duplication.</td>
</tr>
<tr>
<td>title</td>
<td><strong>string</strong> The alarm's configured display name.</td>
</tr>
<tr>
<td>body</td>
<td><strong>string</strong> The alarm's configured message body.</td>
</tr>
<tr>
<td>type</td>
<td><strong>string</strong> The reason for sending the notification message. Valid values: See Message types on page 3459.</td>
</tr>
<tr>
<td>severity</td>
<td><strong>string</strong> The highest severity level of the listed alarms. Valid values: CRITICAL, ERROR, WARNING, and INFO</td>
</tr>
<tr>
<td>timestampEpochMillis</td>
<td><strong>long</strong> The time when the alarm was triggered, in milliseconds since epoch time.</td>
</tr>
<tr>
<td>timestamp</td>
<td><strong>string</strong> The time when the alarm was triggered, in ISO-8601 format. Same information as in timestampEpochMillis.</td>
</tr>
<tr>
<td>alarmMetadata</td>
<td><strong>array of objects</strong> List of alarms related to this notification message.</td>
</tr>
<tr>
<td>version</td>
<td><strong>int</strong> The version of the alarm message format.</td>
</tr>
</tbody>
</table>

**alarmMetadata format:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td><strong>string</strong> The alarm OCID.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm state. Valid values: OK, FIRING</td>
</tr>
<tr>
<td>severity</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm severity level. Valid values: CRITICAL, ERROR, WARNING, INFO</td>
</tr>
<tr>
<td>query</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm's configured query.</td>
</tr>
<tr>
<td></td>
<td>CpuUtilization[1m]{availabilityDomain=&quot;cumS:PHX-AD-1&quot;}.absent()</td>
</tr>
<tr>
<td>totalMetricsFiring</td>
<td>int</td>
</tr>
<tr>
<td>Required</td>
<td>The number of metric streams represented in this notification message.</td>
</tr>
<tr>
<td>dimensions</td>
<td>array of objects</td>
</tr>
<tr>
<td></td>
<td>List of dimension key-value pairs that identify each metric stream. The list is limited to a hundred entries. Empty for an alarm with a status of OK.</td>
</tr>
</tbody>
</table>

Example messages, by subscription protocol, for an alarm titled "High CPU Utilization" that is continuing to be in the FIRING state. In this example, the message includes two metric streams: one for "myinstance1" and another for "myinstance2."

**Email and Slack**

```json
{"dedupeKey":"exampleuniqueID","title":"High CPU Utilization","body":"Follow runbook at http://example.com/runbooks","type":"REPEAT","severity":"CRITICAL","timestampEpochMillis":1542406320000,"timestamp":"2018-11-16T22:12:00Z","alarmMetaData": [{"id":"ocid1.alarm.oc1.iad.exampleuniqueID","status":"FIRING","severity":"CRITICAL","query":"CpuUtilization[1m].mean()>0","totalMetricsFiring":2,"dimensions": [{"instancePoolId":"Default","resourceDisplayName":"myinstance1","faultDomain":"FAULT-DOMAIN-1","resourceId":"ocid1.instance.oc1.iad.exampleuniqueID","imageId":"ocid1.image.oc1.iad.exampleuniqueID","availabilityDomain":"szYB:US-ASHBURN-AD-1","shape":"VM.Standard2.1","region":"us-ashburn-1"},
{"instancePoolId":"Default","resourceDisplayName":"myinstance2","faultDomain":"FAULT-DOMAIN-3","resourceId":"ocid1.instance.oc1.iad.exampleuniqueID","imageId":"ocid1.image.oc1.iad.exampleuniqueID","availabilityDomain":"szYB:US-ASHBURN-AD-1","shape":"VM.Standard2.1","region":"us-ashburn-1"}]
},"version":1.1}
```

**SMS**
Text in example SMS message

```
119L3T: [CRITICAL] "High CPU Utilization" has transitioned to OK_TO_FIRING at 2021-02-10T05:52:00Z
https://cloud.oracle.com/monitoring/alarms/status
```

**Metrics Feature Overview**

The Metrics feature relays *metric* data about the health, capacity, and performance of your cloud resources. A metric is a measurement related to health, capacity, or performance of a given *resource*. Resources, services, and applications emit metrics to the Monitoring service. Common metrics reflect data related to:

- Availability and latency
- Application uptime and downtime
- Completed transactions
- Failed and successful operations
- Key performance indicators (KPIs), such as sales and engagement quantifiers

By querying Monitoring for this data, you can understand how well the systems and processes are working to achieve the service levels you commit to your customers. For example, you can monitor the CPU utilization and disk reads of your Compute *instances*. You can then use this data to determine when to launch more instances to handle increased load, troubleshoot issues with your instance, or better understand system behavior.

**Example Metric: Failure Rate**

For application health, one of the common KPIs is failure rate, for which a common definition is the number of failed transactions divided by total transactions. This KPI is usually delivered through application monitoring and management software.

As a developer, you can capture this KPI from your applications using *custom metrics*. Simply record observations every time an application transaction takes place and then post that data to the Monitoring service. In this case, set up metrics to capture failed transactions, successful transactions, and transaction latency (time spent per completed transaction).
Alarms Feature Overview

The Alarms feature of the Monitoring service works with the Notifications service to notify you when metrics meet alarm-specified triggers. The previous illustration depicts the flow, starting with resources emitting metric data points to Monitoring. When triggered, an alarm sends an alarm message to the configured topic (in Notifications), which then sends the message on to all of the topic's subscriptions. (This illustration does not cover raw and aggregated metric data. For these details, see the "Monitoring Overview" illustration.)

When configured, repeat notifications remind you of a continued firing state at the configured repeat interval. You are also notified when an alarm transitions back to the OK state, or when an alarm is reset.

You can search for alarms using Search-supported attributes. For more information about Search, see Overview of Search on page 4620.

Search-Supported Attributes for Alarms

For attribute descriptions, see Alarm Reference.

- id
- displayName
- compartmentId
- metricCompartmentId
- namespace
- query
- severity
- destinations
- suppression
- isEnabled
- lifecycleState
- timeCreated
- timeUpdated
- tags

Monitoring Concepts

The following concepts are essential to working with Monitoring.
aggregated data

The result of applying a statistic and interval to a selection of raw data points for a given metric. For example, you can apply the statistic max and interval 1h (one hour) to the last 24 hours of raw data points for the metric CpuUtilization. Aggregated data is displayed in default metric charts in the Console. You can also build metric queries for specific sets of aggregated data. For instructions, see Viewing Default Metric Charts on page 3470 and Building Metric Queries on page 3502.

alarm

The alarm query to evaluate and the notification destination to use when the alarm is in the firing state, along with other alarm properties. For instructions on managing alarms, see Managing Alarms on page 3523.

alarm query

The Monitoring Query Language (MQL) expression to evaluate for the alarm. An alarm query must specify a metric, statistic, interval, and a trigger rule (threshold or absence). The Alarms feature of the Monitoring service interprets results for each returned time series as a Boolean value, where zero represents false and a non-zero value represents true. A true value means that the trigger rule condition has been met. For more information, see Building Metric Queries on page 3502 and the query attribute description in the Alarm API reference.

data point

A timestamp-value pair for the specified metric. Example: 2018-05-10T22:19:00Z, 10.4

A data point is either raw or aggregated. Raw data points are posted by the metric namespace to the Monitoring service using the PostMetricData operation. The frequency of the data points posted varies by metric namespace. For example, your custom namespace might send data points for a given metric at a 20-second frequency.

Aggregated data points are the result of applying a statistic and interval to raw data points. The interval of the aggregated data points is determined by the SummarizeMetricsData request. For example, a request specifying the statistic sum and interval 1h (one hour) returns a sum value for each hour of available raw data points for the given metric.

dimension

A qualifier provided in a metric definition. Example: Resource identifier (resourceId), provided in the definitions of oci_computeagent metrics. Use dimensions to filter or group metric data. Example dimension name-value pair for filtering by availability domain: availabilityDomain = "VeBZ:PHX-AD-1"

frequency

The time period between each posted raw data point for a given metric. (Raw data points are posted by the metric namespace to the Monitoring service.) While frequency varies by metric, default service metrics typically have a frequency of 60 seconds (that is, one data point posted per minute). See also resolution.

interval

The time window used to convert the given set of raw data points.

The timestamp of the aggregated data point corresponds to the end of the time window during which raw data points are assessed. For example, for a five-minute interval, the timestamp "2:05" corresponds to the five-minute time window from 2:00 to 2:05:00.
The following example query specifies a 5-minute interval. `CpuUtilization[5m].max()` For supported values, see Monitoring Query Language (MQL) Reference on page 3546.

**Note:**
Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the 1h or 1d interval values are supported.

To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced mode.

See also resolution.

**message**

The content that the Alarms feature of the Monitoring service publishes to topics in the alarm's configured notification destinations. A message is sent when the alarm transitions to another state, such as from "OK" to "FIRING." For more information about messages, see How Monitoring Works on page 3459.

**metadata**

A reference provided in a metric definition. Example: unit (bytes), provided in the definition of the oci_computeagent `metricDiskBytesRead`. Use metadata to determine additional information about a given metric. For metric definitions, see Supported Services on page 3468.

**metric**

A measurement related to health, capacity, or performance of a given resource. Example: The oci_computeagent `metricCpuUtilization`, which measures usage of a Compute instance. For metric definitions, see Supported Services on page 3468.

**metric definition**

A set of references, qualifiers, and other information provided by a metric namespace for a given metric. For example, the oci_computeagent `metricDiskBytesRead` is defined by dimensions (such as resource identifier) and metadata (specifying bytes for unit) as well as identification of its metric namespace (oci_computeagent). Each posted set of data points carries this information. Use the ListMetricData API operation to get metric definitions. For metric definitions, see Supported Services on page 3468.

**metric namespace**

Indicator of the resource, service, or application that emits the metric. Provided in the metric definition. For example, the CpuUtilization metric definition emitted by the Oracle Cloud Agent software on Compute instances lists the metric namespace oci_computeagent as the source of the CpuUtilization metric. For metric definitions, see Supported Services on page 3468.

**metric stream**

An individual set of aggregated data for a metric. A stream can be either specific to a single resource or aggregated across all resources in the compartment. Within a metric chart in the Console, each metric stream is represented as a line. By default, metric streams are resource-specific, so the chart displays a line for each resource. If you choose to aggregate all metric streams, then the chart displays one line for all resources.

**notification destination**

Protocol and other details for sending messages when the alarm transitions to another state, such as from "OK" to "FIRING." The details and setup may vary by destination service. For the Notifications service,
each destination includes a topic and subscription protocol (such as PagerDuty). For more information about messages, topics, and subscriptions, see Notifications Overview on page 4248.

**Oracle Cloud Agent software**

Software that allows a Compute instance to post raw *data points* to the Monitoring service. Automatically installed with the latest versions of supported images. See Enabling Monitoring for Compute Instances on page 1154.

**query**

The Monitoring Query Language (MQL) expression to evaluate for returning *aggregated data*. The query must specify a *metric*, *statistic*, and *interval*. For more information, see Building Metric Queries on page 3502.

**resolution**

The period between time windows, or the regularity at which time windows shift. For example, use a resolution of 1 minute to retrieve aggregations every minute.

To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

### Note:

For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see `SummarizeMetricsData`.

### Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

### See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1 minute, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest
data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

As shown in the following illustration, resolution controls the start time of each aggregation window relative to the previous window while interval controls the length of the windows. Both requests apply the statistic max to the data within each five-minute window (from the interval), resulting in a single aggregated data point representing the highest CPU utilization counter for that window. Only the resolution value differs. This resolution changes the regularity at which the aggregation windows shift, or the start times of successive aggregation windows. Request A does not specify a resolution and thus uses the default value equal to the interval (5 minutes). This request's five-minute aggregation windows are thus taken from the sets of data points emitted from 0:0 to 5:00, 5:00 to 10:00, and so forth. Request B specifies a 1-minute resolution, so its five-minute aggregation windows are taken from the set of data points emitted every minute from 0:0 to 5:00, 1:0 to 6:00, and so forth.

As shown in the following illustration, resolution controls the start time of each aggregation window relative to the previous window while interval controls the length of the windows. Both requests apply the statistic max to the data within each five-minute window (from the interval), resulting in a single aggregated data point representing the highest CPU utilization counter for that window. Only the resolution value differs. This resolution changes the regularity at which the aggregation windows shift, or the start times of successive aggregation windows. Request A does not specify a resolution and thus uses the default value equal to the interval (5 minutes). This request's five-minute aggregation windows are thus taken from the sets of data points emitted from 0:0 to 5:00, 5:00 to 10:00, and so forth. Request B specifies a 1-minute resolution, so its five-minute aggregation windows are taken from the set of data points emitted every minute from 0:0 to 5:00, 1:0 to 6:00, and so forth.

resource group

A custom string provided with a custom metric that can be used as a filter or to aggregate results. The resource group must exist in the definition of the posted metric. Only one resource group can be applied per metric.

statistic

The aggregation function applied to the given set of raw data points. For supported statistics, see Monitoring Query Language (MQL) Reference on page 3546.

suppression

A configuration to avoid publishing messages during the specified time range. Useful for suspending alarm notifications during system maintenance. Each suppression applies to a single alarm. In the Console, you
can apply one definition of a suppression to multiple alarms. The result is an individual suppression for each alarm. For instructions on suppressing alarms, see To suppress alarms on page 3543.

**trigger rule**

The condition that must be met for the alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

**Availability**

The Monitoring service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

**Supported Services**

The following services have resources or components that can emit metrics to Monitoring:

- API Gateway - see API Gateway Metrics on page 456
- Application Performance Monitoring - see Application Performance Monitoring Metrics
- Bastion - see Bastion Metrics
- Big Data - see View Cluster Metrics
- Block Volume - see Block Volume Metrics on page 770
- Blockchain Platform - see Blockchain Platform Metrics
- Compute - see these topics:
  - Compute Instance Metrics on page 1158
  - Instance Pool Metrics on page 1163
  - Infrastructure Health Metrics on page 1165
  - Compute Management Metrics on page 1167
- Container Engine for Kubernetes - see Container Engine for Kubernetes Metrics on page 1319
- Data Catalog - see Data Catalog Metrics
- Data Flow - see Data Flow Metrics
- Data Integration - see Data Integration Metrics
- Data Science - see About Notebook Session Metrics
- Data Transfer - see these topics:
  - Disk-Based Data Import: Viewing Data Transfer Metrics on page 1525
  - Appliance-Based Data Import: Viewing Data Transfer Metrics on page 1586
  - Data Export: Viewing Data Transfer Metrics on page 1633
- Database - see Database Metrics on page 2109
- Database Migration - see Database Migration Metrics
- DevOps - see DevOps Metrics
- Digital Assistant - see Digital Assistant Metrics
- DNS - see DNS Metrics on page 2292

• Vault - see Vault Metrics on page 5080
• Vulnerability Scanning - see Scanning Metrics
• WAF - see WAF Metrics on page 5288

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric resources do not have OCIDs.</td>
</tr>
</tbody>
</table>

Ways to Access Monitoring

You can access the Monitoring service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

Console: To access Monitoring using the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

Open the navigation menu and click Observability & Management. Under Monitoring, click Service Metrics.

API: To access Monitoring through APIs, use Monitoring API for metrics and alarms and Notifications API for notifications (used with alarms).

Moving Alarms to a Different Compartment

You can move alarms from one compartment to another. When you move an alarm to a new compartment, its associated metrics remain where they are. After you move the alarm to the new compartment, inherent policies apply immediately and affect access to the alarm through the Console. For more information on moving resources to other compartments, see To move a resource to a different compartment on page 3139.
Important:
To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see Details for Monitoring on page 3013.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2820 and Restrict user access to a specific metric namespace on page 2820. For a common alarms policy, see Let users view alarms on page 2821. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group. Use the dynamic group's matching rules to add the resources, and then create a policy that allows that dynamic group access to metrics. See Let instances make API calls to access monitoring metrics in the tenancy on page 2821.

Limits on Monitoring

See Monitoring Limits on page 262 for a list of applicable limits and instructions for requesting a limit increase. Other limits include the following.

Storage Limits

<table>
<thead>
<tr>
<th>Item</th>
<th>Time range stored</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric definitions</td>
<td>14 days</td>
</tr>
<tr>
<td>Alarm history entries</td>
<td>90 days</td>
</tr>
</tbody>
</table>

Returned Data Limits (Metrics)

When you query metrics and view metric charts, the returned data is subject to certain limits. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

Troubleshooting Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Viewing Default Metric Charts

This topic describes how to view metric charts for selected resources or a single resource and create alarms based on queries used for charts. Charts are available using the Console.
Prerequisites

- IAM policies: Viewing metric charts is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2820 and Restrict user access to a specific metric namespace on page 2820.

- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 1154.

Working with Default Metric Charts

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview on page 3462. For default metrics by service, see Supported Services on page 3468.

Default metric charts use predefined service queries. You can select resources of interest and update the interval, statistic, and time range.

**Note:**

Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

Using the Console

**To view default metric charts for all resources**

2. Choose a Compartment you have permission to work in.
   
   The list of metric namespaces is updated for the selected compartment.
3. Choose the Metric namespace for the resource types of interest in the selected compartment.
   
   For example, choose oci_lbaas to see metrics for load balancers.

Default charts are displayed for all resources in the selected Metric namespace and Compartment. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

**Don't see all expected resources or metrics?**

- Try a different time range.
- Make sure the correct Compartment is selected.

Metric namespaces are shown only when associated resources exist in the selected compartment. For example, the oci_autonomous_database namespace is shown only when Autonomous Databases exist in the selected compartment.

- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances on page 1154.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

**To investigate missing resources or metrics**

- Try a different time range.
Monitoring

- Make sure the correct **Compartment** is selected.
  
  Metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.
- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances on page 1154.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

**To filter results**

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or region of interest.

Filtering of default metric charts is done through selected **dimensions**; available dimensions vary by metric.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. Choose a **Compartment** and **Metric namespace** to view the default charts for the resources of interest.
3. To the right of **Dimensions**, click **Add**.
4. In the **Edit dimensions** dialog box, select a **Dimension name** and **Dimension value**.
   
   **Dimension fields**
   - **Dimension name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.
   
   ```
   Note:
   Long lists of dimensions are trimmed.
   • To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
   • To retrieve all dimensions for a given metric, use the following API operation: ListMetrics
   ```
   - **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
   - **Additional dimension**: Adds another name-value pair for a dimension.
5. Click **Done**.

The default charts show the filtered results of your query.

**To select different resources**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. Choose a **Compartment** and **Metric namespace** to view the default charts for the resources of interest.
3. To select resources on a different compartment, select the **Compartment** and then re-select the **Metric namespace**.

   The default charts update to show results for the selected compartment.
4. To select a specific resource within the selected compartment, filter results by a resource-specific dimension, such as `resourceDisplayName`:
   a. To the right of **Dimensions**, click **Add**.
   b. For **Dimension name**, select `resourceDisplayName` or other resource-specific dimension.
   
   ```
   Note:
   Long lists of dimensions are trimmed.
   • To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
   ```
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- For Dimension value, select the value corresponding to the resource you want.
- Click Done.

The default charts update to show filtered results.

**To aggregate data from all metric streams**

Aggregate all metric streams to return the combined value of all metric streams for the selected statistic. For example, aggregate all metric streams for CPU Utilization to return the combined value across all resources.

By default, a chart represents each metric stream with a line, which results in multiple lines per chart. When you aggregate metric streams, a chart represents all metric streams with a single line, which results in just one line per chart.

The Aggregate metric streams option is equivalent to the grouping() query component.

2. Choose a Compartment and Metric namespace to view the default charts for the resources of interest.
3. Select Aggregate metric streams.

**To change the time range**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the 1h or 1d interval values are supported.

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the SummarizeMetricsData operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While
the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

1. Open the navigation menu and click **Observability & Management.** Under **Monitoring,** click **Service Metrics.**
2. Choose a **Compartment** and **Metric namespace** to view the default charts for the resources of interest.
3. Select a period of time from **Quick Selects.**

   For example, **Last hour.**
4. To specify the start or end of a period time, click in **Start time** or **End time** and then type a value.

### To change a chart interval or statistic

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

For metric queries, the **interval** you select drives the default **resolution** of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see [SummarizeMetricsData](#).

### Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to **Advanced mode.**

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the [SummarizeMetricsData](#) operation.

### See examples of returned data

**Example 1:** One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of **1m,** and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

**Example 2:** Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

1. Open the navigation menu and click **Observability & Management.** Under **Monitoring,** click **Service Metrics.**
2. Choose a **Compartment** and **Metric namespace** to view the default charts for the resources of interest.
3. At the top of the chart you want, select an **Interval** or **Statistic.**

   For supported values, see [Monitoring Query Language (MQL) Reference](#) on page 3546.
To go back to the default charts
On the upper right of the Service Metrics page, click Reset charts.

To view chart details
Chart details include the query as a Monitoring Query Language (MQL) expression and the names and OCIDs of represented resources.

2. Choose a Compartment and Metric namespace to view the default charts for the resources of interest.
3. Click the chart you want.
4. To view a list of resources represented in the chart, click the arrow to the left of the query displayed under the chart.

You can copy the OCID for a resource by clicking Copy to the right of the resource OCID.

To share a chart

Note:
The person you share the chart with must have the required IAM policies for access to metrics.

On the Service Metrics page, on the upper right of the chart you want, go to Options, and then click Copy Chart URL.

To view a query in Metrics Explorer
On the Service Metrics page, on the upper right of the chart you want, go to Options, and then click View Query in Metrics Explorer.

To copy a query (MQL expression)
On the Service Metrics page, on the upper right of the chart you want, go to Options, and then click Copy Query (MQL).

To view default metric charts for a single resource
On the page for the resource of interest, under Resources, click Metrics.

For example, to view metric data for a Compute instance:

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance you're interested in.
3. On the instance details page, under Resources, click Metrics.

A chart is shown for each metric. For a list of metrics related to Compute instances, see Compute Instance Metrics on page 1158.

The Console displays the last hour of metric data for the selected resource. A chart is shown for each metric emitted by the selected resource.

For a list of metrics emitted by your resource, see Supported Services on page 3468.

To create an alarm from a chart query
Follow the instructions for the page on which the query appears: Service Metrics or Metrics Explorer.

Service Metrics page
To create an alarm from a chart query (Service Metrics)

2. Choose a Compartment and Metric namespace to view the default charts for the resources of interest.
3. At the top of the chart you're interested in, go to Options, and then select Create an Alarm on this Query.
4. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

**Basic Mode (default)**

By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm name:**
  
  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity:** The perceived type of response required when the alarm is in the firing state.

- **Alarm body:** The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional):** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description:** The metric to evaluate for the alarm condition.

  - **Compartment:** The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

  - **Metric namespace:** The service or application emitting metrics for the resources that you want to monitor.

  - **Resource group (optional):** The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

  - **Metric name:** The name of the metric. Only one metric can be specified. Example: CpuUtilization

  - **Interval:** The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

*Note:*

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**
For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic:** The aggregation function.

**Statistic values**
- **Count** - The number of observations received in the specified time period.
- **Max** - The highest value observed during the specified time period.
- **Mean** - The value of Sum divided by Count during the specified time period.
- **Min** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **Rate** - The per-interval average rate of change.
- **Sum** - All values added together.

- **Metric dimensions:** Optional filters to narrow the metric data evaluated.

**Dimension fields**
- **Dimension name:** A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

**Note:**
Long lists of dimensions are trimmed.
- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic.
  - The **Aggregate metric streams** option is equivalent to the `grouping()` query component.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
- **Operator**: The operator used in the condition threshold.
  - **Operator values**
    - greater than
    - greater than or equal to
    - equal to
    - less than
    - less than or equal to
    - between (inclusive of specified values)
    - outside (inclusive of specified values)
    - absent
- **Value**: The value to use for the condition threshold.
- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 3546.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.

  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

  - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.

  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

  - **Query code editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

    ```
    CpuUtilization[1m]
    {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
    ```

    For query syntax and examples, see Working with Metric Queries on page 3503.

  - **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

**Notifications settings**

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
    
    Available options:
    - **Notifications Service**.
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
  - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
    
    - **Topic name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic description**: Description of the new topic.
    - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      
      **Email subscription**
      
      Sends an email message when you publish a *message* to the subscription's parent *topic*.
      
      Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
      
      Some message types allow **friendly formatting**.
      
      - **Subscription protocol**: Select Email.
      - **Subscription Email**: Type an email address.

  - **Function subscription**
    
    Runs the specified *function* when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

  **Note:**

  You must have **FN_INVOCATION** permission against the function to be able to add the function as a subscription to a topic.

  The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at [Function not invoked or run](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/user-guide/monitoring.html#Function-not-invoked) on page 4284.
Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select **Function**.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a `message` to the subscription's parent `topic`.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the `integration key` portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a `message` to the subscription's parent `topic`.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a `message` to the subscription's parent `topic`.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a `message` to the subscription's parent `topic`. Supported endpoint formats: E.164 format.

**Note:**

- International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.
- SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>

</tr>
</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**

Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression description**
  - **Start time**
  - **End time**

6. If you want to disable the new alarm, clear **Enable this alarm?**.
7. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

For more information about alarms, see **Alarms Feature Overview** on page 3463.

**Metrics Explorer page**

To create an alarm from a chart query (Metrics Explorer)

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Click **Create Alarm**.
4. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

**Basic Mode (default)**

By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm name:**
  
  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>

</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity:** The perceived type of response required when the alarm is in the firing state.
- **Alarm body:** The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description:** The metric to evaluate for the alarm condition.
  - **Compartment:** The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace:** The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group (optional):** The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric name:** The name of the metric. Only one metric can be specified. Example: CpuUtilization
  - **Interval:** The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

**Note:**

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**
For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  **Statistic values**
  - **Count** - The number of observations received in the specified time period.
  - **Max** - The highest value observed during the specified time period.
  - **Mean** - The value of Sum divided by Count during the specified time period.
  - **Min** - The lowest value observed during the specified time period.
  - **P50** - The value of the 50th percentile.
  - **P90** - The value of the 90th percentile.
  - **P95** - The value of the 95th percentile.
  - **P99** - The value of the 99th percentile.
  - **P99.5** - The value of the 99.5th percentile.
  - **Rate** - The per-interval average rate of change.
  - **Sum** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

  **Note:**
  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: `ListMetrics`

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic.

The `Aggregate metric streams` option is equivalent to the `grouping()` query component.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.
  - **Operator values**
    - greater than
    - greater than or equal to
    - equal to
    - less than
    - less than or equal to
    - between (inclusive of specified values)
    - outside (inclusive of specified values)
    - absent
  - **Value**: The value to use for the condition threshold.

- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See **Monitoring Query Language (MQL) Reference** on page 3546.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>

</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.

- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
Monitoring

more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

• **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.

  • **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

  • **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.

  • **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

  • **Query code editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.</td>
</tr>
</tbody>
</table>

Example alarm query:

```
CpuUtilization[1m] {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 3503.

• **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

**Notifications settings**

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    - **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    - **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
    - **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.

    - **Topic name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic description**: Description of the new topic.
    - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

      **Email subscription**

      Sends an email message when you publish a *message* to the subscription's parent *topic*.

      Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

      Some message types allow friendly formatting.

      - **Subscription protocol**: Select Email.
      - **Subscription Email**: Type an email address.

    **Function subscription**

    Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

    **Note:**

    You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.

    The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at **Function not invoked or run** on page 4284.
Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select **Function**.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The <webhook-token> portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a message to the subscription's parent topic. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>
<td>CA</td>
</tr>
<tr>
<td>Chile</td>
<td>CL</td>
</tr>
<tr>
<td>China</td>
<td>CN</td>
</tr>
<tr>
<td>Costa Rica</td>
<td>CR</td>
</tr>
<tr>
<td>Croatia</td>
<td>HR</td>
</tr>
<tr>
<td>Czechia</td>
<td>CZ</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
<tr>
<td>Germany</td>
<td>DE</td>
</tr>
<tr>
<td>Hungary</td>
<td>HU</td>
</tr>
<tr>
<td>India</td>
<td>IN</td>
</tr>
<tr>
<td>Ireland</td>
<td>IE</td>

<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**

Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.

**Note:**

- **Suppression description**
- **Start time**
- **End time**

6. If you want to disable the new alarm, clear **Enable this alarm**.
7. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

For more information about alarms, see **Alarms Feature Overview** on page 3463.

**resource page**

Examples of resource pages are Compute instance detail pages and Block Volume volume detail pages. Alarms are available from these pages for resources that emit metrics.

To create an alarm from a chart query (resource page)

1. To view charts: On the resource page, under **Resources**, click **Metrics**.
2. At the top of the chart you're interested in, go to **Options**, and then select **Create an Alarm on this Query**.
3. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

Basic Mode (default)
By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm name:**
  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity:** The perceived type of response required when the alarm is in the firing state.
- **Alarm body:** The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description:** The metric to evaluate for the alarm condition.
  - **Compartment:** The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace:** The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric name:** The name of the metric. Only one metric can be specified. Example: **CpuUtilization**
  - **Interval:** The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

**Note:**
Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**
For alarm queries, the specified `interval` has no effect on the `resolution` of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see [Alarm](#).

- **Statistic:** The aggregation function.

  **Statistic values**
  - **Count** - The number of observations received in the specified time period.
  - **Max** - The highest value observed during the specified time period.
  - **Mean** - The value of Sum divided by Count during the specified time period.
  - **Min** - The lowest value observed during the specified time period.
  - **P50** - The value of the 50th percentile.
  - **P90** - The value of the 90th percentile.
  - **P95** - The value of the 95th percentile.
  - **P99** - The value of the 99th percentile.
  - **P99.5** - The value of the 99.5th percentile.
  - **Rate** - The per-interval average rate of change.
  - **Sum** - All values added together.

- **Metric dimensions:** Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension name:** A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

  **Note:**
  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic.

The *Aggregate metric streams* option is equivalent to the *grouping()* query component.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
- **Operator**: The operator used in the condition threshold.

  **Operator values**
  - greater than
  - greater than or equal to
  - equal to
  - less than
  - less than or equal to
  - between (inclusive of specified values)
  - outside (inclusive of specified values)
  - absent
- **Value**: The value to use for the condition threshold.
- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See **Monitoring Query Language (MQL) Reference** on page 3546.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Query code editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  **Note:**
  
  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

Example alarm query:

```plaintext
CpuUtilization[1m]
{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 3503.

- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
4. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
  - Available options:
    - **Notifications Service**.
  - **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
  - **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
    - **Topic name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic description**: Description of the new topic.
    - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      - **Email subscription**: Sends an email message when you publish a message to the subscription's parent topic.
        - Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        - Some message types allow friendly formatting.
      - **Subscription protocol**: Select Email.
      - **Subscription Email**: Type an email address.

- **Function subscription**
  - Runs the specified function when you publish a message to the subscription's parent topic. For example, runs a function to resize VMs when an associated alarm is triggered.

**Note:**

You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.

The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at [Function not invoked or run](#) on page 4284.
Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select Function.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>

</tr>
<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**
Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
- **Suppression description**
- **Start time**
- **End time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

For more information about alarms, see **Alarms Feature Overview** on page 3463.

### Building Metric Queries

This topic describes how to query metrics for resources of interest, create alarms from a given query, and share Console charts.

### Prerequisites

- **IAM policies**: Querying metrics is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2820 and Restrict user access to a specific metric namespace on page 2820.
- **Metrics exist in Monitoring**: The resources that you want to monitor must emit metrics to the Monitoring service.
- **Compute instances**: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send
metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 1154.

**Working with Metric Queries**

This section shows MQL syntax of metric and alarm queries.

Use metric queries to actively and passively monitor your cloud resources. Actively monitor with metric queries that you generate spontaneously, on demand. In the Console, update a chart to show data from multiple queries. Store queries you want to reuse. Passively monitor with alarms that add a condition, or trigger rule, to a metric query.

Metric query syntax (boldface elements are required):

```
metric[interval]{dimensionname=dimensionvalue}.groupingfunction.statistic
```

Threshold Alarm query syntax (boldface elements are required):

```
metric[interval]{dimensionname=dimensionvalue}.groupingfunction.statistic almoperator alarmvalue
```

For supported parameter values, see Monitoring Query Language (MQL) Reference on page 3546.

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview on page 3462.

**Example queries**

**Simple metric query**

Maximum CPU Utilization at a one-minute interval.

Number of lines displayed in the metric chart (Console): 1 per resource.

```
CpuUtilization[1m].max()
```

**Filtered metric query**

Maximum CPU Utilization at a one-minute interval, filtered to a single resource.

Number of lines displayed in the metric chart (Console): 1.

```
CpuUtilization[1m]{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
```

**Aggregated metric query**

All IopsRead at a one-minute interval, filtered to a compartment, aggregated for the maximum.

Number of lines displayed in the metric chart (Console): 1.

```
IopsRead[1m]{compartmentId="ocid1.compartment.oc1.phx..exampleuniqueID"}.grouping().max()
```

**Group-aggregated metric query**

Aggregated average of CPU Utilization by availability domain and pool ID, filtered to Compute instances that use the specified shape.

Number of lines displayed in the metric chart (Console): 1 per pool and 1 per availability domain.

```
CPUUtilization[1m]{shape="VM.Standard2.8"}.groupBy(availabilityDomain,poolId).mean()
```

**Alarm query (threshold)**

Triggered when the 90th percentile of CPU Utilization, aggregated by pool ID, and filtered to the specified availability domain, exceeds 85.
Number of lines displayed in the metric chart (Console): 1 per pool.

\[
\text{CpuUtilization}[1m]\{\text{availabilityDomain}="\text{VeBZ:PHX-AD-1}"\}.\text{groupBy(poolId).percentile(0.9)} > 85
\]

**Grouped count of resources (alarm query or metric query)**

**Note:**

Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.

An example of a nested query is a grouped count of hosts with up time greater than zero, where the alarm query to identify these hosts is defined within parentheses:

\[
(metric[1h].\text{groupBy(host).min()} > 0).\text{grouping().count()}
\]

You can use such a query to either define an alarm or query a metric.

**Using the Console**

**To create a query**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.

   The **Metrics Explorer** page displays an empty chart with fields to build a query.

2. Fill in the fields for a new query.

   - **Compartment**: The compartment containing the resources that you want to monitor. By default, the first accessible compartment is selected.
   - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.
   - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
   - **Metric name**: The name of the metric. Only one metric can be specified. Metric selections depend on the selected compartment and metric namespace. Example: **CpuUtilization**
   - **Interval**: The aggregation window.

**Interval values**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

   - **1m** - 1 minute
   - **5m** - 5 minutes
   - **1h** - 1 hour
   - **1d** - 1 day

**Note:**

For metric queries, the **interval** you select drives the default **resolution** of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see **SummarizeMetricsData**.

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.
The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st.
Monitoring

Therefore, only 5 days of metric data points can be returned in this example.

- **Statistic**: The aggregation function.

**Statistic values**

- **Count**: The number of observations received in the specified time period.
- **Max**: The highest value observed during the specified time period.
- **Mean**: The value of Sum divided by Count during the specified time period.
- **Min**: The lowest value observed during the specified time period.
- **P50**: The value of the 50th percentile.
- **P90**: The value of the 90th percentile.
- **P95**: The value of the 95th percentile.
- **P99**: The value of the 99th percentile.
- **P99.5**: The value of the 99.5th percentile.
- **Rate**: The per-interval average rate of change.
- **Sum**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

**Dimension fields**

- **Dimension name**: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
- To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.

- **Aggregate metric streams**: Plots a single line on the metric chart to represent the combined value of all metric streams for the selected statistic.

3. Click **Update Chart**.

The chart shows the results of your new query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

4. To change the view of the query results, click the appropriate option above the results, on the right:

- **Show Data Table**: Lists data points, indicating time stamp and bytes for each.
- **Show Graph** (default): Plots data points on a graph.
5. To customize the y-axis label or range, type the label you want into **Y-Axis Label** or type the minimum and maximum values you want into **Y-Axis Min value** and **Y-Axis Max value**.

Only numeric characters are allowed for custom ranges. Custom labels and ranges are not persisted in shared queries (MQL).

6. To view the query as a Monitoring Query Language (MQL) expression, select **Advanced Mode**.

**Advanced Mode** is located on the right, under the chart.

Use **Advanced Mode** to edit your query using MQL syntax to aggregate results by group. The MQL syntax also supports additional parameter values. For more information about query parameters in Basic Mode and Advanced Mode, see **Monitoring Query Language (MQL) Reference** on page 3546.

7. To create another query, click **Add Query** below the chart.

### To change the time range

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

For metric queries, the **interval** you select drives the default **resolution** of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see **SummarizeMetricsData**.

#### Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to **Advanced mode**.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the **SummarizeMetricsData** operation.

#### See examples of returned data

**Example 1:** One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of **1m**, and the end time defaults to the current time (**2019-01-08T10:00:00.789Z**). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (**2019-01-01T10:00:00.789Z**).

**Example 2:** Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (**2019-01-06T10:00:00.789Z**), the earliest data point possible within this seven-day period would be 10:00 on January 1st (**2019-01-01T10:00:00.789Z**). Therefore, only 5 days of metric data points can be returned in this example.

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. Select a period of time from **Quick Selects**. For example, **Last hour**.

3. To specify the start or end of a period time, click in **Start time** or **End time** and then type a value.

**To filter results**

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or pool of interest. Filtering is done through selected **dimensions**; available dimensions vary by metric.

You can also match **resource groups** provided with the metric. Blank (null) for resource group returns metric data that does not have a resource group.

**To filter by dimensions**

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Under **Metric dimensions**, select a **Dimension name** and **Dimension value**.

**Dimension fields**

- **Dimension name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

  **Note:**

  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
  - To retrieve all dimensions for a given metric, use the following API operation: `ListMetrics`.

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.

4. To add a dimension name-value pair, click **+ Additional dimension**.

5. Click **Update Chart**.

The chart shows the filtered results of your query.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of **metric streams**, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and **time range maximums** (determined by resolution, which relates to interval). See **MetricData Reference**.

6. To view the query as a Monitoring Query Language (MQL) expression, select **Advanced Mode**.

The dimension name-value fragment appears after the metric-interval fragment.

In the following example query, the dimension name-value fragment is `{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}`, which filters results by the specified resource identifier.

```csharp
CpuUtilization[1m]
{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
```

The **MQL** syntax supports more parameter values. See **Monitoring Query Language (MQL) Reference** on page 3546.
To match resource group

You can match resource groups provided with the metric.

Note:
Blank (null) for resource group returns metric data that does not have a resource group.

2. If necessary, open the query for editing: Click Edit queries.
3. Select the Resource group you want to use as a filter.
4. Click Update Chart.

The chart shows query results that match the resource group.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To aggregate all results

Aggregate all metric streams to return the combined value of all metric streams for the selected statistic. For example, aggregate all metric streams for CPU Utilization to return the combined value across all resources.

By default, a chart represents each metric stream with a line, which results in multiple lines per chart. When you aggregate metric streams, a chart represents all metric streams with a single line, which results in just one line per chart.

The Aggregate metric streams option is equivalent to the grouping() query component.

2. If necessary, open the query for editing: Click Edit queries.
3. Select Aggregate metric streams.
4. Click Update Chart.

The chart shows the results of your query.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

5. To view the query as a Monitoring Query Language (MQL) expression, select Advanced Mode.

The grouping() function appears before the statistic. For example, the following query returns the maximum (max()) IopsRead metric data at a one-minute interval, filtered to a compartment, with all results aggregated.

IopsRead[1m]{compartmentID = "<compartment_OCID">}.grouping().max()

Edit your query in MQL to aggregate results by group. The MQL syntax also supports more parameter values. See Monitoring Query Language (MQL) Reference on page 3546.
To aggregate results by group

Note:

Aggregating query results by group requires the `groupBy()` function, which is available in **Advanced Mode** only.

Aggregate query results by group to plot a value for each group. This option returns the combined value of all metric streams in each specified group for the selected statistic. Each group’s combined value is plotted as a single line on the metric chart. This option is helpful when you want to identify trends by group rather than individual resource.

For example, the following query returns the `(mean())` CPU Utilization metric data at a one-minute interval. Results are filtered to the specified `shape` and grouped by `availability domain`. If you have Compute instances of this shape sending metrics across three availability domains, then three lines are plotted on the metric chart.

```plaintext
CPUUtilization[1m]{shape="VM.Standard1.1"} .groupBy(availabilityDomain) .mean()
```

You can also aggregate by **resource groups** when provided with the metric `(groupBy(resourceGroup))`.

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Select **Advanced Mode** below the chart on the right.
4. In the **Query code editor** box, insert the `groupBy({dimension})` function between the metric-interval fragment and the statistic, where `{dimension}` is the name of a dimension provided in the definition of the indicated metric.

For example, insert the following fragment to group by availability domain, assuming that the dimension is available for the selected metric.

```plaintext
groupBy(availabilityDomain)
```

The **MQL** syntax supports more parameter values. See **Monitoring Query Language (MQL) Reference** on page 3546.

5. Click **Update Chart**.

The chart is updated to show a single line for each grouped result.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of **metric streams**, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and **time range maximums** (determined by resolution, which relates to interval). See **MetricData Reference**.

**To edit a query using MQL syntax**

Edit your query using **MQL** syntax to aggregate results by group or for more parameter values. See **Monitoring Query Language (MQL) Reference** on page 3546.

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Click **Advanced Mode**.

The query is displayed as a Monitoring Query Language (MQL) expression.

4. In the **Query Code Editor** box, edit the query as needed.
5. Click **Update Chart**.
   The chart is updated.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and **time range maximums** (determined by resolution, which relates to interval). See **MetricData Reference**.

**To create an alarm from a query**

Create an alarm to passively monitor for a condition in results from metric queries. Creating an alarm from a query involves adding a trigger rule to the query and setting up notifications.

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Click **Create Alarm**.
4. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

**Alarm settings**

**Basic Mode (default)**

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.

- **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

- **Metric name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  **Interval values**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.</td>
</tr>
</tbody>
</table>

  | 1m  - 1 minute |
  | 5m  - 5 minutes |
  | 1h  - 1 hour   |
  | 1d  - 1 day    |

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm</td>
</tr>
</tbody>
</table>
query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

• **Statistic**: The aggregation function.

  **Statistic values**
  - **Count**: The number of observations received in the specified time period.
  - **Max**: The highest value observed during the specified time period.
  - **Mean**: The value of Sum divided by Count during the specified time period.
  - **Min**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **Rate**: The per-interval average rate of change.
  - **Sum**: All values added together.

• **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension name**: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

  **Note:**
  
  Long lists of dimensions are trimmed.
  
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

• **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.

• **+ Additional dimension**: Adds another name-value pair for a dimension.

• **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic.

  The Aggregate metric streams option is equivalent to the grouping() query component.

• **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

• **Operator**: The operator used in the condition threshold.

  **Operator values**
  
  • greater than
  • greater than or equal to
  • equal to
  • less than
  • less than or equal to
  • between (inclusive of specified values)
  • outside (inclusive of specified values)
  • absent

• **Value**: The value to use for the condition threshold.

• **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 3546.

• **Alarm name**: 

  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

• **Alarm severity**: The perceived type of response required when the alarm is in the firing state.

• **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

• **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Query code editor box**: The alarm query as a Monitoring Query Language (MQL) expression.

  **Note:**

  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

  Example alarm query:

  ```
  CpuUtilization[1m]
  {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries on page 3503.

- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

**Notifications settings**

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
    - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
      
      - **Topic name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
      - **Topic description**: Description of the new topic.
      - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
        
        **Email subscription**
        
        Sends an email message when you publish a *message* to the subscription's parent *topic*.
        
        Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        
        Some message types allow friendly formatting.
        
        - **Subscription protocol**: Select Email.
        - **Subscription Email**: Type an email address.

    - **Function subscription**
      
      Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.

    **Note:**

    You must have **FN_INVOCATION** permission against the function to be able to add the function as a subscription to a topic.
    
    The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at [Function not invoked or run](#) on page 4284.
Confirmation is not required for function subscriptions.

- **Subscription protocol**: Select **Function**.
- **Function Compartment**: Select the compartment containing your function.
- **Function Application**: Select the application containing your function.
- **Function**: Select your function.

**HTTPS (Custom URL) subscription**

Sends specified information when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL using HTTPS protocol):

```markdown
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a message to the subscription's parent topic. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>

</tr>
</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**
Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression description**
  - **Start time**
  - **End time**

6. If you want to disable the new alarm, clear **Enable this alarm?**.
7. Click **Save alarm**.
   
The new alarm is listed on the **Alarm Definitions** page.

For more information about alarms, see **Alarms Feature Overview** on page 3463.

**To hide a query from the chart**

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. Under the chart and to the left, click the **Toggle query on chart** icon for the query that you want to hide.

**To share a query**

1. View the **Metrics Explorer** page: Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**.
2. If necessary, open the query for editing: Click **Edit queries**.
3. Select **Advanced Mode**.
4. In the **Query code editor** box, copy the query.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use this API operation to find metric names and dimensions (view **metric definitions**):

**ListMetrics**
Use this API operation to query metrics by name (and optionally filter by dimension):

**SummarizeMetricsData**

**Publishing Custom Metrics**

This topic describes how to publish your own custom metrics to the Monitoring service.

You can publish your own metrics to Monitoring using the API. You can view charts of your published metrics using the Console, query metrics using the API, and set up alarms using the Console or API.

**Prerequisites**

IAM policies: To publish custom metrics, you must be given the required type of access in a policy written by an administrator. This requirement applies whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. Administrators: For a related common policy, see Let users publish custom metrics on page 2820.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

**Note:**

When defining your custom metrics, note the following:

- Ensure that your custom metrics do not exceed limits. For example, note the valid range of dimensions and maximum number of streams for custom metrics. See PostMetricData.
- Define your metrics with aggregation in mind. While custom metrics can be posted as frequently as every second (minimum frequency of one second), the minimum aggregation interval is one minute.
- Define your metrics with return limits in mind. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.
- When retrieving custom metrics, you can match to a resource group. Blank (null) for resource group returns metric data that does not have a resource group.

Use this API operation to publish custom metrics:

**PostMetricData**

**Note:**

Oracle recommends the following:

- Send batched requests to maximize metric streams per request. A batched request contains multiple metrics or metric namespaces. Note limits. See PostMetricData.
- Publish metrics only when relevant contexts require monitoring; that is, when data points need to be collected. If you want to publish metrics during inactive periods when no observations exist, then you can manually create "0" values for publishing.

You can access your published custom metrics the same way you access any other metrics stored by the Monitoring service. View charts from queries using the Console, query metrics using the CLI or API, and set up alarms using the Console, CLI, or API.
Example of a batched request

This example shows a single request containing data points for metrics across two metric namespaces.

```json
[
    {
        "namespace": "myFirstNamespace",
        "compartmentId": "ocid1.compartment.oc1..exampleuniqueID",

            "unit": "bytes",
            "displayName": "MyAppB Delivery Rate"
        }
    }
]
```
Managing Alarms

This topic describes how to create, update, suppress, and delete alarms, as well as how to retrieve alarm history. See also Best Practices for Your Alarms on page 3544.

Prerequisites

- IAM policies: Managing alarms is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For a common alarms policy, see Let users view alarms on page 2821.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 1154.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Using the Console

To see all firing alarms

Open the navigation menu and click Observability & Management. Under Monitoring, click Alarm Status.

You can suppress alarms during a given time range. You can also disable and delete alarms.

To create an alarm

This section includes steps to create example alarms as well as any kind of alarm.

To create an example threshold alarm

This procedure walks through creation of an example threshold alarm to detect Compute instances operating at non-optimal thresholds. A threshold alarm is an alarm that checks for metric values outside a given range or value. The procedure uses options as displayed in Basic Mode.
1. Open the navigation menu and click **Observability & Management.** Under **Monitoring,** click **Alarm Definitions.**

2. Click **Create alarm.**

3. On the **Create Alarm** page, under **Define alarm,** fill in or update the alarm settings:

   - **Alarm name:** Non-Optimal Alarm
   - **Alarm severity:** Warning
   - **Alarm body:** Non-optimal utilization detected. An application or process may be consuming more CPU than usual.
   - **Metric description:**
     - **Compartment:** (select your `compartment`)
     - **Metric namespace:** `oci_computeagent`
     - **Metric name:** `CpuUtilization`
     - **Interval:** 1m

   **Note:**
   - Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.
   - **Statistic:** Count
   - **Trigger rule:**
     - **Operator:** between
     - **Value:** 60
     - **Value:** 80
     - **Trigger delay minutes:** 10

4. Set up an email notification under **Notifications, Destinations:**

   - **Destination service:** `Notifications Service`
   - **Compartment:** (select your `compartment`)
   - **Topic:** Click **Create a topic**
     - **Topic name:** Operations Team
     - **Topic description:** Resource Monitoring Channel
     - **Subscription protocol:** Email
     - **Subscription Email:** (type an email address for the operations team here)

5. Repeat notifications every day:

   - **Repeat notification?:** (select this option)
   - **Notification frequency:** 24 hours

6. Click **Save alarm.**

   **To create an example absence alarm**

   This procedure walks through creation of an **example absence alarm** to detect resources that may be down or unreachable. An **absence alarm** is an alarm that checks for absent metrics (using the absent operator). The procedure uses options as displayed in Basic Mode.

   1. Open the navigation menu and click **Observability & Management.** Under **Monitoring,** click **Alarm Definitions.**
   2. Click **Create alarm.**
3. On the Create Alarm page, under Define alarm, fill in or update the alarm settings:
   - **Alarm name**: Up/Down Resource Alarm
   - **Alarm severity**: Critical
   - **Alarm body**: Resource may be down. Please investigate. Move workloads to another available resource.
   - **Metric description**:
     - **Compartment**: (select your *compartment*)
     - **Metric Namespace**: oci_computeagent
     - **Metric Name**: CpuUtilization
     - **Interval**: 1m
     - **Statistic**: Count
     - **Trigger rule**:
       - **Operator**: absent
       - **Trigger delay minutes**: 5

   **Note:**
   Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.

4. Set up an email notification under Notifications, Destinations:
   - **Destination service**: Notifications Service
   - **Compartment**: (select your *compartment*)
   - **Topic**: Click Create a topic
     - **Topic name**: Operations Team
     - **Topic description**: Resource Up/Down Channel
     - **Subscription protocol**: Email
     - **Subscription Email**: (type an email address for the operations team here)

   **Note:**
   To add a notification (subscription) for another protocol, such as PagerDuty, create a copy of this alarm and choose the corresponding protocol. For more information about subscription protocols, see To create a subscription on page 4256.

5. Repeat notifications every minute:
   - **Repeat notification?**: (select this option)
   - **Notification frequency**: 1 minute

6. Click Save alarm.

*To create an alarm (any kind)*

2. Click Create alarm.

   **Note:**
   You can also create an alarm from a predefined query on the Service Metrics page. Expand Options and click Create an Alarm on this Query. For more information about service metrics, see Viewing Default Metric Charts on page 3470.
3. On the Create Alarm page, under Define alarm, fill in or update the alarm settings:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To toggle between Basic Mode and Advanced Mode, click Switch to Advanced Mode or Switch to Basic Mode (to the right of Define Alarm).</td>
</tr>
</tbody>
</table>

**Basic Mode (default)**

By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm name:**
  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity:** The perceived type of response required when the alarm is in the firing state.
- **Alarm body:** The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description:** The metric to evaluate for the alarm condition.
  - **Compartment:** The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace:** The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group (optional):** The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric name:** The name of the metric. Only one metric can be specified. Example: CpuUtilization
  - **Interval:** The aggregation window, or the frequency at which data points are aggregated.

  **Interval values**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To</td>
</tr>
</tbody>
</table>
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**
For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic:** The aggregation function.

**Statistic values**
- **Count** - The number of observations received in the specified time period.
- **Max** - The highest value observed during the specified time period.
- **Mean** - The value of Sum divided by Count during the specified time period.
- **Min** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **Rate** - The per-interval average rate of change.
- **Sum** - All values added together.

- **Metric dimensions:** Optional filters to narrow the metric data evaluated.

**Dimension fields**
- **Dimension name:** A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

**Note:**
Long lists of dimensions are trimmed.
- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
Monitoring

To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic. The Aggregate metric streams option is equivalent to the grouping() query component.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
- **Operator**: The operator used in the condition threshold.
  - **Operator values**
    - greater than
    - greater than or equal to
    - equal to
    - less than
    - less than or equal to
    - between (inclusive of specified values)
    - outside (inclusive of specified values)
    - absent
- **Value**: The value to use for the condition threshold.
- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 3546.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
Monitoring

more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Query code editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

**Note:**

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

Example alarm query:

```
CpuUtilization[1m] {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 3503.

- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

4. To change the view of the query results, click the appropriate option above the results, on the right:

- **Show Data Table**: Lists data points, indicating time stamp and bytes for each.
- **Show Graph** (default): Plots data points on a graph.
5. Set up notifications: Under **Notifications**, fill in the fields.

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
    - Available options:
      - **Notifications Service**.
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
  - **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
    - **Topic name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic description**: Description of the new topic.
    - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      - **Email subscription**: Sends an email message when you publish a *message* to the subscription's parent *topic*.
        - Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).
        - Some message types allow friendly formatting.
        - **Subscription protocol**: Select Email.
        - **Subscription Email**: Type an email address.
      - **Function subscription**: Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.
        - **Note:** You must have **FN_INVOCATION** permission against the function to be able to add the function as a subscription to a topic.
        - The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at [Function not invoked or run](#) on page 4284.
        - Confirmation is not required for function subscriptions.
        - **Subscription protocol**: Select Function.
        - **Function Compartment**: Select the compartment containing your function.
        - **Function Application**: Select the application containing your function.
        - **Function**: Select your function.
      - **HTTPS (Custom URL) subscription**: Sends specified information when you publish a *message* to the subscription's parent *topic*.
        - **Endpoint format (URL using HTTPS protocol):**
          - https://<anyvalidURL>
        - Basic access authentication is supported, allowing you to specify a username and password in the URL, as in https://user:password@domain.com or https://user@domain.com.
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a message to the subscription's parent topic. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>
</tr>
<tr>
<td>Canada</td>

</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **Additional destination service**: Adds another destination service and topic to use for notifications.

  **Note:**
  
  Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  
  - **Suppression description**
  - **Start time**
  - **End time**

6. If you want to disable the new alarm, clear **Enable this alarm?**.
7. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

**To disable or enable an alarm**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.
2. Click the alarm that you want to disable or enable.
3. On the alarm detail page, select or clear **Alarm is enabled**.

  **Note:**
  
  You can also disable and enable alarms when creating or editing an alarm.

**To move an alarm to a different compartment**

Associated metrics remain in their current compartments. For more information, see Moving Alarms to a Different Compartment on page 3469.

  **Note:**
  
  To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see Details for Monitoring on page 3013.
1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.
2. In the **List Scope** section, select a compartment.
3. Click the alarm that you want to move.
4. On the alarm detail page, click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

**To update an alarm**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.
2. Click the alarm that you want to update.
3. Go to **Actions** on the right, and then click **Edit alarm**.
4. On the **Edit Alarm** page, under **Define alarm**, update alarm settings as needed:

   **Basic Mode (default)**
   
   By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

   - **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

   **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

   - **Alarm severity**: The perceived type of response required when the alarm is in the firing state.

   - **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

   - **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.

- **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

- **Metric name**: The name of the metric. Only one metric can be specified. Example: CpuUtilization

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note: For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm**
query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  **Statistic values**
  - **Count**: The number of observations received in the specified time period.
  - **Max**: The highest value observed during the specified time period.
  - **Mean**: The value of Sum divided by Count during the specified time period.
  - **Min**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **Rate**: The per-interval average rate of change.
  - **Sum**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension name**: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

  **Note**:
  Long lists of dimensions are trimmed.
  
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate metric streams**: Returns the combined value of all metric streams for the selected statistic.
  
  The **Aggregate metric streams** option is equivalent to the `grouping()` query component.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
- **Operator**: The operator used in the condition threshold.
  
  **Operator values**
  - greater than
  - greater than or equal to
  - equal to
  - less than
  - less than or equal to
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - absent
- **Value**: The value to use for the condition threshold.
- **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 3546.

- **Alarm name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
Monitoring

more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.

  - **Compartment**: The `compartment` containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

  - **Metric namespace**: The service or application emitting metrics for the resources that you want to monitor.

  - **Resource group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

  - **Query code editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  ```
  Note:
  
  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.
  ```

  Example alarm query:

  ```csharp
  CpuUtilization[1m]
  {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries on page 3503.

  - **Trigger delay minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, update settings as needed:

- **Destinations**
  - **Destination service**: The provider of the destination to use for notifications.
  
  Available options:
  - **Notifications Service**.
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The topic to use for notifications. Each topic supports a **subscription** protocol, such as PagerDuty.
  - **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.

  - **Topic name**: User-friendly name for the new topic. Example: "Operations Team" for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
  - **Topic description**: Description of the new topic.
  - **Subscription protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    **Email subscription**
    
    Sends an email message when you publish a *message* to the subscription's parent *topic*.
    
    Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
    
    Some message types allow friendly formatting.
    
    - **Subscription protocol**: Select Email.
    - **Subscription Email**: Type an email address.

    **Function subscription**
    
    Runs the specified function when you publish a *message* to the subscription's parent *topic*. For example, runs a function to resize VMs when an associated alarm is triggered.
    
    **Note:**
    
    You must have FN_INVOCATION permission against the function to be able to add the function as a subscription to a topic.
    
    The Notifications service has no information about a function after it's invoked. For more details, see the troubleshooting information at Function not invoked or run on page 4284.
    
    Confirmation is not required for function subscriptions.
    
    - **Subscription protocol**: Select Function.
    - **Function Compartment**: Select the compartment containing your function.
    - **Function Application**: Select the application containing your function.
    - **Function**: Select your function.

  - **HTTPS (Custom URL) subscription**
    
    Sends specified information when you publish a *message* to the subscription's parent *topic*.
    
    Endpoint format (URL using HTTPS protocol):
    
    ```
    https://<anyvalidURL>
    ```
    
    Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

International SMS capabilities are required if SMS messages come from a phone number in another country. We continuously add support for more countries so that more users can receive SMS messages from local phone numbers.

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.
The Notifications service delivers SMS messages from a preconfigured pool of numbers. You might receive SMS messages from multiple numbers.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>

</tr>
</tbody>
</table>

- **Subscription protocol**: Select SMS.
- **Country**: Select the country for the phone number.
- **Phone Number**: Enter the phone number, using E.164 format. Example: +14255550100
- **+ Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**
Each alarm is limited to one destination per supported destination service.

- **Repeat notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification frequency**: The period of time to wait before resending the notification.
- **Suppress notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression description**
  - **Start time**
  - **End time**

6. Select or clear **Enable this alarm?**.
7. Click **Save alarm**.

The updated alarm settings are listed on the **Alarm Definitions** page.

**To update an alarm after moving a resource**

This section shows how to update the metric compartment of an alarm after you move a resource that is emitting metrics monitored by the alarm. For example, if you move a block volume to another compartment, then the alarm must be updated if you want to continue monitoring metrics from the moved block volume.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Alarm Definitions**.
2. Click the alarm that you want to update.
3. Go to **Actions** on the right, and then click **Edit alarm**.
4. Update the metric compartment: On the **Edit Alarm** page, under **Metric description** (or **Metric description, dimensions, and trigger rule** for Advanced Mode), change the **Compartment** to the compartment where the resource has been moved.

The chart below the **Define alarm** section dynamically updates according to the selected compartment, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

If the chart is not showing the expected data, then the old compartment might be specified in the query (MQL), as in the following example:

```sql
IopsRead[1m]
{compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID"}.grouping()
```
5. If the old compartment is specified in the query, then update the query to reference the new compartment:
   a. Click Advanced Mode or Switch to Advanced Mode to view the alarm query as a Monitoring Query Language (MQL) expression.
   b. In Query code editor, update the query to reference the new compartment.

   **View example**

   Original query:

   ```mql
   IopsRead[1m]
   (compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID").grouping().max()
   ```

   Updated query:

   ```mql
   Read[1m]
   (compartmentId="ocid1.compartment.oc1.phx..newcompartmentexampleuniqueID").grouping().max()
   ```

   For more information about query syntax and more examples, see Working with Metric Queries on page 3503.

   The chart below the Define alarm section dynamically updates according to the updated query, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

   If the chart is not showing the expected data, then confirm that every compartment reference (Compartment, Query code editor) points to the new compartment.

6. Click Save alarm.

   The alarm now monitors metrics from the new compartment.

**To suppress alarms**

**Important:**

Only one suppression can be configured per alarm. Any existing suppression for the alarm is overwritten when you apply a new suppression.

2. On the Alarm Definitions page, select the check boxes for the alarms you want to suppress.

**Note:**

You can also suppress alarms from the Alarm Status page or when creating or editing an alarm.

3. Go to Actions and select Add suppressions.
4. In the Suppress alarms dialog box, select a Start time and End time and then optionally fill in a Suppression description.
5. Click Apply suppressions.

A suppression is created for each selected alarm. The updated alarm settings are listed on the Alarm Definitions page and on the detail page for each alarm.

**Note:**

Expired suppressions continue to be listed on pages in the Console. A suppression expires when the end time passes. To remove suppressions, go to Actions and select Remove suppressions.
To delete alarms

2. On the Alarm Definitions page, select the check boxes for the alarms you want to delete.

   **Note:**
   You can also delete an alarm from its detail page.
3. Go to Actions and select Delete alarms.

   The deleted alarms are removed from the compartment and are no longer displayed on the Alarm definitions page.

To view alarm history

2. On the Alarm Definitions page, click the alarm that you want to view history for.

   The alarm detail page displays a chart showing data for the indicated time range and a list of timestamped transitions, such as Firing to OK.

   Alarm history is retained for 90 days.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage alarms:
- ListAlarms
- GetAlarm
- CreateAlarm
- ChangeAlarmCompartment
- UpdateAlarm
- DeleteAlarm
- ListAlarmsStatus
- RemoveAlarmSuppression
- GetAlarmHistory

Best Practices for Your Alarms

This topic describes best practices for working with your alarms.

Create a Set of Alarms for Each Metric

For each metric emitted by your resources, create alarms that define the following resource behaviors:

- At risk. The resource is at risk of becoming inoperable, as indicated by metric values.
- Non-optimal. The resource is performing at non-optimal levels, as indicated by metric values.
- Resource is up or down. The resource is either not reachable or not operating.

The following examples use the CpuUtilization metric emitted by the oci_computeagent metric namespace. This metric monitors the utilization of the Compute instance and the activity level of any services and applications running on the instance. CpuUtilization is a key performance metric for a cloud service because it indicates CPU usage for the Compute instance and it can be used to investigate performance issues. To learn more about CPU usage, see the following URL: https://en.wikipedia.org/wiki/CPU_time.
At-Risk Example
A typical at-risk threshold for the CpuUtilization metric is any value greater than 80 percent. A Compute instance breaching this threshold is at risk of becoming inoperable. Often the cause of this behavior is one or more applications consuming a high percentage of the CPU.

In this example, you decide to notify the operations team immediately, setting the severity of the alarm as “Critical” because repair is required to bring the instances back to optimal operational levels. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and appropriate fixes before the instances go into an inoperable state. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of `supressing the alarm`. Once metrics return to optimal values, you remove the suppression.

Non-Optimal Example
A typical non-optimal threshold for the CpuUtilization metric is from 60 to 80 percent. When the metric values for a Compute instance are within this range, the instance is above the optimal operational range.

In this example, you decide to notify the appropriate individual or team that an application or process is consuming more CPU than usual. You configure a threshold alarm to notify the appropriate contacts, setting the severity of the alarm as “Warning,” as no immediate actions are required to investigate and reduce the CPU. You set notification to email only, directed to the appropriate developer or team, with repeat notifications every 24 hours to reduce email notification noise.

Resource is Up or Down Example
A typical indicator of resource availability is a five-minute absence of the CpuUtilization metric. A Compute instance breaching this threshold is either not reachable or not operating. The resource may have stopped responding, or it might have become unavailable because of connectivity issues.

In this example, you decide to notify the operations team immediately, setting the severity of your absence alarm as “Critical” because repair is required to bring the instances online. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and a move of the workloads to another available resource. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of `supressing the alarm`. When the CpuUtilization metric is once again detected from the resource, you remove the suppression.

Select the Correct Alarm Interval for your Metric
Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.

Suppress Alarms During Investigations
Once a team member responds to an alarm, `suppress` notifications during the effort to investigate or mitigate the issue. Temporarily stopping notifications helps to avoid distractions during the investigation and mitigation. Remove the suppression when the issue has been resolved. For instructions, see To suppress alarms on page 3543.

Routinely Tune Your Alarms
On a regular basis, such as weekly, review your alarms to ensure optimal configuration. Calibrate each alarm's threshold, severity, and notification details, including method, frequency, and targeted audience.
Optimal alarm configuration addresses the following factors:

- Criticality of the resource.
- Appropriate resource behavior. Assess behavior singly and within the context of the service ecosystem. Review metric value fluctuations for a given period of time and then adjust thresholds as needed.
- Acceptable notification noise. Assess the notification method (for example, email or PagerDuty), the appropriate recipients, and the frequency of repeated notifications.

For instructions, see To update an alarm on page 3534.

**Monitoring Query Language (MQL) Reference**

This topic describes the components that appear in Monitoring Query Language (MQL) expressions, the order that they appear in, and valid values.

*MQL* syntax governs expressions for querying metrics that are published to the Monitoring service. In the Console, MQL expressions appear in Advanced Mode. If you don't need to aggregate results by group or to use other advanced query functionality, then you can create simpler versions of metric queries using Basic Mode in the Console.

**Components in an MQL Expression**

An MQL expression includes the following components:

- *metric*
- *interval*
- *dimensions*, as one or more name-value pairs (optional)
- grouping function (optional)
- *statistic*
- comparison operation (optional). Useful for defining alarms.

The query components appear in the following order (boldface components are required):

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Comparison operation queries used for *alarms* can take the following formats (boldface components are required):

- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic (where the statistic is absent())`
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator value`
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator (value1, value2)`

You can nest alarm queries and metric queries.
Monitoring

Note:
Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.

In a nested query, the alarm portion appears at the beginning (surrounded with parentheses), followed by the grouping function (optional) and the statistic. The following syntax indicates required components using boldface type.

```
(metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic).groupingfunction.
```

Example 1: The number of hosts with CPU utilization greater than 80 percent:

```
(CpuUtilization[1m].max() > 80).grouping().sum()
```

Example 2: The number of availability domains with a success rate lower than 0.99:

```
(SuccessRate[1m].groupBy(availabilityDomain).mean() < 0.99).grouping().sum()
```

**Metric Query Component**

The `metric` component of the query appears before the interval.

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Valid values for `metric` depend on the `resource`. An example of a metric is `CpuUtilization`, sent by Compute instances. For a list of supported resources with links to their metric references, see Supported Services on page 3468. You can also use the ListMetrics operation to find metrics sent by a particular service, such as the Compute service. This operation returns metric definitions.

**Interval Query Component**

The `interval` component of the query appears between the metric and statistic (before the optional dimension name-value pair and grouping function).

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the `1h` or `1d` interval values are supported.

The Monitoring Query Language (MQL) syntax (Advanced Mode in the Console) supports the following range of values for `interval`:

- `1m` - 1 minute
- `5m` - 5 minutes
- `1h` - 1 hour
- `1d` - 1 day

**Note:**
Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.
Note:

For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see [SummarizeMetricsData](#).

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to *Advanced mode*.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the [SummarizeMetricsData](#) operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see [Alarm](#).
**Dimension Query Component**

The `dimensionname="dimensionvalue"` component of the query appears between the interval and statistic (before the optional grouping function).

\[
\text{metric\[interval\]}\{\text{dimensionname="dimensionvalue"}\}\text{.groupingfunction.statistic}
\]

Surround the dimension value with double quotes. Example dimension name-value pair for filtering by availability domain: `availabilityDomain = "VeBZ:PHX-AD-1"`

You can specify multiple dimension name-value pairs. Place each pair within the brackets and separate the pairs with commas.

Valid values for `dimensionname` depend on the `metric`. An example of a dimension name is `resourceDisplayName`, included with the `CpuUtilization` metric sent by Compute instances. For a list of supported resources with links to their metric references, including dimensions, see Supported Services on page 3468. You can also use the ListMetrics operation to find metrics (and their dimensions) sent by a particular application or service, such as the Compute service.

**Grouping Function Query Component**

The `groupingfunction` component of the query appears between the interval and statistic (after the optional dimension name-value pair).

\[
\text{metric\[interval\]}\{\text{dimensionname="dimensionvalue"}\}.\text{groupingfunction.statistic}
\]

Valid grouping functions are as follows.

<table>
<thead>
<tr>
<th>Grouping function (MQL expression; Advanced Mode in the Console)</th>
<th>Grouping function option (Basic Mode in the Console)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>groupBy()</code></td>
<td>(not available)</td>
<td>Aggregates query results by group (dimension or resource group). For example, <code>groupBy(availabilityDomain)</code> groups results by availability domain so that results from each availability domain are together.</td>
</tr>
<tr>
<td><code>grouping()</code></td>
<td>Aggregate Metric Streams</td>
<td>Returns the combined value of all metric streams for the selected statistic.</td>
</tr>
</tbody>
</table>

**Statistic Query Component**

The `statistic` component of the query appears after the interval and optional dimension name-value pair and grouping function.

\[
\text{metric\[interval\]}\{\text{dimensionname="dimensionvalue"}\}.\text{groupingfunction.statistic}
\]

Valid statistics are as follows.

<table>
<thead>
<tr>
<th>Statistic (MQL expression; Advanced Mode in the Console)</th>
<th>Statistic option (Basic Mode in the Console)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>absent()</code></td>
<td>(see <code>absent</code>)</td>
<td>Returns 1 if the metric is not present in the whole interval. Otherwise, returns 0. Useful for defining alarms.</td>
</tr>
<tr>
<td>Statistic (MQL expression; Advanced Mode in the Console)</td>
<td>Statistic option (Basic Mode in the Console)</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>--------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>avg()</td>
<td>(not available)</td>
<td>Returns the value of Sum divided by Count during the specified time period. Identical to mean().</td>
</tr>
<tr>
<td>count()</td>
<td>COUNT</td>
<td>Returns the number of observations received in the specified time period.</td>
</tr>
<tr>
<td>increment()</td>
<td>(not available)</td>
<td>Returns the per-interval change.</td>
</tr>
<tr>
<td>max()</td>
<td>MAX</td>
<td>Returns the highest value observed during the specified time period.</td>
</tr>
<tr>
<td>mean()</td>
<td>MEAN</td>
<td>Returns the value of Sum divided by Count during the specified time period.</td>
</tr>
<tr>
<td>min()</td>
<td>MIN</td>
<td>Returns the lowest value observed during the specified time period.</td>
</tr>
<tr>
<td>percentile()</td>
<td>P50</td>
<td>Returns the estimated value of the specified percentile. Valid values are greater than 0.0 and less than 1.0. For example, percentile(0.8) returns the value of the 80th percentile.</td>
</tr>
<tr>
<td></td>
<td>P90</td>
<td></td>
</tr>
<tr>
<td></td>
<td>P95</td>
<td></td>
</tr>
<tr>
<td></td>
<td>P99</td>
<td></td>
</tr>
<tr>
<td></td>
<td>P99.9</td>
<td></td>
</tr>
<tr>
<td>rate()</td>
<td>RATE</td>
<td>Returns the per-interval average rate of change. The unit is per-second.</td>
</tr>
<tr>
<td>sum()</td>
<td>SUM</td>
<td>Returns all values added together.</td>
</tr>
</tbody>
</table>

### Operator and Value Query Component

The **operator value** component of the query appears after the statistic in threshold alarm queries. Either one or two values are needed, depending on the operator:

- \texttt{metric[\textit{interval}]{\textit{dimensionname}="\textit{dimensionvalue}"}.\textit{groupingfunction}.\textit{statistic} \textit{operator value}
- \texttt{metric[\textit{interval}]{\textit{dimensionname}="\textit{dimensionvalue}"}.\textit{groupingfunction}.\textit{statistic} \textit{operator} (\textit{value1}, \textit{value2})

Valid operators are as follows.

<table>
<thead>
<tr>
<th>Operator (MQL expression; Advanced Mode in the Console)</th>
<th>Operator option (Basic Mode in the Console)</th>
<th>Number of values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>1</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>1</td>
</tr>
<tr>
<td>==</td>
<td>equal to</td>
<td>1</td>
</tr>
<tr>
<td>!= (not equal to)</td>
<td>(not available)</td>
<td>1</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>1</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>1</td>
</tr>
<tr>
<td>Operator (MQL expression; Advanced Mode in the Console)</td>
<td>Operator option (Basic Mode in the Console)</td>
<td>Number of values</td>
</tr>
<tr>
<td>-------------------------------------------------------</td>
<td>---------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>in (inclusive of specified values)</td>
<td>between (inclusive of specified values)</td>
<td>2</td>
</tr>
<tr>
<td>not in (inclusive of specified values)</td>
<td>outside (inclusive of specified values)</td>
<td>2</td>
</tr>
<tr>
<td>Not applicable. See absent().</td>
<td>absent</td>
<td>0</td>
</tr>
</tbody>
</table>
Chapter

33

Network Load Balancer

This chapter explains how to set up a network load balancer.

Overview of Flexible Network Load Balancing

Learn about how Network Load Balancers can provide automated traffic distribution from one entry point to multiple servers in a backend set. Network Load Balancers ensure that your services remain available by directing traffic only to healthy servers.

The Oracle Cloud Infrastructure Flexible Network Load Balancing service (Network Load Balancer) provides automated traffic distribution from one entry point to multiple backend servers in your virtual cloud network (VCN). It operates at the connection level and load balances incoming client connections to healthy backend servers based on Layer 3/Layer 4 (IP protocol) data. The service offers a load balancer with your choice of a regional public or private IP address that is elastically scalable and scales up or down based on client traffic with no bandwidth configuration requirement.

Network Load Balancer provides the benefits of flow high availability, source and destination IP addresses, and port preservation. It is designed to handle volatile traffic patterns and millions of flows, offering high throughput while maintaining ultra low latency. It is the ideal load balancing solution for latency sensitive workloads. It is also optimized for long-running connections in the order of days or months. A given flow is always forwarded to the same backend for the lifetime of the connection, making it best suited for your database type applications. You can configure application-specific health checks to ensure that the load balancer directs traffic only to healthy backends.

Network Load Balancer Types

Learn about the types of network load balancers you can create within your VCN.

The Flexible Network Load Balancing service enables you to create a public or private network load balancer in your VCN. A public network load balancer has a public IP address that is accessible from the internet. A private network load balancer has an IP address from the hosting subnet, which is visible only within your VCN. You can configure multiple listeners for an IP address to load balance Layer 4 (TCP/UDP/ICMP) traffic. Both public and private load balancers can route data traffic to any backend server that is inside the VCN.

Public Network Load Balancer

To accept traffic from the internet, create a public network load balancer. The service assigns it a public IP address that serves as the entry point for incoming traffic. Associate the public IP address with a friendly DNS name through any DNS vendor. A public load balancer is regional in scope. A public network load balancer requires a regional subnet. Network Load Balancer ensures high availability and accessibility even when one of the availability domain has an outage.

Note:

You cannot specify a private subnet for your public load balancer. See Public vs. Private Subnets on page 3609 for more information.
**Private Network Load Balancer**

To isolate your network load balancer from the internet and simplify your security posture, create a private network load balancer. The network load balancer assigns it a private IP address that serves as the entry point for incoming traffic. The network load balancer is accessible only from within the VCN that contains the host regional subnet, or as further restricted by your security rules.

**Using Private Network Load Balancer as Next Hop Route Target with VCN Transit Routing**

Use a private network load balancer as the next-hop private IP route target with VCN transit routing. This method enables the network load balancer to operate as a bump-in-the-wire layer 3 transparent load balancer to which packets are forwarded along the path to their final destination. *Transit routing* refers to a network topology in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. Connect the on-premises network to the VCN with FastConnect on page 4051 or Site-to-Site VPN on page 3808, and then configure the VCN routing so that traffic *transits through the VCN* to its destination beyond the VCN. See *Transit routing through a private IP in the VCN* on page 3658 for more information.

The network load balancer routes user traffic to the firewall instances hosted behind network load balancer in the Hub VCN using VCN route tables. This user traffic that would otherwise flow from source directly to destination. In this mode, network load balancer does not modify the client packet characteristics and preserves the client source and destination IP header information. This method enables the firewall appliances to inspect the original client packet and apply security policies before forwarding it to the application backend servers in the spoke VCNs.

The following illustrates the network load balancer architecture.

---

**All Network Load Balancers**

Your network load balancer has a backend set to route incoming traffic to your Compute instances. The backend set is a logical entity that includes:

- A list of backend servers
- A load balancing policy
- A health check policy

The backend servers (compute instances) associated with a backend set can exist anywhere, as long as the associated network security groups (NSGs), security lists, and route tables allow the intended traffic flow.

If your VCN uses NSGs, you can associate your load balancer with an NSG. An NSG has a set of security rules that controls allowed types of inbound and outbound traffic. The rules apply only to the resources in the group. Contrast NSGs with a security list, where the rules apply to all the resources in any subnet that uses the list. See *Network Security Groups* on page 3718 for more information about NSGs.
If you prefer to use security lists for your VCN, the Load Balancing service can suggest appropriate security list rules. You also can configure them yourself through the Networking service. See Security Lists on page 3727 for more information. See Security Rules on page 3710 for detailed information comparing NSGs and security lists.

Oracle recommends that you distribute your backend servers across all availability domains within the region.

Private IP Address Consumption

A public network load balancer created in a public subnet consumes one private IP address from the host subnet.

A private network load balancer created in a single subnet consumes one private IP address from the host subnet.

Network Load Balancer Concepts

Learn about Network Load Balancer concepts to better understand and use the feature.

**BACKEND SERVER**

An application server responsible for generating content in reply to the incoming client traffic. You typically identify application servers with a unique combination of overlay (private) IPv4 address and port, for example, 10.10.10.1:8080 and 10.10.10.2:8080. For more information, see Backend Server Management on page 3579.

**BACKEND SET**

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy. The backend set determines how the network load balancer directs traffic to the collection of backend servers. For more information, see Backend Set Management on page 3572.

**HEALTH CHECK**

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server later passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level, UDP-level, or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- UDP-level health checks attempt to make a UDP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window. For more information on health check configuration, see Health Check Policy Management on page 3589.

**HEALTH STATUS**

An indicator that reports the general health of your network load balancers and their components. For more information, see Health Status Management on page 3570.

**LISTENER**

A logical entity that checks for incoming traffic on the network load balancer's IP address. You configure a listener's protocol and port number, and the optional SSL settings.

Supported protocols include:

- TCP
- UDP
• ICMP
For more information, see Listener Management on page 3585.

NETWORK LOAD BALANCING POLICY
A network load balancing policy tells the network load balancer how to distribute incoming traffic to the backend servers.

Common load balancer policies include:
• 5-Tuple Hash
• 3-Tuple Hash
• 2-Tuple Hash
For more information, see Network Load Balancer Policies on page 3557.

REGIONS AND AVAILABILITY DOMAINS
The Network Load Balancer service manages application traffic across availability domains within a region. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of several availability domains. For more information, see Regions and Availability Domains on page 208.

SUBNET
A subdivision you define in a virtual cloud network (VCN), such as 10.0.0.0/24 and 10.0.1.0/24. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing and security rules that apply to it. For more information on subnets, see VCNs and Subnets on page 3693 and Public IP Address Ranges on page 3611.

TAGS
You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

VIRTUAL CLOUD NETWORK (VCN)
A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice in the allowed IP address ranges. You need at least one virtual cloud network before you launch a network load balancer. For information about setting up virtual cloud networks, see Networking Overview on page 3604.

VISIBILITY
Specifies whether your network load balancer is public or private.

PUBLIC
A public network load balancer has a public IP address that you can access from the internet.

PRIVATE
A private network load balancer has a private IP address from a VCN local subnet.
You can access the private network load balancer using methods and technology that can provide access to a private IP, such as:
• Cross-VCN (using LPG peering)
• From another region (using RPC)
• From on-prem (using FC private peering)
For more information, see Network Load Balancer Management on page 3558.
WORK REQUEST
An object that reports on the current state of a network load balancer request. Network Load Balancer handles requests asynchronously. Each request returns a work request ID (OCID) as the response. You can view the work request item to see the status of the request. For more information, see Work Request Management on page 3597.

Resource Identifiers
Learn about how Network Load Balancer resources use resource identifiers.

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

Ways to Access Oracle Cloud Infrastructure
Learn the different ways you can access Oracle Cloud Infrastructure.

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:
- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Monitoring Resources
Learn how to monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications.

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring the traffic passing through your network load balancer, see Network Load Balancer Metrics on page 3600.

Authentication and Authorization
Learn how Network Load Balancer uses authentication and authorization to manage access to its features and functionality.

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Network Load Balancing Resources
Learn about the limits on Network Load Balancer resources.
Each load balancer has the following configuration limits:

- One IP address
- 50 backend sets
- 512 backend servers per backend set
- 1024 backend servers total
- 50 listeners

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

Required IAM Policies

Learn about Identify and Access Management policies and how they apply to the Network Load Balancer service.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2807.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2983.

If you are new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Network Load Balancer Policies

Learn how you can apply Network Load Balancer resource policies to control traffic distribution to your backend servers.

After you create a network load balancer, you can apply policies to control traffic distribution to your backend servers. See Creating Network Load Balancers on page 3558.

The Network Load Balancer service supports three primary network load balancer policy types:

- **5-Tuple Hash**: Routs incoming traffic based on 5-Tuple (source IP and port, destination IP and port, protocol) Hash. This is the default network load balancer policy.
- **3-Tuple Hash**: Routs incoming traffic based on 3-Tuple (source IP, destination IP, protocol) Hash.
- **2-Tuple Hash**: Routs incoming traffic based on 2-Tuple (source IP Destination, destination IP) Hash.

The 5-Tuple Hash policy provides session affinity within a given TCP or UDP session, where packets in the same session are directed to the same backend server behind the flexible network load balancer. Use a 3-Tuple or 2-Tuple network load balancing policy to provide session affinity beyond the lifetime of a given session.

When processing load or capacity varies among backend servers, you can refine each of these policy types with backend server weighting. Weighting affects the proportion of requests directed to each server. For example, a server weighted as 3 receives three times the number of connections as a server weighted as 1. You assign weights based on criteria of your choosing, such as each server’s traffic-handling capacity.

Connections Idle Timeout

Learn how to configure Network Load Balancer to route many incoming requests from multiple clients to the destination backend server through a single or multiple backend connections.

The network load balancer tracks the state of all TCP and UDP flows passing through it. A combination of IP protocol and source and destination IP addresses and ports define a flow. The flow can be removed if no traffic is received from either the client or the server for longer than the idle timeout. Any TCP packets received after the idle timeout are dropped. For UDP flows, a subsequent packet is considered as a new flow and routed to a new backend.

The idle timeout duration for TCP flows is 6 minutes and for UDP flows is 2 minutes. You cannot change the idle timeout duration.
Network Load Balancer

Logging
Learn about how you can access logging for a Network Load Balancer resource.

Network load balancing activities are logged through the virtual cloud network (VCN) flow logs. See VCN Flow Logs on page 3732 for more information.

Network Load Balancer Management
Learn how to create and manage Network Load Balancer resources.

The following sections describe how to manage Network Load Balancer resources, including creating, editing, and deleting them.

Creating Network Load Balancers
Create a Network Load Balancer resource.

Use one of the following methods to create a network load balancer.

To create a network load balancer using the Console
Use the OCI Console to create a Network Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Choose a Compartment you have permission to work in under List Scope.

   Note:
   If you select a different compartment in the Management tab under the Advanced Options, that compartment contains the network load balancer you are creating instead of the compartment specified here.

3. Click Create Load Balancer.
   The Select Load Balancer Type appears.
4. Select Network Load Balancer and click Create Load Balancer.
   The Create Load Balancer dialog box appears. Creating a Network Load Balancer leads you through the following sections:
   • Add Details
   • Configure Listener
   • Choose Backends
   By default, the Add Details page appears first.
5. Run each of the following workflows in order. You can return to a previous page by clicking Previous.

Step 1 - Add Details

Specify the attributes of the load balancer.

- **Load Balancer Name:** Required. Accept the default name or specify a friendly name for the load balancer. It does not have to be unique, but it cannot be changed in the Console. (You can, however, change it with the API.) Avoid entering confidential information.

- **Choose Visibility Type:** Specify whether your load balancer is public or private.
  - **Public:** Choose this option to create a public load balancer. You can use the assigned public IP address as a front end for incoming traffic and to balance that traffic across all backend servers.
  - **Private:** Choose this option to create a private load balancer. You can use the assigned private IP address as a front end for incoming internal VCN traffic and to balance that traffic across all backend servers.

- **Choose Networking**

If the current compartment contains at least one VCN, the Console provides a list of VCNs for you to choose from.

- **Virtual Cloud Network in <compartment>:** Required. Specify a VCN for the load balancer.
  
  By default, the Console shows a list of VCNs in the compartment you’re currently working in. Click the Change Compartment link to select a VCN from a different compartment.

- **Subnet in <compartment>:** Required. Select an available subnet. For a public load balancer, it must be a public subnet.
  
  By default, the Console shows a list of subnets in the compartment you’re currently working in. Click Change Compartment to select a subnet from a different compartment.

If the current compartment contains no virtual cloud networks, the Load Balancing service offers to create a VCN for you.

- **Virtual Cloud Network in <compartment>:** When the current compartment contains no virtual cloud networks, the list is disabled. The system offers to create a VCN for you.
  
  If you want to use an existing VCN in another compartment, click the Change Compartment link and choose that compartment from the list.

  - **Virtual Cloud Network Name:** Optional, when the system creates a VCN for you. Specify a friendly name for the new cloud network. It doesn’t have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
  
  If you do not specify a name for the new VCN, the system generates a name for you.

- **Use Network Security Groups to Control Traffic:** Check this box if you want to add your load balancer to a network security group (NSG). For more information about NSGs, see Network Security Groups on page 3718.

- **Network Security Groups in <compartment>:** Choose an NSG to add your load balancer to.
  
  By default, the Console shows a list of NSGs in the compartment you’re currently working in. Click the Change Compartment link to select an NSG from a different compartment.

- **(Optional) Click + Another Network Security Group** to add your load balancer to another NSG.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can change the NSGs that your load balancer belongs to after you create it. On the Load Balancer Details page, click the Edit link that appears beside the list of associated network security groups.</td>
</tr>
</tbody>
</table>

- **Show Advanced Options:** Click this link to display the following options:
  - **Management:**
Network Load Balancer

- **Create in Compartment**: Optionally, you can select a different compartment to host the load balancer. The compartment you select here overrides the compartment listed under **Scope** selected when first creating the load balancer.

- **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace.

  **Note:**

  If you are not sure about whether to apply tags, then skip this option (you can apply tags later) or ask your administrator.

  Complete the following:

  - **Tag Namespace**
  - **Tag Key**
  - **Value**

  Click **+Additional Tag** to add another tag. Click **X** to remove the associated tag.

  See [Tagging Overview](#) on page 4958 for descriptions of these fields.

  Click **Next**.

  The **Configure Listener** page appears.

  **Step 2 - Configure Listener**

  Complete the following to configure the listener.

  - **Listener Name**: Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.

    If you do not specify a name, the Load Balancing service creates one for you.

  - **Specify the type of traffic your listener handles**: Required. Specify the protocol to use. Choices are:
    - **UDP**
    - **TCP**
    - **UDP/TCP**

  - **Ingress Traffic Port**: Required. Select one of the following options to specify the port your listener monitors for ingress traffic depending on the traffic type:
    - **UDP and TCP**: Select one of the following options:
      - **Use any port**: This option uses a 0 or wildcard as the port.
      - **Select the Port**: Enter the port you want to use.
    - **UDP/TCP**: Uses any port.

  Click **Next**.

  The **Choose Backends** page appears.

  **Step 3 - Choose Backends**

  A load balancer distributes traffic to backend servers within a backend set. A backend set is a logical entity defined by a load balancing policy, a list of backend servers (Compute instances), and a health check policy.

  The load balancer creation workflow creates one backend set for your load balancer. Optionally, you can add backend sets and backend servers after you create the load balancer.

  - **Backend Set Name**: Required. Specify a friendly name for the backend set. The name must be unique, and cannot be changed. Avoid entering confidential information.

    If you do not specify a name, the Network Load Balancer service creates one for you.

  - **Select Backend Servers**: Optional. Add backend servers to the backend set.
Click **Add Backends** to select resources from a list of available Compute instances.

The **Add Compute Instance Backends** dialog box appears. Complete the following:

- **Instance in <compartment>**: Select the instance you want to include in the load balancer's backend set contained in the selected compartment. To select instances from a different compartment, use the **Change Compartment** link and choose a compartment from the list.
- **IP Address**: Select one of the available IP addresses for the instance you selected from the list.
- **Availability Domain**: Read-only. Displays the availability domain for the instance you selected.
- **Port**: Enter the communication port for the backend server.
- **Weight**: Enter the load balancing policy weight number assigned to the server. Backend servers with a higher weight receive a larger proportion of incoming traffic.

Click **Add More Backends** to add another backend.

Click **Add Backends** when have set up all the backends you want to add.

After you add instances to the backend set, they appear in the **Select Backend Servers** table. You can:

- Specify the server **Port** to which the load balancer must direct traffic. The default is port 80.
- Specify the server **Weight** that specifies the proportion of incoming traffic the backend handles. The higher the number, the more traffic is received.
- Remove any instance by checking it and clicking **Remove**. You can also select **Remove** from the **Action** menu at the end of an instance entry.

Check **Preserve Source IP** to preserve the original source and destination header (IP addresses and ports) of each incoming packet all the way to the backend server.

- **Specify Health Check Policy**: Required. Specify the test parameters that confirm the health of your backend servers.
  - **Protocol**: Required. Specify the protocol to use for health check queries, either HTTP or TCP.
    
    **Important:**
    
    Configure your health check protocol to match your application or service. See **Health Check Policy Management** on page 3589.

  - **Port**: Optional. Specify the backend server port against which to run the health check.
    
    **Tip:**
    
    You can enter the value '0' to have the health check use the backend server's traffic port.

  - **Interval in MS**: Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
  - **Timeout in MS**: Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
  - **Number of retries**: Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.
  - **Status Code**: Optional. Specify the status code a healthy backend server must return.
  - **URL Path (URI)**: Required. Specify a URL endpoint against which to run the health check.
  - **Response Body Regex**: Optional. Provide a regular expression for parsing the response body from the backend server.

- **Show Advanced Options**: Click this link to access more options. Select the tab for the corresponding functionality:
  
  - **Security List**: Choose to manually configure subnet security list rules to allow the intended traffic or allow the system to create security list rules for you. To learn more about these rules, see **Parts of a Security Rule** on page 3714.
• **Manually configure security list rules after the load balancer is created**: When you choose this option, you must configure security list rules after load balancer creation.

• **Automatically add security list rules**: Default. When you choose this option, the Load Balancing service creates security list rules for you.

  The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet.

  You can choose whether to apply the proposed rules for each affected subnet.

• **Load Balancing Policy**: Select one of the following load balancing policies:
  
  • **5-Tuple Hash**: Routs incoming traffic based on 5-Tuple (source IP and port, destination IP and port, protocol) Hash.
  
  • **3-Tuple Hash**: Routs incoming traffic based on 3-Tuple (source IP, destination IP, protocol) Hash.
  
  • **2-Tuple Hash**: Routs incoming traffic based on 2-Tuple (source IP Destination, destination IP) Hash.

6. Click **Create Load Balancer**.

  The network load balancer you created appears in the **Load Balancer** list.

**To create a network load balancer using the CLI**

Use the command line interface (CLI) to create a Network Load Balancer resource.

Enter the following command:

```
oci nlb network-load-balancer create --compartment-id compartment_id --display-name display_name --subnet-id subnet_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancer create --help
```

**To create a network load balancer using the API**

Use the API to create a Network Load Balancer resource.

Run the **CreateNetworkLoadBalancer** method to create a network load balancer. See [CreateNetworkLoadBalancer](https://docs.oracle.com/en_us/oci/Compute/nlb/using/oci-nlb-network-load-balancer-create.html) for a complete description.

**Listing Network Load Balancers**

List the Network Load Balancer resources in your OCI tenancy.

Use one of the following methods to display a list of network load balancers in your tenancy.

**To list the network load balancers using the Console**

Use the OCI Console to list the Network Load Balancer resources in your tenancy.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.

2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.

**To list the network load balancers using the CLI**

Use the command line interface (CLI) to list the Network Load Balancer resources in your tenancy.

Enter the following command:

```
oci nlb network-load-balancer list --compartment-id compartment_id [OPTIONS]
```
See the CLI online help for a list of options:

```bash
oci nlb network-load-balancer list --help
```

See `oci nlb network-load-balancer list` for a complete description of the command.

**To list the network load balancers using the API**

Use the API to list the Network Load Balancer resources in your tenancy.

Run the `ListNetworkLoadBalancers` method to display a list of network load balancers. See `ListNetworkLoadBalancers` for a complete description.

**Getting Network Load Balancer Details**

Get the details of a Network Load Balancer resource.

Use one of the following methods to display the details of a selected network load balancer.

**To get the details of a network load balancer using the Console**

Use the OCI Console to get the details of a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer whose details you want to get.

   The Network Load Balancer Details dialog box appears.

   The Details page contains information about the network load balancer, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the network load balancer's configuration. See **Editing Network Load Balancers** on page 3563.

**To get the details of a network load balancer using the CLI**

Use the command line interface (CLI) to get the details of a Network Load Balancer resource.

Enter the following command:

```bash
oci nlb network-load-balancer get --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci nlb network-load-balancer get --help
```

See `oci nlb network-load-balancer get` for a complete description of the command.

**To get the details of a network load balancer using the API**

Use the API to get the details of a Network Load Balancer resource.

Run the `GetNetworkLoadBalancer` method to display the details of a network load balancer. See `GetNetworkLoadBalancer` for a complete description.

**Editing Network Load Balancers**

Update a Network Load Balancer resource.

Use one of the following methods to edit and update the settings of a selected network load balancer.

**To edit a network load balancer using the Console**

Use the OCI Console to update a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.

5. Select the network load balancer that you want to edit.

   The Network Load Balancer Details dialog box appears.

6. Update any of the following items:

   - Enable or disable the network load balancer so that the original source and destination IP addresses and ports contained in the header of each incoming packet are preserved all the way to the backend server. See **Editing Network Load Balancer Preservation** on page 3567.
   - Move the network load balancer resource to another compartment. See **Moving Network Load Balancers Between Compartments** on page 3565.
   - Add, edit, or delete tags for the network load balancer. See **Tagging Network Load Balancers** on page 3566.
   - Change the current network security group to which the network load balancer belongs. See **Updating Network Security Groups** on page 3568.

   See **Tagging Network Load Balancers** on page 3566 to add tags to your network load balancer.

**To edit a network load balancer using the CLI**

Use the command line interface (CLI) to update a Network Load Balancer resource.

Enter the following command:

```
oci nlb network-load-balancer update --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancer update --help
```

See **oci nlb network-load-balancer update** for a complete description of the command.

**To edit a network load balancer using the API**

Use the API to update a Network Load Balancer resource.

Run the **UpdateNetworkLoadBalancer** method to edit a network load balancer. See **UpdateNetworkLoadBalancer** for a complete description.

See **Tagging Network Load Balancers** on page 3566 to add tags to your network load balancer.

**Deleting Network Load Balancers**

Delete a Network Load Balancer resource.

Use one of the following methods to delete a selected network load balancer.

**To delete a network load balancer using the Console**

Use the OCI Console to delete a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.

   All load balancers and network load balancers in that compartment are listed in tabular form.

2. Select the **Compartment** from the list.

   (optional) Select a **State** from the list to limit the load balancers displayed to that state.

3. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.

   Select the network load balancer you want to delete.

   The Network Load Balancer Details dialog box appears.
6. Click **Delete**.

   Alternatively, click the **Actions** icon ( ⚙️ ) for the network load balancer you want to delete and click **Terminate**.

7. Confirm the deletion when prompted.

**To delete a network load balancer using the CLI**

Use the command line interface (CLI) to delete a Network Load Balancer resource.

Enter the following command:

```bash
oci nlb network-load-balancer delete --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci nlb network-load-balancer delete --help
```

See [oci nlb network-load-balancer delete](#) for a complete description of the command.

**To delete a network load balancer using the API**

Use the API to delete a Network Load Balancer resource.

Run the **DeleteNetworkLoadBalancer** method to delete a network load balancer. See [DeleteNetworkLoadBalancer](#) for a complete description.

**Moving Network Load Balancers Between Compartments**

Change the compartment of a Network Load Balancer resource.

Use one of the following methods to move a selected network load balancer to a different compartment. See [Managing Compartments](#) on page 3126 for information about compartments and access control.

**To move a network load balancer between compartments using the Console**

Use the OCI Console to change the compartment of a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.

5. Select the network load balancer that you want to move to a different compartment.

   The Network Load Balancer Details dialog box appears.

6. Click **Move Resource**.

   Alternatively, click the **Actions** icon ( ⚙️ ) for the network load balancer you want to delete and click **Move Resource**.

   The Move Resource to a Different Compartment dialog box appears.

7. Select the compartment to which you want to move your network load balancer from the **Choose New Compartment** list.

8. Click **Move Resource**.

**To move a network load balancer between compartments using the CLI**

Use the command line interface (CLI) to change the compartment of a Network Load Balancer resource.

Enter the following command:

```bash
oci nlb network-load-balancer change-compartment --compartment-id compartment-id --network-load-balancer-id network-load-balancer-id [OPTIONS]
```
See the CLI online help for a list of options:

```
oci nlb network-load-balancer change-compartment --help
```

See `oci network-load-balancer nlb change-compartment` for a complete description of the command.

**To move a network load balancer between compartments using the API**

Use the API to change the compartment of a Network Load Balancer resource.

Run the ChangeNetworkLoadBalancerCompartment method to move a network load balancer to a different compartment. See `ChangeNetworkLoadBalancerCompartment` for a complete description.

**Tagging Network Load Balancers**

Learn how to add metadata to Network Load Balancer resources, which enables you to define keys and values and associate them with resources.

You can apply tags to your Network Load Balancer resources to help you organize them according to your business needs. Apply tags at the time you create a network load balancer, or update the network load balancer with tags later. For more information about applying tags, see Tagging Overview on page 4958.

**Note:**

If you are not sure whether to apply tags, ask your administrator for guidance.

**To apply tags at create using the Console**

Use the OCI Console to add metadata to a Network Load Balancer resource when you create it.

1. Begin the steps for creating a network load balancer using the OCI Console as described in Creating Network Load Balancers on page 3558.

2. At the end of Step 1 - Add Details, click Show Advanced Options.

   The advanced options appear.

3. Click the Tagging tab.

4. Complete the following: See Tagging Overview on page 4958 for descriptions of these fields.
   
   • Tag Namespace
   • Tag Key
   • Value

5. Click +Additional Tag to add another tag. Click X to remove the associated tag.

6. Click Next to continue with the network load balancer creation.

**To apply tags at create using the CLI**

Use the command line interface (CLI) to add metadata to a Network Load Balancer resource when you create it.

Use the `--defined-tags` or `--freeform-tags` options when running the following command:

```
oci nlb network-load-balancer create [...] [--defined-tags | --freeform-tags] tags [OPTIONS]
```

See the CLI online help for more information on these options:

```
oci nlb network-load-balancer create --help
```

See `oci nlb network-load-balancer create` for a complete description of the command, including the tagging options.

**To apply tags at create using the API**

Use the API to add metadata to a Network Load Balancer resource when you create it.

Run the CreateNetworkLoadBalancer method to create a network load balancer. Include the `definedTags` and `freeformTags` attributes and their values. See `CreateNetworkLoadBalancer` for a complete description of these attributes.
To apply tags at update using the Console
Use the OCI Console to add metadata to a Network Load Balancer resource when you update it.

1. Begin the steps for editing a network load balancer using the OCI Console as described in Editing Network Load Balancers on page 3563.
2. In the Details page of the selected network load balancer, click Add Tags.

Alternatively, click the Actions icon ( ) for the network load balancer to which you want to add tags, and then click Add Tags.

The Add One or More Tags To This Resource dialog box appears.
3. Complete the following:
   - Tag Namespace
   - Tag Key
   - Value
   See Tagging Overview on page 4958 for descriptions of these fields.
4. Click +Additional Tag to add another tag. Click X to remove the associated tag.
5. Click Add Tags.

The dialog box closes and you are returned to the Details page.

To apply tags at update using the CLI
Use the command line interface (CLI) to add metadata to a Network Load Balancer resource when you update it.

Use the --defined-tags or --freeform-tags options when running the following command:

```bash
oci nlb network-load-balancer update --network-load-balancer-id network_load_balancer_id [--defined-tags | --freeform-tags] tags
```

See the CLI online help for more information on these options:

```bash
oci nlb network-load-balancer update --help
```

See oci nlb network-load-balancer update for a complete description of the command, including the tagging options.

To apply tags at update using the API
Use the API to add metadata to a Network Load Balancer resource when you update it.

Run the UpdateNetworkLoadBalancer method to create a network load balancer. Include the definedTags and freeformTags attributes and their values. See UpdateNetworkLoadBalancer for a complete description of these attributes.

Editing Network Load Balancer Preservation
Configure your Network Load Balancer resource so that the original source and destination header (IP addresses and ports) of each incoming packet is preserved all the way to the backend server.

You can configure your network load balancer so that the original source and destination IP addresses and ports contained in the header of each incoming packet are preserved all the way to the backend server. No network address translation (NAT) occurs.

If enabled, the compute instance selects the backends. Otherwise, you can add the backend servers using IP addresses.

Note:
- The Source/Destination Preservation feature is only available on the private network load balancers.
- Enabling this feature affects all backend sets in the network load balancer.

Update your route table to utilize this feature.
To edit network load balancer preservation from the Console
Use the OCI Console to configure the Network Load Balancer resource to preserve the header information (IP addresses and ports) of incoming packets all the way to the backend server.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer that you want to preserve the header information of incoming packets.
   The Network Load Balancer Details dialog box appears.
6. Click Edit Preservation.
   The Edit Preservation dialog box appears.
7. Check Preserve Source/Destination Header (IP, Port) to enable this feature.
8. Click Save Changes.

To edit network load balancer preservation from the CLI
Use the command line interface (CLI) to configure the Network Load Balancer resource to preserve the header information (IP addresses and ports) of incoming packets all the way to the backend server.

Include the --is-preserve-source-destination true option when updating the network load balancer. For example:

```
oci nlb network-load-balancer update --network-load-balancer-id network_load_balancer_id --is-preserve-source-destination true [OPTIONS]
```

When enabled, skipSourceDestinationCheck is automatically turned on the load balancer VNIC, and packets are sent to the backend with the entire IP header intact.

See `oci network-load-balancer update` for a complete description of the command.

To edit network load balancer preservation from the API
Use the API to configure the Network Load Balancer resource to preserve the header information (IP addresses and ports) of incoming packets all the way to the backend server.

Include the isPreserveSourceDestination=true option when updating the network load balancer. When enabled, skipSourceDestinationCheck parameter is automatically turned on the load balancer VNIC, and packets will be sent to the backend with the entire IP header intact. See `UpdateNetworkLoadBalancer` for a complete description.

Updating Network Security Groups
Update the network security groups for a Network Load Balancer resource.

See Network Security Groups on page 3718 for information on this feature.

Use one of the following methods to update the network security groups for a selected network load balancer.

To update the network security groups using the Console
Use the OCI Console to update the network security groups for a Network Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Click the network load balancer whose network security groups (NSGs) you want to edit.
   The Network Load Balancer Details dialog box appears.
6. Click **Edit** next to **Network Security Groups**.

   The Edit NSGs dialog box appears.

7. Select an NSG from the list to use with your network load balancer. Click **Change Compartment** if you want to select an NSG from a different compartment than the one indicated.

   Click **+Add Another Security Group** to add another NSG to the list. Click **X** to remove an NSG.

8. Click **Submit**.

**To update the network security groups using the CLI**

Use the command line interface (CLI) to update the network security groups for a Network Load Balancer resource.

Enter the following command:

```
oci nlb network-load-balancer update-network-security-groups --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancer update-network-security-groups --help
```

See **oci nlb network-load-balancer update-network-security-groups** for a complete description of the command.

**To update the network security groups using the API**

Use the API to update the network security groups for a Network Load Balancer resource.

Run the **UpdateNetworkSecurityGroups** method to update the network security groups for a network load balancer. See **UpdateNetworkSecurityGroups** for a complete description.

**Listing Network Load Balancers Policies**

List the policies for a Network Load Balancer resource.

Use one of the following methods to display a list of policies for a selected network load balancer.

**To list network load balancer policies using the Console**

Use the OCI Console to list the policies for a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Click the network load balancer that you want to edit.
   
   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. View the policies under the **Load Balancing Policy** column.

**To list network load balancer policies using the CLI**

Use the command line interface (CLI) to list the policies for a Network Load Balancer resource.

Enter the following command:

```
oci nlb network-load-balancing-policy list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancing-policy list --help
```
See `oci nlb network-load-balancing-policy list` for a complete description of the command.

**To list network load balancer policies using the API**
Use the API to list the policies for a Network Load Balancer resource.

Run the `ListNetworkLoadBalancersPolicies` method to display a list of policies for a network load balancer. See `ListNetworkLoadBalancersPolicies` for a complete description.

### Listing Network Load Balancers Traffic Protocols

List the traffic protocols of a Network Load Balancer resource.

Use one of the following methods to display a list of traffic protocols for a selected network load balancer.

**To list network load balancers traffic protocols using the Console**
Use the OCI Console to list the traffic protocols for a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Click the network load balancer that you want to edit.
   - The Network Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   - The **Listeners** list appears. All listeners are listed in tabular form.
7. View the protocols under the **Protocol** column.

**To list network load balancers traffic protocols using the CLI**
Use the command line interface (CLI) to list the traffic protocols for a Network Load Balancer resource.

Enter the following command:

```
oci nlb listener-protocols list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb listener-protocols list --help
```

See `oci nlb listener-protocols list` for a complete description of the command.

**To list network load balancers traffic protocols using the API**
Use the API to list the traffic protocols for a Network Load Balancer resource.

Run the `ListNetworkLoadBalancersProtocols` method to display a list of traffic protocols for a network load balancer. See `ListNetworkLoadBalancersProtocols` for a complete description.

### Health Status Management

Learn how to understand and use health status indicators to report on the general health of your Network Load Balancer resources and their components.

The Network Load Balancer service provides health status indicators that use your health check policies to report on the general health of your network load balancers and their components. You can see health status indicators in the OCI Console for network load balancers, backend sets, and backend servers. You also can use the command line interface (CLI) and API to retrieve this information.

**Network Load Balancer Health Summary**
The OCI Console list of a network load balancer's backend sets provides health status summaries that indicate the overall health of each backend set. Health status indicators have the following levels:

- **OK**: All backend servers in the backend set return a status of OK.
- **WARNING**: Both of the following conditions are true:
  - Half or more of the backend set's backend servers return a status of OK.
  - At least one backend server returns a status of WARNING, CRITICAL, or UNKNOWN.
- **CRITICAL**: Fewer than half of the backend set's backend servers return a status of OK.
- **UNKNOWN**: At least one of the following conditions is true:
  - More than half of the backend set's backend servers return a status of UNKNOWN.
  - The system could not retrieve metrics for any reason.
  - The backend set does not have a listener attached.

For guidance on detecting and correcting common issues, see Health Check Policy Management on page 3589.

**Backend Set Health Details**

The backend set's Details page provides the same **Overall Health** status indicator found in the network load balancer's list of backend sets. It also includes counters for the **Backend Health** status values reported by the backend set's backend servers.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

**Listing Network Load Balancer Health Status Summaries**

List the health status summaries of a Network Load Balancer resource.

Use one of the following methods to display a list of health status summaries for a selected network load balancer.

**To list the network load balancer health status summaries using the Console**

Use the OCI Console to list the health status summary of the Network Load Balancer resources in your tenancy.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Review the **Overall Health** column in the list for a summary of each network load balancer.

**To list the network load balancer health status summaries using the CLI**

Use the command line interface (CLI) to list the health status summaries for a Network Load Balancer resources in your tenancy.

Enter the following command:

```
oci nlb network-load-balancer-health list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancer-health list --help
```

See **oci nlb network-load-balancer-health list** for a complete description of the command.
To list the network load balancer health status summaries using the API
Use the API to list the health status summaries for a Network Load Balancer resources in your tenancy.

Run the `ListNetworkLoadBalancerHealths` method to display a list of health status summaries for a network load balancer. See `ListNetworkLoadBalancerHealths` for a complete description.

Getting Network Load Balancer Health Status Details
Get the health status details of a Network Load Balancer resource.

Use one of the following methods to display the health status details of a selected network load balancer.

To get network load balancer health status details using the Console
Use the OCI Console to get the health status details of a Network Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Click the network load balancer that you want to edit.
   - The Network Load Balancer Details dialog box appears.
6. View the Overall Health and Backend Sets Health indicators.

To get network load balancer health status details using the CLI
Use the command line interface (CLI) to get health status details for a Network Load Balancer resource.

Enter the following command:

```
oci nlb network-load-balancer-health get --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb network-load-balancer-health get --help
```

See `oci nlb network-load-balancer-health get` for a complete description of the command.

To get network load balancer health status details using the API
Use the API to get the health status details for a Network Load Balancer resource.

Run the `GetNetworkLoadBalancerHealth` method to display the health status details for a network load balancer. See `GetNetworkLoadBalancerHealth` for a complete description.

Backend Set Management
Learn how to use backend sets to create logical entities consisting of a network load balancing policy, health check policy, and a list of backend servers for a Network Load Balancer resource.

A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers. To create a backend set, you must specify a load balancing policy and health check script, and then add a list of backend servers (Compute instances). A backend set must be associated with one or more listeners for the network load balancer to work.

Creating Backend Sets
Create a backend set for a Network Load Balancer resource.

Use one of the following methods to create a backend set for a selected network load balancer.

To create a backend set using the Console
Use the OCI Console to create a backend set for a network load balancer.
1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer for which you want to create a backend set.

   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.

   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click **Create Backend Set**.

   The Create backend set dialog box appears.
8. Enter the following:

- **Name:** Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.

  Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Preserve Source ID:** Optional. Check to preserve the original source and destination header (IP addresses and ports) of each incoming packet all the way to the backend server.

- **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.
  - **Protocol:** Required. Specify the protocol:
    - HTTP
    - HTTPS
    - TCP
    - UDP

  **Important:**
  Configure your health check protocol to match your application or service. See Health Check Policy Management on page 3589.

- **Port:** Optional. Specify the backend server port against which to run the health check.

  **Tip:**
  You can enter the value '0' to have the health check use the backend server's traffic port.

- **Interval in MS:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

- **Timeout in MS:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

- **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.

- **Status Code:** (HTTP and HTTPS only) Optional. Specify the status code a healthy backend server must return.

- **URL Path (URI):** (HTTP and HTTPS only) Required. Specify a URL endpoint against which to run the health check.

- **Response Body Regex:** (HTTP and HTTPS only) Optional. Provide a regular expression for parsing the response body from the backend server.

- **Request Data:** (TCP and UDP only) Required for UDP, optional for TCP.

- **Response Data:** (TCP and UDP only) Required for UDP, optional for TCP.

- **Show Advanced Options:** Click this link to access more options. Select the tab for the corresponding functionality:

  - **Load Balancing Policy:** Select one of the following load balancing policies:
    - **5-Tuple Hash:** This policy distributes incoming traffic based on 5-Tuple (source IP and port, destination IP and port, protocol) Hash.
    - **3-Tuple Hash:** This policy ensures that requests from a particular client are always directed to the same backend server based on 3-Tuple (source IP, destination IP, protocol) Hash.
    - **2-Tuple Hash:** This policy routes incoming traffic to the same backend server based on 2-Tuple (Source/Destination) Hash.

9. Click **Create Backend Set.**

The backend set you created appears in the **Backend Set** list.
**To create a backend set using the CLI**

Use the command line interface (CLI) to create a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-set create --name name --network-load-balancer-id network_load_balancer_id --health-checker health_checker --policy policy
```

See the CLI online help for a list of options:

```
oci nlb backend-set create --help
```

See `oci nlb backend-set create` for a complete description of the command.

**To create a backend set using the API**

Use the API to create a backend set for a Network Load Balancer resource.

Run the `CreateBackendSet` method to create a backend set for a network load balancer. See `CreateBackendSet` for a complete description.

**Listing Backend Sets**

Use the OCI Console to list the backend sets for a load balancer in your tenancy.

Use one of the following methods to display a list of backend sets for a selected load balancer.

**To list the backend sets using the Console**

Use the OCI Console to list the backend sets for a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the backend sets that you want to list.
   
   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   
   The **Backend Sets** list appears. All backend sets are listed in tabular form.

**To list the backend sets using the CLI**

Use the command line interface (CLI) to list the backend sets for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-set list --network-load-balancer-id network_load_balancer_id
```

See the CLI online help for a list of options:

```
oci nlb backend-set list --help
```

See `oci nlb backend-set list` for a complete description of the command.

**To list the backend sets using the API**

Use the API to list the backend sets for a Network Load Balancer resource.

Run the `ListBackendSets` method to display a list of backend sets for a network load balancer. See `ListBackendSets` for a complete description.
Getting Backend Set Details
Get the details of a backend set for a Network Load Balancer resource.

Use one of the following methods to display the details of a backend set for a selected network load balancer.

To get the details of a backend set using the Console
Use the OCI Console to get the details of a backend set for a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer containing the backend set for which you want to get details.
   The Network Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.

To get the details of a backend set using the CLI
Use the command line interface (CLI) to get the details of a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-set get --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:
```
oci nlb backend-set get --help
```

See `oci nlb backend-set get` for a complete description of the command.

To get the details of a backend set using the API
Use the API to get the details of a backend set for a Network Load Balancer resource.

Run the GetBackendSet method to display the details of a backend set for a network load balancer. See `GetBackendSet` for a complete description.

Editing Backend Sets
Update a backend set for a selected Network Load Balancer resource.

Use one of the following methods to edit and update the settings of a backend set for a selected network load balancer.

```
Note:
Changing the load balancing policy of a backend set temporarily interrupts traffic and can drop active connections.
```

To edit a backend set using the Console
Use the OCI Console to update a backend set for a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.

5. Select the network load balancer containing the backend set that you want to edit.

   The Network Load Balancer Details dialog box appears.

6. Click Backend Sets under Resources.

   The Backend Sets list appears. All backend sets are listed in tabular form.

7. Click the backend set that you want to edit.

   The Backend Set Details dialog box appears.

8. Click Edit.

   Alternatively, click the Actions icon ( ) for the backend set you want to edit and click Edit.

   The Edit Backend Set dialog box appears.

9. Edit any of the following:

   • Specify a Load Balancing Policy: Select a different policy from the following:
     • 5-Tuple Hash: This policy distributes incoming traffic based on 5-Tuple (source IP and port, destination IP and port, protocol) Hash.
     • 3-Tuple Hash: This policy ensures that requests from a particular client are always directed to the same backend server based on 3-Tuple (source IP, destination IP, protocol) Hash.
     • 2-Tuple Hash: This policy routes incoming traffic to the same backend server based on 2-Tuple (Source/Destination) Hash.
     • Preserve Source IP: Check to preserve the header information (IP addresses and ports) of incoming packets all the way to the backend server. Uncheck to disable this feature.

10. Click Save Changes.

To edit a backend set using the CLI

Use the command line interface (CLI) to update a backend set for a Network Load Balancer resource.

Enter the following command:

```bash
oci nlb backend-set update --backend-set-name backend_set_name --network-load-balancer-id network_load-balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci nlb backend-set update --help
```

See oci nlb backend-set update for a complete description of the command.

To edit a backend set using the API

Use the API to update a backend set for a Network Load Balancer resource.

Run the UpdateBackendSet method to edit a backend set for a network load balancer. See UpdateBackendSet for a complete description.

Deleting Backend Sets

Delete a backend set from a selected Network Load Balancer resource.

Use one of the following methods to delete a backend set from a selected network load balancer.

- **Note:**
  
  You cannot delete a backend set used by an active listener.

To delete a backend set using the Console

Use the OCI Console to delete a backend set from a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the backend set that you want to delete.
   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set that you want to edit.
   The Backend Set Details dialog box appears.
8. Click **Delete**.
   Alternatively, click the **Actions** icon (🗑️) for the backend set you want to delete and click **Delete**.
9. Confirm the deletion when prompted.

To delete a backend set using the CLI

Use the command line interface (CLI) to delete a backend set from a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-set delete --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer-id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb backend-set delete --help
```

To delete a backend set using the API

Use the API to delete a backend set from a Network Load Balancer resource.

Run the [DeleteBackendSet](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/api-ref/nlb/DeleteBackendSet.html) method to delete a backend set from a network load balancer. See [DeleteBackendSet](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/api-ref/nlb/DeleteBackendSet.html) for a complete description.

Getting Backend Set Heath Status Details

Get the health status details of a backend set for a selected Network Load Balancer resource.

Use one of the following methods to display the health status details of a backend set for a selected network load balancer.

To get the details of a backend set's heath status using the Console

Use the OCI Console to get the status details of a backend set for a network load balancer.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the backend set for which you want to get health status details.
   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.

   The Backend Set Details dialog box appears.

8. View the Overall Health and Backends Health indicators.

To get the details of a backend set's health status using the CLI

Use the command line interface (CLI) to get health status details of a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-set-health get --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer-id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb backend-set-health get --help
```

See `oci nlb backend-set-health get` for a complete description of the command.

To get the details of a backend set's health status using the API

Use the API to get the health status details of a backend set for a Network Load Balancer resource.

Run the `GetBackendSetHealth` method to display the health status details of a backend set for a network load balancer. See `GetBackendSetHealth` for a complete description.

Backend Server Management

Learn how to specify the backend servers that receive incoming traffic based on the policies you specified for the backend set that contains it for the Network Load Balancer resource.

When you create a Network Load Balancer resource, you must specify the backend servers (Compute instances) to include in each backend set. The load balancer routes incoming traffic to these backend servers based on the policies you specified for the backend set. You can use the Console to add and remove backend servers in a backend set.

To route traffic to a backend server, the Load Balancing service requires the IP address of the compute instance and the relevant application port. If the backend server resides within the same VCN as the load balancer, Oracle recommends that you specify the compute instance's private IP address. You also must ensure that the VCN's security rules allow Internet traffic.

Note:

- You cannot add backend servers using public IPs.
- You cannot place backend servers behind an internet gateway or dynamic routing gateways (DRGs).

When you add backend servers to a backend set, you specify either the instance OCID or an IP address for the server to add. An instance with multiple VNICs attached can have multiple IP addresses pointing to it.

- If you identify a backend server by OCID, Load Balancing uses the primary VNIC's primary private IP address.
- If you identify the backend servers to add to a backend set by their IP addresses, you can point to the same instance more than one time.

To enable backend traffic, your backend server subnets must have appropriate ingress and egress security rules. When you add backend servers to a backend set, you can specify the applicable network security groups (NSGs). If you prefer to use security lists for your VCN, the Load Balancing service Console can suggest security list rules for you. You also can configure them yourself through the Networking service. See Security Lists on page 3727 for more information.
Tip:
To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets. See Stateful Versus Stateless Rules on page 3716 for more information.

You can add and remove backend servers without disrupting traffic.

Adding Backend Servers
Add a backend server to a backend set for a Network Load Balancer resource.

Use one of the following methods to add a backend server to a backend set for a selected network load balancer.

To add a backend server using the Console
Use the OCI Console to add a backend server to a backend set for a Network Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer for which you want to add a backend server.
   The Network Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.
8. Click Backend under Resources.
   The Backends list appears. All backend servers are listed in tabular form.
9. Click Add Backends.
   The Add Backends dialog box appears.
10. Complete the following:
    • Instance in <compartment>: Select the instance you want to include in the load balancer's backend set contained in the selected compartment. To select instances from a different compartment, use the Change Compartment link and choose a compartment from the list.
    • IP Address: Select one of the available IP addresses for the instance you selected from the list.
    • Availability Domain: Read-only. Displays the availability domain for the instance you selected.
    • Port: Enter the communication port for the backend server.
    • Weight: Enter the load balancing policy weight number assigned to the server. Backend servers with a higher weight receive a larger proportion of incoming traffic.

   Click Add More Backends to add another backend.
11. Click Add Backends.
   The backend server you added appears in the backend list of the backend set.

To add a backend server using the CLI
Use the command line interface (CLI) to add a backend server to a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend create --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id --port port [OPTIONS]
```
Network Load Balancer

See the CLI online help for a list of options:

```
oci nlb backend create --help
```

See `oci nlb backend create` for a complete description of the command.

**To add a backend server using the API**

Use the API to add a backend server contained within a backend set for a Network Load Balancer resource.

Run the `CreateBackend` method to add a backend server to a backend set for a network load balancer. See `CreateBackend` for a complete description.

**Listing Backend Servers**

List the backend servers contained within a backend set for a Network Load Balancer resource.

Use one of the following methods to display a list of backend servers contained within a backend set for a selected network load balancer.

**To list the backend servers using the Console**

Use the OCI Console to list the backend servers for a backend set for a load balancer in your tenancy.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the backend servers that you want to list.
   The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.
8. Click **Backends** under **Resources**.
   The Backends list appears. All backend servers are listed in tabular form.

**To list the backend servers using the CLI**

Use the command line interface (CLI) to list the backend servers for a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend list --backend-set-name backend_set_name --compartment-id compartment_id --network-load-balancer-id network_load_balancer_id
```

See the CLI online help for a list of options:

```
oci nlb backend list --help
```

See `oci nlb backend list` for a complete description of the command.

**To list the backend servers using the API**

Use the API to list the backend servers contained within a backend set for a network load balancer in your tenancy.

Run the `ListBackends` method to display a list of backend servers for a backend set for a network load balancer. See `ListBackends` for a complete description.
Getting Backend Server Details
Get the details of a backend server contained within a backend set for a Network Load Balancer resource.

Use one of the following methods to display the details of a backend server contained within a backend set for a selected network load balancer.

To get the details of a backend server using the CLI
Use the command line interface (CLI) to get the details of a backend server contained within a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend get --backend-set-name backend_set_name --compartment-id compartment_id --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb backend get --help
```

See `oci nlb backend get` for a complete description of the command.

To get the details of a backend server using the API
Use the API to get the details of a backend server contained within a backend set for a Network Load Balancer resource.

Run the `GetBackend` method to display the details of a backend server for a backend set for a network load balancer. See `GetBackend` for a complete description.

Editing Backend Servers
Update a backend server contained within backend set for a selected Network Load Balancer resource.

Use one of the following methods to edit and update the settings of a backend server contained within a backend set for a selected network load balancer.

To edit a backend server using the Console
Use the OCI Console to update a backend server for a backend set for a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Click the network load balancer containing backend server that you want to edit.
   The Network Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.
8. Click Backends under Resources.
   The Backends list appears. All backend servers are listed in tabular form.
9. Check the backend server that you want to edit in the list and click Edit. You can select multiple backend servers and update them all at the same time.
   Alternatively, click the Actions icon for the backend server you want to edit and click Edit.
   The Edit Backend dialog box appears.
10. Edit any of the following:

- **Weight**: Change the load balancing policy weight number assigned to the server. Backend servers with a higher weight receive a larger proportion of incoming traffic.
- **Drain**: If you set the server's drain status to `True`, the load balancer stops forwarding new TCP connections and new non-sticky HTTP requests to this backend server. This setting allows an administrator to take the server out of rotation for maintenance purposes.
- **Offline**: If you set the server's offline status to `True`, the load balance forwards no ingress traffic to this backend server.
- **Backup**: If you set the server's backup status to `True`, the load balancer forwards ingress traffic to this backend server only when all other backend servers not marked as backup fail the health check policy. This configuration is useful for handling disaster recovery scenarios.

11. Click **Save Changes**.

**To edit a backend server using the CLI**

Use the command line interface (CLI) to update a backend server for a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend update --backend-name backend_name --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id
```

See the CLI online help for a list of options:

```
oci nlb backend update --help
```

See **oci nlb backend update** for a complete description of the command.

**To edit a backend server using the API**

Use the API to update a backend server contained within a backend set for a Network Load Balancer resource.

Run the **UpdateBackend** method to edit a backend server for a backend set for a network load balancer. See **UpdateBackend** for a complete description.

**Deleting Backend Servers**

Delete a backend server from a backend set for a selected Network Load Balancer resource.

Use one of the following methods to delete a backend server from a backend set for a selected network load balancer.

**To delete a backend server using the Console**

Use the OCI Console to delete a backend server from a backend set from a network load balancer.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Click the network load balancer containing backend server that you want to delete.
   
   The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   
   The Backend Set Details dialog box appears.
8. Click **Backends** under **Resources**.
   
The Backends list appears. All backend servers are listed in tabular form.

9. Check the backend server that you want to delete in the list and click **Delete**. You can select multiple backend servers and delete them all at the same time.

   Alternatively, click the **Actions** icon (●) for the backend server you want to delete and click **Delete**.

10. Confirm the deletion when prompted.

### To delete a backend server using the CLI

Use the command line interface (CLI) to delete a backend server from a backend set from a Network Load Balancer resource.

Enter the following command:

```bash
oci nlb backend delete --backend-name backend_name --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id
```

See the CLI online help for a list of options:

```bash
oci nlb backend delete --help
```

See [oci nlb backend delete](#) for a complete description of the command.

### To delete a backend server using the API

Use the API to delete a backend server from a backend set for a Network Load Balancer resource.

Run the `DeleteBackend` method to delete a backend server from a backend set for a network load balancer. See `DeleteBackend` for a complete description.

### Getting Backend Server Health Status Details

Get the health status details of a backend server contained within a backend set for a Network Load Balancer resource.

See [Health Status Management](#) on page 3570 for general information on getting and understanding health status details for Network Load Balancer resources and their components.

### Backend Server Health Details

The Details page for a backend set provides the same **Overall Health** status indicator found in the backend set's list of backend servers. It also reports the following data for the two health checks performed against each backend server:

**IP ADDRESS**

The IP address of the health check status report provider, which is a Compute instance managed by the Load Balancing service. This identifier helps you differentiate same-subnet load balancers that report health check status.

The Load Balancing service ensures high availability by providing one primary and one standby load balancer. To diagnose a backend server issue, you must know the source of the health check report. For example, a misconfigured security rule might cause one load balancer instance to report that a backend server is healthy. The other load balancer instance might return an unhealthy status. In this case, one of the two load balancer instances cannot communicate with the backend server. Reconfigure the security rules to restore the backend server's health status.

**STATUS**

The status returned by the health check. Possible values include:
Network Load Balancer

- OK
  The backend server's response satisfied the health check policy requirements.
- INVALID_STATUS_CODE
  The HTTP response status code did not match the expected status code specified by the health policy.
- TIMED_OUT
  The backend server did not respond within the timeout interval specified by the health policy.
- REGEX_MISMATCH
  The backend server response did not satisfy the regular expression specified by the health policy.
- CONNECT_FAILED
  The health check server could not connect to the backend server.
- IO_ERROR
  An input or output communication error occurred while reading or writing a response or request to the backend server.
- OFFLINE
  The backend server is set to offline, so health checks are not run.
- UNKNOWN
  Health check status is not available.

LAST CHECKED
The date and time of the most recent health check.
Health status is updated every three minutes. No finer granularity is available.

Use one of the following methods to display the health status details of a backend server contained within a backend set for a selected network load balancer.

To get the details of a backend server's health status using the CLI
Use the command line interface (CLI) to get health status details of a backend server contained within a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb backend-health get --backend-name backend_name --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id
```

See the CLI online help for a list of options:

```
oci nlb backend-health get --help
```

See oci nlb backend-health get for a complete description of the command.

To get the details of a backend server's health status using the API
Use the API to get the health status details of a backend server contained within a backend set for a Network Load Balancer resource.

Run the GetBackendHealth method to display the health status details of a backend server for a network load balancer. See GetBackendHealth for a complete description.

Listener Management
Learn how to set up listeners that check for incoming traffic on the IP address of the Network Load Balancer resource.

A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.
To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.

When you create a listener, you must ensure that your VCN’s security rules allow the listener to accept traffic. See Security Rules on page 3710 for more information.

Tip:

To accommodate high-volume traffic, Oracle strongly recommends that you use your load balancer subnets. See Stateful Versus Stateless Rules on page 3716 for more information.

Creating Listeners

Create a listener for a Network Load Balancer resource.

Use one of the following methods to create a listener for a selected network load balancer.

To create a listener using the Console

Use the OCI Console to create a listener for a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list. All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer for which you want to create a listener.

   The Network Load Balancer Details dialog box appears.
6. Click Listeners under Resources.
   The Listeners list appears. All listeners are listed in tabular form.
7. Click Create Listener.

   The Create Listener dialog box appears.
8. Complete the following:

   • Name: Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.
   • Protocol: Required. Select one of the following options:
     • UDP
     • TCP
     • UDP/TCP
   • Ingress Traffic Port: Required. Select one of the following options to specify the port your listener monitors for ingress traffic depending on the traffic type:
     • UDP and TCP: Select one of the following options:
       • Use any port: This option uses a 0 or wildcard as the port.
       • Select the Port: Enter the port you want to use.
     • UDP/TCP: Uses any port.
   • Backend Set: Required. Specify the default backend set to which the listener routes traffic from the list.
9. Click Create Listener.

   The listener you create appears in the Listener list of the network load balancer.

To create a listener using the CLI

Use the command line interface (CLI) to create a listener for a Network Load Balancer resource.
Enter the following command:

```
oci nlb listener create --name name --default-backend-set-name default_backend_set_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb listener create --help
```

See `oci nlb listener create` for a complete description of the command.

**To create a listener using the API**

Use the API to create a listener for a Network Load Balancer resource.

Run the `CreateListener` method to create a listener for a network load balancer. See `CreateListener` for a complete description.

**Listing Listeners**

List the listeners for a Network Load Balancer resource.

Use one of the following methods to display a list of listeners for a selected network load balancer.

**To list the listeners using the Console**

Use the OCI Console to create a listener for a network load balancer.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the listeners that you want to list.
   - The Network Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   - The **Listeners** list appears. All listeners are listed in tabular form.

**To list the listeners using the CLI**

Use the command line interface (CLI) to list the listeners for a Network Load Balancer.

Enter the following command:

```
oci nlb listener list --compartment-id compartment_id --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb listener list --help
```

See `oci nlb listener list` get for a complete description of the command.

**To list the listeners using the API**

Use the API to list the listeners for a Network Load Balancer resource.

Run the `ListListeners` method to display a list of listeners for a network load balancer. See `ListListeners` for a complete description.

**Getting Listener Details**

Get the details of a listener for a Network Load Balancer resource.
Use one of the following methods to display the details of listeners for a selected network load balancer.

**To get the details of a listener using the CLI**
Use the command line interface (CLI) to get the details of a listener for a Network Load Balancer.

Enter the following command:

```
oci nlb listener get --listener-name listener_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb listener get --help
```

See [oci nlb listener get](#) for a complete description of the command.

**To get the details of a listener using the API**
Use the API to get the details of a listener for a Network Load Balancer resource.

Run the `GetListener` method to display the details of a listener for a network load balancer. See [GetListener](#) for a complete description.

**Editing Listeners**
Update a listener for a Network Load Balancer resource.

Use one of the following methods to edit and update the settings of a listener for a selected network load balancer.

**To edit a listener using the Console**
Use the OCI Console to update a listener for a Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the listener that you want to edit.
   
   The Network Load Balancer Details dialog box appears.
6. Click **Listeners** under **Resources**.
   
   The **Listeners** list appears. All listeners are listed in tabular form.
7. Click the **Actions** icon (▲) for the listener you want to edit, and then click **Edit**.
   
   The Edit Listener dialog box appears.
8. Edit any of the following:
   
   - **Protocol**: Select a different protocol from the list.
   - **Ingress Traffic Port**: Change the port option to either any port (uses a wildcard or "0" as the port) or a port you specify.
   - **Backend Set**: Select a different backend set from the list.
9. Click **Save Changes**.

**To edit a listener using the CLI**
Use the command line interface (CLI) to update a listener for a Network Load Balancer.

Enter the following command:

```
oci nlb listener update --listener-name listener_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```
See the CLI online help for a list of options:

```
oci nlb listener update --help
```

See `oci nlb listener update` for a complete description of the command.

**To edit a listener using the API**

Use the API to update a listener for a Network Load Balancer resource.

Run the `UpdateListener` method to edit a listener for a network load balancer. See `UpdateListener` for a complete description.

**Deleting Listeners**

Delete a listener from a Network Load Balancer resource.

Use one of the following methods to delete a listener for a selected network load balancer.

**To delete a listener using the Console**

Use the OCI Console to delete a listener from a network load balancer.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer containing the listener that you want to delete.
   The Network Load Balancer Details dialog box appears.
6. Click Listeners under Resources.
   The Listeners list appears. All listeners are listed in tabular form.
7. Click the Actions icon (изации) for the listener you want to delete, and then click Delete.
8. Confirm the deletion when prompted.

**To delete a listener using the CLI**

Use the command line interface (CLI) to delete a listener from a Network Load Balancer resource.

Enter the following command:

```
oci nlb listener delete --listener-name listener_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb listener delete --help
```

See `oci nlb listener delete` for a complete description of the command.

**To delete a listener using the API**

Use the API to delete a listener from a network load balancer.

Run the `DeleteListener` method to delete a listener for a network load balancer. See `DeleteListener` for a complete description.

**Health Check Policy Management**

Learn how to set up and use health checks to determine the availability of backend servers.

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the network load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the network load balancer takes the server
temporarily out of rotation. If the server later passes the health check, the network load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

**Configuring your health check protocol to match your application or service**

If you run an HTTP service, be sure to configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, customers might experience transaction failures. For example:

- The backend HTTP service has issues when talking to the health check URL and the health check URL returns 5XX messages. An HTTP health check catches the message from the health check URL and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service might not be usable.
- The backend HTTP service responds with 4XX messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

**Heath Status Indicators**

Learn about the different health status indicators for Network Load Balancer resources.

The Network Load Balancer service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console List and Details pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

Health status indicators have four levels. The following table provides the general meaning of each level:

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
<td>Green</td>
<td>No attention required. The resource is functioning as expected.</td>
</tr>
<tr>
<td>Warning</td>
<td>Yellow</td>
<td>Some reporting entities require attention. The resource is not functioning at peak efficiency or the resource is incomplete and requires further work.</td>
</tr>
<tr>
<td>Critical</td>
<td>Red</td>
<td>Some or all reporting entities require immediate attention. The resource is not functioning or unexpected failure is imminent.</td>
</tr>
</tbody>
</table>
### Network Load Balancer

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown</td>
<td>Gray</td>
<td>Health status cannot be determined. The resource is not responding or is in transition and might resolve to another status over time.</td>
</tr>
</tbody>
</table>

The precise meaning of each level differs among the following components:

- Network load balancers
- Backend sets
- Backend servers

### Using Health Status

At the highest level, load balancer health reflects the health of its components. The health status indicators provide information you might need to drill down and investigate an existing issue. Some common issues that the health status indicators can help you detect and correct include:

**A health check is misconfigured.**

In this case, all the backend servers for one or more of the affected listeners report as unhealthy. If your investigation finds that the backend servers do not have problems, then a backend set probably includes a misconfigured health check.

**A listener is misconfigured.**

All the backend server health status indicators report OK, but the load balancer does not pass traffic on a listener. The listener might be configured to:

- Listen on the wrong port.
- Use the wrong protocol.
- Use the wrong policy.

If your investigation shows that the listener is not at fault, check the security list configuration.

**A security rule is misconfigured.**

Health status indicators help you diagnose two cases of misconfigured security rules:

- All entity health status indicators report OK, but traffic does not flow (as with misconfigured listeners). If the listener is not at fault, check the security rule configuration.
- All entity health statuses report as unhealthy. You have checked your health check configuration and your services run properly on your backend servers.

In this case, your security rules might not include the IP range for the source of the health check requests. You can find the health check source IP on the Details page for each backend server. You can also use the API to find the IP in the `sourceIpAddress` field of the `HealthCheckResult` object.

**Note:**

Source IP

The source IP for health check requests comes from a Compute instance managed by the Load Balancing service.

**One or more of the backend servers reports as unhealthy.**

A backend server might be unhealthy or the health check might be misconfigured. To see the corresponding error code, check the `status` field on the backend server's Details page. You can also use the API to find the error code in the `healthCheckStatus` field of the `HealthCheckResult` object.
Other cases in which health status might prove helpful include:

- VCN network security groups or security lists block traffic.
- Compute instances have misconfigured route tables.

Health status is updated every three minutes. No finer granularity is available.

Health status does not provide historical health data.

**Health Check Best Practices**

Configure your health check protocol to match your application or service. If you run an HTTP service, be sure to configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, customers might experience transaction failures.

For example:

- The backend HTTP service has issues when talking to the health check URL and the health check URL returns 5XX messages. An HTTP health check catches the message from the health check URL and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service might not be usable.
- The backend HTTP service responds with 4XX messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

**Configure the Health Check**

To configure the health check, use the following procedure:

1. Open the navigation menu, click **Networking** and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the backend set that you want to edit.
   - The Network Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**.
   - The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set that you want to edit.
   - The Backend Set Details dialog box appears.
8. Click **Update Health Check**.
   - The Health Check section appears.
9. Specify the test parameters to confirm the health of backend servers. All parameters are required when updating an existing health check policy.

- **Protocol**: Required. Specify the protocol to use, either HTTP or TCP.

  **Note:**
  Configure your health check protocol to match your application or service.

- **Port**: Required. Specify the backend server port against which to run the health check.

  **Note:**
  You can enter the value '0' to have the health check use the backend server's traffic port.

- **URL Path (URI)**: (HTTP only) Required. Specify a URL endpoint against which to run the health check. For example:

  /health

  (This value is a commonly used path for a health check application).

- **Interval in ms**: Required. Specify how frequently to run the health check, in milliseconds. Default is 10000 (10 seconds).

- **Timeout in ms**: Required. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. Default is 3000 (3 seconds).

  **Note:**
  Enter a timeout value that is smaller than the interval value to ensure the health check works correctly.

- **Number of retries**: Required. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.

- **Status Code**: (HTTP only) Required. Specify the status code a healthy backend server must return.

- **Response Body Regex**: (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server. The system treats a blank entry here as the value ".*".

  **Note:**
  Health checks require all fields to match. Your status code and response body both must match, as specified.

10. Click **Save**.

**Common Side effects of health check misconfiguration**

The following are common side effects of health check misconfiguration, and can be used to troubleshoot issues.

- **Wrong Port**

  In this scenario, all the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the port. Your port must be listening and has allowed traffic on the backend.

  OCI Logging Error: `errno":"EHOSTUNREACH","syscall":"connect"`. 
Network Load Balancer

- **Wrong Patch**
  In this scenario, all the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the path for the HTTP health check it needs to match an actual application on the backend. In you can use a curl test from a system in the same network.
  
  For example:

  ```
  $ curl -i http://10.0.0.5/health
  ```

  You receive the configured status code in the response OCI Logging Error:

  ```json
  "msg":"invalid statusCode","statusCode":404,"expected":"200".
  ```

- **Wrong Protocol**
  In this scenario, all the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting the protocol it needs to match the protocol that is listening on the backend. For example: We only support TCP and HTTP health checks. If your backend is using HTTPS then you would need to use TCP as the protocol.

  OCI Logging Error:

  ```json
  "code":"EPROTO","errno":"EPROTO".
  ```

- **Wrong Status Code**
  In this scenario, all the backend servers report as unhealthy. If the backend servers do not have any problems, for an HTTP health check you might have made a mistake setting the status code to match the actual status code being returned from the backend. A common scenario is when a backend is returning a 302 and you are expecting a 200. This result is likely the backend sending you to a login page or another location on the server. In this scenario, you can either fix the backend to return the expected code or use 302 in your health check config.

  OCI Logging Error:

  ```json
  "msg":"invalid statusCode","statusCode":XX,"expected":"200"
  ```

  where XX to be the status code that is returned.

- **Wrong Regex Pattern**
  All the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake setting an incorrect regex pattern consistent with the body, or the backend is not returning the expected body. In this scenario, you can either change the backend to match the pattern or correct the pattern to match the backend. The following are some specific pattern examples.

  - Any Content - ".\.*"
  - A page returning the value "Status:OK:" - "Status:OK:.\.*"
  - OCI Logging Error: "response match result: failed"

- **Misconfigured Network Security Groups, Security Lists, or Local Firewall**
  All or some of the backend servers report as unhealthy. If the backend servers do not have any problems, you might have made a mistake configuring either the NSGs, Security Lists, or local firewalls such as firewalld, iptables, or SELinux. In this scenario you can use a curl or netcat test from a system that belongs to the same subnet and NSG as your LBaaS instance HTTP:

  For example:

  ```
  $ curl -i http://10.0.0.5/health TCP: ex: nc -zvw3 10.0.05 443.
  ```

  You can check your local firewall by using the following command:

  ```
  firewall-cmd --list-all --zone=public.
  ```
If your firewall is missing the expected rules you can use a command set like this to add the service: (this example is for HTTP port 80):

```
• firewall-cmd --zone=public --add-service=http
• firewall-cmd --zone=public --permanent --add-service=http
```

**Getting Health Check Policy Details**

Get the health check policy details for a Network Load Balancer resource and backend set.

Use one of the following methods to display the health check policy details for a selected network load balancer and backend set.

**To get the details of a health check policy using the Console**

Use the OCI Console to get the details of a health check policy for a Network Load Balancer resource and backend set.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list. All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under Type to only display network load balancers.
5. Select the network load balancer for whose health check policies whose details you want to get.

   The Load Balancer Details dialog box appears.
6. Click **Backend Sets** under **Resources**. The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.

    The Backend Set Details dialog box appears.
8. Click **Update Health Check**.

    Alternatively, click the **Actions** icon ( toured Actions icon ) for the backend set whose health check you want to update, and then click **Update Health Check**.

    The Update Health Check dialog box appears.

**To get the details of a health check policy using the CLI**

Use the command line interface (CLI) to get the health check policy details of a listener for a Network Load Balancer resource and backend set.

Enter the following command:

```
oci nlb health-checker get --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb health-checker get --help
```

See **oci nlb health-checker get** for a complete description of the command.

**To get the details of a health check policy using the API**

Use the API to get the details of a health check policy of a backend set for a Network Load Balancer resource.

Run the **GetHealthChecker** method to display the details of a health check policy of a backend set for a network load balancer. See **GetHealthChecker** for a complete description.
Editing Health Check Policies
Update the health check policy for a Network Load Balancer resource and backend set.

Use one of the following methods to edit and update the health check policy for a selected network load balancer and backend set.

To edit a health check policy using the Console
Use the OCI Console to update a health check policy of a backend set for a Network Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Load Balancer under Type to only display network load balancers.
5. Select the network load balancer for whose health check policies you want to edit.
   The Network Load Balancer Details dialog box appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   The Backend Set Details dialog box appears.
8. Click Update Health Check.
   Alternatively, click the Actions icon (⋮) for the backend set whose health check you want to update, and then click Update Health Check.
   The Update Health Check dialog box appears.
9. Update any of the following:

- **Protocol**: Required. Specify the protocol:
  - HTTP
  - HTTPS
  - TCP
  - UDP

  **Important:**
  Configure your health check protocol to match your application or service. See Health Check Policy Management on page 3589.

- **Port**: Optional. Specify the backend server port against which to run the health check.

  **Tip:**
  You can enter the value '0' to have the health check use the backend server's traffic port.

- **Interval in MS**: Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

- **Timeout in MS**: Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

- **Number of retries**: Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.

- **Status Code**: (HTTP and HTTPS only) Optional. Specify the status code a healthy backend server must return.

- **URL Path (URI)**: (HTTP and HTTPS only) Required. Specify a URL endpoint against which to run the health check.

- **Response Body Regex**: (HTTP and HTTPS only) Optional. Provide a regular expression for parsing the response body from the backend server.

- **Request Data**: (TCP and UDP only) Required for UDP, optional for TCP.

- **Response Data**: (TCP and UDP only) Required for UDP, optional for TCP.

10. Click **Save Changes**.

**To edit a health check policy using the CLI**

Use the command line interface (CLI) to update a health check policy of a backend set for a Network Load Balancer resource.

Enter the following command:

```
oci nlb health-checker update --backend-set-name backend_set_name --network-load-balancer-id network_load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb health-checker update --help
```

See [oci nlb health-checker update](#) for a complete description of the command.

**To edit a health check policy using the API**

Use the API to update a health check policy of a backend set for a Network Load Balancer resource.

Run the `UpdateHealthChecker` method to edit a health check policy of a backend set for a load balancer. See [UpdateHealthChecker](#) for a complete description.

**Work Request Management**

Learn to generate information on each Network Load Balancer service operation’s work requests.
Many of the Network Load Balancer requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment.

To provide visibility for in-progress workflows, Network Load Balancer creates a work request object. Because some operations depend on the completion of other operations, you must monitor each operation’s work request and confirm it has succeeded before proceeding to the next operation. For example, if you want to create a backend set and add a backend server to the new set, you first must create the backend set. After that operation completes, you can add the backend server.

If you try to add a backend server before the backend set creation completes, the system cannot ensure that the request to add the server succeeds. You can monitor the request to add a backend set to determine when that workflow is complete, and then add the backend server.

The work request states are:

**ACCEPTED**

The request is in the work request queue to be processed.

**IN PROGRESS**

A work request record exists for the specified request, but no associated WORK_COMPLETED record is present.

**SUCCEEDED**

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.

**FAILED**

A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

**Note:**

Network Load Balancer does not use the common Work Requests API to support work request operations. Instead, the Network Load Balancer API supports Network Load Balancer work requests. See Using the Console to View Work Requests on page 303 for information on viewing work requests for other services.

### Listing Work Requests

List the work requests for Network Load Balancer resource.

Use one of the following methods to display a list of work requests for a selected network load balancer.

**To list the work requests using the Console**

Use the OCI Console to list the work requests for a Network Load Balancer resource in your tenancy.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the work requests you want to list.
6. Click **Work Requests** under **Resources**.

The **Work Requests** list appears. All work requests are listed in tabular form.

**To list the work requests using the CLI**

Use the command line interface (CLI) to list the work requests for a compartment.
Enter the following command:

```
oci nlb work-request list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb work-request list --help
```

See `oci nlb work-request list` for a complete description of the command.

**To list the work requests using the API**

Use the API to list the work requests for a Network Load Balancer resource.

Run the `ListWorkRequests` method to display a list of work requests for a network load balancer. See `ListWorkRequests` for a complete description.

**Getting Work Request Details**

Get the details of a work request for a Network Load Balancer resource.

Use one of the following methods to display the details of a selected work request for a network load balancer.

**To get the details of a work request using the CLI**

Use the command line interface (CLI) to get the details of a work request for a Network Load Balancer resource.

Enter the following command:

```
oci nlb work-request get --work-request-id work_request_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb work-request get --help
```

See `oci nlb work-request get` for a complete description of the command.

**To get the details of a work request using the API**

Use the API to get the details of a work request for a Network Load Balancer resource.

Run the `GetWorkRequest` method to display the details of a work request for a network load balancer. See `GetWorkRequest` for a complete description.

**Listing Work Request Errors**

List the work requests for Network Load Balancer resource.

Use one of the following methods to display a list of work requests for a selected network load balancer.

**To list the work request errors using the Console**

Use the OCI Console to list the work request errors for Network Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer containing the work requests errors you want to list.
   
   The Network Load Balancer Details dialog box appears.
6. Click **Work Requests** under **Resources**.
   
   The **Work Requests** list appears. All work requests are listed in tabular form.
7. View the **Error Details** column.
To list the work request errors using the CLI
Use the command line interface (CLI) to list the work request errors for Network Load Balancer resource.

Enter the following command:

```
oci nlb work-request-error list --compartment-id compartment_id --work-request-id work_request_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb work-request-error list --compartment-id --help
```

See `oci nlb work-request-error list` for a complete description of the command.

To list the work request errors using the API
Use the API to list the work request errors for a Network Load Balancer resource.

Run the `ListWorkRequestErrors` method to display a list of work request errors for a network load balancer. See `ListWorkRequestErrors` for a complete description.

Listing Work Request Logs
List the work requests for Network Load Balancer resource.

Use one of the following methods to display a list of work requests for a selected network load balancer.

To list the work request logs using the CLI
Use the command line interface (CLI) to list the logs for a work request.

Enter the following command:

```
oci nlb work-request-log-entry list --compartment-id compartment_id --work-request-id work_request_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci nlb work-request-log-entry list --compartment-id --help
```

See `oci nlb work-request-log-entry list` for a complete description of the command.

To list the work request logs using the API
Use the API to list the work request logs for a Network Load Balancer resource.

Run the `ListWorkRequestLogs` method to display a list of work request errors for a network load balancer. See `ListWorkRequestLogs` for a complete description.

Network Load Balancer Metrics
Learn how to set up and use metrics to measure the number and type of connections, and quantity of data managed by your Network Load Balancer resource.

The Network Load Balancer service metrics help you monitor the number and type of connections, and quantity of traffic processed by your network load balancer. You can use metrics data to diagnose and troubleshoot network load balancer and client issues.

To view a default set of metrics charts in the OCI Console, navigate to the network load balancer or backend set you are interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.

To view metrics from the OCI Console:

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Select the network load balancer whose metrics you want to view.

   The Network Load Balancer Details dialog box appears.

6. Click **Metrics** under **Resources**.

   The **Metrics** section appears.

   You can specify the start and end time periods for which the metrics apply. You can also select various commands and view types from the **Options** list.

---

**Prerequisites**

- **IAM policies:** To monitor resources, you must be given the required type of access in a *policy* written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

- The metrics listed on this page are automatically available for any load balancer, listener, and backend set you create. You do not need to enable monitoring on the resource to get these metrics.

---

**Available Metrics:** *oci_flexible_nlb*

Network Load Balancer metrics include the following *dimensions*:

**RESOURCENAME**

The display name of the network load balancer resource to which the metrics apply.

Networking Overview

When you work with Oracle Cloud Infrastructure, one of the first steps is to set up a virtual cloud network (VCN) for your cloud resources. This topic gives you an overview of Oracle Cloud Infrastructure Networking components and typical scenarios for using a VCN.

Networking Components

The Networking service uses virtual versions of traditional network components you might already be familiar with:
VIRTUAL CLOUD NETWORK (VCN)

A virtual, private network that you set up in Oracle data centers. It closely resembles a traditional network, with firewall rules and specific types of communication gateways that you can choose to use. A VCN resides in a single Oracle Cloud Infrastructure region and covers one or more CIDR blocks (IPv4 and IPv6, if enabled). See Allowed VCN Size and Address Ranges on page 3606. The terms virtual cloud network, VCN, and cloud network are used interchangeably in this documentation. For more information, see VCNs and Subnets on page 3693.

SUBNETS

Subdivisions you define in a VCN (for example, 10.0.0.0/24, 10.0.1.0/24, or 2001:DB8::/64). Subnets contain virtual network interface cards (VNICs), which attach to instances. Each subnet consists of a contiguous range of IP addresses (for IPv4 and IPv6, if enabled) that do not overlap with other subnets in the VCN. You can designate a subnet to exist either in a single availability domain or across an entire region (regional subnets are recommended). Subnets act as a unit of configuration within the VCN: All VNICs in a given subnet use the same route table, security lists, and DHCP options (see the definitions that follow). You can designate a subnet as either public or private when you create it. Private means VNICs in the subnet can't have public IPv4 addresses and internet communication with IPv6 endpoints will be prohibited. Public means VNICs in the subnet can have public IPv4 addresses and internet communication is permitted with IPv6 endpoints. See Access to the Internet on page 3609.

VNIC

A virtual network interface card (VNIC), which attaches to an instance and resides in a subnet to enable a connection to the subnet's VCN. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC), and remove them as you like. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance. For more information, see Virtual Network Interface Cards (VNICs) on page 3733. A VNIC attached to a compute instance and residing in an IPv6-enabled subnet can optionally be assigned an IPv6 address.

PRIVATE IP

A private IPv4 address and related information for addressing an instance (for example, a hostname for DNS). Each VNIC has a primary private IP, and you can add and remove secondary private IPs. The primary private IP address on an instance doesn't change during the instance's lifetime and cannot be removed from the instance. For more information, see Private IP Addresses on page 3742.

PUBLIC IP

A public IPv4 address and related information. You can optionally assign a public IP to your instances or other resources that have a private IP. Public IPs can be either ephemeral or reserved. For more information, see Public IP Addresses on page 3753.

IPV6

An IPv6 address and related information. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

DYNAMIC ROUTING GATEWAY (DRG)

An optional virtual router that you can add to your VCN. It provides a path for private network traffic between your VCN and on-premises network. You can use it with other Networking components and a router in your on-premises network to establish a connection by way of Site-to-Site VPN or Oracle Cloud Infrastructure FastConnect. It can also provide a path for private network traffic between your VCN and another VCN in a different region. For more information, see Access to Your On-Premises Network on page 3610, Dynamic Routing Gateways (DRGs) on page 3793, and Remote VCN Peering using an RPC on page 4152.
INTERNET GATEWAY
Another optional virtual router that you can add to your VCN for direct internet access. For more information, see Access to the Internet on page 3609 and also Scenario A: Public Subnet on page 3614.

NETWORK ADDRESS TRANSLATION (NAT) GATEWAY
Another optional virtual router that you can add to your VCN. It gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections. For more information, see Public vs. Private Subnets on page 3609 and also NAT Gateway on page 4119.

SERVICE GATEWAY
Another optional virtual router that you can add to your VCN. It provides a path for private network traffic between your VCN and supported services in the Oracle Services Network (examples: Oracle Cloud Infrastructure Object Storage and Autonomous Database). For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. For more information, see Access to Oracle Services: Service Gateway on page 4127.

LOCAL PEERING GATEWAY (LPG)
Another optional virtual router that you can add to your VCN. It lets you peer one VCN with another VCN in the same region. Peering means the VCNs communicate using private IP addresses, without the traffic traversing the internet or routing through your on-premises network. A given VCN must have a separate LPG for each peering it establishes. For more information, see Local VCN Peering using Local Peering Gateways on page 4139.

REMOTE PEERING CONNECTION (RPC)
A component that you can add to a DRG. It lets you peer one VCN with another VCN in a different region. For more information, see Remote VCN Peering using an RPC on page 4152.

ROUTE TABLES
Virtual route tables for your VCN. They have rules to route traffic from subnets to destinations outside the VCN by way of gateways or specially configured instances. Your VCN comes with an empty default route table, and you can add custom route tables of your own. For more information, see VCN Route Tables on page 3702.

SECURITY RULES
Virtual firewall rules for your VCN. They are ingress and egress rules that specify the types of traffic (protocol and port) allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. For example, you can allow incoming SSH traffic from anywhere to a set of instances by setting up a stateful ingress rule with source CIDR 0.0.0.0/0, and destination TCP port 22. To implement security rules, you can use network security groups or security lists. A network security group consists of a set of security rules that apply only to the resources in that group. Contrast this with a security list, where the rules apply to all the resources in any subnet that uses the list. Your VCN comes with a default security list with default security rules. For more information, see Security Rules on page 3710.

DHCP OPTIONS
Configuration information that is automatically provided to the instances when they boot up. For more information, see DHCP Options on page 3789.

Allowed VCN Size and Address Ranges
A VCN covers one or more IPv4 CIDR blocks of your choice. The allowable VCN size range is /16 to /30. Example: 10.0.0.0/16. The Networking service reserves the first two IP addresses and the last one in each subnet's CIDR. You can enable IPv6 for your VCNs when you create them, or you can enable IPv6 on existing IPv4-only VCNs. IPv6-enabled VCNs use a /56 IPv6 CIDR block.

For your VCN, Oracle recommends using the private IP address ranges specified in RFC 1918 (10.0.0.0/16, 172.16/16, and 192.168/16). However, you can use a publicly routable range. Regardless, this documentation uses the
term *private IP address* when referring to IP addresses in your VCN's CIDR. Address ranges that are disallowed are described in [IP Addresses Reserved for Use by Oracle](#) on page 3611. For IPv6-enabled VCNs, Oracle will allocate a globally unicast address /56 CIDR.

The VCN's CIDR blocks must not overlap with each other, with CIDRs in your on-premises network, or with the CIDRs of another VCN you peer with. The subnets in a given VCN must not overlap with each other. For reference, here's a [CIDR calculator](#).

IPv6 addressing is supported for all commercial and government regions. For more information, see [IPv6 Addresses](#) on page 3768.

**Availability Domains and Your VCN**

Your VCN resides in a single Oracle Cloud Infrastructure region. A region can have multiple availability domains to provide isolation and redundancy. For more information, see [Regions and Availability Domains](#).

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all *AD-specific*, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or *regional*. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.
Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. Oracle recommends using regional subnets because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

**Default Components that Come With Your VCN**

Your VCN automatically comes with these default components:

- Default route table, with no route rules
- Default security list, with default security rules
- Default set of DHCP options, with default values
You can't delete these default components. However, you can change their contents (for example, the rules in the default security list). And you can create your own custom versions of each kind of component in your VCN. There are limits to how many you can create and the maximum number of rules. For more information, see Service Limits on page 243.

Each subnet always has these components associated with it:

- One route table
- One or more security lists (for the maximum number, see Service Limits on page 243)
- One set of DHCP options

During subnet creation, you can choose which route table, security list, and set of DHCP options the subnet uses. If you don't specify a particular component, the subnet automatically uses the VCN's default component. You can change which components the subnet uses at any time.

**Tip:**

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

### Connectivity Choices

You can control whether subnets are public or private, and whether instances get public IP addresses. You can set up your VCN to have access to the internet if you like. You can also privately connect your VCN to public Oracle Cloud Infrastructure services such as Object Storage, to your on-premises network, or to another VCN.

#### Public vs. Private Subnets

When you create a subnet, by default it's considered public, which means instances in that subnet are allowed to have public IPv4 addresses and internet communication is permitted with IPv6 endpoints. Whoever launches the instance chooses whether it has a public IPv4 address or specifies whether an IPv6 address from the allocated CIDR will be assigned. You can override that behavior when creating the subnet and request that it be private, which disallows the use of public IPv4 addresses and internet communication with IPv6 endpoints. Network administrators can therefore ensure that instances in the subnet have no internet access, even if the VCN has a working internet gateway, and security rules and firewall rules allow the traffic.

### How IP Addresses Are Assigned

Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC) and remove them as you like.

Every VNIC has a private IP address from the associated subnet's CIDR. You can choose the particular IP address (during instance launch or secondary VNIC creation), or Oracle can choose it for you. The private IP address does not change during the lifetime of the instance and cannot be removed. You can also add secondary private IPv4 addresses or secondary IPv6 addresses to a VNIC.

If the VNIC is in a public subnet, then each private IP on that VNIC can have a public IPv4 address or IPv6 address assigned to it at your discretion. For IPv4, Oracle chooses the particular IP address. For IPv6, you can specify the IP address. There are two types of public IPs: *ephemeral* and *reserved*. An ephemeral public IP exists only for the lifetime of the private IP it's assigned to. In contrast, a reserved public IP exists as long as you want it to. You maintain a pool of reserved public IPs and allocate them to your instances at your discretion. You can move them from resource to resource in a region as you need to.

### Access to the Internet

There are two optional gateways (virtual routers) that you can add to your VCN depending on the type of internet access you need:

- **Internet gateway:** For resources with public IP addresses that need to be reached from the internet (example: a web server) or need to initiate connections to the internet.
• **NAT gateway**: For resources without public IP addresses that need to initiate connections to the internet (example: for software updates) but need to be protected from inbound connections from the internet.

Just having an internet gateway alone does not expose the instances in the VCN's subnets directly to the internet. The following requirements must also be met:

• The **internet gateway** must be enabled (by default, the internet gateway is enabled upon creation).
• The subnet must be **public**.
• The subnet must have a **route rule** that directs traffic to the internet gateway.
• The subnet must have **security list rules** that allow the traffic (and each instance's firewall must allow the traffic).
• The instance must have a **public IP address**.

**Tip:**

To access public services such as Object Storage from your VCN without the traffic going over the internet, use a **service gateway**.

Also, notice that traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure (such as Object Storage) is routed without being sent over the internet.

You can also give a subnet **indirect access** to the internet by setting up an internet proxy in your on-premises network and then connecting that network to your VCN by way of a DRG. For more information, see **Access to Your On-Premises Network** on page 3610.

**Access to Public Oracle Cloud Infrastructure Services**

You can use a service gateway with your VCN to enable private access to public Oracle Cloud Infrastructure services such as Object Storage. For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. No internet gateway or NAT is required. For more information, see **Access to Oracle Services: Service Gateway** on page 4127.

**Access to Your On-Premises Network**

There are two ways to connect your on-premises network to Oracle Cloud Infrastructure:

• **Site-to-Site VPN**: Offers multiple IPSec tunnels between your existing network's edge and your VCN, by way of a DRG that you create and attach to your VCN.
• **Oracle Cloud Infrastructure FastConnect**: Offers a private connection between your existing network's edge and Oracle Cloud Infrastructure. Traffic does not traverse the internet. Both private peering and public peering are supported. That means your on-premises hosts can access private IPv4 or IPv6 addresses in your VCN as well as regional public IPv4 or IPv6 addresses in Oracle Cloud Infrastructure (for example, Object Storage or public load balancers in your VCN).

You can use one or both types of the preceding connections. If you use both, you can use them simultaneously, or in a redundant configuration. These connections come to your VCN by way of a single DRG that you create and attach to your VCN. Without that DRG attachment and a route rule for the DRG, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining components that form the rest of the connection. You could then reattach the DRG again, or attach it to another VCN.

**Access to Another VCN**

You can connect your VCN to another VCN over a private connection that doesn't require the traffic to traverse the internet. In general, this type of connection is referred to as **VCN peering**. Each VCN must have specific components to enable peering. The VCNs must also have specific IAM policies, route rules, and security rules that permit the connection to be made and the wanted network traffic to flow over the connection. For more information, see **Access to Other VCNs: Peering** on page 4136.

**Connection to Oracle Cloud Infrastructure Classic**

You can set up a connection between your Oracle Cloud Infrastructure environment and Oracle Cloud Infrastructure Classic environment. This connection can facilitate hybrid deployments between the two environments, or migration
from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. For more information, see Access to Oracle Cloud Infrastructure Classic on page 4178.

Connection to Microsoft Azure

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. For more information, see Access to Microsoft Azure on page 4188.

Connection to Other Clouds with Libreswan

You can connect your VCN to another cloud provider by using Site-to-Site VPN with a Libreswan VM as the customer-premises equipment (CPE). For more information, see Access to Other Clouds with Libreswan on page 4200.

Networking Scenarios

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See these topics:

- Scenario A: Public Subnet on page 3614
- Scenario B: Private Subnet with a VPN on page 3618
- Scenario C: Public and Private Subnets with a VPN on page 3626

Transit Routing

Scenarios A–C show your on-premises network connected to one or more VCNs by way of a DRG and FastConnect or Site-to-Site VPN, and accessing only the resources in those VCNs.

The following advanced routing scenarios give your on-premises network access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the DRG, and then transits through the DRG to its destination. See these topics:

- Transit Routing inside a hub VCN on page 3667: Your on-premises network has access to multiple VCNs in the same region over a single FastConnect private virtual circuit or Site-to-Site VPN. The DRG and attached VCNs are in a hub-and-spoke topology, with the on-premises network connected to the DRG which acts as the hub. The spoke VCNs are peered.
- Private Access to Oracle Services on page 3653: Your on-premises network has private access to Oracle services in the Oracle Services Network by way of a connected VCN and the VCN’s service gateway. The traffic does not go over the internet.

Regions and Availability Domains

Your VCN resides in a single Oracle Cloud Infrastructure region. Each subnet resides in a single availability domain (AD). Availability domains are designed to provide isolation and redundancy in your VCN, as illustrated in Scenario B and C earlier. For example, you could set up your primary set of subnets in a single AD, and then set up a duplicate set of subnets in a secondary AD. The two ADs are isolated from each other in the Oracle data centers, so if one fails, you can easily switch over to the other AD. For more information, see Regions and Availability Domains.

Public IP Address Ranges

For a list of Oracle Cloud Infrastructure public IP ranges, see IP Address Ranges on page 222.

IP Addresses Reserved for Use by Oracle

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

**169.254.0.0/16**

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.
Class D and Class E

All addresses from 224.0.0.0 to 239.255.255.255 (Class D) are prohibited for use in a VCN, they are reserved for multicast address assignments in the IP standards. See RFC 3171 for details.

All addresses from 240.0.0.0 to 255.255.255.255 (Class E) are prohibited for use in a VCN, they are reserved for future use in the IP standards. See RFC 1112, Section 4 for details.

Three IP Addresses in Each Subnet

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 5528.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.
Networking

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Limits on Your Networking Components**

See [Service Limits](#) on page 243 for a list of applicable limits and instructions for requesting a limit increase.

**Networking scenarios**

**Basic scenarios**

All but the first of these basic routing scenarios send traffic from a subnet in the VCN to the DRG. To accomplish this, you must set up a rule in the subnet's route table. The rule's destination CIDR is the CIDR of the network that is being reached through the DRG, and the rule's target is the DRG. For more information, see VCN Route Tables on page 3702.

- Scenario A: Public Subnet on page 3614 (no DRG required)
- Scenario B: Private Subnet with a VPN on page 3618
- Scenario C: Public and Private Subnets with a VPN on page 3626

**Peering**

These scenarios all allow traffic to flow from one VCN to another.

- Peering VCNs in the same region through a DRG on page 4162
- Peering VCNs in different regions through a DRG on page 4169
- Local VCN Peering using Local Peering Gateways on page 4139
- Remote VCN Peering using an RPC on page 4152

**Advanced scenarios using a single DRG**

**VCN Ingress Routing**: Some of the following advanced scenarios require ingress routing of traffic entering the VCN from a DRG through the VCN attachment. To accomplish this, you must associate a VCN route table (this is a route table created inside your VCN) with the VCN attachment. After a VCN route table is associated with a VCN attachment, there must always be a VCN route table associated with that attachment (that is, you cannot update the field in the corresponding data object to "Null"). Removing the VCN ingress routing functionality from a VCN attachment can only be accomplished by emptying the associated VCN route table or updating the attachment to refer to an empty VCN route table.

- Using a DRG to route traffic through a centralized network virtual appliance on page 3644
- Private Access to Oracle Services on page 3653
- Transit Routing inside a hub VCN on page 3667

**Advanced scenario with multiple DRGs and multiple VCNs**

There's an extra advanced scenario that illustrates the use of multiple DRGs and VCNs. In this case, each VCN has its own dynamic routing gateway (DRG) and its own FastConnect private virtual circuit. Contrast this with Transit Routing inside a hub VCN on page 3667, in which there's a single DRG with either Site-to-Site VPN or a single FastConnect private virtual circuit.

Here are some restrictions for using the scenario that has multiple DRGs:

- The scenario works only with FastConnect through a third-party provider or through colocation with Oracle. It is not supported for FastConnect through an Oracle partner.
- The scenario is supported only for VCNs in the same region and same tenancy. This is because all the virtual circuits use a single cross-connect, a regional resource.

See FastConnect with Multiple DRGs and VCNs on page 3689.
Scenario A: Public Subnet

This topic explains how to set up Scenario A, which consists of a virtual cloud network (VCN) and a regional public subnet. Public servers are in separate availability domains for redundancy. The VCN is directly connected to the internet by way of an internet gateway. The gateway is also used for connectivity to your on-premises network. Any resource in the on-premises network that needs to communicate with resources in the VCN must have a public IP address and access to the internet.

The subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only allow traffic. Any traffic not explicitly covered by a security list rule is implicitly denied.

This scenario does not use a DRG.

In this scenario, you add more rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.

<table>
<thead>
<tr>
<th>Tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security lists are one way to control traffic in and out of the VCN’s resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.</td>
</tr>
</tbody>
</table>

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the internet gateway.

See the following figure.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message...
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you’re a member of the Administrators group, you already have the required access to implement Scenario A. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 3709.

**Setting Up Scenario A in the Console**

Setup is easy in the Console.

**Task 1: Create the VCN**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.

   **Note:**
   
   To create any new resource the service limit for that resource must not already have been reached. Once the service limit for a resource type has been reached, you can either remove unused resources of that type or request a service limit increase.

3. Click Create Virtual Cloud Network.
4. Enter the following:
   - **Name:** A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **CIDR Blocks:** One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment:** This option is available for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.
   - **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN’s default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (\(<VCN\ DNS label>\).oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

**Task 2: Create the regional public subnet**

1. While still viewing the VCN, click Create Subnet.
2. Enter the following:

- **Name**: A friendly name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Regional or Availability Domain-Specific**: Select *Regional* (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it in any availability domain in the region. For more information, see Overview of VCNs and Subnets on page 3694.

- **CIDR Block**: A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You cannot change this value later. For reference, here's a CIDR calculator.

- **Enable IPv6 Address Assignment**: This option is available only if the VCN is enabled for IPv6. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

- **Route Table**: Select the default route table.

- **Private or public subnet**: Select *Public Subnet*, which means instances in the subnet can optionally have public IP addresses. For more information, see Access to the Internet on page 3609.

- **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and also when you plan to use the VCN’s default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or let the Console generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the subnet (<subnet_DNS_label>..<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.

- **DHCP Options**: Select the default set of DHCP options.

- **Security Lists**: Ensure that the default security list is selected.

- **Tags**: Leave as is. You can add tags later. For more information, see Resource Tags on page 239.

3. Click **Create Subnet**.

   The subnet is then created and displayed on the **Subnets** page.

**Task 3: Create the internet gateway**

1. Under **Resources**, click **Internet Gateways**.
2. Click **Create Internet Gateway**.
3. Enter the following:

- **Name**: A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Create in Compartment**: Leave as is.

- **Tags**: Leave as is. You can add tags later. For more information, see Resource Tags on page 239.

4. Click **Create Internet Gateway**.

   Your internet gateway is created and displayed on the **Internet Gateways** page. The gateway is already enabled, but you must add a route rule that allows traffic to flow to the gateway.

**Task 4: Update the default route table to use the internet gateway**

The default route table starts out with no rules. Here you add a rule that routes all traffic destined for addresses outside the VCN to the internet gateway. The existence of this rule also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security list rules to control the types of traffic that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required to route traffic within the VCN itself.

1. Under **Resources**, click **Route Tables**.
2. Click the default route table to view its details.
3. Click **Add Route Rule**.
4. Enter the following:
   - **Target Type:** Internet Gateway
   - **Destination CIDR block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule)
   - **Compartment:** The compartment where the internet gateway is located.
   - **Target:** The internet gateway you created.
   - **Description:** An optional description of the rule.

5. Click **Add Route Rule**.

The default route table now has a rule for the internet gateway. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.

**Task 5: Update the default security list**

Earlier you set up the subnet to use the VCN's default security list. Now you add security list rules that allow the types of connections that the instances in the VCN need.

For example: For a public subnet with an internet gateway, the (web server) instances you launch might need to receive inbound HTTPS connections from the internet. Here's how to add another rule to the default security list to enable that traffic:

1. Under **Resources**, click **Security Lists**.
2. Click the default security list to view its details. By default, you land on the **Ingress Rules** page.
3. Click **Add Ingress Rule**.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 443
   - **Description:** An optional description of the rule.
5. Click **Add Ingress Rule**.

**Important:**

Security List Rule for Windows Instances

If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see **Security Lists** on page 3727.

For a production VCN, you typically set up one or more custom security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

**Task 6: Create instances in separate availability domains**

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a public subnet, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you must give each instance a
public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

Setting Up Scenario A with the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

1. **CreateVcn**: Always include a DNS label for the VCN if you want the instances to have hostnames (see DNS in Your Virtual Cloud Network on page 3781).

2. **CreateSubnet**: Create one regional public subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.

3. **CreateInternetGateway**

4. **UpdateRouteTable**: To enable communication with the internet gateway, update the default route table to include a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway. This rule routes all traffic destined for addresses outside the VCN to the internet gateway. No route rule is required to route traffic within the VCN itself.

5. **UpdateSecurityList**: To allow specific types of connections to and from the instances in the subnet.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security List Rule for Windows Instances</td>
</tr>
</tbody>
</table>

If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Lists on page 3727.

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a public subnet, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you must give each instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

**Scenario B: Private Subnet with a VPN**

This topic explains how to set up Scenario B, which consists of a virtual cloud network (VCN) with a regional private subnet. Other servers are in separate availability domains for redundancy. The VCN has a dynamic routing gateway (DRG) and Site-to-Site VPN for connectivity to your on-premises network. The VCN has no direct connection to the internet. Any connection to the internet would need to come indirectly by way of the on-premises network.

The subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only allow traffic. Any traffic not explicitly covered by a security list rule is denied.

This scenario can use a legacy or upgraded DRG.

In this scenario, you add rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.
Networking

**Tip:**

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the DRG. No route rule is required to route traffic within the VCN itself.

See the following figure.

![Diagram of VCN with Default Route Table and Default Security List](image)

**Tip:**
The scenario uses Site-to-Site VPN for connectivity. However, you could instead use Oracle Cloud Infrastructure FastConnect.

**Prerequisites**

To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the *customer-premises equipment* (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You provide Oracle this information and in return receive the information your network administrator must have to configure the CPE at your end of the VPN.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to implement Scenario B. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 3709.

**Setting Up Scenario B**

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you perform the individual operations yourself.

### Important:

Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the necessary Networking components. But there’s also a critical step that requires a network administrator in your organization to take information you receive from setting up the components and use it to configure the CPE at your end of the VPN. Therefore you can't complete this process in one short session. Plan to take a break while the network administrator completes the configuration and return afterward to confirm communication with your instances over the VPN.

**Using the Console**

*Task 1: Set up the VCN and subnet*

1. Create the VCN:
   
   a. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
   
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.

   c. Click **Create Virtual Cloud Network**.

   d. Enter the following:

   - **Name**: A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **CIDR Block**: One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

   - **Use DNS Hostnames in this VCN**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (\(<VCN DNS label>\).oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.

   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

   e. Click **Create Virtual Cloud Network**.

The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.
2. Create the regional private subnet:
   a. While still viewing the VCN, click **Create Subnet**.
   b. Enter the following:
      - **Name**: A friendly name for the subnet (for example, *Regional Private Subnet*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Regional or Availability Domain-Specific**: Select *Regional* (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any availability domain in the region. For more information, see Overview of VCNs and Subnets on page 3694.
      - **CIDR Block**: A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You *cannot* change this value later. For reference, here's a [CIDR calculator](#).
      - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 3768.
      - **Route Table**: Select the default route table.
      - **Private or public subnet**: Select *Private Subnet*, which means instances in the subnet cannot have public IP addresses. For more information, see Access to the Internet on page 3609.
      - **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and also when you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or let the Console generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.
      - **DHCP Options**: Select the default set of DHCP options.
      - **Security Lists**: Select the default security list.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
   c. Click **Create Subnet**.
      The subnet is then created and displayed on the **Subnets** page.
3. Update the default security list to include rules to allow the types of connections that your instances in the VCN need:

   a. While still on the page displaying your VCN's subnets, click Security Lists, and then click the default security list.
   
   b. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with. You can add one rule at a time by clicking either Add Ingress Rule or Add Egress Rule.

   c. Add your wanted rules. Here are suggested ones to add to the default ones already in the default security list:

   Example: Ingress HTTP access
   - **Type:** Ingress
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 80
   - **Description:** An optional description of the rule.

   Example: Ingress HTTPS access
   - **Type:** Ingress
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 443
   - **Description:** An optional description of the rule.

   Example: Ingress SQL*Net access for Oracle databases
   - **Type:** Ingress
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 1521
   - **Description:** An optional description of the rule.

   Example: Ingress RDP access required for Windows instances
   - **Type:** Ingress
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 3389
   - **Description:** An optional description of the rule.

   **Tip:**

   For extra security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. Create...
separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.

For a production VCN, you typically set up one or more custom security lists for each subnet. You can edit the subnet to use different security lists if you like. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

**Task 2: Create instances in separate availability domains**

You can now create one or more instances in the subnet (see Launching an Instance). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

However, you can't yet communicate with the instances because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through setting up Site-to-Site VPN to enable that communication.

**Task 3: Add Site-to-Site VPN to your VCN**

1. Create a customer-premises equipment (CPE) object:
   a. Open the navigation menu and click Networking. Under Customer Connectivity, click Customer-Premises Equipment.
   b. Click Create Customer-Premises Equipment.
   c. Enter the following:
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - **Name**: A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **IP Address**: The public IP address of the CPE at your end of the VPN (see Prerequisites on page 3619).
   d. Click Create.

   The CPE object is in the "Provisioning" state for a short period.

2. Create a dynamic routing gateway (DRG):
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
   b. Click Create Dynamic Routing Gateway.
   c. For **Create in Compartment**: Leave the default value (the compartment you're currently working in).
   d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   e. Click Create.

   The DRG is in the "Provisioning" state for a short period. Wait until the DRG is fully provisioned before continuing.

3. Attach the DRG to your VCN:
   a. Click the DRG that you created.
   b. Under Resources, click Virtual Cloud Networks.
   c. Click Attach to Virtual Cloud Network.
   d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called transit routing, which is not relevant here.
   e. Click Attach.

   The attachment is in the "Attaching" state for a short period. Wait for this process to finish.
4. Update the default route table (which has no rules yet):
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Click your VCN.
   c. Under Resources, click Route Tables, and then click the default route table.
   d. Click Add Route Rule.
   e. Enter the following:
      • **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table go to the target specified in this rule).
      • **Description**: An optional description of the rule.
   f. Click Add Route Rule.

   The VCN's default route table now directs outbound traffic to the DRG and ultimately to your on-premises network.

5. Create an IPSec Connection:
   a. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   b. Click Create IPSec Connection.
   c. Enter the following:
      • **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      • **Name**: Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
      • **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
      • **Customer-Premises Equipment**: Select the CPE object you created earlier.
      • **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
      • **Dynamic Routing Gateway**: Select the DRG that you created earlier.
      • **Static Route CIDR**: Enter at least one static route CIDR (see Prerequisites on page 3619). If you need to add another, click Add Static Route. You can enter up to 10 static routes, and you can change the static routes later.
   d. Click Show Advanced Options and optionally provide the following items:
      • **CPE IKE Identifier**: Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
      • **Tunnel 1 and Tunnel 2**: Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing on page 4037.
      • **Tags**: Leave as is. You can add tags later. For more information, see Resource Tags on page 239.
   e. Click Create IPSec Connection.

   The IPSec connection is created and displayed on the page. The connection is in the Provisioning state for a short period.

   The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click View Shared Secret.

   f. Copy the Oracle VPN IP address and shared secret for each of the tunnels and share them with the network engineer who configures the on-premises router.

   For more information, see CPE Configuration on page 3844. You can view this tunnel information here in the Console at any time.

You have now created all the components required for Site-to-Site VPN. Next, your network administrator must configure the CPE device before network traffic can flow between your on-premises network and VCN.
**Task 4: Configure your CPE**

These instructions are for the network administrator.

1. Ensure you have the tunnel configuration information Oracle provided during VPN Connect setup. See Task 3: Add Site-to-Site VPN to your VCN on page 3623.
2. Configure your CPE according to the information in CPE Configuration on page 3844.

If instances are already in the subnet, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations:

1. **CreateVcn**: Always include a DNS label for the VCN if you want the instances to have hostnames (see DNS in Your Virtual Cloud Network on page 3781).
2. **CreateSubnet**:
   Create one regional private subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.
3. **CreateDrg**:
   Creates a dynamic routing gateway (DRG)
4. **CreateDrgAttachment**:
   Attaches the DRG to the VCN.
5. **CreateCpe**:
   Provide the public IP address of the CPE at your end of the VPN (see Prerequisites on page 3619).
6. **CreateIPSecConnection**:
   Provide the static routes for your on-premises network (see Prerequisites on page 3619). The command returns the configuration information that your network administrator needs to configure your CPE. If you need that information later, you can get it with GetIPSecConnectionDeviceConfig. For more information about the configuration, see CPE Configuration on page 3844.
7. **UpdateRouteTable**:
   To enable communication through the VPN, update the default route table to include this route: a route rule with destination = 0.0.0.0/0, and destination target = the DRG you created earlier.
8. First call GetSecurityList to get the default security list, and then call UpdateSecurityList to add rules for the types of connections that your instances in the VCN need. Be aware that UpdateSecurityList overwrites the entire set of rules. Here are some suggested rules to add:
   - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=80 (for HTTP).
   - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=443 (for HTTPS).
   - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=1521 (for SQL*Net access to Oracle databases).
   - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port=all, destination port=3389 (for RDP; required only if using Windows instances).
9. **LaunchInstance**:
   Create one or more instances in the subnet. The scenario’s diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics. For more information, see Creating an Instance on page 1023.

**Tip:**

For more security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. Create separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.

**Important:**

Although you can create instances in the subnet, you can't communicate with them from your on-premises network until your network administrator configures your CPE (see CPE Configuration on page 3844). After that, Site-to-Site VPN should be up and running. You can confirm its status by
Networking

You can also confirm Site-to-Site VPN is up by connecting to the instances from your on-premises network.

**Scenario C: Public and Private Subnets with a VPN**

This topic explains how to set up Scenario C, which is a simple example of a multi-tier setup. It consists of a virtual cloud network (VCN) with a regional **public subnet** to hold public servers (such as web servers), and a regional **private subnet** to hold private servers (such as database servers). Servers are in separate **availability domains** for redundancy.

The VCN has a **dynamic routing gateway** (DRG) and Site-to-Site VPN for connectivity to your on-premises network. Instances in the public subnet have direct access to the internet by way of an **internet gateway**. Instances in the private subnet can initiate internet connections by way of a **NAT gateway** (for example, to get software updates), but cannot receive inbound connections from the internet through that gateway.

Each subnet uses the **default security list**, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only **allow** traffic. Any traffic not explicitly covered by a security list rule is denied.

**Tip:**

Security lists are one way to control traffic in and out of the VCN's resources. You can also use **network security groups**, which let you apply a set of security rules to a set of resources that all have the same security posture.

This scenario can use a legacy or upgraded **DRG**.

Each subnet also has its own custom security list and custom route table with rules specific to the needs of the subnet's instances. In this scenario, the VCN's default route table (which is always empty to start with) is not used.

See the following figure.

**Tip:**

The scenario uses Site-to-Site VPN for connectivity. However, you could instead use **Oracle Cloud Infrastructure FastConnect**.

![Diagram of Scenario C: Public and Private Subnets with a VPN]
Prerequisites

To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the customer-premises equipment (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You provide Oracle this information and in return receive the information your network administrator needs to configure the on-premises router at your end of the VPN.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to implement Scenario C. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 3709.

Setting Up Scenario C

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you implement the individual operations yourself.

Important:

Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the required Networking components. There's also a critical step that requires a network administrator in your organization to take information you receive while setting up the components and use it to configure the on-premises router at your end of the VPN. Therefore you can't complete this process in one short session. Take a break while the network administrator completes the configuration and then confirm communication with your instances over the VPN.

Using the Console

Task 1: Set up the VCN and subnets

1. Create the VCN:
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.
   c. Click Create Virtual Cloud Network.
   d. Enter the following:
      - **Name**: A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave as is.
      - **CIDR Block**: One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
      - **Enable IPv6 Address Assignment**: IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.
      - **Use DNS Hostnames in this VCN**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the
check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (\(<\text{VCN DNS label}\>\).oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

e. Click **Create Virtual Cloud Network.**

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

2. Create an internet gateway for your VCN:

a. Under **Resources,** click **Internet Gateways.**

b. Click **Create Internet Gateway.**

c. Enter the following:

- **Name:** A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Create in Compartment:** Leave as is.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

d. Click **Create Internet Gateway.**

The internet gateway is then created and listed on the page.

3. Create a NAT gateway for your VCN:

a. Under **Resources,** click **NAT Gateways.**

b. Click **Create NAT Gateway.**

c. Enter the following:

- **Name:** A friendly name for the NAT gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Create in Compartment:** Leave as is.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

d. Click **Create NAT Gateway.**

The NAT gateway is then created and listed on the page.
4. Create the custom route table for the public subnet (which you create later):
   
   a. Under Resources, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      
      - **Name**: A friendly name for the route table (for example, *Public Subnet Route Table*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - Click **+ Additional Route Rule** and enter the following:
         
         - **Target Type**: Internet Gateway.
         - **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
         - **Compartment**: Leave as is.
         - **Target**: The internet gateway you created.
         - **Description**: An optional description of the rule.
      
      d. **Tags**: Leave as is. You can add tags later. For more information, see [Resource Tags](#) on page 239.
   
   d. Click **Create Route Table**.

   The route table is then created and listed on the page.

5. Create the custom route table for the private subnet (which you create later):

   a. Click **Create Route Table**.
   b. Enter the following:
      
      - **Name**: A friendly name for the route table (for example, *Private Subnet Route Table*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - Click **+ Additional Route Rule** and enter the following:
         
         - **Target Type**: NAT Gateway.
         - **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
         - **Compartment**: Leave as is.
         - **Target**: The NAT gateway you created.
         - **Description**: An optional description of the rule.
      
      c. **Tags**: Leave as is. You can add tags later. For more information, see [Resource Tags](#) on page 239.
   
   d. Click **Create Route Table**.

   The route table is then created and listed on the page. After you set up Site-to-Site VPN, you update the Private Subnet Route Table so it routes traffic from the private subnet to the on-premises network by way of the DRG.

6. Update the **default security list** to include rules to allow the types of connections that your instances in the VCN need:

   a. Under Resources, click **Security Lists**.
   b. Click the default security list to view its details. By default, you land on the **Ingress Rules** page.
   c. Edit each of the existing stateful ingress rules so that the **Source CIDR** is the CIDR for your on-premises network (10.0.0.0/16 in this example) and not 0.0.0.0/0. To edit an existing rule, click the Actions icon (three dots) for the rule, and then click **Edit**.
   d. If you plan to launch Windows instances, add a rule to enable RDP access:
7. Create a custom security list for the public subnet:
   a. Return to the Security Lists page for the VCN.
   b. Click Create Security List.
   c. Enter the following:
      • **Name**: Enter a friendly name for the list (for example, Public Subnet Security List). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • **Create in Compartment**: Leave the default value (the compartment you're currently working in).
   d. Add the following ingress rules:
      Example: Ingress HTTP access
      • **Type**: Ingress
      • **Stateless**: Unselected (this is a stateful rule)
      • **Source Type**: CIDR
      • **Source CIDR**: 0.0.0.0/0
      • **IP Protocol**: TCP
      • **Source Port Range**: All
      • **Destination Port Range**: 80
      • **Description**: An optional description of the rule.
      Example: Ingress HTTPS access
      • **Type**: Ingress
      • **Stateless**: Unselected (this is a stateful rule)
      • **Source Type**: CIDR
      • **Source CIDR**: 0.0.0.0/0
      • **IP Protocol**: TCP
      • **Source Port Range**: All
      • **Destination Port Range**: 443
      • **Description**: An optional description of the rule.
   e. Add the following egress rule:
   f. Click Create Security List.

The custom security list for the public subnet is then created and listed on the page.
8. Create a custom security list for the private subnet:
   a. Click Create Security List.
   b. Enter the following:
      • Name: Enter a friendly name for the list (for example, Private Subnet Security List). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • Create in Compartment: Leave the default value (the compartment you're currently working in).
   c. Add the following ingress rules:
      Example: Ingress SQL*Net access from clients in the public subnet
      • Type: Ingress
      • Stateless: Unselected (this is a stateful rule)
      • Source Type: CIDR
      • Source CIDR: CIDR for the public subnet (172.16.2.0/24 in this example)
      • IP Protocol: TCP
      • Source Port Range: All
      • Destination Port Range: 1521
      • Description: An optional description of the rule.
      Example: Ingress SQL*Net access from clients in the private subnet
      • Type: Ingress
      • Stateless: Unselected (this is a stateful rule)
      • Source Type: CIDR
      • Source CIDR: CIDR for the private subnet (172.16.2.1/24 in this example)
      • IP Protocol: TCP
      • Source Port Range: All
      • Destination Port Range: 1521
      • Description: An optional description of the rule.
   d. Add the following egress rules:
   e. Click Create Security List.
      The custom security list for the private subnet is then created and listed on the page.
9. Create the subnets in the VCN:
   a. Under Resources, click Subnets.
   b. Click Create Subnet.
   c. Enter the following:
      • Name: A friendly name for the regional public subnet (for example, Regional Private Subnet). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • Regional or Availability Domain-Specific: Select Regional (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any
availability domain in the region. For more information, see Overview of VCNs and Subnets on page 3694.

- **CIDR Block**: A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.1.0/24. You cannot change this value later. For reference, here's a CIDR calculator.

- **Enable IPv6 Address Assignment**: This option is available only if the VCN is enabled for IPv6. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

- **Route Table**: Select the Private Subnet Route Table you created earlier.

- **Private or public subnet**: Select Private Subnet, which means VNICs in the subnet are not allowed to have public IP addresses. For more information, see Access to the Internet on page 3609.

- **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and also when you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or let the Console generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.

- **DHCP Options**: Select the default set of DHCP options.

- **Security Lists**: Select two security lists: Both the default security list and the Private Subnet Security List you created earlier.

d. **Click Create Subnet.**

    The private subnet is then created and displayed on the Subnets page.

e. **Repeat the preceding steps a-d to create the regional public subnet.** Instead use a name such as Regional Public Subnet, select Public Subnet instead of Private Subnet, use the Public Subnet Route Table, and use both the default security list and Public Subnet Security List you created earlier.

Example: Ingress RDP access required for Windows instances

- **Type**: Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type**: CIDR
- **Source CIDR**: Your on-premises network (10.0.0.0/16 in this example)
- **IP Protocol**: TCP
- **Source Port Range**: All
- **Destination Port Range**: 3389
- **Description**: An optional description of the rule.

Example: Egress SQL*Net access to Oracle databases

- **Type**: Egress
- **Stateless**: Unselected (this is a stateful rule)
- **Destination Type**: CIDR
- **Destination CIDR**: CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol**: TCP
- **Source Port Range**: All
- **Destination Port Range**: 1521
- **Description**: An optional description of the rule.

Example: Egress SQL*Net access to instances in the private subnet

- **Type**: Egress
- **Stateless**: Unselected (this is a stateful rule)
- **Destination Type**: CIDR
- **Destination CIDR**: CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol**: TCP
• **Source Port Range:** All
• **Destination Port Range:** 1521
• **Description:** An optional description of the rule.

**Task 2: Create instances in separate availability domains**

You can now create one or more instances in the subnet (see [Launching an Instance](#)). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

For each instance in the public subnet, you must assign the instance a public IP address. Otherwise, the instance isn't available from your on-premises network.

You can't yet reach the instances in the private subnet because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through setting up Site-to-Site VPN to enable that communication.

**Task 3: Add Site-to-Site VPN to your VCN**

1. Create a customer-premises equipment object:
   a. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Customer-Premises Equipment**.
   b. Click **Create Customer-Premises Equipment**.
   c. Enter the following:
      • **Create in Compartment:** Leave the default value (the compartment you're currently working in).
      • **Name:** A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • **IP Address:** The IP address of the on-premises router at your end of the VPN (see Prerequisites on page 3627).
   d. Click **Create**.

   The CPE object is in the "Provisioning" state for a short period.

2. Create a dynamic routing gateway (DRG):
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
   b. Click **Create Dynamic Routing Gateway**.
   c. For **Create in Compartment:** Leave the default value (the compartment you're currently working in).
   d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   e. Click **Create**.

   The DRG is in the "Provisioning" state for a short period. Wait until it is fully provisioned before continuing.

3. Attach the DRG to your VCN:
   a. Click the DRG that you created.
   b. Under **Resources**, click **Virtual Cloud Networks**.
   c. Click **Attach to Virtual Cloud Network**.
   d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called transit routing, which is not relevant here.
   e. Click **Attach**.

   The attachment is in the "Attaching" state for a short period.
4. Update the private subnet's route table (which already has one rule for the NAT gateway):
   a. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   b. Click your VCN.
   c. Click Route Tables, and then click the Private Subnet Route Table you created earlier.
   d. Click Add Route Rule.
   e. Enter the following:
      • **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • **Destination CIDR Block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
      • **Description:** An optional description of the rule.
   f. Click Add Route Rule.

   The table is updated to route any traffic destined for your on-premises network to the DRG. The original rule for 0.0.0.0/0 routes any remaining traffic leaving the subnet to the NAT gateway.

5. Create an IPSec Connection:
   a. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   b. Click Create IPSec Connection.
   c. Enter the following:
      • **Create in Compartment:** Leave the default value (the compartment you're currently working in).
      • **Name:** Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
      • **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
      • **Customer-Premises Equipment:** Select the CPE object you created earlier.
      • **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
      • **Dynamic Routing Gateway:** Select the DRG that you created earlier.
      • **Static Route CIDR:** Enter at least one static route CIDR (see Prerequisites on page 3627). If you need to add another, click Add Static Route. You can enter up to 10 static routes, and you can change the static routes later.
   d. Click Show Advanced Options and optionally provide the following items:
      • **CPE IKE Identifier:** Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
      • **Tunnel 1** and **Tunnel 2:** Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing on page 4037.
      • **Tags:** Leave as is. You can add tags later. For more information, see Resource Tags on page 239.
   e. Click Create IPSec Connection.

   The IPSec connection is created and displayed on the page. The connection is in the Provisioning state for a short period.

   The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click View Shared Secret.
   f. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who configures the on-premises router.

   For more information, see CPE Configuration on page 3844. You can view this tunnel information here in the Console at any time.

You have now created all the components required for Site-to-Site VPN. Next, your network administrator must configure the on-premises router before network traffic can flow between your on-premises network and VCN.
Networking

**Task 4: Configure your on-premises router (CPE)**

These instructions are for the network administrator.

1. Get the tunnel configuration information that Oracle provided during VPN setup. See **Task 3: Add Site-to-Site VPN to your VCN** on page 3633.
2. Configure your on-premises router according to the information in **CPE Configuration** on page 3844.

If compute instances are already in one of the subnets, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network. To connect to instances in the public subnet, you must connect to the instance's public IP address.

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use the following operations:

1. **CreateVcn**: Always include a DNS label if you want the VCN to use the VCN Resolver (see **DNS in Your Virtual Cloud Network** on page 3781).
2. **CreateInternetGateway**
3. **CreateNatGateway**
4. **CreateRouteTable**: Call it to create the Public Subnet Route Table. To enable communication by way of the internet gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway you created earlier.
5. **CreateRouteTable**: Call it again to create the Private Subnet Route Table. To enable communication by way of the NAT gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the NAT gateway you created earlier.
6. First call **GetSecurityList** to get the default security list, and then call **UpdateSecurityList**:
   - Change the existing stateful ingress rules to use your on-premises network's CIDR as the source CIDR, instead of 0.0.0.0/0.
   - If you plan to launch Windows instances, add this stateful ingress rule: Source type = CIDR, source CIDR = your on-premises network on TCP, source port = all, destination port = 3389 (for RDP).
7. **CreateSecurityList**: Call it to create the Public Subnet Security List with these rules:
   - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 80 (HTTP)
   - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 443 (HTTPS)
   - Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
8. **CreateSecurityList**: Call it again to create the Private Subnet Security List with these rules:
   - Stateful ingress: Source type = CIDR, source CIDR blocks of public subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
   - Stateful ingress: Source type = CIDR, source CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
   - Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
9. **CreateSubnet**: Call it to create regional public subnet. Include a DNS label for the subnet if you want the **VCN Resolver** to resolve hostnames for VNICs in the subnet. Use the Public Subnet Route Table you created earlier. Use both the default security list and the Public Subnet Security List that you created earlier. Use the default set of DHCP options.
10. **CreateSubnet**: Call it again to create regional private subnet. Include a DNS label for the subnet if you want the **VCN Resolver** to resolve hostnames for VNICs in the subnet. Use the Private Subnet Route Table you created earlier. Use both the default security list and the Private Subnet Security List that you created earlier. Use the default set of DHCP options.
11. **CreateDrg**: Creates a dynamic routing gateway (DRG).
12. **CreateDrgAttachment**: Attaches the DRG to the VCN.

13. **CreateCpe**: Here you provide the IP address of the router at your end of the VPN (see Prerequisites on page 3627).

14. **CreateIPSecConnection**: Here you provide the static routes for your on-premises network (see Prerequisites on page 3627). In return, you receive the configuration information your network administrator needs to configure your router. If you need that information later, you can get it with `GetIPSecConnectionDeviceConfig`. For more information about the configuration, see CPE Configuration on page 3844.

15. First call `GetRouteTable` to get the Private Subnet Route Table. Then call `UpdateRouteTable` to add a route rule with destination = the on-premises network CIDR (10.0.0.0/16 in this example), and destination target = the DRG you created earlier.

16. **LaunchInstance**: Launch at least one instance in each subnet. By default, the instances in the public subnets are assigned public IP addresses. For more information, see Creating an Instance on page 1023.

You can now communicate from your on-premises network with the instances in the public subnet over the internet gateway.

**Important:**

Although you can launch instances into the private subnets, you can't communicate with them from your on-premises network until your network administrator configures your on-premises router (see CPE Configuration on page 3844). After that, your IPSec connection is up and running. You can confirm its status by using `GetIPSecConnectionDeviceStatus`. You can also confirm the IPSec connection is up by connecting to the instances from your on-premises network.

---

### On-premises access to multiple DRGs and VCNs in different regions through a single connection

#### Remote on-ramp overview

The remote on-ramp scenario shows how to let your on-premises network access two or more virtual cloud networks (VCNs) through a single FastConnect virtual circuit or Site-to-Site VPN IPSec connection, even if the VCNs are in different regions or tenancies. In this scenario, connectivity is established between VCNs and the on-prem network, but not between VCNs. This choice of routing policy is implemented by configuring the dynamic routing gateway (DRG) routing tables, and otherwise this scenario resembles remote peering.

This scenario is only available to an upgraded DRG.

#### Summary of Networking components for single on-ramp

At a high level, the Networking service components required for single on-ramp include:

- **Two VCNs with non-overlapping CIDRs, in different regions.**

**Note:**

No VCN CIDRs can overlap

The two VCNs in the peering relationship cannot have overlapping CIDRs. Also, if a particular VCN has multiple peering relationships, those other VCNs must not have overlapping CIDRs with each other. For example, if VCN-1 is peered with VCN-2 and also VCN-3, then VCN-2 and VCN-3 must not have overlapping CIDRs.

If you are configuring this scenario, you have to meet this requirement in the planning stage. Routing problems are likely when overlapping CIDRs occur, but the Console or API operations do not prevent you from creating a configuration that causes issues.
• A dynamic routing gateway (DRG) attached to each VCN in the peering relationship. Your VCN already has a DRG if you’re using Site-to-Site VPN or an Oracle Cloud Infrastructure FastConnect private virtual circuit.

• Two custom DRG route tables: one routing traffic to the VCNs, and one routing traffic to the on-premises network. The default DRG route tables (one for local VCN attachments and one for all other attachments) are not used after the configuration is complete.

• A remote peering connection (RPC) on each DRG in the peering relationship.

• An established remote peering connection between those two RPCs.

• Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if wanted).

• Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components. VCN-1 is optional if your primary intent is to access VCN-2.

![Diagram of peering components](image)

**Note:**

A given VCN can use the connected RPCs only to reach your on-premises network or VCNs connected to the DRG. For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could NOT use it to send traffic to endpoints on the internet. For more information, see Important Implications of Peering on page 4137.

**Important implications of peering**

If you haven't yet, read Important Implications of Peering on page 4137 to understand important access control, security, and performance implications for peered VCNs.

Peering VCNs in different tenancies has some permissions complications that need to be resolved in both tenancies. See IAM policies related to DRG peering on page 3806 for details on the permissions needed.
Important remote peering concepts

The following concepts help you understand the basics of VCN peering and how to establish a remote peering.

PEERING

A peering is a single peering relationship between two VCNs. Example: If VCN-1 peers with two other VCNs, two peerings exist. The remote part of remote peering indicates that the VCNs are in different regions. For this method of remote peering, the VCNs can be in the same tenancy or in different tenancies.

VCN ADMINISTRATORS

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, the two administrators must:

• Share some basic information with each other.
• Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
• Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies. The VCNs can be in the same tenancy or in different tenancies.

For more information about the required policies and VCN configuration, see IAM policies related to DRG peering on page 3806.

ACCEPTOR AND REQUESTOR

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the requestor and the other as the acceptor. The requestor must be the one to initiate the request to connect the two RPCs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to RPCs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

REGION SUBSCRIPTION

To peer with a VCN in another region, your tenancy must first be subscribed to that region. For information about subscribing, see Managing Regions on page 3140.

REMOTE PEERING CONNECTION (RPC)

A remote peering connection (RPC) is a component you create on the DRG attached to your VCN. The RPC's job is to act as a connection point for a remotely peered VCN. As part of configuring the VCNs, each administrator must create an RPC for the DRG on their VCN. A given DRG must have a separate RPC for each remote peering it establishes for the VCN (maximum 300 RPCs per tenancy). To continue with the previous example: the DRG on VCN-1 would have two RPCs to peer with two other VCNs. In the API, a RemotePeeringConnection is an object that contains information about the peering. You can't reuse an RPC to later establish another peering with it.

CONNECTION BETWEEN TWO RPCS

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to connect the two RPCs. The requestor must have information to identify each RPC (such as the RPC's region and OCID).

Either VCN administrator can terminate a peering by deleting their RPC. In that case, the other RPC's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules that enable traffic to flow across the connection (see the next section).

ROUTING TO THE DRG

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. For each subnet that needs to communicate with the on-premises network, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your DRG as the target. Your DRG routes traffic that matches that rule to the other DRG, which in turn routes the traffic to the next hop in the other VCN.
SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you can write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.

Setting up single on-ramp

Before you attempt to implement this scenario, be sure that:

1. VCN-1 is attached to DRG-1 in region 1 following the steps in Attaching a VCN to a DRG on page 3800.
2. VCN-2 is attached to DRG-2 in region 2 following the steps in Attaching a VCN to a DRG on page 3800.
3. VCN-2 is peered to VCN-1 following the steps in Peering VCNs in different regions through a DRG on page 4169.
4. Both DRGs are otherwise unmodified.
5. FastConnect virtual circuit 1 is in region 1, connected to DRG-1 following the appropriate method depending on the source of the virtual circuit (Oracle partner, Oracle colocation, third-party provider) as described in the documentation for FastConnect on page 4051.

The following diagram shows the beginning state before implementing this scenario. VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in Subnet A's route table. From there the traffic is routed through the RPCs to DRG-2, and then from there, on to the destination in Subnet X. The on-premises network can address resources in VCN-1 but not in VCN-2.
The implemented onramp scenario described in the next diagram does not allow the VCNs to route traffic to each other. VCN-1 and VCN-2 are peered. Traffic from an on-premises resource in your network (172.16.0.10) destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in the IPSEC_TUNNEL attachment route table To-on-premises. From there the traffic is routed through the RPC attachment to DRG-2, and then to the destination in Subnet X.
As mentioned earlier, a given VCN can use the connected DRG’s RPC attachment to reach only VNICs in your on-premises network, and not destinations on the internet. For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

**Steps**

These steps are all performed on DRG-1:

**Step 1: Create new DRG route tables**

This table doesn't need any static routes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you're interested in, DRG-1.
3. Under Resources, click DRG Route Tables.
4. Click Create DRG Route Table.
5. Enter the following:
   • Name: Enter "RT-VCN" or choose some other descriptive name.
6. Click Create DRG Route Table.

Repeat these steps to create two more empty route tables named "RT-OnPrem" and "RT-RPC" before you move to the next task.

**Step 2: Create an import route distribution for "RT-VCN"**

Create an import route distribution for the DRG attachment used by VCN-1. The import route distribution will contain one statement, accepting routes from attachments of type virtual circuit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in, DRG-1.
3. Under Resources, click Import Route Distributions.
4. Click Create Import Route Distribution.
5. Enter the following:
   • Name: Enter "Import-VCN" or choose some other descriptive name.
   • Priority: Enter "10" or choose some other priority number.
   • Match Type: Choose Attachment Type.
     
     **Attachment Type:** Choose Virtual Circuit.

     **Note:**
     When you use the Attachment Type option, the import route distribution will include routes from all attachments to this DRG with the chosen type.

6. Click Create Import Route Distribution when finished.
8. Click the name of the route table you want to assign to the new import route distribution, "RT-VCN."
9. Click Edit.
10. Click Enable Import Route Distribution: This option allows you to assign an import route distribution to the route table so it dynamically learns new routes based on BGP advertisements.
   • Choose the import route distribution you created in earlier steps, named "Import-VCN".
11. Click Save Changes.

**Step 3: Create an import route distribution for "RT-OnPrem"**

Create an import route distribution for the DRG attachment used by the virtual circuit attachment. The import route distribution will contain two statements, one accepting routes from attachments of type VCN and another accepting routes from attachments of type RPC.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in, DRG-1.
3. Under Resources, click Import Route Distributions.
4. Click Create Import Route Distribution.
5. Enter the following:
   • Name: Enter "Import-OnPrem" or choose some other descriptive name.
   • Priority: Enter "10" or choose some other priority number.
   • Match Type: Choose Attachment Type.
     
     **Attachment Type:** Choose Virtual Cloud Network.
6. Click + Another Statement to add another route distribution statement.
   - **Priority**: Enter "20" or choose some other priority number.
   - **Match Type**: Choose Attachment Type.
   - **Attachment Type**: Choose Remote Peering Connection.

   **Note:**
   When you use the Attachment Type option, the import route distribution will include routes from all attachments to this DRG with the RPC type. Any RPC connection to VCNs in other regions will be included.

7. Click Create Import Route Distribution when finished.
9. Click the name of the route table you want to assign to the new import route distribution, "RT-OnPrem."
10. Click Edit.
11. Click Enable Import Route Distribution: This option allows you to assign an import route distribution to the route table so it dynamically learns new routes based on BGP advertisements.
   - Choose the import route distribution you created in earlier steps, named "Import-OnPrem"
12. Click Save Changes.

**Step 4: Create an import route distribution for "RT-RPC"**

Create an import route distribution for the DRG attachment used by the remote peering connection attachment. The import route distribution will contain one statement, accepting routes from attachments of type virtual circuit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in, DRG-1.
3. Under Resources, click Import Route Distributions.
4. Click Create Import Route Distribution.
5. Enter the following:
   - **Name**: Enter "Import-RPC" or choose some other descriptive name.
   - **Priority**: Enter "10" or choose some other priority number.
   - **Match Type**: Choose Attachment Type.

   Attachment Type: Choose Virtual Cloud Network.
6. Click Create Import Route Distribution when finished.
8. Click the name of the route table you want to assign to the new import route distribution, "RT-RPC."
9. Click Edit.
10. Click Enable Import Route Distribution: This option allows you to assign an import route distribution to the route table so it dynamically learns new routes based on BGP advertisements.
   - Choose the import route distribution you created in earlier steps, named "Import-RPC"
11. Click Save Changes.

**Step 5: Reassign the attachment route tables**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the name of the DRG you're interested in, DRG-1.
4. Click the name of the DRG attachment used by VCN-1.
5. Click Edit.
6. Click Show Advanced Options.
7. Change the DRG route table from the autogenerated route table for VCN attachments to "RT-VCN"
8. Click Save Changes.
9. In the breadcrumb at the top of the screen, click the name of the DRG you're interested in, DRG-1.
11. Click the name of the DRG attachment used by virtual circuit 1.
12. Click Edit.
13. Click Show Advanced Options.
14. Change the DRG route table from the autogenerated route table for RPC, VIRTUAL_CIRCUIT and IPSEC_TUNNEL attachments to "RT-OnPrem."  
15. Click Save Changes.
16. In the breadcrumb at the top of the screen, click the name of the DRG you're interested in, DRG-1.
18. Click the name of the DRG attachment used by RPC-1.
19. Click Edit.
20. Click Show Advanced Options.
21. Change the DRG route table from the autogenerated route table for RPC, VIRTUAL_CIRCUIT and IPSEC_TUNNEL attachments to "RT-RPC."

This completes configuration of single on-ramp. At this point, any packets sent from a local or remote VCN to your on-premises network are sent to the mutually attached DRG, and then to your on-premises network.

Using a DRG to route traffic through a centralized network virtual appliance

The three primary transit routing scenarios are:

- **Access between multiple networks through a single DRG with a firewall between networks**: The scenario covered in this topic. This scenario uses the DRG as the hub, with routing configured to send packets through a firewall instance in a dedicated virtual cloud network (VCN) before they can be sent to another network.
- **Access to multiple VCNs in the same region**: This scenario enables communication between your on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or Site-to-Site VPN, with a VCN as the hub. See Transit Routing inside a hub VCN on page 3667
- **Private access to Oracle services**: This scenario gives your on-premises network private access to Oracle services with a VCN as the hub, so your on-premises hosts can use their private IP addresses and traffic does not go over the internet. See Private Access to Oracle Services on page 3653.

Highlights

- You can use FastConnect or Site-to-Site VPN to connect your on-premises network with multiple VCNs in the same region or in another region, in a hub-and-spoke topology.
- When the dynamic routing gateway (DRG) acts as the hub, all VCNs can be in different regions or tenancies. For accurate routing, the CIDR blocks of the various subnets accessible to the on-premises network and other connected VCNs must not overlap.
- A dynamic routing gateway can act as the hub to communicate between VCNs or with the on-premises network. This DRG has attachments for peering connections to VCNs (referred to as spoke VCNs in this topic).
- To enable the intended traffic between the attached networks through the DRG and a firewall VCN to a peered spoke VCN, create route rules for the DRG, the firewall VCN, or the firewall VCN's DRG attachment, for the spoke VCNs, and for the spoke VCN's subnets.
- You can set up transit routing through a private IP in the firewall VCN. For example, you might want to filter or inspect the traffic between the on-premises network and a spoke VCN. In that case, you route the traffic to a private IP on an instance in the firewall VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the firewall VCN, and transit routing through a private IP.
- By configuring route tables, you can control whether a particular subnet in a peered spoke VCN is advertised to the on-premises network.
There's another scenario that lets you connect your on-premises network to multiple VCNs. Instead of using a single DRG and hub-and-spoke topology, you set up a separate DRG for each VCN and a separate private virtual circuit over a single FastConnect. However, the scenario can be used only with FastConnect through a third-party provider or through colocation with Oracle. The VCNs must be in the same region and same tenancy. For more information, see FastConnect with Multiple DRGs and VCNs on page 3689.

### Overview of Transit Routing through a Private IP

Transit routing is simply routing traffic to either a VCN or an on-premises network through a central hub VCN. Here's a basic example of why you might use transit routing: you have a large organization with different departments, each with their own VCN. Each VCN needs access to the other VCNs, but you want to ensure security by sending all traffic through a virtual network appliance running a firewall.

**Note:**

A hub is a logical concept in a hub-and-spoke topology. If you want spokes to communicate directly to each other, the hub can be just a DRG. If you want all spoke-to-spoke traffic to pass through a firewall, the hub is the combination of the DRG and the firewall VCN.

This networking scenario optionally involves connecting your on-premises network to a VCN with either Oracle Cloud Infrastructure FastConnect or Site-to-Site VPN. These two basic scenarios illustrate that topology: Scenario B: Private Subnet with a VPN on page 3618 and Scenario C: Public and Private Subnets with a VPN on page 3626.

This scenario uses a hub-and-spoke topology, as illustrated in the following diagram. The term hub here means only that a VCN has a firewall that must be routed through when one spoke communicates with another spoke in this hub-and-spoke design. The on-premises network connection shown in the diagram is not covered in the detailed steps that follow, it is shown for reference.
Use this scenario if you want to create a hub-and-spoke topology and route all traffic between *spokes* through a firewall device in the *hub*. All VCNs are in the same region, and connect to a DRG in that region, but they could be in different regions or in different tenancies. The on-premises network shown is optional, and could be a VCN in another region or tenancy. In this scenario, traffic is sent from an on-premises network to the DRG and then to the firewall in VCN-Fire, then back to the DRG to be routed to VCN-B. Similarly, traffic sent from VCN-A is first routed by the DRG to VCN-Fire and then to VCN-C.
Summary of New Concepts for Experienced Networking Service Users

If you're already familiar with the Networking service and local peering, the most important new concepts to understand are:

• For each spoke VCN subnet that needs to communicate with another network attached to the DRG, update the subnet's route table with a rule that sets the target for all traffic (the next hop) as the DRG.

• Add a DRG route table for the firewall VCN attachment, associate it with the VCN attachment (inside the DRG), and add a route rule with a target that depends on your situation:

  • Transit routing through a private IP: Set the target (the next hop) to a private IP on the instance, for all traffic destined for another spoke VCN (or a specific subnet in that VCN). Be sure to disable the source/destination check for the private IP's VNIC.

  • Add another route table to the hub, VCN-Fire, associate it with the firewall VCN's attachment to the DRG (for that spoke), and add a route rule with a target that depends on your situation:

  • Routing traffic to another network: Set the target (the next hop) as the DRG for all traffic destined to another VCN or for the on-premises network (or a specific subnet in that network).

Before you begin

Before you attempt to implement this scenario, ensure that:

1. VCN-A, VCN-B, and VCN-C (the "spoke" VCNs) are all already created, none of which are attached to a DRG.
2. VCN-Fire is already created and its subnet Subnet-H has a compute instance with a private IPv4 address running firewall software. This VCN is not yet attached to any DRG.
3. All VCNs in the scenario have non-overlapping CIDRs.
4. The on-premises network is connected to DRG with FastConnect prereq.
5. All necessary IAM policies are in already in place. See IAM policies related to DRG peering on page 3806 for details.

Process summary

Configuring transit routing involves these steps:

1. Create a DRG named DRG-Transit.
2. Attach spoke VCNs VCN-A, VCN-B, and VCN-C to DRG-Transit.
3. Attach VCN-Fire to DRG-Transit.
4. Create a route table named "To-Firewall" in DRG-Transit with a single static rule sending all traffic to the VCN-Fire's attachment.
5. Change the DRG route table used by the spoke VCN attachments to "To-Firewall."
6. Create an import DRG route distribution in DRG-Transit called Import_Spoke_Routes with three statements, each importing routes from the VCN attachments used by VCN-A, VCN-B, and VCN-C.
7. Create a DRG route table named "From-Firewall" in DRG-Transit and specify its import route distribution to Import_Spoke_Routes.
8. Update the DRG route table of VCN-Fire's attachment to use the "From-Firewall" route table.
9. Configure VCN-Fire's default route table to send all incoming traffic to the firewall instance.
10. Configure Subnet-H to send all traffic destined to addresses in the VCN CIDRs of VCN-A, VCN-B, and VCN-C to the DRG attachment.

Turning off transit routing

To turn off transit routing, remove the rules from:

• The route table associated with the DRG attachment.

• The route table on the firewall VCN.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.
A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table’s rules, or delete some or all rules.

**Example: Transit routing with a DRG hub and a firewall in an attached VCN**

The examples in this section show a DRG acting as a hub and an attached VCN with a firewall, you can configure as many spoke VCNs as necessary by repeating Task 2: Attach the spoke VCNs on page 3650. The FastConnect link in the diagram is not covered in the detailed steps that follow, it is shown for reference.
### Task 1: Create DRG-Hub
Create the DRG (named DRG-Transit) that routes traffic between all attached VCNs.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.
3. Click Create Dynamic Routing Gateway.
4. Enter the following items:
   - Name: DRG-Transit
   - Create in Compartment: The compartment where you want to create the DRG, which could be different from the compartment you're currently working in.
5. Click Create Dynamic Routing Gateway.

The new DRG is created and then displayed on the Dynamic Routing Gateways page of the compartment you chose. The DRG is in the "Provisioning" state for a short period. You can connect it to other parts of your network only after provisioning is complete.

Provisioning a DRG includes creating two default route tables: one DRG route table for VCN attachments and one DRG route table for all other resources such as virtual circuits and IPSec tunnels. These route tables are used to route traffic coming into the DRG.

### Task 2: Attach the spoke VCNs
Attach VCN-A, VCN-B, and VCN-C to DRG-Transit.

#### Note:
The VCN subnet route tables sending traffic to the DRG attachment need to account for the CIDRs of the other two VCNs.

#### Note:
A DRG can be attached to many VCNs, but VCN can be attached to only one DRG at a time. The attachment is automatically created in the compartment that holds the VCN. A VCN does not need to be in the same compartment as the DRG.

You can eliminate local peering connections from your overall network design if you connect several VCNs in the same region to the same DRG and configure the DRG routing tables appropriately.

The following instructions have you navigate to the DRG and then choose which VCN to attach. Repeat this task for all three VCNs (VCN-A, VCN-B, and VCN-C), and create a different DRG attachment for each VCN.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to attach to VCN A, DRG-Transit.
4. Click Create VCN attachment.
   - (Optional) Enter Spoke-A, or give the attachment point some other descriptive name. If you don't specify a name, one is created for you. are suggested.
   - Select VCN-A from the list.
5. Click Create VCN attachment.

The attachment is in the "Attaching" state for a short period. Each of the spoke VCNs get a unique attachment.

Once you have done this for all three VCNs (VCN-A, VCN-B, and VCN-C) you have direct routing between these VCNs.
Task 3: Attach the firewall VCN

Attach VCN-Fire to DRG-Transit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to attach to a VCN, in this case DRG-Transit.
4. Click Create VCN attachment.
   - (Optional) Enter Firewall-Attach or give the attachment point some other descriptive name. If you don't specify a name, one is created for you.
   - Select VCN-Fire from the list of VCNs.
5. Click Create VCN attachment.

The attachment is in the "Attaching" state for a short period. The VCN attachment uses the default DRG route table for VCNs. Wait for the attachment to complete before moving on.

Task 4: Create the DRG route table sending ingress traffic to the firewall

Create a DRG route table named "To-Firewall" in DRG-Transit with a single static rule sending all traffic to the VCN-Fire's attachment.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in, DRG-Transit.
3. Under Resources, click DRG Route Tables.
4. Click Create DRG Route Table.
5. Enter the following:
   - Name: Enter TO-FIREWALL, or choose some other descriptive name.
   - Destination CIDR: enter the CIDR for VCN-Fire. This example uses 0.0.0.0/0. This is a static route which sends all VCN-A, VCN-B, and VCN-C traffic to the firewall.
   - Next Hop Attachment Type: Choose Virtual Cloud Network.
   - Next hop Attachment: Choose VCN-Fire from the list.
6. Click Create Route Table.

Task 5: Update the route table of spoke VCN attachments

Change the DRG route table used by the spoke VCN attachments to "To-Firewall."

Change the DRG route tables used by the spoke VCN attachments (VCN-A, VCN-B, and VCN-C) to use the route table created in the previous task, which sends all incoming traffic to VCN-Fire.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in, DRG-Transit.
4. Click the name of the DRG attachment used by one of the VCNs.
5. Click Edit.
6. Click Show Advanced Options.
7. In the DRG route table tab, select TO-FIREWALL from the list of available route tables.
8. Click Save Changes.

Repeat this task for all three spoke VCN attachments (VCN-A, VCN-B, and VCN-C) before proceeding to the next task.

Task 6: Create an import route distribution

In this task, you create an import route distribution in DRG-Hub with three statements, each importing routes from the VCN attachments used by VCN-A, VCN-B, and VCN-C.
1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you're interested in, DRG-Transit.
3. Under **Resources**, click **Import Route Distributions**.
4. Click **Create Import Route Distribution**.
5. In the screen that appears, give the import route distribution an easily recognized name like `Import_Spoke_Routes`, then click **+ Another Statement** twice. For each of the three statements, add the following details:
   - **Match Type**: Choose Attachment.
   - **Attachment Type Filter**: Choose Virtual Cloud Network.
   - **DRG Attachment**: Choose a VCN attachment created previously for VCN-A, VCN-B, or VCN-C.
6. Click **Create Import Route Distribution** when finished.

**Task 7: Create a DRG route table for ingress from firewall**

Create a route table named "From-Firewall" in DRG-Hub and set its import route distribution to the distribution created previously.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you're interested in, DRG-Transit.
3. Under **Resources**, click **DRG Route Tables**.
4. Click **Create DRG Route Table**.
5. Assign the DRG route table a name, for example FROM-FIREWALL.
6. Click **Show Advanced Options**.
7. Click **Enable Import Route Distribution**.
8. Choose `Import_Spoke_Routes`, the import route distribution you created in **Task 6**.
9. Click **Create Route Table**.

   The route table is created and then displayed on the **Route Tables** page in the compartment you chose.

**Task 8: Update VCN-Fire's attachment**

Update the DRG route table of VCN-Fire's attachment to use the "From-Firewall" DRG route table.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you're interested in, DRG-Transit.
3. Under **Resources**, click **Virtual Cloud Network Attachments**.
4. Click the name of the DRG attachment used by VCN-Fire.
5. Click **Edit**.
6. Click **Show Advanced Options**.
7. In the DRG route table tab, select FROM-FIREWALL from the list of available route tables.
8. Click **Save Changes**.

**Task 9: Configure routing inside the firewall VCN route tables**

Configure ingress routing in VCN-Fire to send all inbound traffic to the firewall instance.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in, VCN-Fire.
3. Under **Resources**, click **Route Tables**.
4. Click **Create Route Table**.
5. Name the VCN route table VCN-INGRESS, and enter the following route rules:
   - **Target Type**: Choose **Private IP**.
   - **Destination Type**: Choose **CIDR Block**.
   - **Destination CIDR Block**: Enter the CIDR block for VCN-A.
   - **Target Selection**: Enter 10.0.0.10, the private IPv4 address for the firewall instance.
6. Click **+Another Route Rule** and repeat until you have a rule for each of the three spoke VCNs (VCN-A, VCN-B, and VCN-C).
7. Click **Create**.
   
   The VCN route table is created and then displayed on the **Route Tables** page for the VCN.
8. Under **Resources**, click **Dynamic Routing Gateways Attachments**.
9. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
10. Click the DRG you are interested in, DRG-Transit.
11. Under **Resources**, click **Virtual Cloud Network Attachments**.
12. Click the name of the DRG attachment used by VCN-Fire.
13. Click **Edit**.
14. Click **Show Advanced Options**.
15. In the VCN route table tab, click **Select Existing** and select VCN-INGRESS from the list of available route tables.
16. Click **Save Changes**.

**Task 10: Configure VCN egress routing**

Configure VCN egress routing in VCN-Fire's subnet named Subnet-H to send all traffic destined to addresses in the VCN CIDRs of VCN-A, VCN-B, and VCN-C to the DRG attachment.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in, VCN-Fire.
3. Under **Resources**, click **Route Tables**.
4. Click **Create Route Table**.
5. Name the new VCN route table VCN-Egress. Create three new route rules. Click click **+Another Route Rule** twice and enter the following information for VCN-A, VCN-B, and VCN-C respectively:
   - **Target Type**: Choose **Dynamic Routing Gateway**.
   - **Destination CIDR Block**: Enter the CIDR block for one of the three spoke VCNs.
6. When you've created rules for all spoke VCNs, click **Create**.
7. Under **Resources**, click **Subnets**.
8. Click **Subnet-H**, the name of the subnet with the firewall instance.
9. Click **Edit**.
10. Change the route table selected for the subnet to the VCN route table you created, VCN-Egress.
11. Click **Save Changes**.

This completes configuration of transit routing. At this point, any packets sent from one spoke VCN to another are sent to the mutually attached DRG, redirected to a firewall in a hub VCN, and packets the firewall allows are then sent back to the DRG to be routed to their destination VCN.

**Private Access to Oracle Services**

*Transit routing* refers to a network topology in which your on-premises network uses an intermediary to reach Oracle resources or services or VCNs. The intermediary can be a VCN or a *dynamic routing gateway (DRG)* your on-premises network is already attached to. You connect the on-premises network to a DRG with *FastConnect* or *Site-to-Site VPN*, and then configure routing so that traffic *transits through the intermediary* to its destination.

The three primary transit routing scenarios are:
- **Private access to Oracle services**: The scenario covered in this topic. This scenario gives your on-premises network private access to Oracle services, so that your on-premises hosts can use their private IP addresses and...
the traffic does not go over the public internet. Instead, the traffic travels over a FastConnect private virtual circuit or Site-to-Site VPN, transits through a virtual cloud network (VCN), and then through a service gateway to the Oracle service of interest. This scenario is available to an implementation using either a legacy or upgraded DRG.

- **Access between multiple networks through a single DRG with a firewall between networks:** This scenario connects several VCNs to a single DRG, with all routing configured to send packets through a firewall in a hub VCN before they can be sent to another network. See Using a DRG to route traffic through a centralized network virtual appliance on page 3644. This scenario is only available to an implementation using an upgraded DRG.

- **Access to multiple VCNs in the same region:** This scenario enables communication between an on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or Site-to-Site VPN and uses a VCN as the hub. See Transit Routing inside a hub VCN on page 3667. This scenario is available to an implementation using a legacy DRG.

**Highlights**

- You can set up a VCN so that your on-premises network has private access to Oracle services in the Oracle Services Network by way of the VCN. The hosts in your on-premises network communicate with their private IP addresses.
- The VCN uses a dynamic routing gateway (DRG) to communicate with the on-premises network. Access to Oracle services is through a service gateway on the VCN. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the public internet.
- The service gateway is regional and enables access only to supported Oracle services in the same region as the VCN.
- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.
- The service gateway uses the concept of a service CIDR label, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, OCI PHX Object Storage is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service's public IP addresses change in the future, you don't have to adjust those rules.
- To enable the intended traffic from the on-premises network through the VCN to Oracle services, you implement route rules for the VCN's DRG attachment and service gateway.
- If you want, you can set up transit routing through a private IP in the VCN. For example, you might want to filter or inspect the traffic between the on-premises network and the Oracle service. In that case, you route the traffic to a private IP on an instance in the VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the VCN, and transit routing through a private IP.

**Overview of the Oracle Services Network**

The Oracle Services Network is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the public internet. However, you can access the Oracle Services Network without the traffic going over the public internet. There are different ways, depending on which of your hosts need the access:

- **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or Site-to-Site VPN: This scenario is covered in this topic. The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the VCN's service gateway.
  - Public access with FastConnect public peering: The on-premises hosts use public IP addresses.
- **Hosts in your VCN:**
  - Private access through a service gateway: The VCN's hosts use private IP addresses.

**Overview of On-Premises Network Private Access to Oracle Services**

The following diagram illustrates the basic layout for giving your on-premises network private access to Oracle services.
Your on-premises network connects to the VCN by way of a FastConnect private virtual circuit or Site-to-Site VPN on page 3808. Each of these types of connections terminates on a dynamic routing gateway (DRG) that is attached to the VCN. The VCN also has a service gateway, which gives the VCN access to the Oracle Services Network. The traffic from your on-premises network transits through the VCN, through the service gateway, and to the Oracle service of interest. The responses return through the service gateway and VCN to your on-premises network.

When you set up a service gateway, you enable a service CIDR label, which is a string that represents all the regional public IP address ranges for the service or group of services that you want to access through the service gateway. For example, All PHX Services in Oracle Services Network is the service CIDR label for the Oracle services available in US West (Phoenix) through a service gateway. Oracle uses Border Gateway Protocol (BGP) on the DRG to advertise those regional public IP address ranges to the edge device (also called the customer-premises equipment or CPE) in your on-premises network. For a list of those ranges available through the service gateway, see Public IP Addresses for VCNs and the Oracle Services Network on page 222.

Multiple Connection Paths to Oracle Services

You can configure your on-premises network with multiple connection paths to Oracle Cloud Infrastructure and Oracle services for redundancy or other reasons. For example, you could use both FastConnect public peering and FastConnect private peering. If you have multiple paths, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network on page 3818.

Multiple VCNs with Private Access to Oracle Services

Your organization might choose to use multiple VCNs, each with a service gateway to give the VCN's resources access to Oracle services. For example, you might have a different VCN for each department in your organization.

If you also want to set up your on-premises network with private access to Oracle services through a VCN with a service gateway, this section describes two different network layouts you could use.

In the first layout, you set up a single DRG, with the VCNs in a hub-and-spoke layout as shown in the next diagram. The VCN that acts as the hub is dedicated to providing the on-premises network with private access to Oracle services. The other VCNs are locally peered with the hub VCN. You configure only the hub VCN according to instructions in Setting Up Private Access to Oracle Services on page 3660. This hub-and-spoke layout is recommended and described further in Transit Routing inside a hub VCN on page 3667.
In the second layout, there's a separate DRG for each VCN, with a separate FastConnect private virtual circuit or Site-to-Site VPN from your on-premises network to each DRG. You dedicate one DRG and VCN to providing your on-premises network with private access to Oracle services. In the next diagram, it's the VCN in the center. To configure that VCN, follow the instructions in Setting Up Private Access to Oracle Services on page 3660.

Notice that in both of these layouts, the on-premises network can reach the Oracle services only through a single VCN's service gateway (the one dedicated for this purpose) and not through the service gateways of the other VCNs. For those other VCNs, only the resources inside those VCNs can reach Oracle services through their VCN's service gateway.

Regardless of which layout you choose, you can write an IAM policy to restrict access to an Object Storage bucket so that only requests that come through a specific VCN's service gateway are allowed for that bucket. With either of these layouts, you might want to write the policy to allow requests from multiple VCNs. To restrict access to specific VCNs, create a network source to specify the allowed VCN, and then write the policy restricting access to only the network source. One network source can specify multiple VCNs or you can create one network source for each VCN. For information on creating networks sources, see Managing Network Sources on page 3123.

The following example policy assumes you set up one network source for each of your VCNs. The policy lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a
Networking compartment called ABC. When writing a policy like this one, you can specify one or more network sources. This example shows three.

Allow group ObjectBackup to read buckets in compartment ABC

Allow group ObjectBackup to manage objects in compartment ABC where
  all {target.bucket.name='db-backup',
       any {request.networkSource.name='<hub_VCN_network_source>',
           request.networkSource.name='<spoke_1_VCN_network_source>',
           request.networkSource.name='<spoke_2_VCN_network_source>'},
       any {request.permission='OBJECT_CREATE',
           request.permission='OBJECT_INSPECT'}}

For more information, see Setting Up a Service Gateway in the Console on page 4131 in the procedure for setting up a service gateway.

Requests from Oracle Services to Your Clients

The service gateway does not allow incoming connection requests to the VCN or your on-premises network. Any connection requests coming from an Oracle service to your on-premises network must come over a public path such as the internet or FastConnect public peering.

If you use Oracle Analytics Cloud so that it initiates connection requests to clients, and you also want to set up private access to Oracle services for your on-premises network, see this known issue.

Transit Routing Options for Private Access to Oracle Services

Two options exist for routing through the VCN for private access to Oracle services:

- **Transit routing directly through gateways:** You route the traffic directly through the VCN, from one gateway to the other.
- **Transit routing through a private IP:** You set up an instance in the VCN to filter or inspect the traffic between the on-premises network and Oracle Services Network, and route traffic through a private IP on the instance.

The examples shown in the following sections assume that the VCN contains no workloads that need to access the on-premises network or Oracle Services Network. The VCN is being used only for transit routing of traffic through the VCN.

**Transit routing directly through gateways**

In this example, you route directly through the two gateways on the VCN: the dynamic routing gateway (DRG) and the service gateway. See the following diagram.
The diagram shows two route tables, each associated with a different resource:

- **DRG attachment:**
  - The VCN route table is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The VCN route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send that traffic to the service gateway.

- **Service gateway:**
  - This VCN route table is associated with the service gateway.
  - The VCN route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the DRG.

Transit routing through a private IP in the VCN

In this example, you set up an instance in the VCN to act as a firewall or intrusion detection system to filter or inspect the traffic between the on-premises network and Oracle Services Network. See the following diagram.
The instance has two VNICs, each with a private IP. One of the VNICs is in a subnet that faces the on-premises network (referred to here as the *frontend subnet*). The other VNIC is in a subnet that faces the Oracle Services Network (referred to here as the *backend subnet*). The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.

The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - This VCN route table is associated with the DRG attachment. Why the attachment and not the DRG itself?
  - Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The VCN route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send the traffic to the private IP in the frontend subnet.

- **Service gateway:**
  - This VCN route table is associated with the service gateway.
  - The VCN route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.

- **Subnet-frontend:**
  - This VCN route table is associated with Subnet-frontend.
  - It includes a rule to enable traffic with the on-premises network.

- **Subnet-backend:**
  - This VCN route table is associated with Subnet-backend.
  - It includes a rule to enable traffic with the regional Oracle Services Network.

**Important Transit Routing Restrictions to Understand**

This section includes some additional important details about routing:

- **Route table for the DRG attachment:**
  - A VCN route table that is associated with a DRG attachment can only have rules that target a service gateway, a private IP, or a local peering gateway.
  - A DRG attachment always has a route table associated with it, but you can associate a *different* route table, edit the table's rules, or delete some or all rules.

- **Route table for a service gateway:**
  - A VCN route table that is associated with a service gateway can only have rules that target a DRG or a private IP.
  - A service gateway can exist without a route table associated with it. However, after you associate a route table with a service gateway, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

- **Traffic transiting through the VCN:** The route tables discussed here are intended only for moving traffic *through* the VCN between locations in the on-premises network and the Oracle Services Network. If you're using a private IP in the VCN, you configure the route tables so that the private IP is placed in that traffic path going *through* the VCN.

- **Inbound traffic to the VCN:** Even though the preceding statement is true (about traffic *through* the VCN), inbound traffic to subnets *within the VCN* is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or service gateway's route table. When this kind of inbound traffic reaches the DRG or the service gateway, the traffic is automatically routed to its destination in the VCN by the **VCN local routing**. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a subsection) as the rule's destination.

- **VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you only use the VCN for *transit* between the on-premises network and spoke VCNs. **Do not set up workloads in the VCN itself.** More explicitly, if you set up transit routing through a private IP in the VCN, you can't also route the VCN's traffic through that private IP. Referring to the preceding diagram, if you were to change the route rule in the service gateway's route table so that the destination CIDR is 0.0.0.0/0 instead
of 172.16.0.0/12, only traffic coming from the Oracle Services Network and destined for addresses outside the VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the service gateway's route table (in general, over any of the VCN's route tables).

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See IAM Policies for Networking on page 3709.

**Setting Up Private Access to Oracle Services**

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network private access to Oracle services.

*For routing directly between gateways*

**Tip:**

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Task 4 is the most important. It enables traffic routing between your on-premises network and the Oracle Services Network.

**Task 1: Set up the VCN**

In this task, you set up the VCN. For this example, no subnet is required.

For more information and instructions:

- VCNs and Subnets on page 3693

**Task 2: Add a service gateway to the VCN**
In this task, you add a service gateway to the VCN and enable the gateway for the regional Oracle Services Network. Notice that you do not yet create the route table that will be associated with the service gateway. That comes in a later task.

1. In the Console, view the VCN's details.
2. Under Resources, click Service Gateways.
3. Click Create Service Gateway.
4. Enter the following values:
   - Name: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - Create in compartment: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - Services: All <region> Services in Oracle Services Network.
5. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network

In this task, you set up either FastConnect or Site-to-Site VPN between your VCN and your on-premises network. As part of this process, you attach a DRG to the VCN and set up routing between the VCN and your on-premises network. Do not create the route table associated with the DRG attachment yet. That comes in a later task. For more information and instructions:

- FastConnect on page 4051
- Site-to-Site VPN on page 3808
- Dynamic Routing Gateways (DRGs) on page 3793
Important:

If you're using Site-to-Site VPN with static routing, and the VCN is configured to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 222.

Task 4: Set up ingress routing for the DRG and service gateway

In this task, you set up the route tables for the DRG attachment and the service gateway.

Prerequisites:

• You already have a DRG attached to the VCN.
• You already have a service gateway.

1. Create a route table for the DRG attachment:
   a. In the Console, view the VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      • Name: A descriptive name for the route table. Example: VCN ingress route table. Avoid entering confidential information.
      • Create in Compartment: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Service gateway.
      • Destination Service: All <region> Services in Oracle Services Network.
      • Compartment: The compartment where the service gateway is located.
      • Target: The service gateway.
      • Description: An optional description of the rule.
   f. Click Create Route Table.

The route table is created and displayed in the list.
2. Associate the route table (called VCN ingress route table in this example) with the VCN’s DRG attachment:
   a. While still viewing the VCN’s details, click Dynamic Routing Gateways to view the attached DRG.
   b. Click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the DRG attachment.
      • Route Table: Select the route table for the DRG attachment.
   d. Click Associate.

3. Create a route table for the service gateway:
   a. While still viewing the VCN's details, click Route Tables.
   b. Click Create Route Table.
   c. Enter the following:
      • Create in Compartment: Leave as is.
      • Name: A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.
   d. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • Destination CIDR Block: The on-premises network’s CIDR (172.16.0.0/12 in the earlier example).
      • Description: An optional description of the rule.
   e. Click Create Route Table.

4. Associate the route table (called Service Gateway Route Table in this example) with the service gateway:
   a. While still viewing the VCN's details, click Service Gateways.
   b. For the service gateway, click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the service gateway.
      • Route Table: Select the route table for the service gateway.
   d. Click Associate.

The route table is associated with the service gateway.

For routing through a private IP

Tip:

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Tasks 4 and 5 are the most important. They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the VCN
In this task, you set up the VCN. This example also has two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional private subnets.

For more information and instructions:
- VCNs and Subnets on page 3693

Task 2: Add a service gateway to the VCN

In this task, you add a service gateway to the VCN and enable the gateway for the regional Oracle Services Network. Notice that you do not yet create the route table that will be associated with the service gateway. That comes in a later task.

1. In the Console, view the VCN's details.
2. Under Resources, click Service Gateways.
3. Click Create Service Gateway.
4. Enter the following values:
   - **Name**: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - **Services**: All `<region>` Services in Oracle Services Network.
5. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network
In this task, you set up either FastConnect or Site-to-Site VPN between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not create the route table associated with the DRG attachment yet. That comes in a later step. For more information and instructions:

- [FastConnect](#) on page 4051
- [Site-to-Site VPN](#) on page 3808
- [Dynamic Routing Gateways (DRGs)](#) on page 3793

**Important:**

If you're using Site-to-Site VPN with static routing, and the VCN is configured to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see [Public IP Addresses for VCNs and the Oracle Services Network](#) on page 222.

**Task 4: Set up the private IPs on an instance in the VCN**

In this task, you set up the instance to have two private IPs. Prerequisites:

- You already have a VCN with two subnets.
- Review this information: [Using a Private IP as a Route Target](#) on page 3703.

1. If you haven't already, create the instance in the VCN. See [Creating an Instance](#) on page 1023. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See [Using the Console](#) on page 3736.
3. Disable the source/destination check on each of the VNICs. See [Overview of VNICs and Physical NICs](#) on page 3733.
For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC’s primary private IP, assign that secondary private IP and configure the OS to use it. See Using the Console on page 3744.

For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).

Configure the instance as necessary for the job it performs (for example, configure the firewall or intrusion detection system on the instance).

Task 5: Set up ingress routing for the DRG and service gateway

In this task, you set up the route tables for the DRG attachment and service gateway.

Prerequisites:

- You already have a DRG attached to the VCN.
- You already have a service gateway.
- You already have the two private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
   a. In the Console, view the VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      - Name: A descriptive name for the route table. Example: VCN ingress route table. Avoid entering confidential information.
      - Create in Compartment: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      - Target Type: Private IP.
      - Destination: Service.
      - Destination Service: All <region> Services in Oracle Services Network.
      - Compartment: The compartment where the frontend subnet's private IP is located.
      - Target: The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
      - Description: An optional description of the rule.
   f. Click Create Route Table.

The route table is created and displayed in the list.
2. Associate the route table (called *VCN ingress route table* in this example) with the VCN’s DRG attachment:
   a. While still viewing the VCN’s details, click **Dynamic Routing Gateways** to view the attached DRG.
   b. Click the Actions icon (three dots), and then click **Associate Route Table**.
   c. Select the route table.
   d. Click **Associate Route Table**.

   The route table is associated with the DRG attachment.

3. Create a route table for the service gateway:
   a. While still viewing the VCN's details, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      • **Create in Compartment**: Leave as is.
      • **Name**: A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.
   d. Click **+ Additional Route Rule**, and enter this information for the route rule:
      • **Target Type**: Private IP.
      • **Destination**: CIDR Block.
      • **Destination CIDR Block**: The on-premises network’s CIDR (172.16.0.0/12 in the earlier example).
      • **Compartment**: The compartment where the private IP is located.
      • **Target**: The backend subnet’s private IP, which you recorded in the previous task (10.0.8.3 in the example).
      • **Description**: An optional description of the rule.
   e. Click **Create Route Table**.

   The route table is created and displayed in the list.

4. Associate the route table (called *Service Gateway Route Table* in this example) with the service gateway:
   a. While still viewing the VCN's details, click **Service Gateways**.
   b. For the service gateway, click the Actions icon (three dots), and then click **Associate With Route Table**.
   c. Enter the following:
      • **Route Table Compartment**: Select the compartment of the route table for the service gateway.
      • **Route Table**: Select the route table for the service gateway.
   d. Click **Associate**.

   The route table is associated with the service gateway.

**Turning Off Transit Routing**

To turn off transit routing, remove the rules from:

- The route table associated with the DRG attachment.
- The route table associated with service gateway.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.

A DRG attachment or service gateway can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or service gateway, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all rules.

**Transit Routing inside a hub VCN**

*Transit routing* refers to a network topology in which your on-premises network uses an intermediary to reach Oracle resources or services or VCNs. The intermediary can be a VCN or a *dynamic routing gateway (DRG)* your on-premises network is already attached to. You connect the on-premises network to a DRG with FastConnect or Site-to-Site VPN, and then configure routing so that traffic *transits through the intermediary* to its destination.
The three primary transit routing scenarios are:

- **Access between multiple networks through a single DRG with a firewall between networks**: This scenario uses the DRG as the hub, with routing configured to send packets through a firewall in a VCN before they can be sent to another network. See Using a DRG to route traffic through a centralized network virtual appliance on page 3644. This scenario is only available to an implementation using an upgraded DRG.

- **Access to multiple VCNs in the same region**: The scenario covered in this topic. This scenario uses a VCN as the hub, and enables communication between your on-premises network and multiple VCNs (connected via local peering) in the same region over a single FastConnect private virtual circuit or Site-to-Site VPN. Oracle recommends you use the previous scenario instead. This scenario is available to an implementation using a legacy DRG.

- **Private access to Oracle services**: This scenario uses a VCN as the hub, and gives your on-premises network private access to Oracle services, so that your on-premises hosts can use their private IP addresses and the traffic does not go over the internet. See Private Access to Oracle Services on page 3653. This scenario is available to an implementation using either a legacy or upgraded DRG.

**Highlights**

- You can use a single FastConnect or Site-to-Site VPN connection between your on-premises network with multiple VCNs in the same region, in a hub-and-spoke topology.

- The VCNs must be in the same region but can be in different tenancies. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.

- The VCN that acts as the hub uses a dynamic routing gateway (DRG) to communicate with the on-premises network. This hub VCN peers with each VCN that is acting as a spoke (referred to as spoke VCNs in this topic). The hub and spoke VCNs use local peering gateways (LPGs) to communicate.

- To enable the intended traffic from the on-premises network through the hub to a peered spoke VCN, you implement route rules for the hub DRG or the hub VCN's DRG attachment and LPG, and for the spoke VCN's subnets.

- If you like, you can set up transit routing through a private IP in the hub VCN. For example, you might want to filter or inspect the traffic between the on-premises network and a spoke VCN. In that case, you route the traffic to a private IP on an instance in the hub VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the hub VCN, and transit routing through a private IP.

- Configuring route tables that reside in the hub VCN lets you control whether a particular subnet in a peered spoke VCN is advertised to the on-premises network, and whether a particular subnet in the on-premises network is advertised to a peered spoke VCN.

**Tip:**

There's another scenario that lets you connect your on-premises network to multiple VCNs. Instead of using a single DRG and hub-and-spoke topology, you set up a separate DRG for each VCN and a separate private virtual circuit over a single FastConnect. However, the scenario can be used only with FastConnect through a third-party provider or through colocation with Oracle. The VCNs must be in the same region and same tenancy. For more information, see FastConnect with Multiple DRGs and VCNs on page 3689.

**Overview of Transit Routing**

*Transit routing* is simply routing traffic to either a virtual cloud network (VCN) or an on-premises network through a central hub VCN. Here’s a basic example of why you might use transit routing: you have a large organization with different departments, each with their own VCN. Your on-premises network needs access to the different VCNs, but you don't want the administration overhead of maintaining a secure connection from each VCN to the on-premises network. Instead you want to use a single FastConnect or Site-to-Site VPN.

A basic networking scenario involves connecting your on-premises network to a VCN with either Oracle Cloud Infrastructure FastConnect or an Site-to-Site VPN. These two basic scenarios illustrate that topology: Scenario B: Private Subnet with a VPN on page 3618 and Scenario C: Public and Private Subnets with a VPN on page 3626.
This scenario uses a *hub-and-spoke* topology, as illustrated in the following diagram. The term *hub* here means only that a VCN is acting as the hub in this hub-and-spoke design.

![Diagram of a hub-and-spoke topology](image)

One of the VCNs acts as the hub (VCN-H) and connects to your on-premises network by way of FastConnect or an *Site-to-Site VPN*. The other VCNs are locally peered with the hub VCN. The traffic between the on-premises network and the peered VCNs transits through the hub VCN. The VCNs must be in the same region but can be in different tenancies.

**Gateways Involved in Transit Routing**

The next diagram shows the gateways on the VCNs. The hub VCN has a *dynamic routing gateway* (DRG), which is the communication path with the on-premises network. For each locally peered spoke VCN, a pair of *local peering gateways* (LPGs) that anchor the peering connection. One LPG is on the hub VCN, and the other is on the spoke VCN.
Summary of New Concepts for Experienced Networking Service Users

If you're already familiar with the Networking service and local VCN peering, these are the most important new concepts to understand:

- For each spoke VCN subnet that needs to communicate with the on-premises network, update the subnet's route table with a rule that sets the target (the next hop) as the spoke VCN's LPG for all traffic destined for the on-premises network.
- Add a route table to the hub VCN, associate it with the DRG attachment, and add a route rule with a target that sets the target (the next hop) to the hub VCN's LPG (for that spoke) for all traffic destined for that spoke VCN (or a specific subnet in that VCN).
- Add another route table to the hub VCN, associate it with the hub VCN's LPG (for that spoke), and add a route rule that sets the target (the next hop) as the DRG for all traffic destined for the on-premises network (or a specific subnet in that network).

For transit routing directly through gateways, see these specific tasks for more information:

- For routing directly between gateways on page 3677
- Task 6: Set up ingress routing for the DRG and LPG on the hub VCN on page 3680

For transit routing through a private IP: see these specific tasks for more information:

- Task 5: Add a route rule to the spoke VCN's subnet on page 3680
- Task 6: Set up the private IPs on an instance in the hub VCN on page 3685
- Task 7: Set up ingress routing for the DRG and LPG on the hub VCN on page 3686
**Example: Components and Routing for a Hub and Single Spoke**

The examples in this section show a VCN acting as a hub and only a single spoke VCN for simplicity.

**Note:**

In a hub-and-spoke model, the hub VCN can have multiple spokes and therefore multiple LPGs (one per spoke). This topic uses the phrase *the hub VCN’s LPG*, which could therefore be ambiguous. When the phrase is used here, it means the hub LPG for the *particular spoke of interest*. In the following diagrams, the hub is LPG-H-1. More spokes would involve creation of an LPG-H-2, LPG-H-3, and so on.

*For transit routing directly through gateways*

The following diagram shows the required Networking service route tables and route rules for transit routing directly through gateways. Although the hub VCN does not require a subnet to make transit routing work, the example presented here includes a subnet called Subnet-H.

The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG *attachment*. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send that traffic to LPG-H-1.
• **LPG-H-1:**
  - This route table belongs to the hub VCN and is associated with LPG-H-1.
  - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the DRG.

• **Subnet-H:**
  - This route table belongs to the hub VCN and is associated with Subnet-H.
  - This route table has a rule to route traffic that is destined for the on-premises network to the DRG. It has another rule to route traffic that is destined for the spoke VCN to LPG-H-1.

• **Subnet-1:**
  - This route table belongs to the spoke VCN and is associated with Subnet-1.
  - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

*For transit routing through a private IP*

The following diagram shows the required Networking service route tables and route rules for transit routing through a private IP on an instance in the hub VCN. You can choose to implement this scenario with either a single VNIC or multiple VNICs. The next diagram shows two VNICs: one in a subnet called Subnet-H-Frontend, and another in a subnet called Subnet-H-Backend. The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.

The diagram shows five route tables, each associated with a different resource:

• **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send the traffic to the private IP in the frontend subnet.

• **LPG-H-1:**
  - This route table belongs to the hub VCN and is associated with LPG-H-1.
  - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.
• **Subnet-H-Frontend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Frontend.
  - This route table has a rule to route traffic that is destined for the on-premises network to the DRG.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. The second rule is shown here to give a better picture of routing for this example.

• **Subnet-H-Backend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Backend.
  - This route table has a rule to route traffic that is destined for the spoke VCN (VCN-1) to LPG-H-1.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The second rule is shown here to give a better picture of routing for this example.

• **Subnet-1:**
  - This route table belongs to the spoke VCN and is associated with Subnet-1.
  - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

**Important Transit Routing Restrictions to Understand**

This section includes some additional important details about routing:

• **Route table for the DRG attachment:**
  - A route table that is associated with a DRG attachment can have only rules that target an LPG or a private IP.
  - A DRG attachment always has a route table associated with it, but you can associate a different route table, edit the table's rules, or delete some or all rules.

• **Route table for an LPG:**
  - A route table that is associated with an LPG can have only rules that target a DRG or a private IP.
  - An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all rules.

• **Traffic through the hub VCN:** The route tables discussed here are intended only for moving traffic through the hub VCN between locations in the on-premises network and locations in the spoke VCN. If you're using a private IP in the hub, you configure those route tables so that the private IP is placed in that traffic path going through the hub.

• **Inbound traffic to the hub VCN:** Even though the preceding statement is true (about traffic through the hub), inbound traffic to subnets within the hub VCN is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or hub LPG's route table. When this kind of inbound traffic reaches the DRG or the hub LPG, the traffic is automatically routed to its destination in the hub VCN by the VCN local routing. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a subsection) as the rule's destination.

• **Hub VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you only use the hub VCN for transit between the on-premises network and spoke VCNs. **Do not set up workloads in the hub VCN itself.** More explicitly, if you set up transit routing through a private IP in the hub VCN, you can't also route the hub VCN's traffic through that private IP. For example, in the preceding diagram, if you were to change the route rule in the LPG-H-1 route table so that the destination CIDR is 0.0.0.0/0 instead of 172.16.0.0/12, only traffic coming from VCN-1 and destined for addresses outside the hub VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the LPG-H-1 route table (in general, over any of the VCN's route tables).
About CIDR Overlap

In this example, the various networks do not have overlapping CIDR blocks (172.16.0.0/12 versus 10.0.0.0/16 versus 192.168.0.0/16). The Networking service does not allow local VCN peering between two VCNs with overlapping CIDRs. That means each spoke must not overlap with the hub.

However, the Networking service does not validate whether the spoke VCNs overlap with each other, or if any of the VCNs overlap with the on-premises network. Ensure that CIDRs for all the subnets that need to communicate with each other don't overlap. Otherwise, traffic is dropped.

A Networking service route table cannot contain two rules with the exact same destination CIDR. However, if two rules in the same route table have overlapping destination CIDRs, the most specific rule in the table is used to route the traffic (that is, the rule with the longest prefix match).

Route Advertisement to the On-Premises Network and Spoke VCNs

From a security standpoint, you can control route advertisement so that only specific subnets in the on-premises network are advertised to the spoke VCNs. Similarly, you can control which subnets in the spoke VCNs are advertised to the on-premises network.

The routes advertised to the on-premises network consist of:

- The rules listed in the route table associated with the DRG attachment (192.168.0.0/16 in the preceding diagram)
- The individual subnets in the hub VCN

The routes advertised to the spoke VCN consist of:

- The individual subnets in the hub VCN
- The rules listed in the route table associated with the hub VCN's LPG for the spoke (172.16.0.0/12 in the preceding diagram)

Therefore, the administrator of the hub VCN alone can control which routes are advertised to the on-premises network and spoke VCNs.

In the preceding example, the relevant routes use the full CIDR block of the on-premises network (172.16.0.0/12) and spoke VCN (192.168.0.0/16) as the destination, but they could instead use a subnet of those networks to restrict routing to specific subnets.

Details About Routing for Different Traffic Paths

To further illustrate how routing takes place in the preceding example, let's look more closely at different paths of traffic. Here are the same diagrams again.

First, if you are transit routing directly through gateways on the hub VCN:
Second, if you are transit routing through a private IP in the hub VCN:

Traffic from the on-premises network to the spoke VCN

1. Traffic leaves the on-premises network and reaches the DRG. The traffic's destination is in Subnet-1 (for example, 192.168.0.5).
2. The DRG attachment's associated route table has a rule for 192.168.0.0/16. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways:** The rule's target is LPG-H-1.
   - **Transit routing through a private IP:** The rule's target is the private IP 10.0.4.3. The instance receives and processes the traffic and sends any resulting traffic out of the backend subnet's VNIC. The backend subnet's route table sends that traffic to LPG-H-1.

Remember that you can use the rules in the DRG attachment's route table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a subnet of the spoke VCN.

3. LPG-H-1 receives the traffic.

4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.

5. LPG-1 receives the traffic.

6. Traffic coming in to a VCN through the LPG is automatically routed to the destination within the VCN because of VCN local routing. No explicit route rules are required.

**Traffic from the spoke VCN to the on-premises network**

1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in the on-premises network (for example, 172.16.0.3).

2. Subnet-1's associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target, LPG-1.

3. LPG-1 receives the traffic.

4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.

5. LPG-H-1 receives the traffic.

6. LPG-H-1’s associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways:** The rule's target is the DRG.
   - **Transit routing through a private IP:** The rule's target is the private IP 10.0.8.3. The instance receives and processes the traffic and sends any resulting traffic out of the frontend subnet's VNIC. The frontend subnet's route table sends that to the DRG.

Remember that you can use the rules in the LPG's route table to control which subnets in the on-premises network are advertised to the spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network.

7. The DRG receives the traffic.

8. Egress traffic leaving the VCN through the DRG is routed based on Site-to-Site VPN and FastConnect configuration. No explicit rules in the DRG attachment's route table are required.

Notice that Subnet-1 in the spoke VCN and LPG-H-1 both have route rules with 172.16.0.0/12 as the destination CIDR. Those rules don't have to use the exact same CIDR block. However, ensure both rules cover the traffic you want to route from the spoke to the on-premises network. The rule in Subnet-1’s route table controls which traffic is routed from Subnet-1 to LPG-H-1. The rule in LPG-H-1’s route table controls which traffic is routed from the spoke VCN to the on-premises network. If LPG-H-1’s route rule is more restrictive than Subnet-1’s route rule, some traffic leaving the subnet could ultimately be dropped and not reach the DRG.

**Traffic from the spoke VCN to a subnet in the hub VCN (routing directly between gateways only)**

Depending on your situation, you might want to enable traffic between instances in the hub VCN and a spoke VCN, and not just traffic between the on-premises network and a spoke VCN. You can do this if you're routing directly between gateways. **You can't route the traffic from a spoke VCN through the private IP and on to other instances in the hub VCN.** The note at the end of this section explains why.

Here's how traffic would flow from the spoke VCN to a destination with an address in the hub VCN:
1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in a subnet in the hub VCN (for example, 10.0.0.3).
2. Subnet-1's associated route table has a rule for 10.0.0.0/16. It matches the destination and sends the traffic to the route target, LPG-1.
3. LPG-1 receives the traffic.
4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.
5. LPG-H-1 receives the traffic.
6. Traffic coming in to a VCN through an LPG and destined for an address in the VCN is automatically routed to the destination by VCN local routing. No explicit route rules are required.

A similar series of routing steps occurs for traffic going from Subnet-H to Subnet-1, but in the reverse direction. Subnet-H's route table has a rule that matches the spoke VCN's CIDR (192.168.0.0/16) and sends the traffic to LPG-H-1, which forwards it on to LPG-1.

**Note:**

If you set up transit routing through a private IP in the hub VCN, remember that the LPG-H-1 route table only controls routing of traffic that is destined for addresses outside the hub VCN. Traffic destined for addresses within the VCN is handled by the hub VCN local routing, which takes precedence and always routes the traffic directly to the packet's destination address. This means that you cannot route traffic that is destined for addresses inside the hub VCN through the private IP that is being used for the transit traffic through the hub. Even if the LPG-H-1 route rule uses a destination = 0.0.0.0/0 and target = 10.0.8.3, the hub VCN local routing takes precedence and routes the traffic directly to the destination in the hub VCN instead of the private IP.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See IAM Policies for Networking on page 3709.

**Setting Up VCN Transit Routing in the Console**

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network access to multiple VCNs in the same region.

*For routing directly between gateways*

**Tip:**

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network topology with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Task 5 and Task 6 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the hub VCN
In this task, you set up the hub VCN. A subnet in the hub VCN is optional. However, this example includes one. The subnet can contain cloud resources that your on-premises network or the spoke VCN need to use.

For more information and instructions:
- VCNs and Subnets on page 3693

Task 2: Connect the hub VCN with your on-premises network

In this task, you set up either FastConnect or Site-to-Site VPN between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not create the route table associated with the DRG attachment yet. That comes in a later step. For more information and instructions:
- FastConnect on page 4051
- Site-to-Site VPN on page 3808
- Dynamic Routing Gateways (DRGs) on page 3793

Task 3: Set up a spoke VCN with at least one subnet
In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- [VCNs and Subnets](page 3693)

Task 4: Set up a local peering between the hub VCN and the spoke VCN

In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.
Important:

When setting up local peering between two VCNs, be sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not create the route table associated with the LPG on the hub VCN (LPG-H-1) yet. That comes in a later step. For more information and instructions:

- Setting Up a Local Peering on page 4143

Task 5: Add a route rule to the spoke VCN's subnet

In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram). Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      • Target Type: Local Peering Gateway.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • Compartment: The compartment where the spoke VCN's LPG is located.
      • Target Local Peering Gateway: The spoke VCN's LPG.
      • Description: An optional description of the rule.
   c. Click Add Route Rules.

Task 6: Set up ingress routing for the DRG and LPG on the hub VCN
In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

Prerequisites:
- You already have a DRG attached to the hub VCN.
- You already have a hub VCN LPG for the spoke of interest.

1. Create a route table for the DRG attachment:
   a. In the Console, view the hub VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      - **Name**: A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
      - **Create in Compartment**: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      - **Target Type**: Local Peering Gateway.
      - **Destination CIDR Block**: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-
premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that the on-premises network.

- **Compartment**: The compartment where the hub VCN's LPG is located.
- **Target**: The hub VCN's LPG.
- **Description**: An optional description of the rule.

f. Click **Create Route Table**.

The route table is created and displayed in the list.

2. Associate the route table (called *DRG Route Table* in this example) with the hub VCN's DRG attachment:
   a. While still viewing the hub VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.
   b. Click the Actions icon (three dots), and then click **Associate Route Table**.
   c. Select the route table.
   d. Click **Associate Route Table**.

The route table is associated with the DRG attachment.

3. Create a route table for the hub VCN's LPG for this spoke:
   a. While still viewing the hub VCN's details, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      - **Create in Compartment**: Leave as is.
      - **Name**: A descriptive name for the route table. Example: Hub LPG-# Route Table (where # indicates which spoke). Avoid entering confidential information.
   d. Click **+ Additional Route Rule**, and enter this information for the route rule:
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).

Remember that you can use the routes in this table to control which subnets in the on-premises network are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network that needs to communicate with this spoke.

- **Description**: An optional description of the rule.
   e. Click **Create Route Table**.

The route table is created and displayed in the list.

4. Associate the route table (called *Hub LPG-# Route Table* in this example) with the hub VCN's LPG for the spoke of interest:
   a. While still viewing the hub VCN's details, click **Local Peering Gateways** to view the hub VCN's LPG for this spoke.
   b. For the LPG you're interested in, click the Actions icon (three dots), and then click **Associate With Route Table**.
   c. Enter the following:
      - **Route Table Compartment**: Select the compartment of the route table for the LPG.
      - **Route Table**: Select the route table for the LPG.
   d. Click **Associate**.

The route table is associated with the LPG.

Later if you need more spoke VCNs

1. Repeat Tasks 3 through 5 for the new spoke VCN.
2. Repeat Task 6 with these changes:

- For Step 1: Instead of creating a route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the hub VCN's LPG for the new spoke.
- For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
- For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, Hub LPG-2 Route Table for the second spoke).
- For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.

For routing through a private IP

Tip:

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network topology with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Tasks 5 through 7 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the hub VCN

In this task, you set up the hub VCN. The hub VCN must have two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional private subnets, unless there are resources in the frontend subnet that need internet access.

For more information and instructions:
- [VCNs and Subnets](#) on page 3693

Task 2: Connect the hub VCN with your on-premises network
In this task, you set up either FastConnect or Site-to-Site VPN between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not create the route table associated with the DRG attachment yet. That comes in a later step. For more information and instructions:

- FastConnect on page 4051
- Site-to-Site VPN on page 3808
- Dynamic Routing Gateways (DRGs) on page 3793

**Task 3: Set up a spoke VCN with at least one subnet**

In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- VCNs and Subnets on page 3693

**Task 4: Set up a local peering between the hub VCN and the spoke VCN**

In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.

**Important:**

When setting up local peering between two VCNs, be sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not create the route table associated with the LPG on the hub VCN (LPG-H-1) yet. That comes in a later step. For more information and instructions:

- Setting Up a Local Peering on page 4143

**Task 5: Add a route rule to the spoke VCN's subnet**
Networking

In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram). Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      • Target Type: Local Peering Gateway.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • Compartment: The compartment where the spoke VCN's LPG is located.
      • Target Local Peering Gateway: The spoke VCN's LPG.
      • Description: An optional description of the rule.
   c. Click Add Route Rules.

Task 6: Set up the private IPs on an instance in the hub VCN

In this task, you set up the instance to have two private IPs.

Prerequisites:
• You already have a hub VCN with a subnet.
• Review this information: Using a Private IP as a Route Target on page 3703.

1. If you haven't already, create the instance in the hub VCN. See Creating an Instance on page 1023. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See Using the Console on page 3736.
3. Disable the source/destination check on each of the VNICs. See Overview of VNICs and Physical NICs on page 3733.

4. For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC’s primary private IP, assign that secondary private IP and configure the OS to use it. See Using the Console on page 3744.

5. For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).

6. Configure the instance as necessary for the job it performs (for example, configure the firewall or intrusion detection system on the instance).

Task 7: Set up ingress routing for the DRG and LPG on the hub VCN

In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

Prerequisites:
- You already have a DRG attached to the hub VCN.
- You already have a hub VCN LPG for the spoke of interest.
- You already have the two private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
   a. In the Console, view the hub VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      - Name: A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
      - Create in Compartment: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      - Target Type: Private IP.
      - Destination CIDR Block: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-
Networking

premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that
the on-premises network.

- **Compartment:** The compartment where the frontend subnet's private IP is located.
- **Target:** The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the
  example).
- **Description:** An optional description of the rule.

f. Click **Create Route Table.**

The route table is created and displayed in the list.

2. Associate the route table (called **DRG Route Table** in this example) with the hub VCN's DRG attachment:

   a. While still viewing the hub VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.
   b. Click the Actions icon (three dots), and then click **Associate With Route Table.**
   c. Enter the following:
      - **Route Table Compartment:** Select the compartment of the route table for the DRG attachment.
      - **Route Table:** Select the route table for the DRG attachment.
   d. Click **Associate.**

   The route table is associated with the DRG attachment.

3. Create a route table for the hub VCN's LPG for this spoke:

   a. While still viewing the hub VCN's details, click **Route Tables.**
   b. Click **Create Route Table.**
   c. Enter the following:
      - **Create in Compartment:** Leave as is.
      - **Name:** A descriptive name for the route table. Example: Hub LPG-# Route Table (where # indicates which
        spoke). Avoid entering confidential information.
   d. Click **+ Additional Route Rule,** and enter this information for the route rule:
      - **Target Type:** Private IP.
      - **Destination CIDR Block:** The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
        Remember that you can use the routes in this table to control which subnets in the on-premises network
        are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises
        network that needs to communicate with this spoke.
      - **Compartment:** The compartment where the private IP is located.
      - **Target:** The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the
        example).
      - **Description:** An optional description of the rule.
   e. Click **Create Route Table.**

   The route table is created and displayed in the list.

4. Associate the route table (called **Hub LPG-# Route Table** in this example) with the hub VCN's LPG for the spoke
   of interest:

   a. While still viewing the hub VCN's details, click **Local Peering Gateways** to view the hub VCN's LPG for this
      spoke.
   b. For the LPG you're interested in, click the Actions icon (three dots), and then click **Associate With Route
      Table.**
   c. Enter the following:
      - **Route Table Compartment:** Select the compartment of the route table for the LPG.
      - **Route Table:** Select the route table for the LPG.
   d. Click **Associate.**

   The route table is associated with the LPG.
Although Oracle does not recommend putting workloads in the hub VCN's subnets, to give you a better picture of routing in the example, the diagram shows two more route rules in the hub VCN's subnet route tables. For the frontend subnet, there's a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. For the backend subnet, there's a route rule to route traffic that is destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The following procedure adds those two route rules.

1. For the spoke VCN, view the list of subnets.
2. For the frontend subnet, look at its details and click the link for its associated route table.
3. Edit the frontend subnet's route table to include a rule that sends traffic destined for the spoke VCN to the private IP in the frontend subnet:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      • Target Type: Private IP.
      • Destination CIDR Block: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example).
      • Compartment: The compartment where the frontend subnet's private IP is located.
      • Target: The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
      • Description: An optional description of the rule.
   c. Click Add Route Rules.
4. For the backend subnet, look at its details and click the link for its associated route table.
5. Edit the backend subnet's route table to include a rule that sends traffic destined for the on-premises network to the private IP in the backend subnet:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      • Target Type: Private IP.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • Compartment: The compartment where the backend subnet's private IP is located.
      • Target: The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
      • Description: An optional description of the rule.
   c. Click Add Route Rules.

Later if you need more spoke VCNs

1. Repeat Tasks 3 through 5 for the new spoke VCN.
2. Repeat task 7 with these changes:
   • For Step 1: Instead of creating a route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the frontend subnet private IP 10.0.4.3.
   • For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
   • For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, Hub LPG-2 Route Table for the second spoke).
   • For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.

**Turning Off Transit Routing**

To turn off transit routing, remove the rules from:

• The route table associated with the DRG attachment.
• The route table associated with each LPG on the hub VCN.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.
A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table’s rules, or delete some or all rules.

Changes to the API

For information about changes to the Networking service API to support transit routing, see the transit routing release notes.

FastConnect with Multiple DRGs and VCNs

This topic summarizes an advanced networking scenario that enables communication between an on-premises network and multiple virtual cloud networks (VCNs) over a single Oracle Cloud Infrastructure FastConnect. Each VCN has its own dynamic routing gateway (DRG), and you set up a separate FastConnect private virtual circuit to each DRG. This scenario is available to an implementation using either a legacy or upgraded DRG.

This scenario is supported for only certain FastConnect setups:

• Using a third-party provider or a Colocation with Oracle in a FastConnect location is fully supported.
• Using multiple DRGs and VCNs with an Oracle partner depends on your partner’s support of this feature. Some partners also provide alternative solutions to achieve the same goal, so check with your chosen Oracle partner for details.

There’s a scenario called transit routing that also involves using multiple VCNs, but only a single DRG. It can be used with Site-to-Site VPN or FastConnect. It involves setting up the VCNs in a hub-and-spoke layout and filtering DRG traffic between spokes through a hub VCN, after which the DRG performs transit routing of traffic to the other VCNs. You might use this scenario if you need multiple VCNs for different parts of your organization, but you want to use one VCN for centralized services that all parts of the organization need. For more information, see Using a DRG to route traffic through a centralized network virtual appliance on page 3644.

Highlights

• You can use a single FastConnect to connect your on-premises network with multiple VCNs in the same region. The scenario is supported only for FastConnect through a third-party provider or through colocation with Oracle. You need at least one physical connection (cross-connect) in your connection.
• The VCNs must be in the same region and same tenancy. The VCNs can be in the same compartment or different ones in the tenancy. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.
• Each VCN has its own dynamic routing gateway (DRG) and private virtual circuit. Always use a different VLAN and different set of BGP IP addresses for each private virtual circuit.
• You can also use FastConnect public peering to give your on-premises network access to public endpoints of Oracle services and public resources inside a VCN via internet gateway. In this case, you set up a single public virtual circuit. With public peering, configure your edge device (also known as your customer-premises equipment or CPE) to prefer FastConnect over your ISP for the Oracle Cloud Infrastructure public IP prefixes. Or, if you plan to also set up private access to Oracle services through one of the VCNs, see the important routing details in Routing Details for Connections to Your On-Premises Network on page 3818.

Overview of the Scenario

In this scenario, you have a single FastConnect that connects your existing on-premises network to Oracle Cloud Infrastructure. That FastConnect has at least one physical connection, or cross-connect.

In Oracle Cloud Infrastructure, you have multiple VCNs, all in the same region. Each VCN has its own DRG. For each VCN, there’s a private virtual circuit that runs on the FastConnect and terminates at your CPE on one end, and on the VCN's DRG on the other end. The private virtual circuit enables communication that uses private IP addresses between the VCN and the on-premises network. See the following diagram.
Networking

For example, imagine that each department in your organization has its own subnet in your on-premises network and a corresponding departmental VCN in Oracle Cloud Infrastructure. You want to enable private communication between each department's subnet and VCN over the FastConnect.

Or, perhaps all the departments need to communicate with all the VCNs. For example, instead perhaps the VCNs are for separate development, test, and production environments, and each department needs access to all three VCNs.

The FastConnect and virtual circuits give you the general private connection where none of the traffic traverses the internet. You can separately control which on-premises subnets and VCNs can communicate by configuring route rules in your on-premises network and VCN route tables. You can optionally configure VCN security rules and other firewalls that you maintain to allow only certain types of traffic (such as SSH) between your on-premises network and VCN.

### Public Peering

You can also set up public peering on that same FastConnect by creating a public virtual circuit. In the following diagram, the public virtual circuit is shown separate from the private virtual circuits. It terminates at Oracle's edge. The public virtual circuit enables communication *that uses public IP addresses* but does not traverse the internet.

All public resources in a VCN can be reachable over public peering if there is internet access. See FastConnect Public Peering Advertised Routes on page 4099 for more detail. For other important details about how you can control route preferences when you have multiple connections between your on-premises network and Oracle, see Routing Details for Connections to Your On-Premises Network on page 3818.
When you set up public peering for your FastConnect, the public IP prefixes that you designate for the public virtual circuit are advertised to all the VCNs in your tenancy. The routes advertised to your on-premises network are all the Oracle Cloud Infrastructure public IP addresses (including the CIDRs for each of the VCNs in the tenancy).

**Important:**

Your network receives Oracle's public IP addresses through both FastConnect and your Internet Service Provider (ISP). When configuring your edge, give higher preference to FastConnect over your ISP, or you will not receive the benefits of FastConnect. If you plan to also set up private access to Oracle services through one of the VCNs, see the important routing details in Routing Details for Connections to Your On-Premises Network on page 3818.

For more information, see Basic Network Diagrams on page 4054.

**General Setup Process**

The setup process and instructions are in these topics, based on your particular FastConnect setup:

- FastConnect: With a Third-Party Provider on page 4080
- FastConnect: Colocation with Oracle on page 4090

However, remember that:
• You set up a separate DRG for each VCN. A DRG can be attached to multiple VCNs, but each VCN can be attached to only a single DRG. In this example, there is a separate DRG for each VCN.
• You set up a separate private virtual circuit for each DRG.
• For each private virtual circuit, you must specify a different VLAN and a different set of BGP IP addresses.
• When you configure your CPE, you can advertise the same on-premises routes to each VCN, or different ones, based on your own requirements.

Virtual Networking Quickstart

To make it easier to set up a virtual cloud network (VCN) and connect to it, the Console has the following wizards that walk you through network setup.

Create VCN with Internet Connectivity

What this wizard does:
• Checks for resource availability. To create any new resource the service limit for that resource must not already have been reached. Once the service limit for a resource type has been reached, you can either remove unused resources of that type or request a service limit increase.
• Creates a VCN.
• Creates an internet gateway, NAT gateway, and service gateway for the VCN.
• Creates a regional public subnet with routing to the internet gateway. Instances in a public subnet may optionally have public IP addresses.
• Creates a regional private subnet with routing to the NAT gateway and service gateway (and therefore the Oracle Services Network). Instances in a private subnet cannot have public IP addresses.
• Sets up basic security list rules for the two subnets, including SSH access.

Notice that this wizard does not support the creation of a VCN with IPv6 addresses. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

Where to access this wizard:

Option 1:
1. In the Console, click the Oracle Cloud icon at the top of the page to go to the Console home page.
   The page has a Quick Actions section to take you directly to common tasks.
2. Click the quick action for Networking: Set up a network with a wizard.
3. Select VCN with Internet Connectivity, and then click Start Workflow.

Option 2:
1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click Networking Quickstart.
3. Select VCN with Internet Connectivity, and then click Start Workflow.

Add Internet Connectivity and Site-to-Site VPN to a VCN

What this wizard does:
• Checks for resource availability. To create any new resource the service limit for that resource must not already have been reached. Once the service limit for a resource type has been reached, you can either remove unused resources of that type or request a service limit increase.
• Creates an internet gateway for the VCN.
• Creates a regional public subnet with access to the internet gateway. Instances in a public subnet may optionally have public IP addresses.
• Sets up basic security list rules for the subnet, including SSH access.
• Sets up all the Networking service resources required for a Site-to-Site VPN between the VCN and your on-premises network.
Networking

Notice that this wizard does not support the creation of a VCN with IPv6 addresses. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

**Note:**
For the IPSec connection to work, your network engineer must also configure the customer-premises equipment (CPE) in your edge network.

**More information about this wizard:** Site-to-Site VPN Quickstart on page 3814

**Where to access this wizard:**
Option 1:
1. In the Console, click the **Oracle Cloud** icon at the top of the page to go to the Console home page.
   
   The page has a **Quick Actions** section to take you directly to common tasks.
2. Click the quick action for **Networking: Set up a network with a wizard**.
3. Select **VCN with VPN Connect and Internet Connectivity**, and then click **Start Workflow**.

Option 2:
1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click **Networking Quickstart**.
3. Select **VCN with VPN Connect and Internet Connectivity**, and then click **Start Workflow**.

**VCNs and Subnets**

A virtual cloud network (VCN) is a customizable and private network set up in Oracle Cloud Infrastructure.

Create a service request Ask the community

VCN and Subnet Overview
Create a peering connection
Enable transit routing
Troubleshoot VCN issues

Get a high-level overview
of VCNs and subnets.

Connect multiple VCNs to
each other.

Connect your on-premises
network to Oracle resources.

Troubleshoot common
issues and error messages.
Networking

Features

Customizable Virtual Cloud Networks
Fully configurable IP addresses, subnets, routing, and firewalls support new or existing private networks.

End-to-End Security
Multiple security layers, encryption, and private connectivity to other networks and critical Oracle services.

Highest Performance
High bandwidth, microsecond latency network enables high performance and big data applications with networked storage.

Highest Availability
Active and passive logical and physical network redundancy, including default redundant IPSec tunnel connectivity.

Overview of VCNs and Subnets

This topic describes how to manage virtual cloud networks (VCNs) and the subnets in them. This topic uses the terms virtual cloud network, VCN, and cloud network interchangeably. The Console uses the term Virtual Cloud Network, whereas for brevity the API uses VCN.

A VCN is a software-defined network that you set up in the Oracle Cloud Infrastructure data centers in a particular region. A subnet is a subdivision of a VCN. For an overview of VCNs, allowed size, default VCN components, and scenarios for using a VCN, see Networking Overview on page 3604.

A VCN can have multiple non-overlapping IPv4 CIDR blocks that you can change after you create the VCN. Regardless of the number of CIDR blocks, the max number of private IPs you can create within the VCN is 64,000. A VCN can optionally be enabled for IPv6 and Oracle will allocate a /56 CIDR block.

You can privately connect a VCN to another VCN so that the traffic does not traverse the internet. The CIDRs for the two VCNs must not overlap. For more information, see Access to Other VCNs: Peering on page 4136. For an example of an advanced routing scenario that involves the peering of multiple VCNs, see Transit Routing inside a hub VCN on page 3667.

Each subnet in a VCN consists of a contiguous range of IPv4 addresses and optionally IPv6 addresses that do not overlap with other subnets in the VCN. Example: 172.16.1.0/24. With IPv4 addresses as well as IPv6 addresses, the first two addresses and the last in the subnet's CIDR are reserved by the Networking service. You can change the size of the subnet after creation.

Subnets act as a unit of configuration: all instances in a given subnet use the same route table, security lists, and DHCP options. For more information, see Default Components that Come With Your VCN on page 3608.

Subnets can be either public or private (see Public vs. Private Subnets on page 3609). The choice of public or private happens during subnet creation, and you can't change it later.

You can think of each Compute instance as residing in a subnet. But to be precise, each instance is attached to a virtual network interface card (VNIC), which in turn resides in the subnet and enables a network connection for that instance.

IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

About Regional Subnets

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all AD-specific, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or regional. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.
Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. **Oracle recommends using regional subnets** because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

**Caution:**

If anyone in your organization implements a regional subnet, be aware that you **may need to update any client code that works with Networking service subnets and private IPs**. There are possible breaking API changes. For more information, see the [regional subnet release note](#).
Working with VCNs and Subnets

One of the first things you do when working with Oracle Cloud Infrastructure resources is create a VCN with one or more subnets. You can easily get started in the Console with a simple VCN and some related resources that enable you to launch and connect to an instance. See Tutorial - Launching Your First Linux Instance on page 85 or Tutorial - Launching Your First Windows Instance on page 97.

For the purposes of access control, when you create a VCN or subnet, you must specify the compartment where you want the resource to reside. Consult an administrator in your organization if you're not sure which compartment to use.

You may optionally assign descriptive names to the VCN and its subnets. The names don't have to be unique, and you can change them later. Oracle automatically assigns each resource a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can also add a DNS label for the VCN and each subnet, which are required if you want the instances to use the Internet and VCN Resolver feature for DNS in the VCN. For more information, see DNS in Your Virtual Cloud Network on page 3781.

When you create a subnet, you may optionally specify a route table for the subnet to use. If you don't, the subnet uses the cloud network's default route table. You can change which route table the subnet uses at any time.

Also, you may optionally specify one or more security lists for the subnet to use (up to five). If you don't specify any, the subnet uses the cloud network's default security list. You can change which security list the subnet uses at any time. Remember that the security rules are enforced at the instance level, even though the list is associated at the subnet level. Network security groups are an alternative to security lists and let you apply a set of security rules to a set of resources that all have the same security posture, instead of all the resources in a particular subnet.

You may optionally specify a set of DHCP options for the subnet to use. All instances in the subnet receive the configuration specified in that set of DHCP options. If you don't specify a set, the subnet uses the cloud network's default set of DHCP options. You can change which set of DHCP options the subnet uses at any time.

To delete a subnet, it must contain no resources (no instances, load balancers, DB systems, and orphaned mount targets). For more details, see Subnet or VCN Deletion on page 4227.

To delete a VCN, its subnets must contain no resources. Also, the VCN must have no attached gateways. If you're using the Console, there's a “Delete All” process you can use after first ensuring the subnets are empty. See To delete a VCN on page 3700.

For information about the number of VCNs and subnets you can have, see Service Limits on page 243.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to manage VCNs and subnets:

• Subnets in a security zone can't be public. All subnets must be private.
• You can't move a subnet from a security zone to a standard compartment.

Using the Console
To create a VCN

Note:
The following procedure creates a VCN without any subnets or gateways for access. You must manually create the subnets and other resources before you can use the VCN. For a quick procedure that creates a VCN that you can try out immediately (that is, with subnets and an internet gateway), see the information about the "VCN with Internet Connectivity" wizard in Virtual Networking Quickstart on page 3692. Or see Scenario A: Public Subnet on page 3614.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.

Note:
To create any new resource the service limit for that resource must not already have been reached. Once the service limit for a resource type has been reached, you can either remove unused resources of that type or request a service limit increase.

3. Click Create Virtual Cloud Network.
4. Enter the following:
   - **Name**: A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **CIDR Blocks**: One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: This option is available for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.
   - **Use DNS Hostnames in this VCN**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

Next you'll typically want to create one or more subnets in the cloud network.

To create a subnet

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Create Subnet.
4. In the Create Subnet dialog box, you specify the resources to associate with the subnet (for example, a route table). By default, the subnet is created in the current compartment, and you choose the resources from the same
compartment. Click the click here link in the dialog box if you want to enable compartment selection for the subnet and each of those resources.

Enter the following:

- **Create in Compartment**: If you've enabled compartment selection, specify the compartment where you want to put the subnet.
- **Name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Regional or AD-specific subnet**: Oracle recommends creating only **regional subnets**, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose **Availability Domain-Specific** (the only type of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.
- **CIDR Block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Ensure that it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You can change the size of this CIDR block later. See **Allowed VCN Size and Address Ranges** on page 3606. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment**: This option is available for VCNs in all commercial and government regions, provided the VCN is already enabled for IPv6. For more information, see **IPv6 Addresses** on page 3768.
- **Route Table**: The route table to associate with the subnet. If you've enabled compartment selection, under **Route Table Compartment**, you must specify the compartment that contains the route table.
- **Private or public subnet**: This controls whether VNICs in the subnet can have public IP addresses. For more information, see **Access to the Internet** on page 3609.
- **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and also when you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or let the Console generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see **DNS in Your Virtual Cloud Network** on page 3781.
- **DHCP Options**: The set of DHCP options to associate with the subnet. If you've enabled compartment selection, under **DHCP Options Compartment**, you must specify the compartment that contains the set of DHCP options.
- **Security Lists**: One or more security lists to associate with the subnet. If you've enabled compartment selection, you must specify the compartment that contains the security list.
- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**. The subnet is then created and displayed on the **Subnets** page in the compartment you chose.

**To edit a subnet**

You can change these characteristics of a subnet:

- Name
- Size of the CIDR block

**Note:**

- The CIDR block IP range you specify must be completely within one of the VCN's CIDR block ranges.
- The new range must use the same network address as the previous range. For example, the previous and new ranges could be 10.0.0.0/25 and 10.0.0.0/24.
Networking

- If you are reducing the CIDR range, ensure that no IP addresses outside of the reduced range are in use.
- The new CIDR range's broadcast address (last IP address of CIDR range) must not be an IP address in use in the previous CIDR range.
- You cannot create VNICs or private IPs for this subnet while a CIDR block update is in progress.
- After the CIDR block update is complete, the DHCP lease for each host within the subnet must be renewed. Renewal happens automatically within 24 hours. To renew the lease immediately, refer to the applicable operating system documentation for guidance on how to renew the lease manually.
- Ensure that you adjust your secondary VNICs and secondary IPs as applicable to match your updated VCN configuration.

  • Which set of DHCP options the subnet uses
  • Which route table the subnet uses
  • Which security lists the subnet uses

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
5. Click Edit.
7. Click Save Changes.

The changes take effect within a few seconds.

To delete a subnet

Prerequisite: The subnet must have no instances, load balancers, DB systems, and orphaned mount targets in it. For more information, see Subnet or VCN Deletion on page 4227.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
5. Click Terminate.
6. Confirm when prompted.

If the subnet is empty, its state changes to TERMINATING briefly and then TERMINATED. If the subnet is not empty, you get an error indicating that there are still instances or other resources in it that you must delete first.

To add a CIDR block to a VCN

- The CIDR block you add must not overlap with any other CIDR block in the VCN or in a peered VCN.
- The new CIDR block must not include an IP address used in an existing route rule.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click CIDR Blocks.
4. Click Add CIDR Block.
5. Enter the value of the CIDR block you want to add to the VCN.
6. Click Add CIDR Block.

The VCN's state changes to UPDATING. The time to completion can take a few minutes. You can view work requests to monitor the status of the update.
To change a VCN CIDR block

- The CIDR block range you specify must not overlap with any other CIDR block in this VCN or in a peered VCN.
- You cannot change the CIDR block to a range that excludes an IP address in use in the current CIDR block range.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click CIDR Blocks.
4. Find the CIDR block in the list, click the Actions icon (three dots), and then click Edit CIDR Block.
5. Make the applicable change.
6. Click Save Changes.

The VCN's state changes to UPDATING. The time to completion can vary depending on the size of your network. Updating a small network could take about a minute, and updating a large network could take up to an hour. You can view work requests to monitor the status of the update.

To remove a CIDR block from a VCN

- You cannot remove a CIDR block if an IP address in that range is in use.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click CIDR Blocks.
4. Find the CIDR block in the list, click the Actions icon (three dots), and then click Remove CIDR Block.
5. Click Remove CIDR Block.

The VCN's state changes to UPDATING. The time to completion can vary depending on the size of your network. Updating a small network could take about a minute, and updating a large network could take up to an hour. You can view work requests to monitor the status of the update.

To delete a VCN

**Important:**

The Console has an easy "Delete all" process that deletes a VCN and its related Networking resources (subnets, route tables, security lists, sets of DHCP options, internet gateway, and so on). If the VCN is attached to a dynamic routing gateway (DRG), the attachment is deleted, but the DRG remains.

The "Delete All" process deletes one resource at a time and takes a minute or two. A progress report is displayed to show you what's been deleted so far.

Before using the "Delete All" process, verify there are no instances, load balancers, DB systems, or orphaned mount targets in any of the subnets. For more information, see Subnet or VCN Deletion on page 4227.

If there are still resources in any subnet, or if you don't have permission to delete a particular Networking resource, the "Delete All" process stops and an error message is displayed. Any resources deleted up to that point cannot be restored. You might need to contact your tenancy administrator to help you delete any remaining resources.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click **Terminate**.
   
   The resulting dialog box displays a list of the resources to be deleted. The list doesn't include the default components that come with the VCN, but they are deleted along with the VCN.

4. Click **Delete All**.
   
   The process begins. The progress is displayed as each resource is deleted.

5. When the process is complete, click **Close**.

**To manage tags for a VCN**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

**To manage tags for a subnet**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the subnet you're interested in.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

**To move a VCN to a different compartment**

You can move a VCN from one compartment to another. When you move a VCN, its associated VNICs, private IPs, and ephemeral IPs move with it to the new compartment. For more information, see **To move a resource to a different compartment** on page 3139.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Find the VCN in the list, click the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the VCN, update the alarms to reference the new compartment. See **To update an alarm after moving a resource** on page 3542 for more information.

**To move a subnet to a different compartment**

You can move a subnet from one compartment to another. For more information, see **Working with Compartments** on page 3127.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Find the subnet in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

To manage your VCNs, use these operations:

- **ListVcns**
- **CreateVcn**
- **GetVcn**
- **UpdateVcn**
- **AddVcnCidr**
- **ModifyVcnCidr**
Networking

- RemoveVcnCidr
- DeleteVcn: Deletes only the VCN and not its related resources. For more information, see Subnet or VCN Deletion on page 4227. Note that the Console offers a "Delete All" process that makes it easy to delete the VCN and its related resources. See To delete a VCN on page 3700.
- ChangeVcnCompartment

To manage a VCN's subnets, use these operations:

- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

VCN Route Tables

This topic describes how to manage the route tables in a virtual cloud network (VCN). For more on route tables in a Dynamic Routing Gateway (DRG), see Dynamic Routing Gateways (DRGs) on page 3793.

Overview of Routing for Your VCN

Your VCN uses route tables to send traffic out of the VCN (for example, to the internet, to your on-premises network, or to a peered VCN). These route tables have rules that look and act like traditional network route rules you might already be familiar with. Each rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR.

Here are basics about routing in your VCN:

- The primary routing scenario is for sending a subnet's traffic to destinations outside the VCN. A subnet has a single route table of your choice associated with it. All VNICs in that subnet are subject to the rules in the route table. The rules govern how the traffic leaving the subnet is routed.
- Traffic within the VCN's subnets is automatically handled by the VCN local routing. No route rules are required to enable that traffic. And in general: for any route table that belongs to a given VCN, you can't create a rule that lists that VCN's CIDR (or a sub-section) as the rule's destination. Oracle uses a subnet's route table only if the destination IP address is not within the VCN's CIDR block.
- If a route table has overlapping rules, Oracle uses the most specific rule in the table to route the traffic (that is, the rule with the longest prefix match). Two CIDRs are said to overlap if one CIDR is contained within the other.
- If there is no route rule that matches the network traffic you intend to route outside the VCN, the traffic is dropped (blackholed).
- IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

For important details about routing between your VCN and on-premises network, see Routing Details for Connections to Your On-Premises Network on page 3818.

Working with Route Tables and Route Rules

Each VCN automatically comes with a default route table that has no rules. If you don't specify otherwise, every subnet uses the VCN's default route table. When you add route rules to your VCN, you can simply add them to the default table if that suits your needs. However, if you need both a public subnet and a private subnet (for example, see Scenario C: Public and Private Subnets with a VPN on page 3626), you instead create a separate (custom) route table for each subnet.

Each subnet in a VCN uses a single route table. When you create the subnet, you specify which one to use. You can change which route table the subnet uses at any time. You can also edit a route table's rules, or remove all the rules from the table.
You may optionally assign a descriptive name to a custom route table during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the route table a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

A route rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR. Here are the allowed types of targets for a route rule:

- **dynamic routing gateway (DRG)**: For subnets that need private access to networks connected to your VCN (for example, your on-premises network connected with an IPSec VPN or FastConnect, a peered VCN in the same region, or a peered VCN in another region).
- **internet gateway**: For public subnets that need direct access to the internet.
- **NAT gateway**: For subnets with instances that do not have public IP addresses but need outbound access to the internet.
- **service gateway**: For subnets that need private access to Oracle services such as Object Storage.
- **local peering gateway (LPG)**: For subnets that need private access to a peered VCN in the same region.
- **private IP**: For subnets that need to route traffic to an instance in the VCN. For more information, see Using a Private IP as a Route Target on page 3703. Also see Overview of Routing for Your VCN on page 3702.

Note:

You can't delete a particular resource if it's the target in a route rule. For example, you can't delete an internet gateway that has traffic routed to it. You must first delete all rules (in all route tables) with that internet gateway as the target.

When adding a route rule to a route table, you provide the destination CIDR block and target (plus the compartment where the target resides). Exception: if the target is a service gateway, instead of a destination CIDR block, you specify an Oracle-provided string that represents the public endpoints for the service of interest. That way you don't need to know all the service's CIDR blocks, which might change over time.

If you misconfigure a rule (for example, enter the wrong destination CIDR block), the network traffic you intended to route might be dropped (blackholed) or sent to an unintended target.

You can move route tables from one compartment to another. Moving a route table doesn’t affect its attachment to VCNs or subnets. When you move a route table to a new compartment, inherent policies apply immediately and affect access to the route table. For more information, see Access Control on page 3708.

You can't delete a VCN's default route table. To delete a custom route table, it must not be associated with a subnet yet. Or, in the advanced scenario of transit routing, it must not be associated with a DRG attachment or LPG in the VCN.

For information about the maximum number of route tables and route rules, see Service Limits on page 243.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

**Using a Private IP as a Route Target**

If you're not familiar with the definition of a private IP, see Private IP Addresses on page 3742. In short: a private IP is an object that contains a private IP address and related properties and has its own OCID.

**General Use Cases**

As mentioned earlier, Oracle uses a given subnet's route table only for traffic with a destination IP address outside the VCN. Typically you set up one or more rules to route that traffic to a gateway on the VCN (for example, a DRG connected to your on-premises network, or an internet gateway connected to the internet). However, you might want
to route that traffic (going to destinations outside the VCN) through an instance in the VCN first. In that case, you can use a private IP in the VCN as the target instead of a gateway in the VCN. Here are a few reasons you might do this:

- To implement a virtual network appliance (NVA) such as a firewall or intrusion detection that filters outgoing traffic from instances.
- To manage an overlay network on the VCN, which lets you run container orchestration workloads.
- To implement Network Address Translation (NAT) in the VCN. Note that Oracle instead recommends using a NAT gateway with your VCN. In general, NAT enables outbound internet access for instances that don't have direct internet connectivity.

To implement these use cases, there's more to do than simply route traffic to the instance. There's also configuration required on the instance itself.

**Tip:**
You can enable high availability of the private IP route target by using a secondary private IP address. In the event of a failure, you can move the secondary private IP from an existing VNIC to another VNIC in the same subnet. See Using the Console on page 3744 (Console instructions) and UpdatePrivateIp (API instructions).

**Requirements for Using a Private IP as a Target**

- The private IP must be in the same VCN as the route table.
- The private IP's VNIC must be configured to skip the source/destination check so that the VNIC can forward traffic. By default, VNICs are configured to perform the check. For more information, see Overview of VNICs and Physical NICs on page 3733.
- You must configure the instance itself to forward packets.
- The route rule must specify the OCID of the private IP as the target, and not the IP address itself. Exception: If you use the Console, you can instead specify the private IP address itself as the target, and the Console determines and uses the corresponding OCID in the rule.

**Important:**
A route rule with a private IP target can result in blackholing in these cases:

- The instance the private IP is assigned to is stopped or terminated
- The VNIC the private IP is assigned to is updated to enable the source/destination check or is deleted
- The private IP is unassigned from the VNIC

When a target private IP is terminated, in the Console, the route rule displays a note that the target OCID no longer exists.

For failover: If your target instance is terminated before you can move the secondary private IP to a standby, you must update the route rule to use the OCID of the new target private IP on the standby. The rule uses the target's OCID and not the private IP address itself.

**General Setup Process**

1. Determine which instance will receive and forward the traffic (the NAT instance, for example).
2. Choose a private IP on the instance (can be on the instance's primary VNIC or a secondary VNIC). If you want to implement failover, set up a secondary private IP on one of the VNICs on the instance.
3. Disable the source/destination check on the private IP's VNIC. See Overview of VNICs and Physical NICs on page 3733.
4. Get the OCID for the private IP. If you're using the Console, you can get either the OCID or the private IP address itself, along with the name of the private IP's compartment.
5. For the subnet that needs to route traffic to the private IP, view the subnet's route table. If the table already has a rule with the same destination CIDR but a different target, delete that rule.

6. Add a route rule with the following:
   - **Target type:** Private IP.
   - **Destination CIDR block:** If all traffic leaving the subnet needs to go to the private IP, use 0.0.0.0/0.
   - **Compartment:** The compartment of the private IP.
   - **Target:** The OCID of the private IP. If you're using the Console and instead enter the private IP address itself, the Console determines the corresponding OCID and uses it as the target for the route rule.
   - **Description:** An optional description of the rule.

As mentioned earlier, you must configure the instance itself to forward packets.

**Using the Console**

*To view a VCN's default route table*

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
   - The default route table is displayed in the list of tables.
4. Click the default route table to view its details.

*To update rules in an existing route table*

You can add, edit, or delete rules.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click the route table you're interested in.
5. If you want to create a route rule, click **Add Route Rule** and enter the following:
   - **Target Type:** See the list of target types in **Overview of Routing for Your VCN** on page 3702. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself. If the target is a private IP, before you specify the target you must first disable the source/destination check on the private IP's VNIC. For more information, see **Using a Private IP as a Route Target** on page 3703.
   - **Destination CIDR Block:** Only if the target is not a service gateway. The value is the destination CIDR block for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule.
   - **Destination Service:** Only if the target is a service gateway. The value is the service CIDR label that you're interested in.
   - **Compartment:** The compartment where the target is located.
   - **Target:** The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in which case the Console determines the corresponding OCID and uses it as the target for the route rule.
   - **Description:** An optional description of the rule.
6. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
7. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

*To create a route table*

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click **Create Route Table**.
5. Enter the following:
   - **Name:** A friendly name for the route table. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** The compartment where you want to create the route table, if different from the compartment you're currently working in.

6. Optionally, click **Additional Route Rule** to add one or more route rules, each with the following information (remember, a route table can exist with no rules until you're ready to add them):
   - **Target Type:** See the list of target types in **Overview of Routing for Your VCN** on page 3702. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself. If the target is a private IP, before you specify the target you must first disable the source/destination check on the private IP's VNIC. For more information, see **Using a Private IP as a Route Target** on page 3703.
   - **Destination CIDR Block:** Only if the target is not a service gateway. The value is the destination CIDR block for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule.
   - **Destination Service:** Only if the target is a service gateway. The value is the service CIDR label that you're interested in.
   - **Compartment:** The compartment where the target is located.
   - **Target:** The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in which case the Console determines the corresponding OCID and uses it as the target for the route rule.
   - **Description:** An optional description of the rule.

7. **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

8. Click **Create Route Table**.

The route table is created and then displayed on the **Route Tables** page in the compartment you chose. You can now specify this route table when creating or updating a subnet.

---

**To change which route table a subnet uses**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in
5. Click **Edit**.
6. In the **Route Table** section, select the new route table you want the subnet to use.
7. Click **Save Changes**.

The changes take effect within a few seconds.

**To move a route table to a different compartment**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Route Tables**.
4. Find the route table in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

**To delete a route table**

Prerequisite: To delete a route table, it must not be associated with a subnet yet. You can't delete the default route table in a VCN.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.
4. Click the route table you're interested in.
5. Click Terminate.
6. Confirm when prompted.

To manage tags for a route table

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.
4. Click the route table you're interested in.
5. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 239.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage a VCN's route tables, use these operations:

- ListRouteTables
- GetRouteTable
- UpdateRouteTable
- CreateRouteTable
- DeleteRouteTable
- ChangeRouteTableCompartment

Access and Security

See these topics for more information about access and security in your cloud network:

- Ways to Secure Your Network on page 3707
- Access Control on page 3708
- Virtual firewall for your VCN:
  - Security Rules on page 3710
  - Network Security Groups on page 3718
  - Security Lists on page 3727

Ways to Secure Your Network

There are several ways you can control security for your cloud network and compute instances:

- **Public versus private subnets:** You can designate a subnet to be private, which means instances in the subnet cannot have public IP addresses. For more information, see Public vs. Private Subnets on page 3609.
- **Security rules:** To control packet-level traffic in and out of an instance. You configure security rules in the Oracle Cloud Infrastructure API or Console. To implement security rules, you can use network security groups or security lists. For more information, see Security Rules on page 3710.
- **Firewall rules:** To control packet-level traffic in/out of an instance. You configure firewall rules directly on the instance itself. Notice that platform images that run Oracle Linux automatically include default rules that allow ingress on TCP port 22 for SSH traffic. Also, the Windows images include default rules that allow ingress on TCP port 3389 for Remote Desktop access. For more information, see Platform Images on page 943.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firewall rules and security rules both operate at the instance level. However, you configure security lists at the subnet level, which means all</td>
</tr>
</tbody>
</table>
resources in a given subnet have the same set of security list rules. Also, the security rules in a network security group apply only to the resources in the group. When troubleshooting access to an instance, ensure that all the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, Oracle Linux 7, or Oracle Linux Cloud Developer 8, you need to use `firewalld` to interact with the `iptables` rules. For your reference, here are commands for opening a port (1521 in this example):

```bash
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running `firewall-cmd --reload`.

- **Gateways and route tables:** To control general traffic flow from your cloud network to outside destinations (the internet, your on-premises network, or another VCN). You configure your cloud network's gateways and route tables in the Oracle Cloud Infrastructure API or Console. For more information about the gateways, see Networking Components on page 3604. For more information about route tables, see VCN Route Tables on page 3702.

- **IAM policies:** To control who has access to the Oracle Cloud Infrastructure API or Console itself. You can control the type of access, and which cloud resources can be accessed. For example, you can control who can set up your network and subnets, or who can update route tables, network security groups, or security lists. You configure policies in the Oracle Cloud Infrastructure API or Console. For more information, see Access Control on page 3708.

- **Security zones:** To ensure that your network and other cloud resources comply with Oracle security principles and best practices, you can create them in a security zone. A security zone is associated with a compartment and checks all network management operations against security zone policies. For example, a security zone does not permit the use of public IP addresses and can contain only private subnets. For more information, see Security Zones.

### Access Control

This topic gives basic information about using compartments and IAM policies to control access to your cloud network.

**Compartments and Your Cloud Network**

Anytime you create a cloud resource such as a virtual cloud network (VCN) or compute instance, you must specify which IAM compartment you want the resource in. A compartment is a collection of related resources that can only be accessed by certain groups that have been given permission by an administrator in your organization. The administrator creates compartments and corresponding IAM policies to control which users in your organization access which compartments. Ultimately, the goal is to ensure that each person can only access the resources they need.

If your company is starting to try out Oracle Cloud Infrastructure, only a few people need to create and manage the VCN and its components, launch instances into the VCN, and attach block storage volumes to those instances. Those few people need access to all these resources, so all those resources could be in the same compartment.

In an enterprise production environment with a VCN, your company can use multiple compartments to more easily control access to certain types of resources. For example, your administrator could create Compartment_A for your VCN and other networking components. The administrator could then create Compartment_B for all the compute instances and block storage volumes that the HR organization uses, and Compartment_C for all the instances and block storage volumes that the Marketing organization uses. The administrator would then create IAM policies that
Networking

give users only the level of access they need in each compartment. For example, the HR instance administrator is not entitled to modify the existing cloud network. So they would have full permissions for Compartment_B, but limited access to Compartment_A (just what's required to launch instances into the network). If they tried to modify other resources in Compartment_A, the request would be denied.

Network resources such as VCNs, subnets, route tables, security lists, service gateways, NAT gateways, VPN connections, and FastConnect connections can be moved from one compartment to another. When you move a resource to a new compartment, inherent policies apply immediately.

For more information about compartments and how to control access to your cloud resources, see “Setting Up Your Tenancy” in the Oracle Cloud Infrastructure Getting Started Guide and Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

IAM Policies for Networking

The simplest approach to granting access to Networking is the policy listed in Let network admins manage a cloud network on page 2807. It covers the cloud network and all the other Networking components (subnets, security lists, route tables, gateways, and so on). To also give network admins the ability to launch instances (to test network connectivity), see Let users launch compute instances on page 2807.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

For reference material for writing more detailed policies for Networking, see Details for the Core Services on page 2855.

Individual Resource-Types

If you'd like, you can write policies that focus on individual resource-types (for example, security lists only) instead of the broader virtual-network-family. The instance-family resource-type also includes several permissions for VNICs, which reside in a subnet but attach to an instance. For more information, see Details for Verb + Resource-Type Combinations on page 2857 and Virtual Network Interface Cards (VNICs) on page 3733.

There's a resource-type called local-peering-gateways that is included within virtual-network-family and includes two other resource-types related to local VCN peering (within region):

- local-peering-from
- local-peering-to

The local-peering-gateways resource-type covers all permissions related to local peering gateways (LPGs). The local-peering-from and local-peering-to resource-types are for granting permission to connect two LPGs and define a peering relationship within a single region. For more information, see Local VCN Peering using Local Peering Gateways on page 4139.

Similarly, there's a resource-type called remote-peering-connections that is included within virtual-network-family and includes two other resource-types related to remote VCN peering (across regions):

- remote-peering-from
- remote-peering-to

The remote-peering-connections resource-type covers all permissions related to remote peering connections (RPCs). The remote-peering-from and remote-peering-to resource-types are for granting permission to connect two RPCs and define a peering relationship across regions. For more information, see Remote VCN Peering using an RPC on page 4152.

Nuances of Different Verbs

If you'd like, you can write policies that limit the level of access by using a different policy verb (manage versus use, and so on). If you do, there are some nuances to understand about the policy verbs for Networking.

Be aware that the inspect verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).
Also, the following types of abilities are available only with the manage verb, not the use verb:

- Update (enable/disable) internet-gateways
- Update security-lists
- Update route-tables
- Update dhcp-options
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
- Peer VCNs

**Important:**

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to update that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you’re implicitly trusting them with controlling the network’s behavior.

For more information about policy verbs, see Policy Basics on page 2801.

**Security Rules**

The Networking service offers two virtual firewall features that both use security rules to control traffic at the packet level. The two features are:

- **Security lists**: The original virtual firewall feature from the Networking service.
- **Network security groups (NSGs)**: A subsequent feature designed for application components that have different security postures. NSGs are supported only for specific services.

These two features offer different ways to apply security rules to a set of virtual network interface cards (VNICs) in the virtual cloud network (VCN).

This topic summarizes basic differences between the two features. It also explains important security rule concepts that you need to understand. How you create, manage, and apply security rules varies between security lists and network security groups. For implementation details, see these related topics:

- Security Lists on page 3727
- Network Security Groups on page 3718

**Comparison of Security Lists and Network Security Groups**

*Security lists* let you define a set of security rules that applies to all the VNICs in an entire subnet. To use a given security list with a particular subnet, you associate the security list with the subnet either during subnet creation or later. A subnet can be associated with a maximum of five security lists. Any VNICs that are created in that subnet are subject to the security lists associated with the subnet.

*Network security groups* (NSGs) let you define a set of security rules that applies to a group of VNICs of your choice (or the VNICs' parent resources such as load balancers or DB systems). For example: the VNICs that belong to a set of Compute instances that all have the same security posture. To use a given NSG, you add the VNICs of interest to the group. Any VNICs added to that group are subject to that group's security rules. A VNIC can be added to a maximum of five NSGs.

The following diagram illustrates the concept.
Oracle recommends using NSGs instead of security lists because NSGs let you separate the VCN's subnet architecture from your application security requirements.

However, you can use both security lists and NSGs together if you want. For more information, see If You Use Both Security Lists and Network Security Groups on page 3714.

About VNICs and Parent Resources

A VNIC is a Networking service component that enables a networked resource such as a Compute instance to connect to a virtual cloud network (VCN). The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN.

When you create a Compute instance, a VNIC is automatically created for the instance in the instance's subnet. The instance is considered to be the parent resource for the VNIC. You can add more (secondary) VNICs to a Compute instance. For this reason, an instance's VNICs are displayed prominently as part of a Compute instance's related resources in the Console.

There are other types of parent resources that you can create that also result in a VNIC automatically being created. For example: when you create a load balancer, the Load Balancing service automatically creates VNICs for balancing traffic across the backend set. Also, when you create a DB system, the Database service automatically creates VNICs as DB system nodes. Those services create and manage those VNICs for you. For this reason, those VNICs are not readily apparent in the Console the same way VNICs are for Compute instances.

To use an NSG, you put VNICs of your choice into the group. However, you typically work with the parent resource when you add a VNIC to the group, not the VNIC itself. For example, when you create a Compute instance, you can optionally specify an NSG for the instance. Although you conceptually put the instance in the group, you're actually putting the instance's primary VNIC in the network security group. The group's security rules apply to that VNIC, not the instance. Also, if you add a secondary VNIC to the instance, you can optionally specify an NSG for that VNIC, and the rules apply to that VNIC, not the instance. Note that all the VNICs in a given NSG must be in the VCN that the NSG belongs to.

Likewise, when you put a load balancer in a network security group, you conceptually put the load balancer in the group. But you're actually putting VNICs managed by the Load Balancing service into the network security group.

You manage the VNIC membership of an NSG at the parent resource, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the parent resource (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For example, to add an existing Compute instance's VNIC to an NSG, you update that VNIC's properties and specify the NSG. For example, with the REST API, you call UpdateVnic. In the Console, you view the instance and then the VNIC of interest, and then edit the VNIC's properties there.

For a list of parent resources that support the use of NSGs, see Support for Network Security Groups on page 3719.
Network Security Group as Source or Destination of a Rule

There's an important difference in how you can write security rules for NSGs compared to security lists. When writing rules for an NSG, you can specify an NSG as the source of traffic (for ingress rules) or the traffic's destination (for egress rules). Contrast this with security list rules, where you specify a CIDR as the source or destination.

The ability to specify an NSG means that you can easily write rules to control traffic between two different NSGs. The NSGs must be in the same VCN.

Also, if you want to control traffic between VNICs in a specific NSG, you can write rules that specify the rule's own NSG as the source (for ingress rules) or destination (for egress rules).

For more information, see Overview of Network Security Groups on page 3719.

REST API Differences

There are a few basic differences in the REST API model for NSGs compared to security lists. For more information, see Using the API on page 3726.

Default Rules

Your VCN automatically comes with a default security list that contains several default security rules to help you get started using the Networking service. When you create a subnet, the default security list is associated with the subnet unless you specify a custom security list that you've already created in the VCN. For comparison, the VCN does NOT have a default network security group.

Limits

The two features have different limits.

Security List Limits

### Best Practices for Security Rules

#### Use Network Security Groups

Oracle recommends using NSGs for components that all have the same security posture. For example, in a multi-tier architecture, you would have a separate NSG for each tier. A given tier's VNICs would all belong to that tier's NSG. Within a given tier, you might have a particular subset of the tier's VNICs that have additional, special security requirements. Therefore you would create another NSG for those additional rules, and place that subset of VNICs into both the tier's NSG and the additional NSG.

Oracle also recommends using NSGs because Oracle will prioritize NSGs over security lists when implementing future enhancements.

#### Get Familiar with the Default Security List Rules

Your VCN automatically comes with a default security list that contains several default security rules to help you get started using the Networking service. Those rules exist because they enable basic connectivity. Even if you choose not to use security lists or the default security list, get familiar with the rules so you better understand the types of traffic that your networked cloud resources require. You might want to use those rules in your NSGs or any custom security lists that you set up.

The default security list does not include rules to enable ping. If you need to use ping, see Rules to Enable Ping on page 3718.

#### Don't Delete Default Security Rules Indiscriminately

Your VCN might have subnets that use the default security list by default. Do not delete any of the list's default security rules unless you've first confirmed that resources in your VCN do not require them. Otherwise, you might disrupt your VCN's connectivity.

#### Confirm That Your OS Firewall Rules Align with Your Security Rules

Your instances running platform images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance's subnet
- The instance's OS firewall rules
If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, Oracle Linux 7, or Oracle Linux Cloud Developer 8, you need to use `firewalld` to interact with the `iptables` rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running `firewall-cmd --reload`.

**Use VNIC Metrics to Troubleshoot Packets Dropped Because of Security Rules**

The Networking service offers metrics for VNICs, which show the levels of VNIC traffic (packets and bytes). Two of the metrics are for ingress and egress packets that violate security rules and are therefore dropped. You can use these metrics to help you troubleshoot issues related to security rules and whether your VNICs are receiving the desired traffic.

**If You Use Both Security Lists and Network Security Groups**

You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you have security rules that you want to enforce for all VNICs in a VCN: the easiest solution is to put the rules in one security list, and then associate that security list with all subnets in the VCN. This way you can ensure that the rules are applied, regardless of who in your organization creates a VNIC in the VCN. If you like, you can use the VCN's default security list, which automatically comes with the VCN and contains a set of essential rules by default.

If you choose to use both security lists and network security groups, the set of rules that applies to a given VNIC is the union of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

The following diagram is a simple illustration of the idea.

```
A packet in question is allowed if *any rule in any of the relevant lists and groups* allows the traffic (or if the traffic is part of an existing *connection being tracked*). There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules on page 3716.
```

**Parts of a Security Rule**

A security rule allows a particular type of traffic in or out of a VNIC. For example, a commonly used security rule allows ingress TCP port 22 traffic for establishing SSH connections to the instance (more specifically to the instance's VNICs). Without security rules, no traffic is allowed in and out of VNICs in the VCN.

**Note:**

Security rules are not enforced for traffic involving the 169.254.0.0/16 CIDR block, which includes services such as iSCSI and instance metadata.
Networking

Each security rule specifies the following items:

- **Direction (ingress or egress):** Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC. The REST API model for security lists is different from network security groups. With security lists, there is an `IngressSecurityRule` object and a separate `EgressSecurityRule` object. With network security groups, there is only a `SecurityRule` object, and the object's `direction` attribute determines whether the rule is for ingress or egress traffic.

- **Stateful or stateless:** If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. See Stateful Versus Stateless Rules on page 3716.

- **Source type and source (ingress rules only):** The source you provide for an ingress rule depends on the source type you choose.

  **Allowed source types**

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG. This source type is available only if the rule belongs to an NSG and not a security list.</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets coming from an Oracle service through a service gateway. The source service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>

- **Destination type and destination (egress rules only):** The destination you provide for an egress rule depends on the destination type you choose.

  **Allowed destination types**

<table>
<thead>
<tr>
<th>Destination Type</th>
<th>Allowed Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG. This destination type is available only if the rule belongs to an NSG and not a security list.</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets going to an Oracle service through a service gateway. The destination service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>

- **IP Protocol:** Either a single IPv4 protocol or "all" to cover all protocols.

- **Source port:** The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source `port number`, or a range.

- **Destination port:** The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination `port number`, or a range.

- **ICMP type and code:** For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.

- **Description** (NSG rules only): NSG security rules include an optional attribute where you can provide a friendly description of the rule. This is currently not supported for security list rules.

For examples of security rules, see Networking scenarios on page 3613.

For the limit on the number of rules you can have, see Comparison of Security Lists and Network Security Groups on page 3710.
Note:

If you're using NSGs, and two VNICs that are in the same VCN need to communicate using their public IP addresses, you must use the VNIC's public IP address and not the VNIC's NSG as the source (for ingress) or destination (for egress) in the relevant security rules. The packet is routed to the VCN's internet gateway, and at that point, the VNIC's NSG information is not available. Therefore a security rule that specifies the NSG as the source or destination will be ineffective in allowing that specific type of traffic.

Stateful Versus Stateless Rules

When you create a security rule, you choose whether it's stateful or stateless. The difference is described in the next sections. The default is stateful. Stateless rules are recommended if you have a high-volume internet-facing website (for the HTTP/HTTPS traffic).

This section refers specifically to Compute instances and their traffic. However, the discussion is applicable to all types of resources with VNICs. See Comparison of Security Lists and Network Security Groups on page 3710.

Stateful Rules

Marking a security rule as stateful indicates that you want to use connection tracking for any traffic that matches that rule. This means that when an instance receives traffic matching the stateful ingress rule, the response is tracked and automatically allowed back to the originating host, regardless of any egress rules applicable to the instance. And when an instance sends traffic that matches a stateful egress rule, the incoming response is automatically allowed, regardless of any ingress rules. For more details, see Stateful Versus Stateless Rules on page 3716.

The figure below illustrates a stateful ingress rule for an instance that needs to receive and respond to HTTP traffic. Instance A and Host B are communicating (Host B could be any host, whether an instance or not). The stateful ingress rule allows traffic from any source IP address (0.0.0.0/0) to destination port 80 only (TCP protocol). No egress rule is required to allow the response traffic.

Stateful Security Rule: Receive HTTP Traffic

Ingress rule:
Source CIDR = 0.0.0.0/0 (all)
Protocol = TCP
Source port = all
Destination port = 80 (HTTP)

Instance A

port 80

Host B

all (any port)

No egress rule required; response automatically tracked and allowed

Stateless Rules

Marking a security rule as stateless indicates that you do NOT want to use connection tracking for any traffic that matches that rule. This means that response traffic is not automatically allowed. To allow the response traffic for a stateless ingress rule, you must create a corresponding stateless egress rule.
The next figure shows Instance A and Host B as before, but now with stateless security rules. As with the stateful rule in the preceding section, the stateless ingress rule allows traffic from all IP addresses and any ports, on destination port 80 only (using the TCP protocol). To allow the response traffic, there needs to be a corresponding stateless egress rule that allows traffic to any destination IP address (0.0.0.0/0) and any ports, from source port 80 only (using the TCP protocol).

**Stateless Security Rule: Receive HTTP Traffic**

![Stateless Security Rule: Receive HTTP Traffic](image)

If Instance A needs instead to initiate HTTP traffic and get the response, then a different set of stateless rules are required. As the next figure shows, the egress rule would have source port = all and destination port = 80 (HTTP). The ingress rule would then have source port 80 and destination port = all.

**Stateless Security Rule: Initiate HTTP Traffic**

![Stateless Security Rule: Initiate HTTP Traffic](image)

If you were to use port binding on Instance A to specify exactly which port the HTTP traffic would come from, you could specify that as the source port in the egress rule and the destination port in the ingress rule.
If for some reason you use both stateful and stateless rules, and there's traffic that matches both a stateful and stateless rule in a particular direction (for example, ingress), the stateless rule takes precedence and the connection is not tracked. You would need a corresponding rule in the other direction (for example, egress, either stateless or stateful) for the response traffic to be allowed.

**Connection Tracking Details for Stateful Rules**

Oracle uses connection tracking to allow responses for traffic that matches stateful rules (see Stateful Versus Stateless Rules on page 3716). Each instance has a maximum number of concurrent connections that can be tracked, based on the instance's **shape**.

To determine response traffic for TCP, UDP, and ICMP, Oracle performs connection tracking on these items for the packet:

- Protocol
- Source and destination IP addresses
- Source and destination ports (for TCP and UDP only)

**Note:**

For other protocols, Oracle tracks only the protocol and IP addresses, and not the ports. This means that when an instance initiates traffic to another host and that traffic is allowed by egress security rules, any traffic that the instance receives later from that host for a period is considered response traffic and is allowed.

**Enabling Path MTU Discovery Messages for Stateless Rules**

If you decide to use stateless security rules to allow traffic to/from endpoints outside the VCN, it's important to add a security rule that allows ingress ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages. This rule is critical for establishing a connection to your instances. Without it, you can experience connectivity issues. For more information, see Hanging Connection on page 4221.

**Rules to Enable Ping**

The VCN's default security list contains several default rules, but not one to allow ping requests. If you want to ping an instance, ensure that the instance's applicable security lists or NSGs include an additional stateful ingress rule to specifically allow ICMP traffic type 8 from the source network you plan to ping from. To allow ping access from the internet, use 0.0.0.0/0 for the source. Note that this rule for pinging is separate from the default ICMP-related rules in the default security list. Do not remove those rules.

**Rules to Handle Fragmented UDP Packets**

Instances can send or receive UDP traffic. If a UDP packet is too large for the connection, it is fragmented. However, only the first fragment from the packet contains the protocol and port information. If the security rules that allow this ingress or egress traffic specify a particular port number (source or destination), the fragments after the first one are dropped. If you expect your instances to send or receive large UDP packets, set both the source and destination ports for the applicable security rules to ALL (instead of a particular port number).

**Network Security Groups**

The Networking service offers two virtual firewall features to control traffic at the packet level:

- **Network security groups:** Covered in this topic. Network security groups are supported only for specific services.
Networking

- **Security lists**: The original type of virtual firewall offered by the Networking service. See [Security Lists](#) on page 3727.

Both of these features use **security rules**. For important information about how security rules work, and a general comparison of security lists and network security groups, see [Security Rules](#) on page 3710.

**Highlights**

- Network security groups (NSGs) act as a virtual firewall for your Compute instances and **other kinds of resources**. An NSG consists of a set of ingress and egress **security rules** that apply only to a set of **VNICs of your choice in a single VCN** (for example: all the Compute instances that act as web servers in the web tier of a multi-tier application in your VCN).
- Compared to security lists, NSGs let you separate your VCN's subnet architecture from your application security requirements. See [Comparison of Security Lists and Network Security Groups](#) on page 3710.
- You can use NSGs with certain resource types. For more information, see [Support for Network Security Groups](#) on page 3719.
- NSG security rules function the same as security list rules. However, for an NSG security rule's source (for ingress rules) or destination (for egress rules), you can specify an NSG instead of a CIDR. This means you can easily write security rules to control traffic between two NSGs **in the same VCN**, or traffic within a single NSG. See [Parts of a Security Rule](#) on page 3714.
- Unlike with security lists, the VCN does not have a default NSG. Also, each NSG you create is initially empty. It has no default security rules.
- Network security groups have separate and different limits compared to security lists. See [Security List Limits](#) on page 3712.

**Support for Network Security Groups**

NSGs are available for you to create and use. However, they are not yet supported by all the relevant Oracle Cloud Infrastructure services.

Currently, the following types of **parent resources** support the use of NSGs:

- **Compute instances**: When you create an instance, you can specify one or more NSGs for the instance's primary VNIC. If you add a secondary VNIC to an instance, you can specify one or more NSGs for that VNIC. You can also update existing VNICs on an instance so that they are in one or more NSGs.
- **Load balancers**: When you create a load balancer, you can specify one or more NSGs for the load balancer (not the backend set). You can also update an existing load balancer to use one or more NSGs.
- **DB systems**: When you create a DB system, you can specify one or more NSGs. You can also update an existing DB system to use one or more NSGs.
- **Autonomous Databases**: When you create an Autonomous Database on **dedicated Exadata infrastructure**, you can specify one or more NSGs for the infrastructure resource. You can also update an existing dedicated Exadata infrastructure instance to use NSGs.
- **Mount targets**: When you create a mount target for a file system, you can specify one or more NSGs. You can also update an existing mount target to use one or more NSGs.
- **DNS resolver endpoint**: When you create an endpoint for a **private DNS resolver**, you can specify one or more NSGs. You can also update an existing endpoint to use one or more NSGs.
- **Kubernetes clusters**: When you create a Kubernetes cluster using Container Engine for Kubernetes, you can specify one or more NSGs to control access to the Kubernetes API endpoint and to worker nodes. You can also specify NSGs when defining a load balancer for a cluster.

For resource types that do not yet support NSGs, continue to use security lists to control traffic in and out of those parent resources.

**Overview of Network Security Groups**

A network security group (NSG) provides a virtual firewall for a set of cloud resources that all have the same security posture. For example: a group of Compute instances that all perform the same tasks and thus all need to use the same set of ports.

An NSG consists of two types of items (as illustrated in the following diagram):
• **VNICs**: One or more VNICs (for example, the VNICs attached to the set of Compute instances that all have the same security posture). All the VNICs must be in the VCN that the NSG belongs to. Also see Comparison of Security Lists and Network Security Groups on page 3710.

• **Security rules**: Security rules that define the types of traffic allowed in and out of the VNICs in the group. For example: ingress TCP port 22 SSH traffic from a particular source.

The NSG’s rules apply to VNICs that are added to the NSG

![Diagram](image)

If you have resources with different security postures in the same VCN, you can write NSG security rules to control traffic between the resources with one posture versus another. For example, in the following diagram, NSG1 has VNICs running in one tier of a multi-tier architecture application. NSG2 has VNICs running in a second tier. Both NSGs must belong to the same VCN. The assumption is that both NSGs need to initiate connections to the other NSG.

For NSG1, you set up egress security rules that specify NSG2 as the destination, and ingress security rules that specify NSG2 as the source. Likewise for NSG2, you set up egress security rules that specify NSG1 as the destination, and ingress security rules that specify NSG1 as the source. The rules are assumed to be stateful in this example.

![Diagram](image)

The preceding diagram assumes that each NSG needs to initiate connections to the other NSG.

The next diagram assumes that you instead want to only allow connections initiated from NSG1 to NSG2. To do that, remove the ingress rule from NSG1 and the egress rule from NSG2. The remaining rules do not allow connections initiated from NSG2 to NSG1.
The next diagram assumes that you want to control traffic between VNICs in the same NSG. To do that, set the rule's source (for ingress) or destination (for egress) as the rule's own NSG.

A VNIC can be in a maximum of five NSGs. A packet in question is allowed if any rule in any of the VNIC’s NSGs allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless security rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules on page 3716.

Network security groups are regional entities. For limits related to network security groups, see Comparison of Security Lists and Network Security Groups on page 3710.

**Security Rules**

If you're not yet familiar with the basics of NSG security rules, see these sections in the security rules topic:

- Parts of a Security Rule on page 3714
Networking

- Stateful Versus Stateless Rules on page 3716

Working with Network Security Groups

General Process for Working with NSGs

1. Create an NSG.
2. Add security rules to the NSG.
3. Add parent resources (or more specifically, VNICs) to the NSG. You can do this when you create the parent resource, or you can update the parent resource and add it to one or more NSGs. When you create a Compute instance and add it to an NSG, the instance's primary VNIC is added to the NSG. Separately, you can create secondary VNICs and optionally add them to NSGs.

Before deleting an NSG, you must remove all VNICs from it.

See the next sections for more details.

Creating NSGs

Each VCN comes with a default security list that has default security rules in it to enable basic connectivity. However, there is no default NSG in the VCN.

When you create an NSG, it is initially empty, without any security rules or VNICs. If you're using the Console, you can add security rules to the NSG during creation.

You may optionally assign a friendly name to the NSG during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the NSG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers on page 225.

For the purposes of access control, you must specify the compartment where you want the NSG to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see Access Control on page 3708.

Updating Security Rules and Group Membership

After the NSG is created, you can add or remove security rules to allow the types of ingress and egress traffic that the VNICs in the group require.

If you're familiar with security lists and use the REST API, note that the model for updating existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call UpdateNetworkSecurityGroupSecurityRules, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call UpdateSecurityList, you must pass in the entire list of rules, including rules that are not being updated in the call.

When you manage an NSG's VNIC membership, you do it as part of working with the parent resource, not the NSG itself. For more information, see Comparison of Security Lists and Network Security Groups on page 3710.

Specifying an NSG in a Security Rule

As mentioned earlier in Overview of Network Security Groups on page 3719, you can specify an NSG as the source (for ingress rules) or destination (for egress rules) in a given NSG's security rule. The two NSGs must be in the same VCN. For example, if both NSG1 and NSG2 belong to the same VCN, you could add an ingress rule to NSG1 that lists NSG2 as the source. If someone deletes NSG2, the rule becomes invalid. The REST API uses an isValid Boolean in the SecurityRule object to convey that status.

Deleting NSGs

To delete an NSG, it must not contain any VNICs or parent resources. When a parent resource (or a Compute instance VNIC) is deleted, it is automatically removed from the NSGs it was in. You might not have permission to delete a particular parent resource. Contact your administrator to determine who owns a given resource.
The Console displays a list of parent resources that are in an NSG, with a link to each parent resource. If the parent resource is a Compute instance, the Console also displays the instance's VNIC or VNICs that are in the NSG.

To remove a parent resource from its NSGs without deleting the resource, first view the parent resource's details in the Console. There you can see a list of the NSGs that the resource belongs to. From there, you can click Edit and remove the resource from all NSGs. If you're instead working with a Compute instance, view the details of the specific VNIC that you want to remove from the NSGs.

If you're using the REST API: the `ListNetworkSecurityGroupVnics` lists the parent resources and VNICs in an NSG. Use the resource's Update operation to remove the resource from NSGs. For example, for a Compute instance, use the `UpdateVnic` operation. For a load balancer, use the `UpdateNetworkSecurityGroups` operation, and so on.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let network admins manage a cloud network on page 2807 covers management of all Networking components, including NSGs.

If you have security admins who need to manage NSGs but not other components in the Networking service, you could write a more restrictive policy:

```plaintext
Allow group NSGAdmins to manage network-security-groups in tenancy
Allow group NSGAdmins to manage vcn in tenancy
    where ANY {request.operation = 'CreateNetworkSecurityGroup',
                 request.operation = 'DeleteNetworkSecurityGroup'}
Allow group NSGAdmins to read vcn in tenancy
Allow group NSGAdmins to use VNICs in tenancy
```

The first statement lets the NSGAdmins group create and manage NSGs and their security rules.

The second statement is required because the creation or deletion of an NSG affects the VCN that the NSG is in. The statement restricts the VCN-related permissions to only those required to create or delete an NSG. The statement does not allow the NSGAdmins group to create or delete VCNs, or work with any resources in a VCN except NSGs.

The third statement is required for listing the VCNs, which is a prerequisite for creating or deleting an NSG in a VCN. For information about why both the second and third statements are required, see Conditions on page 2828.

The fourth statement is required if the NSGAdmins need to put VNICs into an NSG. Whoever creates the parent resource of the VNIC (for example, a Compute instance) must already have this level of permission to create the parent resource.

For more information about Networking service policies, see IAM Policies for Networking on page 3709.

**Using the Console**

*To view the security rules and resources in an NSG*

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in to view its details.

The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.
5. Under **Resources**, click **VNICs** to see the parent resources that belong to the NSG.

   If the parent resource is a Compute instance, the corresponding VNICs from that instance are also listed on the page.

   For other types of parent resources, the relevant service manages the VNICs on your behalf. Therefore only the parent resource (and not its corresponding VNICs) is listed on the page.

*To create an NSG*

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click **Create Network Security Group**.
5. Enter the following:
   
   **a. Name**: A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   
   **b. Create in Compartment**: The compartment where you want to create the network security group, if different from the compartment you're currently working in.
   
   **c. Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Next**.

   If you want to create the NSG without any rules yet, click **Create** and you're done. Otherwise proceed to the next step.

7. For the first security rule, enter the following items (for examples of rules, see **Networking scenarios** on page 3613):
   
   **• Stateful or stateless**: If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. By default, rules are stateful unless you specify otherwise. See **Stateful Versus Stateless Rules** on page 3716.
   
   **• Direction (ingress or egress)**: Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC.
   
   **• Source Type** and **Source** (for ingress rules only):

   Allowed source types

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets coming from an Oracle service through a service gateway. The source service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>
### Networking

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Security</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
<tr>
<td>Group</td>
<td></td>
</tr>
</tbody>
</table>

- **Destination Type** and **Destination** (for egress rules only):

  Allowed destination types

<table>
<thead>
<tr>
<th>Destination Type</th>
<th>Allowed Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets going to an Oracle service through a service gateway.</td>
</tr>
<tr>
<td>Network Security</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
<tr>
<td>Group</td>
<td></td>
</tr>
</tbody>
</table>

- **IP Protocol:** Either a single IPv4 protocol (for example, TCP or ICMP) or "all" to cover all protocols.

- **Source port range:** The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source port number, or a range.

- **Destination port range:** The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination port number, or a range.

- **ICMP type and code:** For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.

8. To add another security rule, click **Another Rule** and enter the rule's information. Repeat for each rule you want to add.

9. When you're done, click **Create**.

The NSG is created and then displayed on the **Network Security Group** page in the compartment you chose. You can now specify this NSG when creating or managing instances or other types of parent resources.

When you view all the security rules in an NSG, you can filter the list by ingress or egress.

**To add or remove a resource from an NSG**

In general, you manage the resource membership of an NSG at the parent resource, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the parent resource (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For a list of the parent resources that support the use of NSG, see **Support for Network Security Groups** on page 3719.

Example: Compute instances

- **When creating an instance:** In the **Networking** section, under the advanced options, select the check box for **Use network security groups to control traffic**. Then, specify one or more NSGs. The instance's primary VNIC is added to the NSGs. See the procedure in **Creating an Instance** on page 1023.

- **For an existing instance:** Adding an existing instance to an NSG means adding its primary VNIC to the NSG. You can also add a secondary VNIC to an NSG. See **To add or remove a VNIC from a network security group** on page 3737.

Example: Exadata Cloud VM Cluster

- **When creating an Exadata cloud VM cluster:** In the **Network Information** section, you set up the client network and backup network. For each network, select the check box for **Use network security groups to control traffic**, and then specify one or more NSGs for the specific network. See **To create a cloud VM cluster resource** on page 1774. Also see **Network Setup for Exadata Cloud Service Instances** on page 1760.
• **For an existing Exadata Cloud Service instance:** An Exadata cloud VM cluster's details include a list of the NSGs that the client network belongs to (if any), and a list of the NSGs that the backup network belongs to (if any). Next to the relevant **Network Security Groups**, click **Edit** to change that list. See To edit the network security groups (NSGs) for your client or backup network on page 1785.

**To delete an NSG**

Prerequisite: To delete a security list, it must not be associated with a subnet. You can't delete the default security list in a VCN.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. For the security list you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

**To manage security rules for an NSG**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in to view its details.
   
   The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.

**To manage tags for an NSG**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in.
5. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

For more information, see Resource Tags on page 239.

**To move an NSG to a different compartment**

You can move an NSG from one compartment to another. When you move an NSG to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click the the Actions icon (three dots) for the NSG, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage a VCN's network security groups, use these operations:

• ListNetworkSecurityGroups
• GetNetworkSecurityGroup
• UpdateNetworkSecurityGroup
• CreateNetworkSecurityGroup
• DeleteNetworkSecurityGroup
Networking

- ChangeNetworkSecurityGroupCompartment
- ListNetworkSecurityGroupVnics
- AddNetworkSecurityGroupSecurityRules
- RemoveNetworkSecurityGroupSecurityRules
- UpdateNetworkSecurityGroupSecurityRules

There are some differences in the REST API model for NSGs compared to security lists:

- With security lists, there is an IngressSecurityRule object and a separate EgressSecurityRule object. With network security groups, there is only a SecurityRule object, and the object's direction attribute determines whether the rule is for ingress or egress traffic.
- With security lists, the rules are part of the SecurityList object, and you work with the rules by calling the security list operations (such as UpdateSecurityList). With NSGs, the rules are not part of the NetworkSecurityGroup object. Instead you use separate operations to work with the rules for a given NSG (example: UpdateNetworkSecurityGroupSecurityRules).
- The model for updating existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call UpdateNetworkSecurityGroupSecurityRules, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call UpdateSecurityList, you must pass in the entire list of rules, including rules that are not being updated in the call.
- There is a limit of 25 rules when calling the operations to add, remove, or update security rules.

Security Lists

The Networking service offers two virtual firewall features to control traffic at the packet level:

- **Security lists**: Covered in this topic. This is the original type of virtual firewall offered by the Networking service.
- **Network security groups**: Another type of virtual firewall that Oracle recommends over security lists. See Network Security Groups on page 3718.

Both of these features use security rules. For important information about how security rules work, and a general comparison of security lists and network security groups, see Security Rules on page 3710.

Highlights

- Security lists act as virtual firewalls for your Compute instances and other kinds of resources. A security list consists of a set of ingress and egress security rules that apply to all the VNICs in any subnet that the security list is associated with. This means that all the VNICs in a given subnet are subject to the same set of security lists. See Comparison of Security Lists and Network Security Groups on page 3710.
- Security list rules function the same as network security group rules. For a discussion of rule parameters, see Parts of a Security Rule on page 3714.
- Each VCN comes with a default security list that has several default rules for essential traffic. If you don't specify a custom security list for a subnet, the default security list is automatically used with that subnet. You can add and remove rules from the default security list.
- Security lists have separate and different limits compared to network security groups. See Comparison of Security Lists and Network Security Groups on page 3710.

Overview of Security Lists

A security list acts as a virtual firewall for an instance, with ingress and egress rules that specify the types of traffic allowed in and out. Each security list is enforced at the VNIC level. However, you configure your security lists at the subnet level, which means that all VNICs in a given subnet are subject to the same set of security lists. The security lists apply to a given VNIC whether it's communicating with another instance in the VCN or a host outside the VCN.

Each subnet can have multiple security lists associated with it, and each list can have multiple rules (for the maximum number, see Comparison of Security Lists and Network Security Groups on page 3710). A packet in question is allowed if any rule in any of the lists allows the traffic (or if the traffic is part of an existing connection being
Networking

There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules on page 3716.

Security lists are regional entities. For limits related to security lists, see Comparison of Security Lists and Network Security Groups on page 3710.

Security lists can control both IPv4 and IPv6 traffic. IPv6 addressing and related security list rules are supported in all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

**Default Security List**

Unlike other security lists, the default security list comes with an initial set of stateful rules, which should in most cases be changed to only allow inbound traffic from authorized subnets relevant to the region that homes that VCN or subnet. A list of authorized subnet ranges relevant to each region can be found at https://docs.cloud.oracle.com/iaas/tools/public_ip_ranges.json.

- **Stateful ingress**: Allow TCP traffic on destination port 22 (SSH) from authorized source IP addresses and any source port. This rule makes it easy for you to create a new cloud network and public subnet, launch a Linux instance, and then immediately use SSH to connect to that instance without needing to write any security list rules yourself.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using Windows images, make sure to add a stateful ingress rule for TCP traffic on destination port 3389 from authorized source IP addresses and any source port.</td>
</tr>
<tr>
<td>See To enable RDP access for more information.</td>
</tr>
</tbody>
</table>

- **Stateful ingress**: Allow ICMP traffic type 3 code 4 from authorized source IP addresses. This rule enables your instances to receive Path MTU Discovery fragmentation messages.

- **Stateful ingress**: Allow ICMP traffic type 3 (all codes) from your VCN's CIDR block. This rule makes it easy for your instances to receive connectivity error messages from other instances within the VCN.

- **Stateful egress**: Allow all traffic. This allows instances to initiate traffic of any kind to any destination. Notice that this means the instances with public IP addresses can talk to any internet IP address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Stateful Versus Stateless Rules on page 3716.

  The default security list comes with no stateless rules. However, you can always add or remove rules from the default security list.

  If your VCN is enabled for IPv6 addressing the default security list contains some default rules for IPv6 traffic. For more information, see Security Rules for IPv6 Traffic on page 3728.

**Enabling Ping**

The default security list does not include a rule to allow ping requests. If you plan to ping an instance, see Rules to Handle Fragmented UDP Packets on page 3718.

**Security Rules for IPv6 Traffic**

Like route tables, the VCN's network security groups and security listsSecurity Rules on page 3710support both IPv4 and IPv6 rules. For example, a network security group or security list could have these security rules:

- Rule to allow SSH traffic from the on-premises network's IPv4 CIDR
- Rule to allow ping traffic from the on-premises network's IPv4 CIDR
- Rule to allow SSH traffic from the on-premises network's IPv6 CIDR
- Rule to allow ping traffic from the on-premises network's IPv6 CIDR
The default security list in an IPv6-enabled VCN includes default IPv4 rules and the following default IPv6 rules:

- **Stateful ingress:** Allow IPv6 TCP traffic on destination port 22 (SSH) from source ::/0 and any source port. This rule makes it easy for you to create a new VCN with a public subnet and internet gateway, create a Linux instance, add an internet-access-enabled IPv6, and then immediately connect with SSH to that instance without needing to write any security rules yourself.

  **Important:**
  
The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using Windows images, add a stateful ingress rule for TCP traffic on destination port 3389 from source ::/0 and any source port.
  
  See [To enable RDP access](#) for more information.

- **Stateful ingress:** Allow ICMPv6 traffic type 2 code 0 (Packet Too Big) from source ::/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages.

- **Stateful egress:** Allow all IPv6 traffic. This allows instances to initiate IPv6 traffic of any kind to any destination. Notice that this means the instances with an internet-access-enabled IPv6 can talk to any internet IPv6 address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see [Stateful Versus Stateless Rules](#) on page 3716.

### Security Rules

If you're not yet familiar with the basics of security rules, see these sections in the security rules topic:

- [Parts of a Security Rule](#) on page 3714
- [Stateful Versus Stateless Rules](#) on page 3716

### Working with Security Lists

#### General Process for Working with Security Lists

1. Create a security list.
2. Add security rules to the security list.
3. Associate the security list with one or more subnets.
4. Create resources in the subnet (for example, create Compute instances in the subnet). The security rules apply to all the VNICs in that subnet. See [Comparison of Security Lists and Network Security Groups](#) on page 3710.

#### Additional Details

When you create a subnet, you must associate at least one security list with it. It can be either the VCN's default security list or one or more other security lists that you've already created (for the maximum number, see [Service Limits](#) on page 243). You can [change which security lists the subnet uses](#) at any time.

You may optionally assign a friendly name to the security list during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the security list a unique identifier called an Oracle Cloud ID (OCID). For more information, see [Resource Identifiers](#) on page 225.

For the purposes of access control, you must specify the compartment where you want the security list to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see [Access Control](#) on page 3708.

You can move security lists from one compartment to another. Moving a security list doesn't affect its attachment to a subnet. When you move a security list to a new compartment, inherent policies apply immediately and affect access to the security list. For more information, see [Managing Compartments](#) on page 3126.

You can add and remove rules from the security list. A security list can have no rules. Notice that when you update a security list in the API, the new set of rules replaces the entire existing set of rules.

To delete a security list, it must not be associated with a subnet. You can't delete a VCN's default security list.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: The policy in *Let network admins manage a cloud network* on page 2807 covers management of all Networking components, including security lists.

If you have security admins who need to manage security lists but not other components in Networking, you could write a more restrictive policy:

```
Allow group SecListAdmins to manage security-lists in tenancy
Allow group SecListAdmins to manage vcns in tenancy
```

Both statements are needed because the creation of a security list affects the VCN the security list is in. The scope of the second statement *also* allows the SecListAdmins group to create VCNs. However, the group can't create subnets or manage any other components related to any of those VCNs (except for the security lists), because other permissions would be required for those resources. The group also can't delete any existing VCNs that already have subnets in them, because that action would require permissions related to subnets.

For more information, see *IAM Policies for Networking* on page 3709.

**Using the Console**

*To view a VCN's default security list*

1. Open the navigation menu, click *Networking*, and then click *Virtual Cloud Networks*.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. Click the default security list to view its details.

   Under **Resources**, you can click **Ingress Rules** or **Egress Rules** to switch between the different types of rules.

*To update rules in an existing security list*

1. Open the navigation menu, click *Networking*, and then click *Virtual Cloud Networks*.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. Click the security list you're interested in.
5. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
6. If you want to add a rule, click **Add Ingress Rule** (or **Add Egress Rule**). See details of adding a rule in *To create a security list* on page 3730.
7. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
8. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

*To create a security list*

1. Open the navigation menu, click *Networking*, and then click *Virtual Cloud Networks*.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. Click **Create Security List**.
5. Enter the following:
   
   a. **Name**: A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   
   b. **Create in Compartment**: The compartment where you want to create the security list, if different from the compartment you're currently working in.
6. Add either an ingress rule or egress rule (for examples of rules, see Networking scenarios on page 3613):

   a. Click either Add Ingress Rule or Add Egress Rule.
   b. Choose whether it's a stateful or stateless rule (see Stateful Versus Stateless Rules on page 3716). By default, rules are stateful unless you specify otherwise.
   c. Enter either the source CIDR (for ingress) or destination CIDR (for egress). For example, use 0.0.0.0/0 to indicate all IP addresses. Other typical CIDRs you might specify in a rule are the CIDR block for your on-premises network, or for a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see Task 3: (Optional) Update security rules on page 4133.
   d. Select the IP protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).
   e. Enter further details depending on the protocol:
      - If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20–22).
      - If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.
   f. Enter an optional description of the rule to help manage your security list rules.

7. Repeat the preceding step for each rule you want to add to the list.

8. Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

9. When you're done, click Create Security List.

   The security list is created and then displayed on the Security Lists page in the compartment you chose. You can now specify this security list when creating or updating a subnet.

When you view all the rules in a security list, notice that any stateless rules in the list are shown above any stateful rules. Stateless rules in the list take precedence over stateful rules. In other words: If there's traffic that matches both a stateless rule and a stateful rule across all the security lists associated with the subnet, the stateless rule takes precedence and the connection is not tracked.

To change which security lists a subnet uses

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
6. If you want to add a security list, click Add Security List, and select the new security list you want the subnet to use.
7. If you want to remove a security list, click the Actions icon (three dots), and then click Remove. Remember that a subnet must always have at least one security list associated with it.

   The changes take effect within a few seconds.

To move a security list to a different compartment

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Find the security list, click the the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
To delete a security list

Prerequisite: To delete a security list, it must not be associated with a subnet. You can't delete the default security list in a VCN.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the security list you want to delete, click the Actions icon (three dots), and then click Terminate.
5. Confirm when prompted.

To manage tags for a security list

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the security list you're interested in.
5. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

For more information, see Resource Tags on page 239.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage a VCN's security lists, use these operations:

- ListSecurityLists
- GetSecurityList
- UpdateSecurityList
- CreateSecurityList
- DeleteSecurityList
- ChangeSecurityListCompartment

VCN Flow Logs

This topic describes the contents of VCN flow logs and how to set up flow logs for resources in your VCN.

Highlights

- VCN flow logs shows details about traffic that passes through your VCN.
- VCN flow logs help you audit traffic and troubleshoot your security lists.
- Flow logs are enabled and managed using the Logging service. For more information, see Logging Overview on page 3348.
- Flow logs can be generated from VNICs, PEs, and RCEs. For PEs and RCEs, they appear as from the VNIC associated with the PE/RCE.

Overview of Flow Logs

Each instance in a VCN has one or more Virtual Network Interface Cards (VNICs) on page 3733. The Networking service uses Security Lists on page 3727 to determine what traffic is allowed through a given VNIC. The VNIC is subject to all rules in all security lists associated with the VNIC's subnet.

To help you troubleshoot your security lists or audit the traffic in and out of your VNICs, you can set up VCN flow logs. Flow logs record details about traffic that has been accepted or rejected based on the security list rules.

How Flow Logs Are Enabled and Delivered

Flow logs are enabled and managed using the Logging service. You can enable flow logs for a given subnet, which means traffic is logged for all the existing and future VNICs in that subnet. Each flow log record contains information about traffic for a single VNIC. Here are the general steps for setting up flow logs:
1. **Enable flow logs for the subnet:** VCN flow logs are enabled for a subnet using the Logging service.

2. **View the subnet’s flow logs:** Assuming there is traffic for the given subnet, it can take up to 10 minutes for the first flow logs to be delivered. Then you receive batches of flow logs every minute.

After flow logs are enabled for a subnet, a batch of flow logs for each VNIC is collected in one-minute capture windows. It takes under eight minutes to process a batch, after which the flow logs are available for viewing.

**Flow Log Contents**

Each flow log record reflects logged traffic in one direction of a connection between two endpoints. For example, for a single TCP connection, you may have two records in the capture window: one for ingress traffic, and the other for egress traffic.

For more information about flow log contents, examples, and limitations and other considerations, see Details for VCN Flow Logs on page 3397.

**Setting Up Flow Logs for a Subnet**

See Enabling Logging for a Resource on page 3363 for instructions on setting up the Logging service.

**Managing Flow Logs**

Flow log management tasks such as disabling logs, deleting logs, and editing logs are performed using the Logging service. For more information on log management, see Managing Logs and Log Groups on page 3350.

**Use VCN Flow Logs to Audit Traffic and Troubleshoot Security Lists**

To list details about traffic that passes to and from destinations in your VCN, enable flow logs for a given subnet. After you have them enabled, flow logs record traffic for all existing and future VNICs attached to compute instances in that subnet.

Flow logs are enabled and managed using the Logging service. For more information, see Logging Overview on page 3348.

**Virtual Network Interface Cards (VNICs)**

This topic describes how to manage the virtual network interface cards (VNICs) in a virtual cloud network (VCN).

**Overview of VNICs and Physical NICs**

The servers in Oracle Cloud Infrastructure data centers have physical network interface cards (NICs). When you launch an instance on one of these servers, the instance communicates using Networking service virtual NICs (VNICs) associated with the physical NICs. The next sections talk about VNICs and NICs, and how they're related.

**About VNICs**

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN and includes these items:

- One primary private IPv4 address from the subnet the VNIC is in, chosen by either you or Oracle.
- Up to 31 optional secondary private IPv4 addresses from the same subnet the VNIC is in, chosen by either you or Oracle.
- An optional public IPv4 address for each private IP, chosen by Oracle but assigned by you at your discretion.
- An optional hostname for DNS for each private IP address (see DNS in Your Virtual Cloud Network on page 3781).
- A MAC address.
- A VLAN tag assigned by Oracle and available when attachment of the VNIC to the instance is complete (relevant only for bare metal instances).
- A flag to enable or disable the source/destination check on the VNIC's network traffic (see Overview of VNICs and Physical NICs on page 3733).
- Optional membership in one or more network security groups (NSGs) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
Networking

• Up to 32 optional IPv6 addresses. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

Each VNIC also has a friendly name you can assign, and an Oracle-assigned OCID (see Resource Identifiers).

Each instance has a primary VNIC that is automatically created and attached during launch. That VNIC resides in the subnet you specify during launch. The primary VNIC cannot be removed from the instance.

How VNICs and Physical NICs Are Related

This section is relevant to bare metal instances.

The OS on a bare metal instance recognizes two physical network devices and configures them as two physical NICs, 0 and 1. Whether they're both active depends on the underlying hardware. You can determine which NICs are active for a shape by reviewing the network bandwidth specifications for bare metal shapes. If the network bandwidth is listed as "2 x <bandwidth> Gbps," it means that both NIC 0 and NIC 1 are active, and each physical NIC has the indicated amount of bandwidth. If the network bandwidth is listed as "1 x <bandwidth> Gbps," it means that only NIC 0 is active. On current generation Standard and DenseIO shapes, typically both NIC 0 and NIC 1 are active.

NIC 0 is automatically configured with the primary VNIC's IP configuration (the IP addresses, DNS hostname, and so on).

If you add a secondary VNIC to an instance, you must specify which physical NIC the secondary VNIC should use. You must also configure the OS so that the physical NIC has the secondary VNIC's IP configuration. For Linux instances, see Linux: Configuring the OS for Secondary VNICs on page 3739. For Windows instances, see Windows: Configuring the OS for Secondary VNICs on page 3740.

About Secondary VNICs

You can add secondary VNICs to an instance after it's launched. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance.

Here are some reasons why you might use secondary VNICs:

• Use your own hypervisor on a bare metal instance: The virtual machines on the bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For more information, see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.
• Connect an instance to subnets in multiple VCNs: For example, you might set up your own firewall to protect traffic between VCNs, so the instance needs to connect to subnets in different VCNs.

Here are more details about secondary VNICs:

• They're supported for these types of instances:
  • Linux: Both VM and bare metal instances. Also see Linux: Configuring the OS for Secondary VNICs on page 3739.
  • Windows: Both VM and bare metal instances (except for instances that use previous generation Standard1 and StandardB1 shapes). For bare metal instances, secondary VNICs are supported only on the second physical NIC. Remember that the first physical NIC is NIC 0, and the second is NIC 1. Also see Windows: Configuring the OS for Secondary VNICs on page 3740.
• There's a limit to how many VNICs can be attached to an instance, and it varies by shape. For those limits, see Compute Shapes on page 973.
• They can be added only after the instance is launched.
• They must always be attached to an instance and cannot be moved. The process of creating a secondary VNIC automatically attaches it to the instance. The process of detaching a secondary VNIC automatically deletes it.
• They are automatically detached and deleted when you terminate the instance.
• The instance's bandwidth is fixed regardless of the number of VNICs attached. You can't specify a bandwidth limit for a particular VNIC on an instance.
Networking

• Attaching multiple VNICs from the same subnet CIDR block to an instance can introduce asymmetric routing, especially on instances using a variant of Linux. If you need this type of configuration, Oracle recommends assigning multiple private IP addresses to one VNIC, or using policy-based routing as shown in the script later in this topic.

• Adding multiple VNICs might route iSCSI traffic away from the primary VNIC, which breaks the iSCSI volume attachments. To avoid this issue, add specific routes for the new VNICs, and use the primary VNIC router address as the gateway. iSCSI boot volumes use the 169.254.0.2/32 address and block volumes use the 169.254.2.0/24 network.

Source/Destination Check

By default, every VNIC performs the source/destination check on its network traffic. The VNIC looks at the source and destination listed in the header of each network packet. If the VNIC is not the source or destination, then the packet is dropped.

If the VNIC needs to forward traffic (for example, if it needs to perform Network Address Translation (NAT)), you must disable the source/destination check on the VNIC. For instructions, see To update an existing VNIC on page 3737. For information about the general scenario, see Using a Private IP as a Route Target on page 3703.

VNIC Information in the Instance Metadata

The instance metadata service (IMDS) includes information about the VNICs at these URLs:

• IMDS version 2:

• Legacy IMDS version 1:

Here's an example response that shows the VNICs that are attached to an instance:

```json
[ {
    "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
    "privateIp" : "10.0.3.6",
    "vlanTag" : 11,
    "macAddr" : "00:00:00:00:00:01",
    "virtualRouterIp" : "10.0.3.1",
    "subnetCidrBlock" : "10.0.3.0/24",
    "nicIndex" : 0
  }, {
    "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
    "privateIp" : "10.0.4.3",
    "vlanTag" : 12,
    "macAddr" : "00:00:00:00:00:02",
    "virtualRouterIp" : "10.0.4.1",
    "subnetCidrBlock" : "10.0.4.0/24",
    "nicIndex" : 0
  } ]
```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

VNICs reside in a subnet but attach to an instance. The VNIC's attachment to the instance is a separate object from the VNIC or the instance itself. Be aware that the VNIC and subnet always exist together in the same compartment,
Networking

but the VNIC's *attachment to the instance* always exists in the instance's compartment. This distinction isn't important if you have a simple access control scenario where all the cloud resources are in the same compartment (for example, for a proof-of-concept). When you move to a production implementation, you might decide to have network administrators manage the network, and other personnel administer instances. That means you might put instances in a different compartment than the subnet.

For administrators: see [IAM Policies for Networking](#) on page 3709.

**Monitoring VNICS**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see [Monitoring](#) on page 3458 and [Notifications Overview](#) on page 4248.

For information about monitoring the traffic coming in and out of VNICS, see [VNIC Metrics](#) on page 4212.

**Using the Console**

To view an instance's VNICS

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.

   The primary VNIC and any secondary VNICS attached to the instance are displayed. If the instance has two active physical NICs, the VNICS are grouped by NIC 0 and NIC 1.

To create and attach a secondary VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.

   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click Create VNIC.
6. In the Create VNIC dialog box, you specify which VCN and subnet to put the VNIC in. By default, the VNIC will be created in the current compartment. You can choose a VCN and subnet from the same compartment or a different compartment.

Enter the following:

- **Name**: A friendly name for the secondary VNIC. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Virtual cloud network**: The VCN that contains the subnet of interest.
- **Network**: Select Normal Setup: Subnet.
- **Subnet**: The subnet of interest. The secondary VNIC must be in the same availability domain as the instance's primary VNIC, so the subnet list includes any regional subnets or AD-specific subnets in the primary VNIC's availability domain.
- **Physical NIC**: Only relevant if this is a bare metal instance with two active physical NICs. Select which one you want the secondary VNIC to use. When you later view the instance's details and the list of VNICs attached to the instance, they'll be grouped by NIC 0 and NIC 1.
- **Use network security groups to control traffic**: Select this check box to add the secondary VNIC to at least one network security group (NSG) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
- **Skip source/destination check**: By default, this check box is NOT selected, which means the VNIC performs the source/destination check. Only select this check box if you want the VNIC to be able to forward traffic. See Overview of VNICs and Physical NICs on page 3733.
- **Private IP Address**: Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
- **Assign a public IPv4 address**: Whether to assign a public IP address to the VNIC's primary private IP. Available only if the subnet is public. Choose this option to specify an existing reserved public IP address by name, or to create a new reserved IP address by assigning a name and selecting a source IP pool for the address. If you don't select an IP pool you've created, the default Oracle IP pool is used.
- **DNS record**: Whether to assign the VNIC a private DNS record. For more information, see DNS in Your Virtual Cloud Network on page 3781.
- **Hostname**: Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels, and the option to assign a private DNS record is selected.
- **Show tagging options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Save Changes**. The secondary VNIC is created and then displayed on the Attached VNICs page for the instance. It can take several seconds before the secondary VNIC appears on the page.

8. Configure the OS to use the VNIC. See Linux: Configuring the OS for Secondary VNICs on page 3739 or Windows: Configuring the OS for Secondary VNICs on page 3740.

To update an existing VNIC

You can update the VNIC's friendly name or hostname, or whether the VNIC performs the source/destination check.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to edit, click the Actions icon (three dots), and then click **Edit VNIC**.
6. Make your changes. Avoid entering confidential information. Then, click **Save Changes**.

To add or remove a VNIC from a network security group

You can change which network security groups (NSGs) a VNIC belongs to, or remove a VNIC from all NSGs.
1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.

The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.

Each VNIC's details page includes a list of the NSGs that the VNIC belongs to (if any).
7. Make your changes and click Save Changes.

To delete a secondary VNIC

Caution:
If the VNIC has a private IP that is the target of a route rule, deleting the VNIC causes the route rule to blackhole and traffic will be dropped.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.

The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to delete, click the Actions icon (three dots), and then click Delete VNIC.
6. Confirm when prompted.

It takes typically a few seconds before the VNIC is deleted.

If the secondary VNIC is on a Linux instance: If you then run the provided script in Linux: Configuring the OS for Secondary VNICs on page 3739, it removes the secondary VNIC from the OS configuration.

To manage tags for a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.

The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Click the Tags tab to view or edit the existing tags. Or click Add Tags to add new ones.

For more information, see Resource Tags on page 239.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage VNICs on an instance, use these operations:

- ListVnicAttachments: Use this to list the VNICs attached to an instance.
- GetVnicAttachment: Use this to get the VNIC's VLAN tag and other properties.
- GetVnic: Use this to get the VNIC's private IP address, MAC address, optional public IP address, optional DNS hostname, and other properties.
- AttachVnic
- DetachVnic
- UpdateVnic
Linux: Configuring the OS for Secondary VNICs

This section gives details about OS configuration that is required for secondary VNICs on instances that run a variant of Linux.

At the end of the section is a script that you can use to configure secondary VNICs on either VM instances or bare metal instances.

Linux VM Instances

When you add a secondary VNIC to a Linux VM instance, a new interface (that is, an Ethernet device) is added to the instance and automatically recognized by the OS. However, DHCP is not active for the secondary VNIC, and you must configure the interface with the static IP address and default route. The script provided here handles that configuration for you.

Linux Bare Metal Instances

When you add a secondary VNIC to a Linux bare metal instance, the OS does not automatically recognize the secondary VNIC, so you must configure it in the OS. Depending on your requirements, you can configure it as either:

- An SR-IOV virtual function (see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC).
- A VLAN-tagged interface (see the script in the following section).

Configuration Script for Either Linux VM Instances or Linux Bare Metal Instances

The following script works for both VM instances and bare metal instances. It looks at the secondary VNIC information in the instance metadata and configures the OS accordingly. You could run the script periodically to bring the OS configuration up to date with the instance metadata.

For VM instances in particular, the OS automatically recognizes the secondary VNIC's interface, and the script just needs to configure the static IP address and default route.

For bare metal instances in particular, the script creates the interface for the secondary VNIC and configures it with the relevant information. If the instance has two active physical NICs (NIC 0 and NIC 1), the script configures the secondary VNIC to use whichever physical NIC you chose when you added the VNIC to the instance. Note that for NIC 1, if a secondary VNIC has VLAN tag 0, it uses the NIC's interface. The script doesn't create an interface for that secondary VNIC.

Here are some additional notes about how the script works for both VM instances and bare metal instances:

- **Default namespace and policy-based routing**: By default, this script configures the secondary VNIC in the default namespace and with policy-based routing so applications can communicate through the VNIC with hosts outside the VNIC's subnet. This policy-based routing has effect only if the packets are sourced from the IP address of the secondary VNIC. The ability to bind to a specific source IP address or source interface exists in most tools (such as ssh, ping, and wget) and libraries that initiate connections. For example, the `ssh -b` option lets you bind to the private IP address of the secondary VNIC:

```
ssh -b <secondary_VNIC_IP_address> <destination_IP_address>
```

Be aware that if traffic comes in to a service on the instance through a secondary VNIC's interface and the service replies, the reply packets automatically have the VNIC's interface IP address as the source IP address. Policy-based routing is required for that reply to go back out on the same interface and find the correct default gateway.

- **A separate namespace**: If you're familiar with namespaces, you can instead configure the secondary VNIC in another namespace of your choice by running the script with the `-n` option. A separate namespace is required when an instance has secondary VNICs that are attached to subnets in different VCNs, and those subnets have overlapping CIDR blocks.

- **Secondary private IPs**: The instance metadata does not include information about any secondary private IPs assigned to the instance. To include that as part of the script's OS configuration, you must provide the secondary private IP address and OCID at the command line when you run the script.
• **Removal of a secondary VNIC:** After deleting a secondary VNIC from an instance, running the script removes the VNIC's information from the OS configuration.

  **Important:**
  The script uses a simple configuration process that does not persist if you reboot the instance. If you use the script, make sure to rerun it after each reboot.

Here are basic examples of how to run the script:

• `<script_name> -c`: Configure (adds or deletes) secondary VNIC host IP configuration
• `<script_name> -c -n`: Same but uses separate namespaces
• `<script_name> -d`: Force removes all secondary VNIC host IP configuration

See the script's help for more information.

**Important:**
This script is intended for use in situations where non-hypervisor compute instances need to be assigned an additional VNIC and IP address.

For Kernel-based Virtual Machine (KVM) applications on a bare metal instance, refer to the white paper "Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC."

**Tip:**
Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#linux.

---

**Windows: Configuring the OS for Secondary VNICs**

Secondary VNICs are supported on VM and bare metal instances (except for instances that use previous generation Standard1 and StandardB1 shapes). For bare metal instances, secondary VNICs are supported only on the second physical NIC.

**Tip:**
The first physical NIC is NIC 0, and the second is NIC 1.

You must configure the secondary VNIC within the OS. There's an Oracle-provided PowerShell script that performs configuration. When running the script, you can optionally provide the secondary VNIC's OCID (which you can get from the instance's VNIC metadata):

```powershell
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
```

Otherwise, the script shows a list of the secondary VNICs on the instance and asks you to choose the one you want to configure. Here's generally what the script does:

1. The script checks if the network interface has an IP address and a default route.
2. To enable the OS to recognize the secondary VNIC, the script must overwrite the IP address and default route with static settings (which effectively disables DHCP). The script prompts you with a choice: to overwrite with the static settings, or exit.

**Tip:**
Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#windows.
Networking

The overall process for configuration varies slightly depending on the type of instance (VM or bare metal) and how many secondary VNICs you add to the instance.

**Windows VM instances**

Here's the overall process:

1. **Add one or more secondary VNICs** to the instance. Keep each VNIC's OCID handy so you can provide it later when you run the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
3. Run the script:
   a. Open PowerShell as an administrator.
   b. Run the script with the secondary VNIC's OCID:
      ```powershell
      \secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
      ```
4. Repeat the preceding step for each additional secondary VNIC.

**Windows bare metal instances: adding the first secondary VNIC**

If you're adding only a single secondary VNIC to the bare metal instance, here's the overall process:

1. **Add the secondary VNIC** to your instance. Keep the VNIC's OCID handy so you can provide it when later running the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
3. Enable the second physical NIC on the instance:
   a. Open the Device Manager, and then click **Network adapters**.
   b. Right-click the adapter that corresponds to the instance's second physical NIC, and click **Enable**.
4. Run the script:
   a. Open PowerShell as an administrator.
   b. Run the script with the secondary VNIC's OCID:
      ```powershell
      \secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
      ```
   c. When the script prompts you to overwrite the network interface's settings, say yes.

**Windows bare metal instances: adding additional secondary VNICs**

If you have one secondary VNIC on the second physical NIC of a bare metal instance, and you want to one or more additional VNICs, here's the overall process. It includes a task for setting up NIC teaming, which is required if the instance has more than one VNIC on the second physical NIC.

*Note:* If you increase the number of secondary VNICs on the second physical NIC from one to two or more, you must enable NIC teaming for the second physical NIC (see instructions that follow). In your NIC "team," you create a separate interface for *each* secondary VNIC on that physical NIC, including the initial one. This means that the original interface for that first secondary VNIC will no longer work, and any subsequent configuration you want to do for that VNIC must be done instead on the VNIC's new interface that's part of the "team".

1. **Add one or more additional secondary VNICs** to your instance. Keep each VNIC's OCID and VLAN tag handy so you can provide them when later running the configuration script. You can also get the values from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
3. Set up NIC teaming on the instance:
   a. Open the Server manager, and then click Local Server.
   b. In the list of properties, locate NIC Teaming, and then click Disabled to enable and set up NIC teaming.
   c. In the Teams section on the lower-left side of the screen, click Tasks, and then click New Team.
   d. Enter a name for the team, select the check box for the second physical NIC on the instance, and click OK.

   The new team is created and appears in the list of teams in the Teams section.
   e. Click the new team so it's selected, and then in the Adapters and Interfaces section on the right side of the screen, click the Team Interfaces tab.
   f. Click Tasks, and then click Add Interface (you will create a separate interface for each secondary VNIC on the second physical NIC).
   g. Click the radio button for Specific VLAN, and then enter the Oracle-assigned VLAN tag number for the VLAN (for example, 1). You can get the VLAN tag from the Console or the instance's VNIC metadata.
   h. Click OK.
   i. Repeat the four preceding steps (e-h) for each of the other secondary VNICs. You create a separate interface for each secondary VNIC.

4. Run the script:
   a. Open PowerShell as an administrator.
   b. For the first secondary VNIC, run the script with the secondary VNIC's OCID:

   ```
   .\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
   ```
   c. When the script prompts you to overwrite the network interface's settings, say yes.
   d. Repeat the preceding two steps (b and c) for each of the additional secondary VNICs.

**IP Addresses and DNS in Your VCN**

These topics cover how your instances are assigned private and public IP addresses, and the use of DNS within your cloud network.

- Private IP Addresses on page 3742
- Public IP Addresses on page 3753
- Bring Your Own IP on page 3760
- IP Pools on page 3766
- IPv6 Addresses on page 3768
- DNS in Your Virtual Cloud Network on page 3781

**Private IP Addresses**

This topic describes how to manage the IPv4 addresses assigned to an instance in a virtual cloud network (VCN).

IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

**Overview of IP Addresses**

Instances use IP addresses for communication. Each instance has at least one private IP address and optionally one or more public IP addresses. A private IP address enables the instance to communicate with other instances inside the VCN, or with hosts in your on-premises network (via Site-to-Site VPN or Oracle Cloud Infrastructure FastConnect). A public IP address enables the instance to communicate with hosts on the internet. For more information, see these related topics:

- Public vs. Private Subnets on page 3609
- How IP Addresses Are Assigned on page 3609
- Public IP Addresses on page 3753
About the Private IP Object

The Networking service defines an object called a private IP, which consists of:

- Private IPv4 address, assigned by either you or Oracle.
- Optional hostname for DNS (see DNS in Your Virtual Cloud Network on page 3781).

Each private IP object has an Oracle-assigned OCID (see Resource Identifiers). If you’re using the API, you can also assign each private IP object a friendly name.

Each instance receives a primary private IP object during launch. The Networking service uses the Dynamic Host Configuration Protocol (DHCP) to pass the object's private IP address to the instance. This address does not change during the instance's lifetime and cannot be removed from the instance. The private IP object is terminated when the instance is terminated.

If an instance has any secondary VNICs attached, each of those VNICs also has a primary private IP.

A private IP can have a public IP assigned to it at your discretion.

A private IP can be the target of a route rule in your VCN. For more information, see Using a Private IP as a Route Target on page 3703.

About Secondary Private IP Addresses

You can add a secondary private IP to an instance after it's launched. You can add it to either the primary VNIC or a secondary VNIC on the instance. The secondary private IP address must come from the CIDR of the VNIC’s subnet. You can move a secondary private IP from a VNIC on one instance to a VNIC on another instance if both VNICs belong to the same subnet.

Here are a few reasons why you might use secondary private IPs:

- **Instance failover:** You assign a secondary private IP to an instance. Then if the instance has problems, you can easily reassign that secondary private IP to a standby instance in the same subnet. If the secondary private IP has a public IP assigned to it, that public IP moves along with the private IP.

- **Running multiple services or endpoints on a single instance:** For example, you could have multiple container pods running on a single instance, and each uses an IP address from the VCN’s CIDR. The containers have direct connectivity to other instances and services in the VCN. Another example: you could run multiple SSL websites with each one using its own IP address.

Here are more details about secondary private IP addresses:

- They're supported for all shapes and OS types, for both bare metal and VM instances.
- A VNIC can have a maximum of 31 secondary private IPs.
- They can be assigned only after the instance is launched (or the secondary VNIC is created/attached).
- A secondary private IP that is assigned to a VNIC in a regional subnet has a null availability domain attribute. Compare this with the VNIC’s primary private IP, which always has its availability domain attribute set to the instance’s availability domain, regardless of whether the instance's subnet is regional or AD-specific.
- Deleting a secondary private IP from a VNIC returns the address to the pool of available addresses in the subnet.
- They are automatically deleted when you terminate the instance (or detach/delete the secondary VNIC).
- The instance's bandwidth is fixed regardless of the number of private IP addresses attached. You can't specify a bandwidth limit for a particular IP address on an instance.
- A secondary private IP can have a reserved public IP assigned to it at your discretion.

IP Address Information in the Instance Metadata

The instance metadata includes information about the private IP addresses at this URL:

Here's an example response:

```
[ {
  "vnicId" : "ocid1.vnic.oc1.sea.<unique_ID>",
  "privateIp" : "10.0.3.6",
  "vlanTag" : 11,
  "macAddr" : "00:00:00:00:00:01",
  "virtualRouterIp" : "10.0.3.1",
  "subnetCidrBlock" : "10.0.3.0/24"
 }, {
  "vnicId" : "ocid1.vnic.oc1.sea.<unique_ID>",
  "privateIp" : "10.0.4.3",
  "vlanTag" : 12,
  "macAddr" : "00:00:00:00:00:01",
  "virtualRouterIp" : "10.0.4.1",
  "subnetCidrBlock" : "10.0.4.0/24"
 } ]
```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Using the Console

*To view an instance's private IPs*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.

   The primary VNIC and any secondary VNICS assigned to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under Resources, click IP Addresses.

   The VNIC's primary private IP and any secondary private IPs are displayed.

*To assign a new secondary private IP to a VNIC*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.

   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under Resources, click IP Addresses.

   The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click Assign Secondary Private IP Address.
8. Enter the following:

   • **Private IP Address**: Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
   
   • **Unassign if already assigned to another VNIC**: Select this check box to force reassignment of the IP address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a private IP address in the preceding field.
   
   • **Hostname**: Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See [DNS in Your Virtual Cloud Network](#) on page 3781.
   
   • **Public IP Type**: Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See [Public IP Addresses](#) on page 3753.

9. Click **Assign**.

   The secondary private IP is created and then displayed on the **IP Addresses** page for the VNIC.

10. Configure the IP address:

    - For instances running a variant of Linux, see [Linux: Details about Secondary IP Addresses](#) on page 3746.
    
    - For Windows instances, see [Windows: Details about Secondary IP Addresses](#) on page 3748.

*To move a secondary private IP to another VNIC in the same subnet*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click **Assign Secondary Private IP Address**.
8. Enter the following:

   • **Private IP Address**: The secondary private IP address you want to move.

   • **Unassign if already assigned to another VNIC**: Select this check box to move the secondary IP address from the VNIC it's currently assigned to.

   • **Hostname**: Optional. The hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See [DNS in Your Virtual Cloud Network](#) on page 3781.

   • **Public IP Type**: Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See [Public IP Addresses](#) on page 3753.

9. Click **Assign**.

   The private IP address is moved from the original VNIC to the new VNIC.

*To update the hostname for an existing private IP*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the IP address you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. Make your changes and click **Update**.
To delete a secondary private IP from a VNIC

**Caution:**
If the private IP is the target of a route rule, deleting it from the VNIC causes the route rule to blackhole and the traffic will be dropped.

Prerequisite: Oracle recommends removing the IP address from the OS configuration before deleting it from the VNIC. See Linux: Details about Secondary IP Addresses on page 3746 or Windows: Details about Secondary IP Addresses on page 3748.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.
   - The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you want to delete, click the Actions icon (three dots), and then click **Delete Private IP**.
8. Confirm when prompted.

The private IP address is returned to the pool of available addresses in the subnet.

**To manage tags for a private IP**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.
   - The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 239.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage private IPs on a VNIC, use these operations:

- **GetPrivateIp**: Use this to get a single `privateIp` object by specifying its OCID.
- **ListPrivateIps**: Use this to get a single `privateIp` object by specifying the private IP address (for example, `10.0.3.3`) and the subnet's OCID. Or you can list all the `privateIp` objects in a given subnet, or just the ones assigned to a given VNIC.
- **CreatePrivateIp**: Use this to assign a new secondary private IP to a VNIC.
- **UpdatePrivateIp**: Use this to reassign a secondary private IP to a different VNIC in the same subnet, or to update the hostname or display name of a secondary private IP.
- **DeletePrivateIp**: Use this to delete a secondary private IP from a VNIC. The private IP address is returned to the subnet's pool of available addresses.

**Linux: Details about Secondary IP Addresses**

After assigning a secondary private IP to a VNIC, you must configure the OS to use it.
**Basic Commands (Not Persistent Through a Reboot)**

On the instance, run the following command. It works on all variants of Linux, for both bare metal and VM instances:

```
ip addr add <address>/<subnet_prefix_len> dev <phys_dev>
label <phys_dev>:<addr_seq_num>
```

where:
- `<address>`: The secondary private IP address.
- `<subnet_prefix_len>`: The subnet's prefix length. For example, if the subnet is 192.168.20.0/24, the subnet prefix length is 24.
- `<phys_dev>`: The interface to add the address to (for example, ens2f0).
- `<addr_seq_num>`: The sequential number in the stack of addresses on the device (for example, 0).

For example:

```
ip addr add 192.168.20.50/24 dev ens2f0 label ens2f0:0
```

Later if you want to delete the address, you can use:

```
ip addr del 192.168.20.50/24 dev ens2f0:0
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

**Note:**

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**Configuration File (Persistent Through a Reboot)**

You can make the configuration persistent through a reboot by adding the information to a configuration file.

**For Oracle Linux and CentOS**

Create an `ifcfg` file named `/etc/sysconfig/network-scripts/ifcfg-<phys_dev>:<addr_seq_num>`. To continue with the preceding example, the file name would be `/etc/sysconfig/network-scripts/ifcfg-ens2f0:0`, and the contents would be:

```
DEVICE="ens2f0:0"
BOOTPROTO=static
IPADDR=192.168.0.50
NETMASK=255.255.255.0
ONBOOT=yes
```

**Note:**

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**For Ubuntu**

```
auto <phys_dev>:<addr_seq_num>
iface <phys_dev>:<addr_seq_num> inet static
dev <address>
etmask <address_netmask>
```
Where the netmask is not the prefix but the 255.255.x.x. address.

To continue with the earlier example:

```bash
auto ens2f0:0
iface ens2f0:0 inet static
   address 192.168.0.50
   netmask 255.255.255.0
```

**Note:**

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

### Windows: Details about Secondary IP Addresses

After assigning a secondary private IP to a VNIC, you must configure the OS to use it. Here are instructions for using a PowerShell script or the Network and Sharing Center UI.

**Using a PowerShell Script**

You must run PowerShell as an administrator. The script configures two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   ```bash
   ipconfig /all
   ```
3. Note the values for the following items so you can enter them into the script in the next step:
   - Default Gateway
   - DNS Servers
4. Replace the variables in the following PowerShell script with your own values:

   ```powershell
   $netadapter = Get-NetAdapter -Name "Ethernet 2"
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress <secondary_IP_address> -PrefixLength <subnet_prefix_length> -Type Unicast -DefaultGateway <default_gateway>
   Set-DnsClientServerAddress -InterfaceAlias "Ethernet 2" -ServerAddresses <DNS_server>
   ```

   For example:

   ```powershell
   $netadapter = Get-NetAdapter -Name "Ethernet 2"
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress 192.168.0.14 -PrefixLength 24 -Type Unicast -DefaultGateway 192.168.0.1
   Set-DnsClientServerAddress -InterfaceAlias "Ethernet 2" -ServerAddresses 203.0.113.254
   ```
5. Save the script with the name of your choice and a .ps1 extension, and run it on the instance.

If you run `ipconfig /all` again, you'll see that DHCP has been disabled and the secondary private IP address is included in the list of IP addresses.

Later if you want to delete the address, you can use this command:

```
Remove-NetIPAddress -IPAddress 192.168.11.14 -InterfaceAlias Ethernet
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

**Using the Network and Sharing Center UI**

The following instructions configure two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   ```
   ipconfig /all
   ```

3. Note the values for the following items so you can enter them elsewhere in a later step:
   - IPv4 Address
   - Subnet Mask
   - Default Gateway
   - DNS Servers

4. In the instance's **Control Panel**, open the **Network and Sharing Center** (see the image below for the set of dialog boxes you'll see in these steps).

5. For the active networks, click the connection (**Ethernet**).

6. Click **Properties**.

7. Click **Internet Protocol Version 4 (TCP/IPv4)**, and then click **Properties**.
8. Select the radio button for **Use the following IP address**, and then enter the values you noted earlier for the IP address, subnet mask, default gateway, and DNS servers.

9. Click **Advanced**....

10. Under **IP addresses**, click **Add**....
11. Enter the secondary private IP address and the subnet mask you used earlier and click **Add**.

12. Click **OK** until the Network and Sharing Center is closed.
13. Verify the changes by returning to the command prompt and running `ipconfig /all`.

You should now see that DHCP is disabled (static IP addressing is enabled), and the secondary private IP address is in the list of addresses displayed. The address is now configured on the instance and available to use.

![Image of PowerShell output]

**Note:**

You might not see the primary private IP address when you again view the properties for Internet Protocol Version 4 (TCP/IPv4) in the Network and Sharing Center UI. The best way to confirm your changes is to use `ipconfig /all` at the command line.

### Public IP Addresses

This topic describes how to manage public IPv4 addresses on instances in a virtual cloud network (VCN).

IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

**Overview of Public IP Addresses**

A public IP address is an IPv4 address that is reachable from the internet. If a resource in your tenancy needs to be directly reachable from the internet, it must have a public IP address. Depending on the type of resource, there might be other requirements.

Certain types of resources in your tenancy are designed to be directly reachable from the internet and therefore automatically come with a public IP address. For example: a NAT gateway or a public load balancer. Other types of resources are directly reachable only if you configure them to be. For example: instances in your VCN.

This topic focuses on these subjects:

- The types of public IP addresses and their characteristics
- How to control whether an instance has a public IP address
For more information about resources that automatically get a public IP address, see Overview of Public IP Addresses on page 3753.

**Instances and Public IP Addresses**

You can assign a public IP address to an instance to enable communication with the internet. The instance is assigned a public IP address from the Oracle Cloud Infrastructure address pool.

The assignment is actually to a **private IP** object on the instance. The **VNIC** that the private IP is assigned to must be in a **public subnet**. A given instance can have multiple secondary VNICs, and a given VNIC can have multiple secondary private IPs. So you can assign a given instance multiple public IPs across one or more VNICs if you like.

For an instance to communicate directly with the internet, all of the following are required:

- The instance must be in a **public subnet**.
- The instance must have a public IP address.
- The instance's VCN must have an **internet gateway**.
- The public subnet must have route tables and security lists configured accordingly.

**Tip:**

Oracle Cloud Infrastructure FastConnect public peering lets your on-premises network access the public IP addresses of resources in Oracle Cloud Infrastructure **without the traffic traversing the internet**. For more information, see **FastConnect** on page 4051.

**The Public IP Object**

The Networking service defines an object called a **public IP**, which consists of these items:

- Public IPv4 address (chosen by Oracle)
- Properties that further define the public IP's type and behavior

Each public IP object has an Oracle-assigned OCID (see Resource Identifiers). If you're using the API, you can also assign each public IP object a friendly name.

**Types of Public IPs**

There are two types of public IPs:

- **Ephemeral**: Think of it as temporary and existing for the lifetime of the instance.
- **Reserved**: Think of it as persistent and existing beyond the lifetime of the instance it's assigned to. You can unassign it and then reassign it to another instance whenever you like. Exception: reserved public IPs on public load balancers. See Overview of Public IP Addresses on page 3753.

The following table summarizes the differences between the two types.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Ephemeral Public IPs</th>
<th>Reserved Public IPs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allowed assignment</td>
<td>To a VNIC's <strong>primary private IP</strong> only</td>
<td>To either a primary or secondary <strong>private IP</strong></td>
</tr>
<tr>
<td></td>
<td>Limits:</td>
<td>Limit: 32 per <strong>VNIC</strong></td>
</tr>
<tr>
<td></td>
<td>• One per <strong>VNIC</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Two per VM instance, and 16 per bare metal instance</td>
<td></td>
</tr>
<tr>
<td>Characteristic</td>
<td>Ephemeral Public IPs</td>
<td>Reserved Public IPs</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Creation</td>
<td>Optionally created and assigned during instance launch or secondary VNIC creation. You can create and assign one later if the VNIC doesn't already have one.</td>
<td>You create one at any time. You can then assign it when you like. Limit: You can create 50 per region</td>
</tr>
<tr>
<td>Unassignment</td>
<td>You can unassign it at any time, which deletes it. You might do this if whoever launched the instance included a public IP, but you don't want the instance to have one. When you stop an instance, its ephemeral public IPs remain assigned to the instance.</td>
<td>You can unassign it at any time, which returns it to your tenancy's pool of reserved public IPs.</td>
</tr>
<tr>
<td>Moving to a different resource</td>
<td>You cannot move an ephemeral public IP to a different private IP.</td>
<td>If assigned to a secondary private IP: If you move the private IP to a different VNIC (must be in the same subnet), the reserved public IP goes with it. You can move it (unassign and then reassign it) at any time to another private IP in the same region. Can be in a different VCN or availability domain.</td>
</tr>
<tr>
<td>Automatic deletion</td>
<td>Its lifetime is tied to the private IP's lifetime. Automatically unassigned and deleted when: • Its private IP is deleted • Its VNIC is detached or terminated • Its instance is terminated</td>
<td>Never. Exists until you delete it.</td>
</tr>
<tr>
<td>Scope</td>
<td>Availability domain</td>
<td>Regional (can be assigned to a private IP in any availability domain in the region)</td>
</tr>
<tr>
<td>Compartment and availability domain</td>
<td>Same as the private IPs</td>
<td>Can be different from the private IPs</td>
</tr>
</tbody>
</table>

When you launch an instance in a public subnet, by default, the instance gets a public IP unless you say otherwise. See To choose whether an ephemeral public IP is assigned when launching an instance on page 3756.

After you create a given public IP, you can't change which type it is. For example, if you launch an instance that is assigned an ephemeral public IP with address 203.0.113.2, you can't convert the ephemeral public IP to a reserved public IP with address 203.0.113.2.

The preceding table notes the public IP limits per VNIC and instance. If you try to perform any operation that assigns or moves a public IP to a VNIC or instance that has already reached its public IP limit, an error is returned. The operations include:

- Assigning a public IP
Networking

- Creating a new secondary VNIC with a public IP
- Moving a private IP with a public IP to another VNIC
- Moving a public IP to another private IP

Resources That Always Get a Public IP

As mentioned earlier, certain types of resources are designed to be directly reachable from the internet. Examples: a NAT gateway or a public load balancer. These resources automatically get a public IP address upon creation. Oracle chooses the public IP address from the Oracle pool. You can't remove or change the address.

For public load balancers, the address can be either a regional reserved public IP address that you create from a pool and assign to the load balancer at creation time, or an ephemeral public IP address assigned by Oracle for the life of the load balancer. When the load balancer is no longer needed, the ephemeral IP address is returned to the pool of available addresses, but the reserved IP address can be moved to a different resource. While active, this public IP appears in the list of your tenancy's reserved public IPs, which you can view in the Console.

For NAT gateways, the address is a regional ephemeral public IP that is assigned to the NAT gateway. Like other ephemeral public IPs, it's automatically unassigned and deleted when you terminate its assigned resource (the NAT gateway). However, unlike other ephemeral public IPs, you can't edit it or unassign it yourself.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Ephemeral Public IPs: Using the Console

To choose whether an ephemeral public IP is assigned when launching an instance

When you launch an instance into a public subnet, there's an Assign a public IPv4 address check box on the Create Compute Instance page. By default, the check box is selected, which means the instance gets an ephemeral public IP.

If you do NOT want an ephemeral public IP assigned, you can either:

- Select the Do not assign a public IPv4 address option
- Delete the ephemeral public IP after instance launch

To assign an ephemeral public IP when creating a secondary VNIC

When you add a secondary VNIC to an instance, you choose whether the primary private IP on the new VNIC gets an ephemeral public IP. This choice is available only if the secondary VNIC is in a public subnet.

In the Create VNIC dialog box, there's an Assign a public IPv4 address check box. By default, the check box is NOT selected, which means the secondary VNIC does not get an ephemeral public IP. You must select the check box.

For instructions, see Connectivity Choices on page 3609.

To assign an ephemeral public IP to an existing primary private IP

Prerequisite: The primary private IP must not have a reserved or ephemeral public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.
   - The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, for **Public IP type**, select the radio button for **Ephemeral Public IP**.

9. In the **Ephemeral Public IP Name** field, enter an optional friendly name for the public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.

10. Click **Update**.

**To delete an ephemeral public IP from an instance**

Deleting an ephemeral public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.

   The primary VNIC and any secondary VNICS attached to the instance are displayed.

5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.

9. Click **Update**.

**To change the display name for an ephemeral public IP**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.

   The primary VNIC and any secondary VNICS attached to the instance are displayed.

5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, edit the **Ephemeral Public IP Name**. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.

9. Click **Update**.

**Reserved Public IPs: Using the Console**

**To view your reserved public IPs**

1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click **Networking**. Under **IP Management**, click **Reserved IPs**.

   The details of the reserved public IPs in the selected region and compartment are displayed. If the reserved public IP is assigned, there's a link to the relevant VNIC.

**To create a new reserved public IP in your pool**

1. Confirm you're viewing the region and compartment where you want to create the reserved public IP.
2. Open the navigation menu and click **Networking**. Under **IP Management**, click **Reserved IPs**.
3. Click **Create Reserved Public IP**.
4. Enter the following:
   - **Name**: An optional friendly name for the reserved public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Compartment**: Leave as is.
   - **IP Pool**: (optional) The IP pool the reserved public IP is drawn from. If you don't select a pool you've created, the default Oracle pool is used.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Reserved Public IP**.

The new reserved public IP is created and displayed on the page. You can now assign it to an existing private IP if you like.

**To delete a reserved public IP from your pool**

The reserved public IP can be in the "Assigned" state. Deleting a reserved public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu and click **Networking**. Under IP Management, click **Reserved IPs**.
3. For the reserved public IP you want to delete, click the Actions icon (three dots), and then click **Terminate**.
4. Confirm when prompted.

After a few seconds, the reserved public IP is unassigned (if it was assigned) and deleted from your pool.

**To assign a reserved public IP to a private IP**

Prerequisite: The private IP must not have an ephemeral or reserved public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance with the private IP you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Type** section, select the radio button for **Reserved Public IP**.
9. For **Reserved Public IP**, enter the reserved public IP you want to assign. You have three choices:
   - Create a new reserved public IP. You can optionally provide a friendly name for it. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Assign a reserved public IP that isn't already assigned.
   - Move a reserved public IP from another private IP.
10. Click **Update**.

**To unassign a reserved public IP and return it to the pool**

1. Confirm you're viewing the compartment that contains the instance with the reserved public IP you're interested in.
2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
9. Click **Update**.

The reserved public IP is unassigned and returned to your pool.

**To move a reserved public IP from one private IP to another**

Let's say you want to move a reserved public IP from private IP 1 to private IP 2. In summary: Make sure private IP 2 doesn't have a public IP already assigned to it. Then assign the reserved public IP to private IP 2. It will be automatically unassigned from private IP 1 first. Detailed instructions:

1. Confirm you're viewing the compartment that contains the instance with private IP 2.
2. Open the navigation menu and click **Compute**, Under **Compute**, click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For private IP 2, click the Actions icon (three dots), and then click **Edit**.
8. If private IP 2 already has a public IP assigned to it:
   a. In the **Public IP Type** section, select the radio button for **No Public IP**.
   b. Click **Update**.
   c. Again for private IP 2, click the Actions icon (three dots), and then click **Edit**.
9. In the **Public IP Type** section, select the radio button for **Reserved Public IP**.
10. In the **Reserved Public IP** list, select the reserved public IP that you want to assign. It will be moved from the public IP it's currently assigned to.
11. Click **Update**.

**To change the display name for a reserved public IP**

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu and click **Networking**, Under **IP Management**, click **Reserved IPs**.
3. For the reserved public IP you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. Make your changes to the friendly name. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
5. Click **Save**.

**To manage tags for a reserved public IP**

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu and click **Networking**, Under **IP Management**, click **Reserved IPs**.
3. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 239.
To move a reserved public IP to a different compartment

You can move a reserved public IP from one compartment to another. When you move a reserved public IP to a new compartment, inherent policies apply immediately.

1. Open the navigation menu and click Networking. Under IP Management, click Reserved IPs.
2. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage public IPs, use these operations:

- **GetPublicIp**: Use this to get a publicIp object by specifying its OCID.
- **GetPublicIpByIpAddress**: Use this to get a publicIp object by specifying its public IP address.
- **GetPublicIpByPrivateIpId**: Use this to get a publicIp object by specifying the OCID of the private IP it’s assigned to.
- **ListPublicIps**: Use this to list either your ephemeral or reserved publicIp objects.
- **CreatePublicIp**: Use this to create a new reserved public IP in your pool.
- **UpdatePublicIp**: Use this to assign, reassign, or unassign a reserved public IP, or to update the display name of an ephemeral or reserved public IP. You can also update a reserved public IP’s tags.
- **DeletePublicIp**: Use this to delete an ephemeral public IP from its private IP, or delete a reserved public IP from your pool. The operation first unassigns the public IP.
- **ChangePublicIpCompartment**: Use this to move a reserved public IP from one compartment to another. This operation applies only to reserved public IPs. Ephemeral public IPs always belong to the same compartment as their VNIC and move accordingly.

Bring Your Own IP

Oracle Cloud Infrastructure allows you to Bring Your Own IP (BYOIP) address space to use with resources in Oracle Cloud Infrastructure, in addition to using Oracle owned addresses. BYOIP lets you manage your IPv4 CIDR blocks to align with your existing security, management, and deployment policies and achieve:

- **Solution continuity and hardcoded dependencies**: Your VCN is an extension of your public Internet presence, without needing to reinvent policies and management processes. If you have IP addresses hard-coded in devices or built architectural dependencies on specific IP addresses, using BYOIP you have a smooth migration to Oracle Cloud Infrastructure.
- **IP pool management**: Some network administrators require the ability to summarize groups of IP addresses into pools and to create resources for deployment such as load balancers, firewalls, or web servers. IP Pool management provides tools to manage reserved public IP addresses.
- **IP reputation**: Some Internet services rely on a contiguous IP address space (such as a full span of IP addresses from 1 through 255) and act as a trusted contact point between services such as major email service providers and mail delivery systems.

Oracle performs a validation process on imported CIDR blocks, and after validation you are notified that the CIDR block is available for advertisement. You can also create one or many public IP pools from this address space by specifying subranges from the BYOIP CIDR block and use IP pools to allocate specific resources. You can start or stop advertisement of the BYOIP routes when needed.

Requirements and Preparation

- You must have ownership of the public IPv4 CIDR block you want to import into Oracle Cloud Infrastructure, and the ownership must be registered with a supported Regional Internet Registry (RIR). Oracle validates
ownership of your addresses. Only the following registries are supported, and the addresses must have a specified type or status:

- **American Registry for Internet Numbers** (ARIN) - "Direct Allocation" and "Direct Assignment" network types
- **Réseaux IP Européens Network Coordination Centre** (RIPE NCC) - "ALLOCATED PA," "LEGACY," "ASSIGNED PI," and "ALLOCATED-BY-RIR" allocation statuses
- **Asia-Pacific Network Information Centre** (APNIC) – "ALLOCATED PORTABLE" and "ASSIGNED PORTABLE" allocation statuses
- The addresses in the IP address range must have a clean history. We might investigate the reputation of the IP address range and reserve the right to reject an IP address range that contains an IP address that is associated with malicious behavior.

**Limits and Quotas**

- Your addresses can only be imported to a specific Oracle region.
- You can use BYOIP with an IPv4 CIDR block that is a minimum of /24 and a maximum of /8.
- You can't bring the same address range to more than one compartment at a time.
- You can bring up to 10 IPv4 address ranges to your Oracle Cloud Infrastructure account.
- BYOIP is not available with Oracle Cloud Infrastructure Free Tier or Pay As You Go services.

**BYOIP Process Overview**

The steps needed for BYOIP in Oracle Cloud Infrastructure require significant time, so plan accordingly. The process is shown in the following diagram:
1. You request to import a public IPv4 CIDR block you own.
2. Oracle issues a verification token.
3. You modify and add the verification token to the information about that public IPv4 CIDR block kept by your RIR service. The details vary depending on the RIR. It can take up to one day for the update to take effect. If you move to the next step before that update takes effect, a day will be added to the total time to complete the process. See To import a BYOIP CIDR block on page 3763 for details.
4. Create a Route Origin Authorization (ROA) with your RIR. As part of the ROA, provide the Oracle BGP ASN (31898 for the commercial cloud). This allows Oracle to advertise the BYOIP CIDR block.
5. Request that Oracle finish the import request, creating a workflow that could take up to 10 business days to complete, where Oracle communicates with the RIR and verifies that you own the IP addresses in the CIDR block.
6. Oracle provisions the BYOIP CIDR block to your VCN.
7. At this point, the BYOIP CIDR block is yours to manage in your VCN. You can add addresses to an IP pool, and then use them as reserved IP addresses. You can also advertise the IP addresses to the internet.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: see IAM Policies for Networking on page 3709.

**Limits on IAM Resources**

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Managing BYOIP using the console**

*To import a BYOIP CIDR block*

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.
3. Click **Import BYOIP CIDR Block**. The **Import BYOIP CIDR Block** screen appears.
4. In the **Import BYOIP CIDR Block** screen, enter a name for the BYOIP CIDR Block, choose the compartment, and enter the CIDR block you intend to bring to your tenancy. Avoid entering confidential information.
5. Click **Save Changes**. The details page for that BYOIP import request appears.
6. In the **Next Steps** section, make a copy of the validation token. Modify the token slightly, adding the following information as shown. You can use any text editor.

```
OCITOKEN::<CIDRblock>::<validation_token>
```

The completed token string might look something like: `OCITOKEN::10.0.0.0/24:abcdefghij`

7. Create a Route Origin Authorization (ROA) object that authorizes Oracle to advertise the BYOIP CIDR block. The Oracle BGP ASN is 31898 for the commercial cloud. For the US Government Cloud, see Oracle's BGP ASN on page 180. Set an expiry date at least 6 months in the future. Follow the instructions appropriate for your RIR.
   - **ARIN:** ROA Requests
   - **RIPE NCC:** Managing ROAs
   - **APNIC:** Route/ROA management

   **Note:**
   If you do not create an ROA, Oracle can't advertise the BYOIP CIDR block. Without being able to advertise the routes, there may be little point in importing them.

8. Now add the modified validation token to the RIR account information associated with your address range. Each RIR uses a slightly different method:
   - **ARIN:** Add the modified token string in the "Public Comments" section associated with your address range.
   - **RIPE NCC:** Add the modified token string as a new "descr" field associated with your address range.
   - **APNIC:** Add the modified token string to the "remarks" field for your address range by emailing it to helpdesk@apnic.net. The email must be sent from the APNIC authorized contact account for the IP address range.

   **Note:**
   The modified validation string must be associated with the address range information. Do not add it to the information for the organization that owns the address range.
9. Wait until both the ROA and the token registration is complete (up to a day) before you click the **Finish Import** button. Otherwise, the process can be delayed up to one day.

10. Return to the details page for the BYOIP request and click **Finish Import**. A confirmation screen appears.

11. Click **Finish Import**, confirming that you would like to validate the BYOIP request. Allow up to 10 business days for Oracle to contact your RIR, validate the import, and provision the CIDR block. View the work requests to see the status.

**To view your BYOIP CIDR blocks**

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.

**To rename a BYOIP CIDR block**

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Click **Rename**. A window appears.
5. In the window, enter the new name. Avoid entering confidential information.
6. Click **Save Changes**.

**To remove a BYOIP CIDR block from a pool**

**Note:**

To successfully remove a BYOIP CIDR block from a pool, there must be no reserved public IP addresses in that address range. You may have to terminate one or more reserved public IP addresses.

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Click on the Action Icon corresponding to the subrange you want to remove from a public IP pool, and then click on **Remove from Public IP Pool**. A confirmation window appears.
5. If you are sure you want to delete the BYOIP CIDR block, click on **Remove CIDR Block**.

**To delete a BYOIP CIDR block**

To successfully delete a BYOIP CIDR block, it must be in the CREATING, PROVISIONED, ACTIVE, or FAILED state, and it must not have any subranges added to public IP pools.

**Note:**

If you delete a BYOIP CIDR block, you need to repeat the import process to undo your action.

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Click **Delete**. A confirmation window appears.
5. If you are sure you want to delete the BYOIP CIDR block, click **Delete BYOIP CIDR block**.

**To advertise a BYOIP CIDR block**

A BYOIP CIDR block must be provisioned before it can be advertised.

**Note:**

The BYOIP CIDR block is advertised using a BGP ASN owned by Oracle. Oracle's BGP ASN for the commercial cloud is 31898.

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click BYOIP.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Click Advertise. A confirmation window appears.
5. In the confirmation window, click Advertise.

**To withdraw a BYOIP CIDR block**

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click BYOIP.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Click Withdraw. A confirmation window appears.
5. In the confirmation window, click on Withdraw.

**To divide a BYOIP CIDR block and assign subranges to a public IP pool**

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click BYOIP.
3. Click the name of the BYOIP CIDR block you're interested in.
4. Scroll down to the BYOIP CIDR Block Subranges section and click Manage BYOIP CIDR Block. The Manage BYOIP CIDR Blocks screen appears.
5. Either by entering a number for the CIDR suffix or using the up/down arrows next to the suffix, change the suffix number (often a /24). New rows in the table appear, representing possible subranges within the entire CIDR block.
6. For each of the newly created subranges of the BYOIP CIDR block, check the box in the first column of the table and click Add BYOIP CIDR Blocks to Public IP Pools.
   a. Choose whether to Select an Existing Public IP Pool or Create New Public IP Pool.
      - Select an Existing Public IP Pool: Choose an existing IP pool using the selection list.
      - Create New Public IP Pool: Assign the new pool a name and choose a compartment. You can move the public IP pool to another compartment later. Avoid entering confidential information.
   b. Click Add BYOIP CIDR Blocks to Public IP Pools
7. Repeat the previous step until all subranges of the BYOIP CIDR block are assigned to a public IP pool, then click Submit.

**Note:**
If a subrange of a BYOIP CIDR block is left unassigned to a pool, the table may look different after you click Submit.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage the ByoipRange object, use these operations:

- AdvertiseByoipRange
- ChangeByoipRangeCompartment
- CreateByoipRange
- DeleteByoipRange
- GetByoipRange
- ListByoipRanges
- UpdateByoipRange
- ValidateByoipRange
- WithdrawByoipRange
IP Pools

A public IP pool is simply a set of CIDR blocks allocated to a tenancy. These CIDR blocks can be all or part of a BYOIP CIDR block. Public IP CIDR blocks assigned to a pool are only available for your tenancy. Public IP pools are available as a source for IP allocation when launching a NAT gateway, load balancer, or compute instance. You can add more IP CIDR blocks to a public IP pool at any time. You can also:

- **Create a Reserved IP**: You can reserve individual IPs from your public IP pools. These reserved IP addresses can be attached to your resources.
- **Direct launch from pool**: You can launch resources with an IP directly allocated from a public IP pool without previously creating a reserved IP for that resource.
- **Delete CIDR blocks and pools**: You can delete the entire public IP pool or certain IP CIDR blocks within the pool, provided none of the IP addresses are currently attached or reserved.

Requirements and Preparation

- To use public IP pools with BYOIP addresses, you need to import your addresses.
- To reserve Oracle-supplied public IP addresses, select "Oracle" as the public IP pool when creating the reserved public IP address.

Limits and quotas

- You can create one or up to 10 public IP pools in a compartment.
- A public IP pool can have zero or more IP CIDR ranges assigned to it, with a minimum size of /28 to a maximum size of /24.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

Limits on IAM Resources

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing IP pools using the console

To view your public IP pools

1. Confirm you're viewing the region and compartment you're interested in.

To create a public IP pool

1. Confirm you're viewing the region and compartment you're interested in.
3. Click Create Public IP Pool.
   - Give the pool a name. Avoid entering confidential information.
   - Assign the Public IP pool to a compartment.
4. Click Create Public IP Pool.

To delete a public IP pool

1. Confirm you're viewing the region and compartment you're interested in.
3. Select a public IP pool from the list and click **Delete Public IP Pool**.
4. If there are no warnings or errors, click **Delete Public IP Pool**. If this public IP pool contains reserved public IP addresses currently in use, you can't delete the public IP pool.

**To rename a public IP pool**
1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **Public IP Pools**.
3. Click **Rename Public IP Pool**.
   - Enter a new name for the public IP pool. Avoid entering confidential information.
4. Click **Save Changes**.

**To add CIDR blocks to a public IP pool**
1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **Public IP Pools**.
3. Click **Add CIDR Blocks**.
4. Choose a named BYOIP CIDR block.
5. Click **Add CIDR Blocks**.

**To remove CIDR blocks from an IP pool**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To successfully remove a BYOIP CIDR block from a public IP pool, there must be no reserved public IP addresses from that address range. You may have to terminate one or more reserved public IP addresses.</td>
</tr>
</tbody>
</table>

1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **BYOIP**.
3. Click on the BYOIP CIDR block.
4. Click the Action Icon corresponding to the subrange you want to remove from a public IP pool, and then click **Remove from Public IP Pool**. A confirmation window appears.
5. If you are sure you want to delete the BYOIP CIDR block, click **Remove CIDR Block**.

**To reserve a public IP**
1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **Public IP Pools**.
3. Click the name of a public IP pool from the list.
4. Click the **Create Reserved Public IP** button.
5. Enter a name and specify the compartment for the new reserved public IP address. Avoid entering confidential information.
6. When finished, click **Create Reserved Public IP**.

**To move a public IP pool to another compartment**
1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu and click Networking. Under IP Management, click **Public IP Pools**.
3. Click the name of a public IP pool from the list.
4. Click the **Move Public IP Pool** button. An input screen appears.
5. Choose a new compartment for the public IP pool.
6. Click **Move Public IP Pool**.

**Using the API**
For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.
To manage the Public IP Pool object, use these operations:

- AddPublicIpPoolCapacity
- ChangePublicIpPoolCompartment
- CreatePublicIpPool
- DeletePublicIpPool
- GetPublicIpPool
- ListPublicIpPools
- RemovePublicIpPoolCapacity
- UpdatePublicIpPool

**IPv6 Addresses**

This topic describes support for IPv6 addressing in your VCN.

**Highlights**

- IPv6 addressing is supported for all commercial and government regions.
- During VCN creation, you choose whether the VCN is enabled for IPv6, or you can enable IPv6 on existing IPv4-only VCNs. You also choose whether each subnet in an IPv6-enabled VCN is enabled for IPv6.
- IPv6-enabled VCNs use a /56 IPv6 CIDR block. Oracle assigns a /56 globally routable IPv6 CIDR block to the VCN for internet communication. All subnets are /64. You can either permit or prohibit internet communication to a subnet by specifying the "public/private" subnet level flag.
- You also choose whether a given VNIC in an IPv6-enabled subnet has IPv6 addresses (up to 32 maximum per VNIC).
- Only these Networking gateways support IPv6 traffic: dynamic routing gateway (DRG), local peering gateway (LPG), and internet gateway.
- Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network. Communication between resources within your VCN or between VCNs is also supported.
- IPv6 traffic between resources within a region (intra- and inter-VCN) is supported. See other important details in Routing for IPv6 Traffic on page 3771 and Internet Communication on page 3769.
- Both FastConnect and Site-to-Site VPN support IPv6 traffic between your VCN and on-premises network. You must configure FastConnect or Site-to-Site VPN for IPv6.

**Overview of IPv6 Addresses**

Oracle supports dual-stack IPv4/IPv6 addressing for VCNs. Every VCN always supports IPv4, and you can optionally enable IPv6 during VCN creation. Enabling IPv6 for the VCN means that when you create a subnet, you can optionally enable it to also have IPv6 addresses. Therefore a VCN can have a mix of IPv4-only subnets and IPv6-enabled subnets.

After you create a Compute instance, you may optionally add an IPv6 to the VNIC. You can add up to 32 IPv6s to a given VNIC. You can remove an IPv6 from a VNIC at any time.

**CIDRs Assigned to an IPv6-Enabled VCN**

An IPv6-enabled VCN has 2 CIDR blocks assigned to it. Oracle allocates a Global Unicast Address (GUA) IPv6 CIDR, also referred to here as a globally routable IPv6 CIDR. The following table summarizes them.

<table>
<thead>
<tr>
<th>IPv4 or IPv6</th>
<th>Use and Size</th>
<th>Who Assigns the CIDR Block</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private IPv4 CIDR</td>
<td>Private communication /16 to /30</td>
<td>You</td>
<td>Typically RFC 1918 range</td>
</tr>
</tbody>
</table>
### Internet Communication

When you enable IPv6 in your VCN, Oracle assigns a globally unicast address /56 CIDR for customers to use in their VCN. You then have the option to enable IPv6 in subnets (see Task 2: Create a regional IPv6-enabled public subnet on page 3776) and assign IPv6 addresses to an individual instance's VNICs or load balancers if they were launched in an IPv6-enabled subnet with an IPv6 CIDR. You can also determine whether internet communication with IPv6-enabled resources are permitted or prohibited by specifying the subnet is public or private, respectively. If an IPv6-enabled resource is hosted in a public subnet, communication to and from the internet is permitted. If an IPv6-enabled resource is hosted in a private subnet, communication to and from the internet is prohibited.

### Assignment of IPv6 Addresses to a VNIC

To enable IPv6 for a given VNIC, you assign an IPv6 to the VNIC. You can assign up to 32 IPv6s to a VNIC. As with IPv4, when assigning an IPv6, you can specify the particular address you want to use, or let Oracle choose one for you.

You can move an IPv6 address from one VNIC to another in the same subnet.

After adding an IPv6 to a VNIC, you must configure the instance's OS to use the IPv6.

### Format of IPv6 Addresses

IPv6 addresses have 128 bits.

An IPv6 CIDR block for a VCN must be /56 in size. The left 56 bits identify the VCN portion of the address. For example:

```
2001:0db8:0123:7800::/56
```

An IPv6 CIDR block for a subnet must be /64 in size. The right 16 bits in a subnet's CIDR identify the subnet portion of the address. In the following example, the 7811 is the unique portion for the subnet:

```
2001:0db8:0123:7811::/64
```

The right-most 64 bits of an IPv6 address identify the unique portion specific to the particular IPv6 address. For example:

```
2001:0db8:0123:7811:01bc:ef01:2345:6789
```

When you assign an IPv6 to a VNIC, you can specify which specific IPv6 address to use (those 64 bits).

**Example of Enabling IPv6 in your VCN**

In this example, Oracle assigns this CIDR: 2001:0db8:0123:7811::/56.

The following diagram illustrates the VCN and includes two subnets: public subnet 1111 and private subnet 1112.
Access to the internet is determined at the subnet level only, not at the VNIC level.

VNIC1 in SUBNET1 has a primary private IPv4 (10.0.1.4) with an an optional IPv6 address assigned. VNIC1 has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.
Since SUBNET1 has internet access enabled it can only have an internet-routable IPv6 address, which is

The second subnet is private, which means the VNICs don't have IPv4 or IPv6 internet access.

**Routing for IPv6 Traffic**

Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and
between your VCN and your on-premises network. Communication between resources within your VCN or between
VCNs is also supported.

Here are other important details about routing of IPv6 traffic:

- Currently IPv6 traffic is supported only through these gateways:
  - Dynamic routing gateway (DRG): For access to your on-premises network or other networks outside the
    region (using remote peering). Both Oracle Cloud Infrastructure FastConnect and Site-to-Site VPN support
    IPv6 traffic. For more details about IPv6 configuration, see the upcoming sections.
  - Internet gateway: For access to the internet.
  - Local peering gateway: For connecting two VCNs in the same region so that their resources can communicate
    using private IP addresses without routing the traffic over the internet or through your on-premises network.
  - IPv6 traffic between resources within a region (intra- and inter-VCN) is supported. VCNs are dual-stack, meaning
    they support IPv4 and can optionally also support IPv6. Accordingly, a VCN's route tables support both IPv4 and
    IPv6 rules in the same table. IPv4 and IPv6 rules must be discretely specified. Rules to route traffic that matches a
    certain IPv6 CIDR to the VCN's attached DRG, internet gateway, local peering gateway, or an IPv6 Address (next
    hop) are supported.

**VCN Route Tables and IPv6**

The VCN's route tables support both IPv4 rules and IPv6 rules that use a DRG, local peering gateway, or internet
gateway as the target. For example, the route table for a given subnet could have these rules:

- Rule to route traffic that matches a certain IPv4 CIDR to the VCN’s attached DRG
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN's service gateway
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN's NAT gateway
- Rule to route traffic that matches a certain **IPv6** CIDR to the VCN's attached DRG
- Rule to route traffic that matches a certain **IPv6** CIDR to the VCN's attached internet gateway

**Security Rules for IPv6 Traffic**

Like route tables, the VCN’s network security groups and security listsSecurity Rules on page 3710 support both
IPv4 and IPv6 rules. For example, a network security group or security list could have these security rules:

- Rule to allow SSH traffic from the on-premises network's IPv4 CIDR
- Rule to allow ping traffic from the on-premises network's IPv4 CIDR
- Rule to allow SSH traffic from the on-premises network's **IPv6** CIDR
- Rule to allow ping traffic from the on-premises network's **IPv6** CIDR

The default security list in an IPv6-enabled VCN includes default IPv4 rules and the following default IPv6 rules:

- **Stateful ingress:** Allow IPv6 TCP traffic on destination port 22 (SSH) from source ::/0 and any source port. This
  rule makes it easy for you to create a new VCN with a public subnet and internet gateway, create a Linux instance,
  add an internet-access-enabled IPv6, and then immediately connect with SSH to that instance without needing to
  write any security rules yourself.

  **Important:**

  The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using
  Windows images, add a stateful ingress rule for TCP traffic on destination port 3389 from source ::/0 and
  any source port.
Networking

- **Stateful ingress:** Allow ICMPv6 traffic type 2 code 0 (Packet Too Big) from source ::/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages.

- **Stateful egress:** Allow all IPv6 traffic. This allows instances to initiate IPv6 traffic of any kind to any destination. Notice that this means the instances with an internet-access-enabled IPv6 can talk to any internet IPv6 address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Stateful Versus Stateless Rules on page 3716.

**FastConnect and IPv6**

If you use FastConnect, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. In general, you must ensure that the FastConnect virtual circuit has IPv6 BGP addresses, and update the VCN's routing and security rules for IPv6 traffic.

**About the IPv6 BGP Addresses**

A FastConnect virtual circuit always requires IPv4 BGP addresses, but IPv6 BGP addresses are optional and only required for IPv6 traffic. Depending on how you're using FastConnect, you might be asked to provide all of the virtual circuit's BGP addresses yourself (both IPv4 and IPv6).

The addresses consist of a pair: one for your end of the BGP session, and another for the Oracle end of the BGP session.

When you specify a BGP address pair, you must include a subnet mask that contains both of the addresses. Specifically for IPv6, the allowed subnet masks are:

- /64
- /96
- /126
- /127

For example, you could specify 2001:db8::6/64 for the address at your end of the BGP session, and 2001:db8::7/64 for the Oracle end.

**Process to Enable IPv6**

In general, here's how to enable IPv6 for a FastConnect virtual circuit:

- **Virtual circuit BGP:** Ensure the FastConnect virtual circuit has IPv6 BGP addresses. If you're responsible for providing the BGP IP addresses, when you set up a new virtual circuit or edit an existing one, there's a place for the two IPv4 BGP addresses. There's a separate check box for Enable IPv6 Address Assignment and a place to provide the two IPv6 addresses. Be aware that if you're editing an existing virtual circuit to add support for IPv6, it will go down while it's being reprovisioned to use the new BGP information.

- **VCN route tables:** For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the IPv6 subnets in your on-premises network. For example, the Destination CIDR Block for a route rule would be an IPv6 subnet in your on-premises network, and the Target would be the dynamic routing gateway (DRG) attached to the IPv6-enabled VCN.

- **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow IPv6 traffic between the VCN and your on-premises network. See Security Rules for IPv6 Traffic on page 3728.

If you do not yet have a FastConnect connection, see these topics to get started:

- FastConnect Overview on page 4052
- FastConnect Requirements on page 4061

**Site-to-Site VPN and IPv6**

If you use Site-to-Site VPN, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. Here's how to enable IPv6 for the connection:
• **IPSec connection static routes:** Configure the IPSec connection with the IPv6 static routes of your on-premises network.

• **VCN route tables:** For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the IPv6 subnets in your on-premises network. For example, the **Destination CIDR Block** for a route rule would be an IPv6 static route for your on-premises network, and the **Target** would be the **dynamic routing gateway (DRG)** attached to the IPv6-enabled VCN.

• **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow the wanted IPv6 traffic between the VCN and your on-premises network. See **Security Rules for IPv6 Traffic** on page 3728.

If you have an existing Site-to-Site VPN IPSec connection that uses static routing, you can update the list of static routes to include ones for IPv6. Be aware that changing the list of static routes causes Site-to-Site VPN to go down while it's being reprovisioned. See **Changing the Static Routes** on page 4035.

If you do not yet have Site-to-Site VPN, see these topics to get started:

• **Site-to-Site VPN Overview** on page 3809

• **Setting Up Site-to-Site VPN** on page 3825

• **Working with Site-to-Site VPN** on page 4034

**DHCPv6**

DHCPv6 auto-configuration of IP addresses is supported. You do not need to statically configure any IPv6 address.

**DNS**

The VCN's **Internet Resolver** supports IPv6, which means resources in your VCN can resolve IPv6 addresses of hosts outside the VCN. Assignment of a hostname to an IPv6 address is not supported.

**Load Balancers**

When you create a **load balancer**, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. There is no IPv6 communication between the load balancer and the backend servers.

IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.

**Comparison of IPv4 and IPv6 for Your VCN**

The following table summarizes the differences between IPv4 and IPv6 addressing in a VCN.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Addressing type supported</strong></td>
<td>IPv4 addressing is always required, regardless of whether IPv6 is enabled.</td>
<td>IPv6 addressing is optional per VCN, optional per subnet in an IPv6-enabled VCN, and optional per VNIC in an IPv6-enabled subnet.</td>
</tr>
<tr>
<td>Characteristic</td>
<td>IPv4</td>
<td>IPv6</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>----------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Supported traffic types</strong></td>
<td>IPv4 traffic is supported for all gateways. IPv4 traffic between</td>
<td>IPv6 traffic is supported only with these gateways: internet gateway,</td>
</tr>
<tr>
<td></td>
<td>instances within the VCN is supported (east/west traffic).</td>
<td>local peering gateway, and DRG. Both inbound- and outbound-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>initiated IPv6 connections are supported between your VCN and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the internet, and between your VCN and your on-premises network.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>IPv6 traffic between resources within a region (intra- and inter-VCN) is fully supported (east/west traffic). Also see <a href="#">Routing for IPv6 Traffic</a> on page 3771.</td>
</tr>
<tr>
<td><strong>VCN size</strong></td>
<td>/16 to /30</td>
<td>/56 only</td>
</tr>
<tr>
<td><strong>Subnet size</strong></td>
<td>/16 to /30, with 3 addresses reserved in each subnet by Oracle (first 2 and last 1).</td>
<td>/64 only, with 8 addresses in the subnet reserved by Oracle (first 4 and last 4).</td>
</tr>
<tr>
<td><strong>Private and public IP address space</strong></td>
<td>Private: A VCN's private IPv4 CIDR can be from an RFC 1918 range or a publicly routable range (in which case, it's treated as private). You must specify the range, unless you use the Console's VCN creation wizard, which always uses 10.0.0.0/16. Public: The VCN does not have a dedicated public IPv4 address space. Any public addresses in your VCN are always chosen by Oracle.</td>
<td>Unlike with IPv4, your VCN has a dedicated globally routable IPv6 address space, which is always /56 in size. When you assign an IPv6 to a VNIC, you can choose the address, or you can let Oracle choose it.</td>
</tr>
<tr>
<td><strong>IP address assignment</strong></td>
<td>Private: Each VNIC gets a private IPv4 address. You can choose the address or let Oracle choose it. Public: You determine whether the private IPv4 address has a public IP address associated with it (assuming the VNIC is in a public subnet). Oracle chooses the public IP address. From an API standpoint: the <code>PrivateIp</code> object is separate from the <code>PublicIp</code> object. You can remove the public IP address from the private IPv4 address at any time.</td>
<td>You decide whether a VNIC in an IPv6-enabled subnet gets an IPv6. You can choose the IPv6 address or let Oracle choose it. From an API standpoint: IP addresses are included in the <code>Ipv6</code> object and the distinction between public and private is controlled using the public/private subnet flag.</td>
</tr>
</tbody>
</table>
### Characteristic

<table>
<thead>
<tr>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Internet access</strong></td>
<td>You control whether a subnet is public or private. You do not add or remove a public IP address to or from the VNIC as you do with IPv4. Instead you enable or disable the internet access for all IPv6-enabled resources in the subnet using the public/private subnet flag.</td>
</tr>
<tr>
<td>Each VNIC automatically has a primary private IP address, and you can assign up to 31 secondary private IPs per VNIC.</td>
<td>You choose to add an IPv6 to a VNIC. There is no <em>primary</em> or <em>secondary</em> label for it. You can assign up to 32 IPv6s per VNIC.</td>
</tr>
<tr>
<td><strong>Primary and secondary labels</strong></td>
<td><strong>Hostnames</strong></td>
</tr>
<tr>
<td><strong>Route rule limits</strong></td>
<td>You cannot assign hostnames to IPv6 addresses.</td>
</tr>
<tr>
<td><strong>Security rule limits</strong></td>
<td>IPv4 and IPv6 route rules can reside together in the same route table. IPv6 route rules can target only an internet gateway, local peering gateway, or DRG. Limit on number of IPv6 route rules in a route table: 50.</td>
</tr>
<tr>
<td>See Service Limits on page 243.</td>
<td>IPv4 and IPv6 security rules can reside together in same network security group or security list. IPv6 security rules can use only IPv6 CIDR ranges for source or destination, and not a service CIDR label used for a service gateway. Limit on number of IPv6 security rules in a security list: 50 ingress and 50 egress. Limit on number of IPv6 security rules in a network security group: 16 total.</td>
</tr>
<tr>
<td><strong>Reserved public IP addresses</strong></td>
<td>Supported.</td>
</tr>
<tr>
<td><strong>Regional or AD-specific</strong></td>
<td>IPv6 addresses are regional.</td>
</tr>
<tr>
<td>Primary private IPv4 addresses are <em>AD</em>-specific. Secondary private IPv4 addresses are AD-specific unless assigned to a VNIC in a regional subnet. Public IP addresses can be AD-specific or regional depending on the type (ephemeral or reserved). See Public IP Addresses on page 3753.</td>
<td>IPv6 addresses are regional.</td>
</tr>
</tbody>
</table>

### Setting Up an IPv6-Enabled VCN with Internet Access

Use the following process if you want to set up an IPv6-enabled VCN with internet access so you can easily launch an instance and connect to it by using its globally routable IPv6 address.

**Task 1: Create the IPv6-enabled VCN**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2708.

3. Click Create Virtual Cloud Network.

4. Enter the following:
   - **Name**: A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **CIDR Block**: A single, contiguous IPv4 CIDR block for the VCN. For example: 172.16.0.0/16. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: Select the check box. Oracle assigns the IPv6 CIDR for you. You cannot later disable IPv6 for the VCN or change the CIDR. All IPv6-enabled VCNs are always /56 in size.
   - **Use DNS Hostnames in this VCN** (supported for IPv4 only): Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

5. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

**Task 2: Create a regional IPv6-enabled public subnet**

1. While still viewing the VCN, click Create Subnet.

2. Enter the following:
   - **Name**: A descriptive name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Regional or Availability Domain-specific subnet**: Oracle recommends creating only regional subnets, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose Availability Domain-Specific (the only kind of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.
   - **CIDR Block**: A single, contiguous IPv4 CIDR block for the subnet (for example, 172.16.0.0/24). The address block must be within the VCN's IPv4 CIDR block and not overlap any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: Select the check box and enter two hex characters (00-FF). (Example: 7E). You cannot later disable IPv6 for the subnet or change the CIDR. All IPv6-enabled subnets are always /64 in size. For more information about IPv6 address format, see Overview of IPv6 Addresses on page 3768.
   - **Route Table**: Select the default route table.
   - **Private or public subnet**: Select Public Subnet, which means instances in the subnet can optionally have public IPv4 addresses. Internet communication using IPv6 is allowed when IPv6-enabled resources are hosted in a public subnet. For more information, see Access to the Internet on page 3609.
   - **Use DNS Hostnames in this Subnet** (supported for IPv4 only): This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and also when you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or let the Console generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the subnet.
Networking

(<subnet_DNS_label>..<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.

- **DHCP Options**: Select the default set of DHCP options.
- **Security Lists**: Select the default security list.
- **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

3. Click **Create Subnet**.

   The subnet is then created and displayed on the **Subnets** page.

**Task 3: Create the internet gateway**

1. Under **Resources**, click **Internet Gateways**.
2. Click **Create Internet Gateway**.
3. Enter the following:
   - **Name**: A descriptive name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
4. Click **Create Internet Gateway**.

   Your internet gateway is created and displayed on the **Internet Gateways** page. It's already enabled, but you must add route rules that allow IPv4 and IPv6 traffic to flow to the gateway.

**Task 4: Update the default route table to use the internet gateway**

The default route table starts out with no rules. Here you add rules that route all IPv4 and IPv6 traffic destined for addresses outside the VCN to the internet gateway. The existence of these rules also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security rules to control the types of traffic that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required in order to route traffic within the VCN itself.

1. Under **Resources**, click **Route Tables**.
2. Click the default route table to view its details.
3. Click **Add Route Rules**.
4. Enter the following:
   - **Target Type**: Internet Gateway
   - **Destination CIDR block**: 0.0.0.0/0 (which means that all IPv4 non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
   - **Compartment**: The compartment where the internet gateway is located.
   - **Target**: The internet gateway you created.
   - **Description**: An optional description of the rule.
5. Click **+ Additional Route Rule**.
6. Enter the following:
   - **Target Type**: Internet Gateway
   - **Destination CIDR block**: ::/0 (for the IPv6 traffic).
   - **Compartment**: The compartment where the internet gateway is located.
   - **Target**: The internet gateway you created.
   - **Description**: An optional description of the rule.
7. Click **Add Route Rules**.

   The default route table now has two rules for the internet gateway, one for IPv4 traffic and one for IPv6 traffic. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.
**Task 5: Update the default security list (optional)**

**Note:**

This task is about configuring security rules to allow traffic to and from your instances. Although this task uses a security list to implement those rules, you can also use network security groups to implement security rules.

Earlier you set up the subnet to use the VCN's default security list. This list already includes basic rules that allow essential IPv4 and IPv6 traffic. In this task, you add any additional security rules that allow the types of connections that the instances in the VCN will need.

For example: This is a public subnet with an internet gateway, so the instances you create might need to receive inbound HTTPS connections from the internet (if they're web servers). Here's how to add another rule to the default security list to enable that traffic:

2. Click the default security list to view its details. By default, you land on the Ingress Rules page.
3. Click Add Ingress Rule.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - **Stateless:** Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0 (or ::/0 if you want to enable IPv6 traffic with this rule)
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 443
   - **Description:** An optional description of the rule.
5. Click Add Ingress Rule.

**Important:**

Security List Rule for Windows Instances

If you're going to create Windows instances, you need to add a security rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 (and a separate rule with ::/0 for IPv6 traffic) and any source port. For more information, see Security Rules on page 3710.

For a production VCN, you typically set up one or more custom security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages for IPv4.

**Task 6: Create an instance**

Your next step is to create an instance in the subnet. When you create the instance, you choose the availability domain, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IPv4 address. When you create an instance in a public subnet, you choose whether the instance gets a public IPv4 address. A public IPv4 address is NOT required for globally routable IPv6 traffic. But if you want to connect to the instance from an IPv4 host, you must give the instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

For more information and instructions, see Launching an Instance.

**Task 7: Add an IPv6 to the instance**

1. While viewing the instance you just created, click Attached VNICS.
2. Click the VNIC.
4. Click Assign IPv6 Address.
5. Enter the following:
   - **IPv6 Address**: Optional. An available IPv6 address of your choice from the subnet's IPv6 CIDR (otherwise the IP address is automatically assigned).
   - **Unassign if already assigned to another VNIC**: Leave this check box as is (cleared). Use this only to force reassignment of an IPv6 address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a IP address in the preceding field.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
6. Click Assign.

   The IPv6 is created and then displayed on the IPv6 Addresses page for the VNIC.

**Task 8: Configure the instance's OS to use IPv6**

You must configure the instance's OS to use the IPv6. For more information, see Configuring an Instance OS to use IPv6 on page 3781.

Assign the IPv6 address dynamically when using Oracle Linux 8. Enabling IPv6 during the compute launch is not supported, so you may not see the IPv6 address immediately after the instance is launched. Once the compute instance is up, you can wait for the next DHCPv6 cycle to get the IPv6 address, or you can use the dhcpv6 client service to grab the IPv6 address. To use the dhcpv6 client enter:

```
sudo dhclient -6 ens3
```

**Note:**

Your may want to use the following command to allow the DHCPv6 client service from the firewall-cmd daemon on the virtual machine:

```
sudo firewall-cmd --add-service=dhcpv6-client
```

**Managing IPv6s in the Console**

This section includes basic tasks for working with IPv6-related resources.

**To create an IPv6-enabled VCN**

**Important:**

After enabling IPv6 for a VCN, you cannot disable it.

See the instructions in Task 1: Create the IPv6-enabled VCN on page 3775.

**To create an IPv6-enabled subnet**

**Important:**

After enabling IPv6 for a subnet, you cannot disable it.

**Summary:** Creating an IPv6-enabled subnet is similar to creating an IPv4 subnet. The only difference is that you must select the check box for Enable IPv6 Address Assignment and provide 8 bits for the subnet's portion of the IPv6 CIDR. See Overview of IPv6 Addresses on page 3768.

For general instructions, see Task 2: Create a regional IPv6-enabled public subnet on page 3776. If you want a private subnet, select the radio button for Private Subnet when creating the subnet.

**To assign an IPv6 to a VNIC**

The process for adding an IPv6 to a VNIC is similar to adding a secondary private IPv4 address. You can specify the particular IPv6 address to use or let Oracle choose it from the subnet. For more information, see Overview of IPv6 Addresses on page 3768. After assigning the IPv6 to the VNIC, you must configure the OS to use the IPv6.
1. Assign the IPv6. For general instructions, see Task 7: Add an IPv6 to the instance on page 3778.
2. Configure the OS to use the IPv6 address. For more information, see Configuring an Instance OS to use IPv6 on page 3781.

To move an IPv6 to another VNIC in the subnet

The process is similar to moving a secondary private IPv4 address from one VNIC to another (let's call them the original VNIC and the new VNIC). You assign the IPv6 to the new VNIC, specify the IPv6 address, and select the check box for Unassign if already assigned to another VNIC. Oracle automatically unassigns it from original VNIC and assigns it to the new VNIC.

To delete an IPv6 from a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
7. Click Assign Private IP Address.
8. Enter the following:
   • **IPv6 Address**: The IPv6 address that you want to move.
   • **Unassign if already assigned to another VNIC**: Select this check box to move the IPv6 address from the VNIC it's currently assigned to.
   • **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
9. Click Assign.

The IP address is moved from the original VNIC to the new VNIC.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

For IPv6 addressing, there's an Ipv6 object with the following operations:

- ListIpv6s
- GetIpv6
- UpdateIpv6
- CreateIpv6
- DeleteIpv6
Networking

Configuring an Instance OS to use IPv6

After assigning an IPv6 to the VNIC through the Console, an instance needs to learn what address it is assigned. DHCPv6 will automatically assign the instance an IPv6 address, but this may require you to wait for the next refresh cycle. You can also require the instance's operating system to immediately refresh its IPv6 address.

Oracle Linux Configuration

Oracle Linux 8 uses the following command to refresh an IPv6 address on an instance:

```bash
sudo dhclient -6 <interface>
```

**Note:**

If you want to use the DHCLIENT service in Oracle Linux 8, you may first have to run the command below:

```bash
sudo firewall-cmd --add-service=dhcpv6-client
```

If you haven't yet, ensure that the VCN's route table and security rules are configured for the wanted IPv6 traffic. See Routing for IPv6 Traffic on page 3771 and Security Rules for IPv6 Traffic on page 3728.

Windows Configuration

You can use the following Windows command line or the Network Connections UI to ask the instance to refresh the IPv6 address:

```bash
ipconfig /renew6
```

**Command Line**

If you use PowerShell, you must run it as an administrator. The following configuration persists through a reboot of the instance, and should be applied as soon as possible after the instance is created.

Run the following command:

```bash
ipconfig /renew6.
```

If you haven't yet, ensure that the VCN's route table and security rules are configured for the wanted IPv6 traffic. See Routing for IPv6 Traffic on page 3771 and Security Rules for IPv6 Traffic on page 3728.

DNS in Your Virtual Cloud Network

The Domain Name System (DNS) lets computers use hostnames instead of IP addresses to communicate with each other.

**Choices for DNS in Your VCN**

Following are the choices for DNS name resolution for the instances in your VCN. You make this choice for each subnet in the VCN, using the subnet's set of DHCP options. This is similar to how you configure which route table and security lists are associated with each subnet. For more information, see DHCP Options on page 3789.

**Note:**

You use the Domain Name Server DHCP option to specify the DNS Type for the associated subnet. If you change the option's value, either restart the DHCP client on the instance or reboot the instance. Otherwise, the change does not get picked up until the DHCP client refreshes the lease (within 24 hours).
DEFAULT CHOICE: INTERNET AND VCN RESOLVER

This is an Oracle-provided option that includes two parts:

- **Internet Resolver:** Lets instances resolve hostnames that are publicly published on the internet. The instances do not need to have internet access by way of either an internet gateway or a connection to your on-premises network (such as a Site-to-Site VPN IPSec connection through a DRG).
- **VCN Resolver:** Lets instances resolve hostnames (which you can assign) of other instances in the same VCN. For more information, see About the DNS Domains and Hostnames on page 3782.

By default, new VCNs you create use the Internet and VCN Resolver. If you're using the Networking API, this choice refers to the `VcnLocalPlusInternet` enum in the `DhcpDnsOption` object.

**Note:**

By default, the Internet and VCN Resolver does not let instances resolve the hostnames of hosts in your on-premises network connected to your VCN by Site-to-Site VPN or FastConnect. That functionality can be achieved either by using a custom resolver or by configuring the VCN's private DNS resolver.

CUSTOM RESOLVER

Use DNS servers of your choice for resolution (maximum three). They could be DNS servers that are:

- Available through the internet. For example, 216.146.35.35 for Dyn's Internet Guide.
- In your VCN.
- In your on-premises network, which is connected to your VCN by way of a Site-to-Site VPN or FastConnect (through a DRG).

About the DNS Domains and Hostnames

When you initially create a VCN and subnets, you may specify DNS labels for each. Subnet DNS labels can only be set if the VCN itself is created with a DNS label. The labels, along with the parent domain of `oraclevcn.com` form the VCN domain name and subnet domain name:

- **VCN domain name:** `<VCN DNS label>.oraclevcn.com`
- **Subnet domain name:** `<subnet DNS label>.<VCN DNS label>.oraclevcn.com`

When you then launch an instance, you may assign a hostname. It's assigned to the VNIC that's automatically created during instance launch (that is, the primary VNIC). Along with the subnet domain name, the hostname forms the instance's fully qualified domain name (FQDN):

- **Instance FQDN:** `<hostname>.<subnet DNS label>.<VCN DNS label>.oraclevcn.com`

For example: `database1.privatesubnet1.abccorpvcn1.oraclevcn.com`.

The FQDN resolves to the instance's private IP address. The Internet and VCN Resolver also enables reverse DNS lookup, which lets you determine the hostname corresponding to the private IP address.

If you add a secondary VNIC to an instance, you can specify a hostname. The resulting FQDN resolves to the VNIC's private IP address (that is, the primary private IP).

If you add a secondary private IP to a VNIC, you can specify a hostname. The resulting FQDN resolves to that private IP address.

**Important:**

Oracle recommends that you always use the instance FQDN when sending messages to a host, or alternately specify only the hostname for messages sent within a VCN.
Requirements for DNS Labels and Hostnames

- VCN and subnet labels: Max 15 alphanumeric characters and must start with a letter. **Notice that hyphens and underscores are NOT allowed.** The value cannot be changed later.
- Hostnames: Max 63 characters and must be compliant with RFCs 952 and 1123. The value can be changed later.

**Important:**

The Networking service allows hostnames up to 63 characters. However, some older operating systems enforce shorter hostnames. In Linux, here's how to determine the maximum allowed hostname length:

```bash
getconf HOST_NAME_MAX
```

If an instance has a hostname longer than the OS-specific maximum, the instance's FQDN is not resolvable within the VCN. You can use the Networking service to update the VNIC and change the hostname to a shorter value.

Uniqueness:

- VCN DNS label should be unique across your VCNs (not required, but a best practice)
- Subnet DNS labels must be unique within the VCN
- Hostnames must be unique within the subnet

**Tip:**

Don't confuse the DNS label or hostname with the friendly name you can assign to the object (that is, the *display name*), which doesn't have to be unique.

Validation and Generation of the Hostname

If you've set DNS labels for the VCN and subnets, Oracle validates the hostname for DNS compliance and uniqueness during instance launch. If either of these requirements isn't met, the launch request fails.

If you don't specify a hostname during instance launch, Oracle tries to use the instance's display name as the hostname. If the display name does not pass the validation, Oracle automatically generates a DNS-compliant hostname that's unique across the subnet. You can see the generated hostname on the instance's page in the Console. In the API, the hostname is part of the VNIC object.

If you don't provide a hostname or display name during instance launch using the SDK or CLI, Oracle does not generate a display name or hostname. This means the instance won't be resolvable using the Internet and VCN Resolver.

If you don't provide a hostname or display name during instance launch using the Console, Oracle will auto-generate a display name and a corresponding DNS record, provided the subnet has a valid DNS label associated with it.

**Note:**

The Linux OS hostname on the instance is automatically set to the hostname you set during instance launch (or the one generated by Oracle). If you change the hostname directly on the instance, the FQDN of the instance does not get updated.

If you add a secondary VNIC to an instance, or add a secondary private IP to a VNIC, Oracle never tries to generate a hostname. Provide a valid hostname if you want the private IP address to be resolvable using the Internet and VCN Resolver.
DHCP Options for DNS

Two DHCP options are related to DNS in your VCN:

- **Domain Name Server**: To specify your choice for DNS type (either Internet and VCN Resolver, or Custom Resolver).
  - **Default value in the default set of DHCP options**: Internet and VCN Resolver
- **Search Domain**: To specify a single search domain. When resolving a DNS query, the OS appends this search domain to the value being queried. You can specify only one search domain for the set of DHCP options.
  - **Default value in the default set of DHCP options**: The VCN domain name (<VCN DNS label>.oraclevcn.com), if you specified a DNS label for the VCN during creation but did not specify a search domain value. If you specified a search domain value, then that value is used for the Search Domain option. If you did NOT specify a DNS label, the default set of DHCP options does not include a Search Domain option.

**Caution:**

Oracle recommends that you always use the instance FQDN when sending messages to a host in another subnet/VCN and do not rely on the DNS search domain.

**Important:**

In general, when any set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name (<VCN DNS label>.oraclevcn.com) if all of these are true:

- The VCN has a DNS label
- DNS Type = Internet and VCN Resolver
- You did NOT specify a search domain of your choice during creation of the set of DHCP options

After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value.

### How to Enable DNS Hostnames in Your VCN

Only new VCNs created after the release of the Internet and VCN Resolver feature have automatic access to it. How to enable DNS hostnames for a new VCN depends on which interface you're using.

**If you create a VCN and subnets with the Console**

1. When creating the VCN:
   - Select the check box for **Use DNS Hostnames in this VCN**
   - Specify a DNS label of your choice for the VCN. If you check the check box but don't specify a DNS label, the Console assumes that you want to use the Internet and VCN Resolver in your VCN and automatically generates a DNS label for the VCN. The Console takes the VCN name you provided, removes non-alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15 characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the **DNS Label** field. See About the DNS Domains and Hostnames on page 3782.
2. When creating the subnets:
   - Again, select the check box for **Use DNS Hostnames in this Subnet**
   - Specify a DNS label of your choice for each subnet. If you check the check box but don't specify the DNS label for a given subnet, the Console assumes you want to use the Internet and VCN Resolver for the subnet and automatically generates a DNS label for the subnet. The Console takes the subnet name you provided, removes non-alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15
characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the **DNS Label** field. See *About the DNS Domains and Hostnames* on page 3782.

**Note:**

Subnet DNS labels can only be set if the VCN itself is created with a DNS label.

- Associate any set of DHCP options that has DNS type = Internet and VCN Resolver. The default set of DHCP options in the VCN uses the Internet and VCN Resolver by default.

3. When launching instances:

- Select the option to assign a private DNS record.
- Specify a hostname (or at least a display name) for each instance. For more information, see *About the DNS Domains and Hostnames* on page 3782.

If you don't check the check box for **Use DNS Hostnames in this VCN** when creating the VCN, you can't set the DNS label for the VCN or subnets, and you can't specify a hostname during instance launch.

**Note:**

The previous procedure assumes you create the VCN and subnets one at a time in the Console. The Console has a feature that automatically creates a VCN with subnets and an internet gateway all at the same time. If you use that feature to create the VCN and subnets, the Console automatically generates DNS labels for them.

*If you create a VCN and subnets with the API*

1. When creating the VCN:

- Specify a DNS label for the VCN. See *About the DNS Domains and Hostnames* on page 3782. If you don't set a value (if it's null), Oracle assumes that you don't want to use the Internet and VCN Resolver, even if the DHCP options have `DhcpDnsOption serverType=VcnLocalPlusInternet`.

2. When creating the subnets:

- Specify a DNS label for each subnet. See *About the DNS Domains and Hostnames* on page 3782. If you specified a DNS label for the VCN, but you don't specify a DNS label for the subnet, Oracle assumes that you don't want the instances in the subnet to use the Internet and VCN Resolver and the ability to use hostnames to communicate with instances in the VCN is no longer available.

**Note:**

Subnet DNS labels can only be set if the VCN itself was created with a DNS label.

- Associate any set of DHCP options that has `DhcpDnsOption serverType=VcnLocalPlusInternet`, which is the default DHCP option in the VCN.

3. When launching instances:

- Select the option to assign a private DNS record.
- Specify a hostname (or at least a display name) for each instance. For more information, see *About the DNS Domains and Hostnames* on page 3782.

If you don't specify a DNS label when creating the VCN, you can't do the following things:

- Set the DNS label for the subnets (causing the `CreateSubnet` call to fail)
- Specify a hostname during instance launch (causing the `LaunchInstance` call to fail)
- Assign a hostname to a secondary VNIC or a secondary private IP

*Scenario 1: Use Internet and VCN Resolver with DNS Hostnames Across the VCN*

The typical scenario is to enable the Internet and VCN Resolver *across your entire VCN*, which allows all instances in the VCN to communicate with each other without knowing their IP addresses. To do that, follow the instructions in
About the DNS Domains and Hostnames on page 3782, and assign a DNS label to the VCN and every subnet. Then assign every instance a hostname (or at least a display name) at launch. If you add a secondary VNIC or secondary private IP, also assign it a hostname. The instances can then communicate with each other using FQDNs instead of IP addresses.

**Scenario 2: Use a Private DNS Resolver to Resolve DNS Hostnames**

You can use a private DNS resolver to answer DNS queries for a VCN using a configuration you create. The resolver listens on 169.254.169.254 by default, but also allows you to define endpoints for listening for queries and forwarding them to other resolvers in other VCNs, a customer's on-premises network, or other private network. For more information, see [Private DNS resolvers](#).

**Scenario 3: Use Different DHCP Options Per Subnet**

Scenario 1 assumes you want to use the Internet and VCN Resolver the same way across all subnets, and thus all instances in the VCN. You could, however, configure different DNS settings for each subnet, because the DHCP options are configured *at the subnet level*. The important thing to understand is: the subnet where you want to generate the DNS query is where you need to configure the corresponding Internet and VCN Resolver settings.

For example, if you want instance A in subnet A to resolve the hostname of instance B in subnet B, you must configure subnet A to use the Internet and VCN Resolver. Conversely, if you want instance B to resolve the hostname of instance A, you must configure subnet B to use the Internet and VCN Resolver.

You can configure a different set of DHCP options for each subnet. For example, you could set subnet A’s Search Domain to `subneta.vcn1.oraclevcn.com`, which means all instances in subnet A could use just hostnames to communicate with each other. You could similarly set subnet B’s Search domain to `subnetb.vcn1.oraclevcn.com` to enable Subnet B’s instances to communicate with each other with just hostnames.

**Private DNS resolvers**

A private DNS resolver answers DNS queries for a VCN per a configuration you create.

When you create a VCN and select the *Use DNS hostnames in this VCN* option, this choice creates a dedicated private DNS resolver and a default private view with system-managed zones. A private DNS resolver also handles internal DNS queries for your VCN based on private views and the private zones that you have created and the rules you create for the resolver. A private DNS zone has capabilities similar to an internet DNS zone, but only provides responses for clients that can reach it through a VCN. The default view is only used if the resolver does not get a match from the other attached private views, if there are any. A private resolver can be configured to use views and zones as well as conditional forwarding rules to define how to respond to DNS queries. To better understand views and zones, refer to [Private DNS](#) on page 2286.

You can create your own custom domains to use in addition to the system-generated names based on VCNs and subnets, and you can do VCN to VCN and VCN to on-premises resolution.

**To add a private view to a private resolver**

1. From the Virtual Cloud Network Details screen for your VCN, look in the VCN Information tab and click the name of the DNS resolver for the VCN. The Private Resolver Details screen appears.
2. From the Private Resolver Details screen, click Manage Private Views. The Manage Private Views screen appears.
3. Select a previously created private view from the drop down menu in the numbered Private view list.
4. To associate another view, click Additional Private View select another view.
5. When you are finished, click Save Changes.

Views created automatically by Oracle are available in addition to views you create.

**To remove a private view from a private resolver**

1. From the Private Resolver Details screen, click the check box next to the private view you want to remove from the resolver. Remove turns red, and can now be clicked. You can select other private views if necessary.
2. Click **Remove**.

**Note:**
You can also remove a private view from the Manage Private Views screen by clicking the red button labeled - and then clicking **Save Changes**.

To rename a private resolver

1. From the **Private Resolver Details** screen, click **Edit**.
2. Enter the new name for the resolver. Avoid entering confidential information. Then, click **Save Changes**.

To manage DNS zones and views

See Managing DNS Service Zones on page 2267.

**Resolver Endpoints**

A DNS forwarding resolver endpoint is required before you can create a resolver rule. Resolver endpoints are attached to a VCN or a subnet. No listening endpoint is required for compute instances sending queries to 169.254.169.254. Two types of endpoint are used:

- **Listening** - A listening endpoint receives queries from these sources: within the VCN, other VCN Resolvers, or your on-premises network's DNS. Once created, no further configuration is needed for a listening endpoint.
- **Forwarding** - A forwarding endpoint forwards DNS queries to the Listening endpoint for resolvers in other peered VCNs or your on-premises network's DNS. Decisions about where to forward queries are based on resolver rules that you define.

**Note:**
IPv6 is not supported for listening or forwarding endpoints.

An endpoint can only be configured to either forward or listen.

**Note:**
Network security groups (NSGs) act as a virtual firewall for your DNS resolver endpoints. An NSG consists of a set of ingress and egress security rules that apply only to the associated DNS resolver endpoints.

Oracle recommends that you modify your security list or NSG security rules to allow access for UDP Port 53 (and optionally TCP Port 53) to your DNS listener endpoints.

To create a resolver endpoint

1. From the **Virtual Cloud Network Details** screen for your VCN, look in the VCN Information tab and click the name of the DNS resolver for the VCN. The **Private Resolver Details** screen appears.
2. From the **Private Resolver Details** screen, click **Endpoints** in the left-hand navigation.
3. Click **Create Endpoint**. The **Create Endpoint** screen appears.
4. Make choices for the following settings:

   - Select a name for the endpoint. The name can use any combination of letters and numbers, but the only supported special character is an underscore.
   - Select a subnet for the endpoint from the pull-down list.
   - Select the endpoint type, which can be either **Listening** or **Forwarding**. When you make this choice, you provide an IP address, or allow Oracle to assign one for the endpoint. This IP address is used by the resolver to forward DNS queries, or to listen for DNS queries from other systems. The IP address must be in the same CIDR block used by the VCN or subnet associated with the resolver.

   **Optional:** Use a **Network Security Group** to control traffic. To use this feature, select an NSG to use with the endpoint. You can also add an NSG after the endpoint is created.
To delete a resolver endpoint

1. From the Private Resolver Details screen, click the Action button to the right of the endpoint you want to delete, and then click Delete.
2. Confirm the deletion by clicking Delete.

To add an NSG to a resolver endpoint

1. From the Private Resolver Details screen, click the name of the endpoint you want to associate with a Network Security group. The Endpoint Details screen appears.
2. Click Add Network Security Groups, and select up to five security groups to associate with the endpoint.

To remove an NSG from a resolver endpoint

1. From the Private Resolver Details screen, click the name of the endpoint you want to de-associate with a Network Security group. The Endpoint Details screen appears.
2. Click the X button to the right of the listed NSG. You could change to a different NSG if necessary.

Resolver Rules

Rules are used to answer queries that aren't answered by a resolver's views. They are checked in order, and each can optionally have conditions that limit which queries they apply to. Queries not matched by any view or rule are resolved from internet DNS. You can have up to 10 rules per resolver.

Note:
Endpoints are used in the rule, and they must exist before you create a resolver rule.

Use case

The most common application is to have one or more rules that follow this general form:

If <query domain> is <example.com>, forward using <forwarding-endpoint> to IP address X.X.X.X.

Followed by a final rule that follows this form:

If <anything else> , forward using <forwarding-endpoint> to IP address Y.Y.Y.Y.

So if the query is looking for example.com, the resolver internally forwards it to X.X.X.X through the specified forwarding endpoint and responds with the answer it receives. For any other query, it forwards to Y.Y.Y.Y through the same forwarding endpoint and responds with that answer it gets from Y.Y.Y.Y.

To create resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column. Click Manage Rules. The Manage Rules screen appears.
2. You can have up to 10 rules per resolver. For each rule, select:
   - **Rule condition:** Determines whether routing decisions are made based on the query's originating CIDR Block or Domain (up to 10 hostnames), or neither (Select None to match any CIDR Block or Domain).
   - **Client CIDR blocks or Domains:** Up to 10 CIDR blocks or domains.
   - **Rule action:** This field is read-only. Forward is the only option.
   - **Source endpoint:** The private endpoint used to forward queries when the rule condition is met.
   - **Destination IP address:** The address to forward the query to if the rule condition is met.
3. Click +Additional Rule to create another rule if necessary.
4. Click Save Changes when finished.
To edit resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column.
2. Click Manage Rules. The Manage Rules screen appears.
3. Make changes based on your intended design. These changes can include changing options in a rule, changing the order of rules, and removing rules altogether.
4. When finished, click Save Changes.

To remove resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column.
2. Click the check box in the row for the rule or rules you want to delete. Click Remove. The Confirm Removal screen appears.
3. Click Remove.

Reverse DNS (PTR)

A reverse DNS record, also known as a pointer record (PTR), resolves an IP address back to a fully qualified domain name (FQDN). It functions in the opposite way of an A (IPv4) or AAAA (IPv6) forward record. For example:

192.0.2.5 # myhost.mydomain.com

You can request that a PTR record be established for your cloud IP addresses:

1. Create an A (IPv4) or AAAA (IPv6) forward record that points the fully qualified domain name to the IP prior to opening the request. You can create the record using the Oracle Cloud Infrastructure DNS service, or a third-party DNS provider.
2. Open a service request and include the following information:
   a. The IP address and fully qualified domain name (FQDN) you want in the PTR.
   b. The FQDN of the forward record that you created in step 1.

After the service request is received, the forward (A or AAAA) record information is validated to be sure it can be successfully resolved, and Oracle creates the PTR record on your behalf.

Using the API

Use the following operations to manage resolvers and resolver endpoints:

- ListResolvers
- GetResolver
- UpdateResolver
- ChangeResolverCompartment
- ListResolverEndpoints
- CreateResolverEndpoint
- GetResolverEndpoint
- UpdateResolverEndpoint
- DeleteResolverEndpoint

DHCP Options

This topic describes how to manage the Dynamic Host Configuration Protocol (DHCP) options in a virtual cloud network (VCN).

Overview of DHCP Options

The Networking service uses DHCP to automatically provide configuration information to instances when they boot up. Although DHCP lets you change some settings dynamically, others are static and never change. For example, when you launch an instance, either you or Oracle specifies the instance's private IP address. Each time the instance
boots up or you restart the instance's DHCP client, DHCP passes that same private IP address to the instance. The address never changes during the instance's lifetime.

The Networking service provides DHCP options to let you control certain types of configuration on the instances in your VCN. You can change the values of these options at your discretion, unlike the static information that DHCP provides to the instance. The changes take effect the next time you restart a given instance's DHCP client or reboot the instance. For more details, see Important Notes about Your Instances and DHCP Options on page 3791.

Each subnet in a VCN can have a single set of DHCP options associated with it. That set of options applies to all instances in the subnet. Each VCN comes with a default set of DHCP options with initial values that you can change. If you don't specify otherwise, every subnet uses the VCN's default set of DHCP options.

The following table summarizes the available DHCP options you can configure.

<table>
<thead>
<tr>
<th>DHCP Option</th>
<th>Possible Values</th>
<th>Initial Value in the Default DHCP Options</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain Name Server</td>
<td>DNS Type:</td>
<td>DNS Type = Internet and VCN resolver. For more information, see Choices for DNS in Your VCN on page 3781.</td>
<td>If you set DNS Type = Custom Resolver, you can specify up to three DNS servers of your choice. For more information, see Choices for DNS in Your VCN on page 3781.</td>
</tr>
<tr>
<td></td>
<td>• Internet and VCN Resolver</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Custom Resolver</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Search Domain</td>
<td>A single search domain</td>
<td>If you've set up your VCN with a DNS label, the default value for the Search Domain option is the VCN domain name ( (&lt;VCN DNS label&gt;.oraclevcn.com)). Otherwise, the Search Domain option is not present in the default set of DHCP options.</td>
<td>In general, when any set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name ( (&lt;VCN DNS label&gt;.oraclevcn.com)) if all of these are true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The VCN has a DNS label</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• DNS Type = Internet and VCN Resolver</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• You did NOT specify a search domain of your choice during creation of the set of DHCP options</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value. You can specify only a single search domain in a set of DHCP options.</td>
</tr>
</tbody>
</table>
**Working with DHCP Options**

When you create a subnet, you specify which set of DHCP options to associate with the subnet. If you don't, the default set of DHCP options for the VCN is used. You can change which set of DHCP options the subnet uses at any time.

When creating a new set of DHCP options, you may optionally assign it a friendly name. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the set of options a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can change the values of an individual DHCP option in a set, but notice that when you use the REST API to update a single option in a set, the new set of options replaces the entire existing set.

To delete a set of DHCP options, it must not be associated with a subnet yet. You can't delete a VCN's default set of DHCP options.

For information about the maximum number of DHCP options allowed, see Service Limits on page 243.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: see IAM Policies for Networking on page 3709.

**Important Notes about Your Instances and DHCP Options**

Whenever you change the value of one of the DHCP options, you must do one of the following for the change to take effect on existing instances in the subnets associated with that set of DHCP options: either restart the DHCP client on the instance, or reboot the instance.

Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

Any changes you make to the `/etc/resolv.conf` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted.

Changes you make to the `/etc/hosts` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted. To persist your changes to the `/etc/hosts` file in Oracle Linux or CentOS instances, add the following line to `/etc/oci-hostname.conf`:

```
PRESERVE_HOSTINFO=2
```

If the `/etc/oci-hostname.conf` file does not exist, create it.

**Using the Console**

**To view a VCN's set of default DHCP options**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.

The default set and its details are displayed in the list.
To update options in an existing set of DHCP options

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click Edit:
   • For DNS Type: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select Internet and VCN Resolver. Or to use a DNS server of your choice, select Custom Resolver and then enter the server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   • For Search Domain: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. If the Search Domain option is already set to the VCN domain name and you're not sure why, see the details in Overview of DHCP Options on page 3789.
5. When you're done, click Save Changes.
6. If you have any existing instances in a subnet that uses this set of DHCP options, make sure to restart the DHCP client on each affected instance, or reboot the instance itself so that it picks up the new setting.

To create a new set of DHCP options

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. Click Create DHCP Options.
5. Enter the following:
   • Name: A friendly name for the set of options. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   • Create in Compartment: The compartment where you want to create the set of DHCP options, if different from the compartment you're currently working in.
   • DNS Type: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select Internet and VCN Resolver. Or to use a DNS server of your choice, select Custom Resolver and then enter the server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   • Search Domain: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. Be aware that the Networking service automatically sets the Search Domain option in certain situations. See the details in Overview of DHCP Options on page 3789.
   • Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
6. When you're done, click Create DHCP Options.

The set of options is created and then displayed on the DHCP Options page of the compartment you chose. You can now specify this set of options when creating or updating a subnet.

To change which set of DHCP options a subnet uses

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
5. Click Edit.
6. In the DHCP Options section, select the new set of DHCP options you want the subnet to use.
7. Click Save Changes.

The changes take effect within a few seconds.
To delete a set of DHCP options

Prerequisite: To delete a set of DHCP options, it must not be associated with a subnet yet. You can’t delete the default set of DHCP options in a VCN.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you want to delete, click the Actions icon (three dots), and then click Terminate.
5. Confirm when prompted.

To manage tags for a set of DHCP options

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click View Tags. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 239.

To move a set of DHCP options to a different compartment

You can move a set of DHCP options from one compartment to another. When you move a set of DHCP options to a new compartment, inherent policies apply immediately.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage a VCN's DHCP options, use these operations:

- ListDhcpOptions
- GetDhcpOptions
- UpdateDhcpOptions
- CreateDhcpOptions
- DeleteDhcpOptions
- ChangeDhcpOptionsCompartment

Dynamic Routing Gateways (DRGs)

This topic describes how to manage a dynamic routing gateway (DRG). This topic uses the terms dynamic routing gateway and DRG interchangeably. The Console uses the term Dynamic Routing Gateway, whereas for brevity the API uses DRG.

A DRG is a virtual router to which you can attach the following resources:

- VCNs
- Remote Peering Connections
- Site-to-Site VPN IPSec tunnels
Networking

- Oracle Cloud Infrastructure FastConnect virtual circuits

A DRG can have multiple network attachments of each of the following types:

- **VCN attachments**: you can attach multiple VCNs to a single DRG. Each VCN can be in the same or different tenancies as the DRG.
- **RPC attachments**: you can peer a DRG to other DRGs (including DRGs in other regions) using remote peering connections.
- **IPSEC_TUNNEL attachments**: you can use Site-to-Site VPN to attach two or more IPSec tunnels to your DRG to connect to on-premises networks. This is also allowed across tenancies.
- **VIRTUAL_CIRCUIT attachments**: you can attach one or more FastConnect virtual circuits to your DRG to connect to on-premises networks.

Creating DRG route tables and DRG route distributions allows you to define routing policies that route traffic between attachments. Routes can be dynamically imported and exported through these attachments. A route table must be associated with an attachment for that table's configuration to be applied, but an unassociated routing table can exist. DRG route distributions are of an explicit type (either import or export) and do not inherit an action that depends on where they are associated.

**Overview of Dynamic Routing Gateways**

A DRG acts as a virtual router, providing a path for traffic between your on-premises networks and VCNs, and can also be used to route traffic between VCNs. Using different types of attachments, custom network topologies can be constructed using components in different regions and tenancies. Each DRG attachment has an associated route table which is used to route packets entering the DRG to their next hop. In addition to static routes, routes from the attached networks are dynamically imported into DRG route tables using optional import route distributions.

**Working with DRGs and DRG attachments**

When creating a DRG, you must specify the compartment where you want the DRG to reside. Placing the DRG in a compartment helps to limit access control. If you're not sure which compartment to use, put the DRG in the same compartment as a VCN you use regularly. For more information, see Access Control on page 3708.

You might optionally assign a friendly name to the DRG. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the DRG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

To use a DRG, it must be attached to other network resources. In the API, the process of attaching creates a DrgAttachment object with its own OCID. The DrgAttachment has a type field which denotes the type of object being attached to the DRG. The type field can be set to one of the following values:

- VCN
- VIRTUAL_CIRCUIT
- IPSEC_TUNNEL
- REMOTE_PEERING_CONNECTION

To attach a VCN to a DRG, use the CreateDrgAttachment operation or the console to explicitly create the DRG attachment object. Attachments for virtual circuits, IPSec tunnels, and remote peering connections are created (and deleted) automatically on your behalf when you create (or delete) the network object.

**Working with DRG Route Tables and Route Distributions**

When a packet enters a DRG, it is routed using rules in the DRG route table assigned to that attachment. You can assign the same route table to multiple DRG attachments or create a dedicated route table for each attachment depending on the routing policies you want.

When you create a DRG, two default route tables are created for you: one for VCN attachments and one for all other attachments. When a route table is set as the default route table for an attachment type, it is assigned to newly created attachments of that type unless an alternate table is explicitly specified. Route tables specified as the default for any
type cannot be deleted. Ensure that a route table is not currently set as a default route table for an attachment type before trying to delete it.

A VCN attachment has two route tables: One DRG routing table for traffic entering the DRG, and one VCN routing table for traffic entering the VCN. The DRG route table exists in the DRG and is used to route packets entering the DRG through the attachment. The VCN route table is used to route packets entering the VCN through the attachment. If a VCN routing table is not defined, a hidden implicit table always provides connectivity to all subnets in the VCN.

**Dynamic Route Import Distributions**

A distribution is a list of declarative statements that contain a match criteria (such as an OCID or an attachment type) and an action. You can use route distributions to specify how routes get imported from or exported to a DRG attachment.

DRG route tables contain both static and dynamic routes. Static routes are inserted into tables using the API, while dynamic routes are imported from attachments and inserted using an import route distribution. When a statement's criteria matches on an attachment, the routes associated with the network object being attached to the DRG are dynamically imported into the DRG route table assigned to the containing distribution. If the statement is removed from the distribution, the routes are withdrawn from the DRG route tables. Statements in a route distribution are evaluated in priority order: the lowest number has the highest priority. The order in which statements are evaluated doesn't affect the preference set for the routes they import.

When building route distribution statements in the console, you have the option to create a statement whose match type is "Match All". In the API, encode a "match all" statement by setting the match criteria to the empty list.

**How do dynamic routes arrive at an attachment?**

BGP advertises dynamic routes in your on premises network from the CPE to the DRG over IPSec tunnel and virtual circuit attachments. With RPC attachments, dynamic routes are exported to the peer DRG RPC's attachment. Dynamic routes in a VCN include all the subnet CIDRs and all static route CIDRs configured on the VCN route table associated with the DRG attachment.

**Dynamic Route Export Distributions**

When an attachment is assigned to a DRG route table, the contents of that table can be dynamically exported to the attachment. If the default export route distribution is assigned to an attachment, the entire contents of the attachment's assigned DRG route table are dynamically exported to the attachment. If you want to disable dynamic route exports to an attachment, use the API operation `removeExportDrgRouteDistribution` to set the attachment's `exportDrgRouteDistributionId` field to NULL. Dynamic route export to VCN attachments is not supported.

**Route propagation restrictions**

Routes imported from an **IPSec tunnel** or **virtual circuit** are never exported to other **IPSec tunnel** or **virtual circuit** attachments. This holds true regardless of how the export route distribution is configured. In a similar vein, packets which enter a DRG through an IPSec tunnel or virtual circuit attachment can never leave through an IPSec tunnel or virtual circuit attachment. If routing is configured such that packets originating from IPSec tunnel or virtual circuit attachments are sent to IPSec tunnel or virtual circuit attachments, the packets are dropped.

**ECMP**

Equal-cost multi-path routing (ECMP) is a feature which allows flow-based load balancing of network traffic over multiple FastConnect virtual circuits or multiple IPSec tunnels (but not a mix of circuit types) using BGP. This allows active-active load balancing and failover of network traffic between a maximum of eight circuits.

Oracle utilizes the protocol, destination IP, source IP, destination port, and source port to distinguish flows for load balancing purposes using a consistent and deterministic algorithm. Therefore, multiple flows are necessary to utilize all available bandwidth.

ECMP is off by default and can be enabled on a per-route table basis. Oracle only considers routes with identical route preference as eligible for ECMP forwarding. See **Route Conflicts** on page 3797 for more.
Route Source

DRG routes *originate* as either static routes or as dynamic routes from VCN, IPSec tunnel, FastConnect virtual circuit, or RPC attachments. This origin defines their *source*, which is an immutable characteristic of the route. In the API, this is referred to as the *routeProvenance* of a DrgRouteRule.

Routes are *propagated* between DRGs using RPC attachments.

Routes with a source of IPSEC_TUNNEL or VIRTUAL_CIRCUIT are not exported to IPSec tunnel or virtual circuit attachments, regardless of the attachment’s export distribution.

Routing a Subnet's Traffic to a DRG

The basic routing scenario sends traffic from a subnet in the VCN to the DRG. For example, if you're sending traffic from the subnet to your on-premises network, you set up a rule in the subnet's route table. The rule's destination CIDR is the CIDR for the on-premises network (or a subnet within), and the rule's target is the DRG. For more information, see VCN Route Tables on page 3702.

Required IAM Policy

Peering VCNs using a DRG requires specific IAM permissions. See IAM policies related to DRG peering on page 3806 for details on the permissions needed.

DRG versions

DRGs created before May 17, 2021 use the legacy software, and can be upgraded to the most recent version. DRGs created after that have the upgraded features by default.

The following summarizes the difference between an upgraded and legacy DRG:

A legacy DRG:

- Has no programmable route tables. It has a default routing behavior where all traffic is forwarded from on-premises to an associated VCN and from the VCN to on-premises.
- Can attach to a single VCN. The DRG can only be used for remote VCN peering using an RPC.
- Can attach FastConnect or Site-to-Site VPN, or both. You can only reach resources in the local region using these connections.
- Can support an RPC connection with a remote DRG/VCN pair in the same tenancy.

An upgraded DRG:

- Has two route tables by default, and more can be added later.
- Can have many VCNs attached to it within the same region. Local VCN to VCN traffic can pass through a mutually connected DRG instead of an LPG.
- Can attach to on-premises using FastConnect or Site-to-Site VPN, or both. You can reach resources in both local and remote regions using these connections.
- Supports an RPC connection with a DRG/VCN pair in the same or another tenancy.

The rest of this article has recently been updated to reflect the capabilities of an upgraded DRG, as have the common networking scenarios.

Scenarios

We have provided some detailed networking scenarios to help you understand the role of a DRG in the Networking service and how the components work together in general.

**Networking**

**DRG Routing**

**Route Conflicts**

If two routes with identical CIDRs are observed the same DRG route table, the DRG resolves the conflict using the following criteria:

1. Static routes always have higher preference than dynamic routes.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot manually specify two static routes with the same CIDR in the same DRG route table, but it's possible for more than one route with the same CIDR to be imported dynamically.</td>
</tr>
</tbody>
</table>
```

2. Conflicts between dynamic routes are resolved by first analyzing the route's AS Path:
   - Routes with a route source of VCN or STATIC always have an empty AS Path.
   - Routes with a route source of IPSEC_TUNNEL or VIRTUAL_CIRCUIT will have populated AS Path data (see Routing Details for Connections to Your On-Premises Network on page 3818 for more details).

3. Otherwise, the attachment type that imported the route is evaluated according to the following priority based on the attachment type:
   - **VCN**: the DRG makes an arbitrary but stable selection.
   - **VIRTUAL_CIRCUIT**: If ECMP is disabled, the DRG makes an arbitrary but stable selection. If ECMP is enabled, all routes will be added to the route table and the DRG makes routing choices using ECMP. The maximum supported ECMP width inside a DRG is 8.
   - **IPSEC_TUNNEL**: If ECMP is disabled, the DRG makes an arbitrary but stable selection. If ECMP is enabled, all routes will be added to the route table and the DRG makes routing choices using ECMP. The maximum supported ECMP width inside a DRG is 8.
   - **REMOTE_PEERING_CONNECTION**: The DRG will choose the route with the lowest network distance.

   If two routes have identical network distances, the DRG selects the route with the highest priority route source (STATIC > VCN > VIRTUAL_CIRCUIT > IPSEC_TUNNEL).

   If two routes have the same route source, the DRG makes an arbitrary but stable selection.

4. If conflicting routes are imported from attachments of the same type, the conflict is resolved differently depending on the attachment type:
   - **VCN attachments**: If identical CIDRs are imported from two VCN attachments, only one is selected using an arbitrary but stable decision procedure.
   - **VIRTUAL_CIRCUIT and IPSEC_TUNNEL attachments**: If multiple routes with the same CIDR and different AS_PATH lengths are imported into a DRG route table, the route with the lowest AS_PATH length is selected. Otherwise, one route is chosen using an arbitrary but stable decision procedure.
   - **RPC attachments**: If identical CIDRs are imported from two RPC attachments, one of them is chosen using an arbitrary stable decision procedure.

You can observe the results of conflict resolution by listing the contents of the route table. Deprecated routes are marked with the "conflict" status.

**Using BGP to prefer routes from Oracle to your on-premises network**

This section describes in greater detail how the BGP AS_PATH attribute can be used to influence route selection in the context of a single DRG route table.

If the routes for the different paths are the same, **Oracle uses the shortest AS path** when sending traffic to your on-premises network, regardless of which path was used to initiate the connection to Oracle. **Therefore asymmetric routing is allowed.** Asymmetric routing here means that Oracle's response to a request can follow a different path than the request. For example, depending on how your edge device (also called your customer-premises equipment, or CPE) is configured, you could send a request over Site-to-Site VPN, but the Oracle response could come back over FastConnect. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections.
Oracle implements AS path prepending to establish preference on which path to use if your edge device advertises the same route and routing attributes over multiple different connection types between your on-premises network and VCN. The details are summarized in the following table. Unless you're influencing routing in some other way, when the same route is advertised over multiple paths to the DRG at the Oracle end of the connections, Oracle prefers the paths in the following order:

<table>
<thead>
<tr>
<th>Oracle preference</th>
<th>Path</th>
<th>Details of how Oracle prefers the path</th>
<th>Resulting AS path for the route</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FastConnect</td>
<td>Oracle prepends no ASNs to the routes that your edge device advertises, for a total AS path length of 1.</td>
<td>Your ASN</td>
</tr>
<tr>
<td>2</td>
<td>Site-to-Site VPN with BGP</td>
<td>Oracle prepends a single private ASN on all the routes that your edge device advertises over Site-to-Site VPN with BGP, for a total AS path length of 2.</td>
<td>Private ASN, Your ASN</td>
</tr>
<tr>
<td>3</td>
<td>Site-to-Site VPN with static routing</td>
<td>Oracle prepends 3 private ASNs on the static routes that you've provided (Oracle advertises those routes to the dynamic routing gateway (DRG) at the Oracle end of Site-to-Site VPN). This results in a total AS path length of 3.</td>
<td>Private ASN, Private ASN, Private ASN</td>
</tr>
</tbody>
</table>

The preceding table assumes you are sending a single autonomous system number in your AS path. Oracle honors the complete AS path you send. If you use static routing, and also send an AS path that has "Your ASN" plus two or more other ASNs, it can cause unexpected behavior because Oracle's routing preference might change.

While policy-based VPN static routing behavior is documented earlier, Oracle also recommends that if you use FastConnect connections with VPN backup, you employ BGP on your IPSec route-based VPN. This strategy allows you to have full control of failover behavior.

**Using the Console**

In general, to use a DRG, you must complete these minimal steps:

1. Create the DRG.
2. Attach the DRG to one or more VCNs. You can also attach a DRG to your on-premises network using FastConnect virtual circuits and Site-to-Site VPN IPSec tunnels.
3. Route subnet traffic to the DRG by updating the route table associated with each subnet that must send traffic to the DRG.
Creating a DRG

Note:
A DRG created before April 2021 isn't able to perform transit routing between on-premises networks and multiple VCNs, or provide peering between VCNs. If you require that functionality and you see an Upgrade DRG button, click it. Upgrading the DRG resets all existing BGP sessions and temporarily interrupts traffic from the on-premises network. Once it starts, you can't roll back the upgrade. See Upgrading a DRG on page 3799.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.
3. Click Create Dynamic Routing Gateway.
4. Enter the following items:
   - **Create in Compartment:** The compartment where you want to create the DRG, which could be different from the compartment you're currently working in.
   - **Name:** A descriptive name for the DRG. It doesn't have to be unique, and it can be changed later. Avoid entering confidential information.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create Dynamic Routing Gateway.

   The new DRG is created and then displayed on the Dynamic Routing Gateways page of the compartment you chose. The new DRG is in the "Provisioning" state for a short period. You can connect it to other parts of your network only after provisioning is complete.

   Provisioning includes creating two DRG route tables: one route table for connected VCNs and one for other resources such as virtual circuits and IPSec tunnels.

   Note:
   The two default routing tables created implement the same routing behavior used by DRGs created before May 2021 for backward compatibility.

Upgrading a DRG

A DRG created before June 2021 (or April 2021 in San Jose and Montreal regions) must be upgraded before you can connect it to multiple VCNs, use it in cross-tenancy peering scenarios, or modify the internal routing policies. This upgrade process does not change the DRG's OCID.

   Note:
   You can't roll back the change to the DRG. Upgrading the DRG resets existing BGP sessions for both Site-to-Site VPN and FastConnect.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to upgrade.
3. Click Upgrade DRG.
4. A message appears reminding you the action can't be reversed. Click Upgrade DRG.
5. The upgrade takes place in the background. You can continue to make configuration settings while the upgrade takes place. You are notified when the upgrade is complete.
6. When the upgrade finishes, refresh the page to gain access to the new DRG capabilities. Click Refresh page.
Updating the name of a DRG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to update.
3. Click Edit.
4. Edit the display name. Avoid entering confidential information.
5. Click Save Changes.

Attaching a VCN to a DRG

Note:
A DRG can be attached to many VCNs, but VCN can be attached to only one DRG at a time. The attachment is automatically created in the compartment that holds the VCN. A VCN does not need to be in the same compartment as the DRG.

Sometimes, you can choose to connect VCNs in the same region using a single DRG instead of local peering gateways. If left unmodified, the default routing policies in a DRG allow traffic to be routed between all VCNs attached to it.

If you are attaching a DRG to a VCN in another tenancy, you need to have IAM configurations in both tenancies as described in IAM policies related to DRG peering on page 3806.

The following instructions have you navigate to the DRG and then choose which VCN to attach. You could instead navigate to the VCN and then choose which DRG to attach.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you want to attach to a VCN.
4. Click Create Virtual Cloud Network Attachment.
   - (Optional) Give the attachment point a friendly name. If you don't specify a name, one is created for you.
   - Select a VCN from the list. You can also click Change compartment and choose a different compartment that contains a VCN you want to attach to your DRG, then select a VCN from the list.
5. (Optional) If you're setting up an advanced scenario for transit routing, you can associate a VCN route table with the DRG attachment (you can do this later):
   a. Click Show Advanced Options.
   b. Click the VCN route table tab.
   c. Select the route table that you want to associate with the VCN attachment on the DRG. If you select None, the default VCN route table is used.
6. If you are planning to use transit routing and need to associate a specific DRG route table to the attachment:
   a. Click Show Advanced Options.
   b. From the DRG route table tab, choose an existing DRG route table. See To create a DRG route table on page 3802.
7. When you are finished, click Create VCN attachment.

The attachment is in the "Attaching" state for a short period.

When the attachment is ready, create a route rule in the subnet's route table directing subnet traffic to the DRG. See To route a subnet's traffic to a DRG on page 3802.

Updating a VCN attachment

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.
2. Click the DRG with the attachment you want to update.
3. Under Resources, click **Virtual Cloud Networks attachments**.
4. Click the name of the attachment you want to update.
5. Click the **Edit** button.
6. Change the name of the attachment.
7. (Optional) Click **Show advanced options** to change the DRG route table or VCN route table associated with the attachment.
8. When finished, click **Save changes**.

**Deleting a VCN attachment**

How to delete a VCN attachment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG with the attachment you want to delete.
3. Under Resources, click **Virtual cloud network attachments**.
4. Click the name of the attachment you want to delete.
5. Click the **Delete** button.
6. Confirm that you want to delete the attachment. Click **Delete**.

**Moving a virtual circuit to a different DRG**

When you set up FastConnect, the virtual circuits are attached to a DRG you select. You can move the FastConnect virtual circuits to a different DRG by moving the resource. Moving the virtual circuit deletes an existing attachment and creates an attachment that uses the new DRG's default route table for that attachment type.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Select the compartment where the connection resides, and then click a connection to view its details.
3. Click **Move resource** or **Edit** and make your changes. You can change the name of the virtual circuit and change the DRG to which it attaches. Avoid entering confidential information.

   When you move a virtual circuit from one DRG to another DRG, the original DRG attachment is deleted and a new DRG attachment is created. The new attachment uses the target DRG's default route table for that attachment type.

4. Click **Save Changes**.

**Creating a remote peering connection on a DRG**

How to create a remote peering connection attachment from a DRG.

Each administrator creates an RPC for their own VCN's DRG. "You" in the following procedure means an administrator (either the acceptor or requestor).

---

### Note:

**Required IAM Policy to Create RPCs**

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network on page 2807), then they have permission to create, update, and delete RPCs. Otherwise, here's an example policy giving the necessary permissions to a group called RPCAdmins. The second statement is required because creating an RPC affects the DRG it belongs to, so the administrator must have permission to manage DRGs.

- Allow group RPCAdmins to manage remote-peering-connections in tenancy
- Allow group RPCAdmins to manage drgs in tenancy
1. In the Console, confirm you're viewing the compartment that contains the DRG that you want to add the RPC to. For information about compartments and access control, see Access Control on page 3708.

2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.

3. Click the DRG you're interested in.

5. Click Create Remote Peering Connection.

6. Enter the following:
   - Name: A friendly name for the RPC. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - Create in compartment: The compartment where you want to create the RPC, which could be different from the compartment you're currently working in.

7. Click Create Remote Peering Connection.
   The RPC is then created and displayed on the Remote Peering Connections page in the compartment you chose.

8. If you're the acceptor, record the RPC's region and OCID to later give to the requestor.

9. If the two VCNs are in different tenancies, record your tenancy OCID (found on the bottom of the page in the Console). Give the OCID to the other administrator so they can create a matching RPC on their DRG.

**Editing a DRG attachment**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.

2. Click the name of the DRG with the attachment you want to edit.

3. Under Resources, click the type of the attachment you want to edit.
   - Virtual cloud network attachments
   - Virtual circuit attachments
   - IPSec tunnel attachments
   - Remote peering connection attachments

4. Click the name of the attachment.

5. Click Edit.

6. In the screen that appears, you can rename the attachment and change the associated DRG route table.

**To route a subnet’s traffic to a DRG**

For each VCN subnet that must send traffic to the DRG, you must add a route rule to the VCN route table associated with that subnet. If all the subnets in the VCN use the default route table, you must add a rule to only that one table. If all non-intra-VCN traffic that's not covered by another rule in the table must be routed to the DRG, add this new rule:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
- **Destination CIDR Block** = 0.0.0.0/0. If you want to limit the rule to a specific network (for example, your on-premises network), then use that network's CIDR instead of 0.0.0.0/0.

For step-by-step instructions, see To update rules in an existing route table on page 3705.

**To create a DRG route table**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 3708.

3. Click the DRG for which you want to create a route table.
4. Under **Resources**, click **DRG route tables**.
5. Click **Create DRG Route Table**.
6. Enter the following items:
   - **Name**: (Optional) A descriptive name for the route table. Avoid entering confidential information.
   - **Destination CIDR**: The route table must include at least one destination. You can either enter a destination CIDR, enable import route distribution, or enter nothing and the default CIDR 0.0.0.0/32 is applied, allowing all traffic.
   - **Next Hop Attachment Type**: Choose between **Virtual Cloud Network** or **Remote Peering Connection**, as appropriate for the intended target of the static rule.
   - **Next Hop attachment**: Choose a VCN, virtual circuit, IPSec tunnel, or remote peering connection attachment.
7. (Optional) You can also select the following advanced options:
   - **Enable Import Route Distribution**: This option allows you to assign an import route distribution to the route table so it dynamically learns new routes based on BGP advertisements.
   - **Enable ECMP**: Equal-cost multi-path routing (ECMP) can be enabled to disambiguate routing decisions when the same destination can be reached from multiple paths.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
8. Click **Create DRG Route Table**.

**Viewing the contents of your DRG route table**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see **Access Control** on page 3708.
3. Click the DRG with the route table you want to view.
4. Under **Resources**, click **DRG route tables**.
5. Click the name of the route table you want to view.
6. Click **Get All Route Rules**. The list of routes includes both static routes inserted into the table and all dynamic routes which have been imported from other attachments and inserted using an import route distribution.

   You can use this page to validate and troubleshoot the next hop behavior of traffic entering your DRG. For example, use this functionality to confirm the behavior of traffic destined for your on-premises by validating the routes received by way of your Site-to-Site VPN IPSec tunnel or FastConnect virtual circuit.
7. Click **Close** when you are finished.

**To associate a VCN route table with an existing DRG attachment**

---

**Important:**

Perform this task only if you're setting up an advanced scenario for transit routing. See **Transit Routing inside a hub VCN** on page 3667 and **Private Access to Oracle Services** on page 3653.

---

A DRG attachment always has a route table associated with it, but you can associate a different route table, edit the table's rules, or delete some or all rules.

**Prerequisites:** the VCN that the DRG is already attached to must have a route table.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG that is attached to the VCN that has the route table you want to use with the attachment.
3. Click the Actions icon (three dots), and then click either:
   - **Associate Route Table:** If the DRG attachment has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the DRG attachment.

4. Select the route table.
5. Click **Associate Route Table**.

The route table is now associated with the DRG attachment.

**To add a static rule to a DRG route table**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click the route table you're interested in.
5. If you want to create a route rule, click **Add Route Rule** and enter the following:
   - **Target Type:** See the list of target types in **Overview of Routing for Your VCN** on page 3702. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself. If the target is a private IP, before you specify the target you must first disable the source/destination check on the private IP's VNIC. For more information, see **Using a Private IP as a Route Target** on page 3703.
   - **Destination CIDR Block:** Only if the target is not a service gateway. The value is the destination CIDR block for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule.
   - **Destination Service:** Only if the target is a service gateway. The value is the service CIDR label that you're interested in.
   - **Compartment:** The compartment where the target is located.
   - **Target:** The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in which case the Console determines the corresponding OCID and uses it as the target for the route rule.
   - **Description:** An optional description of the rule.
6. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
7. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

**To attach an IPSec connection to a DRG**

This process is required when creating a Site-to-Site VPN connection, and is documented in **Task 2c: Attach the DRG to the VCN** on page 3830

**To detach a DRG from a VCN**

**Note:** You do not need to remove the route rule that routes traffic to the DRG before you detach the DRG from the VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateway**.
2. Click the DRG you want to detach.
3. Under **Resources**, click **Virtual Cloud Networks** to see the VCNs the DRG is attached to. If a VCN is in a different compartment than the one you're working in, choose that compartment from the list on the left side of the page.
4. Click the Actions icon (three dots), and then click **Detach**.
5. Confirm when prompted.

The attachment is in the "Detaching" state for a short period.

**To delete a DRG**

**Prerequisites:**
• The DRG can't be currently attached to a VCN.
• The DRG can't be currently connected to another network by way of Site-to-Site VPN, FastConnect, or remote peering.
• There can't be a route rule that lists the DRG as a target.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in.
3. Click Terminate.
4. Confirm when prompted.

The DRG is in the "Terminating" state for a short period while being deleted. The DRG route tables and DRG route distributions contained in the DRG are deleted along with it.

To manage tags for a DRG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click the DRG you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Add Tags to add new ones.

For more information, see Resource Tags on page 239.

To move a DRG to a different compartment

You can move a dynamic routing gateway from one compartment to another. When you move a dynamic routing gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Find the DRG in the list, click the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 3708. For general information about compartments, see Managing Compartments on page 3126.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage your DRGs, use these operations:

• Drg
  • CreateDrg
  • DeleteDrg
  • GetDrg
  • GetAllDrgAttachments
  • UpgradeDrg
  • GetUpgradeStatus
  • ListDrugs
  • UpdateDrg
  • ChangeDrgCompartment
• **DrgAttachment**
  - **CreateDrgAttachment**: This attaches a DRG to a VCN and results in a DrgAttachment object with its own OCID. You can optionally specify a route table if you're setting up the advanced routing scenario called transit routing.
  - **DeleteDrgAttachment**: This detaches a DRG from a VCN by deleting the DrgAttachment.
  - **ListDrgAttachments**
  - **UpdateDrgAttachment**: Among other things, this associates a route table with an existing DRG attachment for transit routing. This operation is also used when reassigning a DRG route table.
  - **GetDrgAttachment**

• **DrgRouteDistribution**
  - **CreateDrgRouteDistribution**
  - **GetDrgRouteDistribution**
  - **ListDrgRouteDistributions**
  - **UpdateDrgRouteDistribution**
  - **RemoveExportDrgRouteDistribution**
  - **RemoveImportDrgRouteDistribution**

• **DrgRouteDistributionStatement**
  - **AddDrgRouteDistributionStatements**
  - **DeleteDrgRouteDistribution**
  - **ListDrgRouteDistributionStatements**
  - **RemoveDrgRouteDistributionStatements**
  - **UpdateDrgRouteDistributionStatements**

• **DrgRouteRule**
  - **AddDrgRouteRules**
  - **ListDrgRouteRules**: This operation allows you to see both dynamic and static routes in your DRG route tables.
  - **RemoveDrgRouteRules**
  - **UpdateDrgRouteRules**

• **DrgRouteTable**
  - **CreateDrgRouteTable**
  - **GetDrgRouteTable**
  - **ListDrgRouteTables**
  - **UpdateDrgRouteTable**

For information about route table operations, see VCN Route Tables on page 3702.

**Limitations**

Some functions might appear to be possible based on the structure of the resource interaction model, but the following functions are not currently allowed:

1. Explicit creation or deletion of RPC, IPSec tunnel, or virtual circuit attachments
2. Static routes in DRG route tables with next-hop of IPSec tunnel or virtual circuit attachments
3. Use of non-default export route distributions
4. Dynamic route export to VCN attachments

**IAM policies related to DRG peering**

**Explicit Agreement Required from Both Sides**

Peering and transit routing involve two VCNs owned by the same party or two different ones. The two parties might both be in your company but in different departments. Or the two parties might be in entirely different companies (for
example, in a service-provider model). See Accessing Object Storage Resources Across Tenancies on page 4420 for further examples of cross-tenant policies.

The agreement is in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's compartment or tenancy. If the VCNs are in different tenancies, each administrator must provide their tenancy OCID and put in place special policy statements to enable the peering. For details on the IAM policies required to connect to a VCN in another tenancy, see Accessing VCNs in other tenancies using RPCs on page 3807.

**Accessing VCNs in the same tenancy using RPCs**

For details on this use case, see Task C: Set up the IAM policies (VCNs in same tenancy) on page 4158.

**Accessing VCNs in the same tenancy using VCN attachments**

If you want the administrators group to create and manage VCN attachments and assign DRG route tables to the attachments, implement the following policy:

| Allow group <administrators> to manage vcns in tenancy |
| Allow group <administrators> to manage drgs in tenancy |

**Note:**

To associate a VCN route table with the attachment, the administrators also need a policy to "manage route-tables" in the tenancy.

**Accessing VCNs in other tenancies using RPCs**

Both the requestor and acceptor must ensure that the right policies are in place. A minimal policy would consist of:

This example shows the minimal identity policies needed to create a cross-tenancy remote peering connection:

- **Policy R (implemented by the requestor):**

  | Define tenancy Acceptor as <acceptor-tenancy-ocid> |
  | Allow group <requestor-group-name> to manage remote-peering-from in compartment <<requestor-compartment-name>> |
  | Endorse group <requestor-group-name> to manage remote-peering-to in tenancy Acceptor |

- **Policy A (implemented by the acceptor):**

  | Define tenancy Requestor as <requestor-tenancy-ocid> |
  | Define group <requestor-group-name> as <requestor-group-ocid> |
  | Admit group <requestor-group-name> of tenancy Requestor to manage remote-peering-to in compartment <acceptor-compartment-name> |

**Accessing VCNs in other tenancies using VCN attachments**

This example of a set of policies allows the following set of actions:

- DRG administrators in the DRG tenant can create a DRG attachment in the VCN tenant, and associate a specific VCN route table with it as well.
- VCN administrators in the VCN tenant can associate a VCN route table to the attachment (used when the VCN attached is a transit VCN). If the VCN administrator has a policy to manage all-resources in the VCN tenant, they already have this ability, because the VCN attachment resides in the VCN tenancy.
- VCN administrators do not have the ability to change the DRG route table association for the DRG attachment.
- **Requestor IAM policies (DRG in this tenancy)**

  | define tenancy VCN as <vcn-tenant-ocid> |
Networking

define group VCN-Admin as <vcn-group-ocid>
endorse group DRG-Admin to manage drg-attachment in tenancy VCN
admit group VCN-Admin of tenancy VCN to manage drg in tenancy

- **Acceptor IAM policies (VCN in this tenancy)**

define tenancy DRG as <drg-tenant-ocid>
define group DRG-Admin as <drg-group-ocid>
admit group DRG-Admin of tenancy DRG to manage drg-attachment in tenancy
endorse group VCN-Admin to manage drg in tenancy DRG

Controlling the Establishment of Peerings

With IAM policies, you can control:

- Who can **subscribe your tenancy to another region** (required for remote VCN peering).
- Who in your organization has the authority to establish VCN peerings (for example, see the IAM policies in Setting Up a Local Peering on page 4143 and Setting Up a Remote Peering on page 4157). Deletion of these IAM policies does not affect any existing peerings, only the ability for future peerings to be created.
- Who can manage route tables and security lists.

Site-to-Site VPN

Site-to-Site VPN provides an IPSec connection between your on-premises network and your virtual cloud network (VCN).

Troubleshoot VPN issues

Troubleshoot common issues and error messages.
Use cases

**Securely connect to Oracle Cloud**
Securely connect your existing infrastructure to the cloud by using industry-standard encryption algorithms.

**Connect to other public clouds**
Securely connect to workloads in other providers’ cloud services.

**Connect multiple locations to the cloud**
Connect your headquarters, branch locations, and private data centers to Oracle Cloud so all of your offices can access applications.

**Build redundant connectivity for Oracle FastConnect**
Already have Oracle FastConnect? Site-to-Site VPN can provide a redundant connection to Oracle Cloud Infrastructure.

Site-to-Site VPN Overview
Site-to-Site VPN provides a site-to-site IPSec connection between your on-premises network and your virtual cloud network (VCN). The IPSec protocol suite encrypts IP traffic before the packets are transferred from the source to the destination and decrypts the traffic when it arrives. Site-to-Site VPN was previously referred to as VPN Connect and IPSec VPN.

Other secure VPN solutions include OpenVPN, a Client VPN solution that can be accessed in the Oracle Marketplace. OpenVPN connects individual devices to your VCN, but not whole sites or networks.

This topic gives an overview of Site-to-Site VPN for your VCN. For scenarios that include Site-to-Site VPN, see Scenario B: Private Subnet with a VPN on page 3618 and Scenario C: Public and Private Subnets with a VPN on page 3626.

Required Personnel and Knowledge
Typically the following types of personnel are involved in setting up Site-to-Site VPN with Oracle Cloud Infrastructure:

- **Dev Ops team member** (or similar function) who uses the Oracle Cloud Infrastructure Console to set up the cloud components required for the virtual network and Site-to-Site VPN.
- **Network engineer** (or similar function) who configures the customer-premises equipment (CPE) device with information provided by the Dev Ops team member.

**Tip:**
The Dev Ops team member must have the required permission to create and manage the cloud components. If the person is the default administrator for your Oracle Cloud Infrastructure tenancy or a member of the Administrators group, then they have the required permission. For information about restricting access to your networking components, see Access Control on page 3708.

The personnel should be familiar with the following concepts and definitions:

- **The fundamentals of Oracle Cloud Infrastructure**
- **The basic Networking service components**
- **General IPSec tunnel functionality**

CLOUD RESOURCES
Anything you provision on a cloud platform. For example, with Oracle Cloud Infrastructure, a cloud resource can refer to a VCN, compute instance, user, compartment, load balancer, or any other service component on the platform.
ON-PREMISES

A widely used term in cloud technologies that refers to your traditional data center environments. On-premises can refer to a colocation scenario, a dedicated floor space, a dedicated data center building, or a desktop running under your desk.

ORACLE CLOUD IDENTIFIER (OCID)

A unique identifier assigned to each resource that you provision on Oracle Cloud Infrastructure. The OCID is a long string that Oracle automatically generates. You can't choose the value for an OCID or change a resource's OCID. For more information, see Resource Identifiers on page 225.

About the Oracle IPSec Connection

In general, an IPSec connection can be configured in the following modes:

- **Transport mode**: IPSec encrypts and authenticates only the actual payload of the packet, and the header information stays intact.
- **Tunnel mode (supported by Oracle)**: IPSec encrypts and authenticates the entire packet. After encryption, the packet is then encapsulated to form a new IP packet that has different header information.

Oracle Cloud Infrastructure supports only the tunnel mode for IPSec VPNs.

Each Oracle IPSec connection consists of multiple redundant IPSec tunnels. For a given tunnel, you can use either Border Gateway Protocol (BGP) dynamic routing or static routing to route that tunnel's traffic. More details about routing follow.

Site-to-Site VPN IPSec tunnels offer the following advantages:

- Public internet lines are used to transmit data, so dedicated, expensive lease lines from one site to another aren't necessary.
- The internal IP addresses of the participating networks and nodes are hidden from external users.
- The entire communication between the source and destination sites is encrypted, significantly lowering the chances of information theft.

Routing for Site-to-Site VPN

When you set up Site-to-Site VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE device to use both tunnels (if your device supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each IPSec tunnel in Site-to-Site VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
- **Policy-based routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

Important Routing Details for Site-to-Site VPN

Here are important details to understand about routing for your Site-to-Site VPN:
Networking

• **Routing choices:**
  • Originally, Site-to-Site VPN supported only static routing, and you were required to provide at least one static route for the overall IPSec connection.
  • Now two different types of routing are available (BGP and static routing), and you configure the routing type per tunnel. Only one type of routing at a time is supported for a given tunnel.
  • In general, Oracle encourages you to use the same routing type for all tunnels in your IPSec connection. Exception: if you're in the process of transitioning between static routing and BGP, then one tunnel might temporarily still use static routing while the other has already been switched to BGP.
  • When you create an IPSec connection, static routing is the default type of routing for all tunnels unless you explicitly configure each tunnel to use BGP.

• **Routing information required:**
  • If you choose BGP, for each tunnel you must provide two IP addresses (one for each of the two BGP speakers in the tunnel's BGP session). The addresses must be in the encryption domain for the IPSec connection. You must also provide the BGP autonomous system number (BGP ASN) for your network.
  • If you choose static routing, you must provide at least one static route (maximum 10). The static routes are configured with the overall IPSec connection, so the same set of static routes are used for all tunnels in the IPSec connection that are configured to use static routing. You can change the static routes at any time after creating the IPSec connection. If you're doing PAT between your CPE device and VCN, the static route for the IPSec connection is the PAT IP address. See Example Layout with PAT on page 3843.
  • If you choose static routing, you may optionally provide an IP address for each end of the tunnel for the purposes of tunnel troubleshooting or monitoring.
  • If the tunnel is configured to use BGP, the IPSec connection's static routes are ignored. Any static routes associated with the IPSec connection are used for routing a given tunnel's traffic only if that tunnel is configured to use static routing. This is especially relevant if you have Site-to-Site VPN that uses static routing, but want to switch to using BGP.

• **Changing the routing:**
  • If you want to change a tunnel from BGP to static routing, you must first ensure that the IPSec connection itself has at least one static route associated with it.
  • You can change an existing tunnel's routing type at any time (unless the tunnel is currently being provisioned by Oracle). While you change the routing, the tunnel remains up (its IPSec status does not change). However, traffic flowing through the tunnel is disrupted temporarily during reprovisioning and while you reconfigure your CPE device. For information about making changes to Site-to-Site VPN, see Working with Site-to-Site VPN on page 4034.
  • Because you configure the routing type separately for each tunnel, if you want to switch your Site-to-Site VPN from static routing to BGP, you can do it one tunnel at a time. This avoids the entire IPSec connection being down. For instructions, see Changing from Static Routing to BGP Dynamic Routing on page 4037.

**Route Advertisements and Path Preferences When You Have Multiple Connections**

When you use BGP, the DRG attached to your VCN advertises routes to your CPE.

If you set up multiple connections between your on-premises network and VCN, you must understand what routes the DRG advertises and how to set path preferences to use your desired connection.

For important information, see Routing Details for Connections to Your On-Premises Network on page 3818.

**Preferring a Specific Tunnel in Site-to-Site VPN**

Within Site-to-Site VPN, you can influence which tunnel is preferred. Here are items you can configure:

• **Your CPE's BGP local preference:** If you use BGP, you can configure the BGP local preference attribute on your CPE device to control which tunnel is preferred for connections initiated from your on-premises network to your VCN. Because Oracle generally uses asymmetric routing, you must configure other attributes if you want Oracle to respond on that same tunnel. See the next two items.
More specific routes on the preferred tunnel: You can configure your CPE to advertise more specific routes for the tunnel that you want to prefer. Oracle uses the route with the longest prefix match when responding to or initiating connections.

AS path prepending: BGP prefers the shortest AS path, so if you use BGP, you can use AS path prepending to control which tunnel has the shortest path for a given route. Oracle uses the shortest AS path when responding to or initiating connections.

Overview of Site-to-Site VPN Components

If you're not already familiar with the basic Networking service components, see Networking on page 3604 before proceeding.

When you set up Site-to-Site VPN for your VCN, you must create several Networking components. You can create the components with either the Console or the API. See the following diagram and description of the components.

cpe object

At your end of Site-to-Site VPN is the actual device in your on-premises network (whether hardware or software). The term customer-premises equipment (CPE) is commonly used in some industries to refer to this type of on-premises equipment. When setting up the VPN, you must create a virtual representation of the device. Oracle calls the virtual representation a CPE, but this documentation typically uses the term CPE object to help distinguish the virtual representation from the actual CPE device. The CPE object contains basic information about your device that Oracle needs.

DYNAMIC ROUTING GATEWAY (DRG)

At Oracle's end of Site-to-Site VPN is a virtual router called a dynamic routing gateway, which is the gateway into your VCN from your on-premises network. Whether you're using Site-to-Site VPN or Oracle Cloud Infrastructure FastConnect private virtual circuits to connect your on-premises network and VCN, the traffic goes through the DRG. For more information, see Dynamic Routing Gateways (DRGs) on page 3793.

A network engineer might think of the DRG as the VPN headend. After creating a DRG, you must attach it to your VCN, using either the Console or API. You must also add one or more route rules that route traffic...
Networking

from the VCN to the DRG. Without that DRG attachment and the route rules, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining VPN components. You can then reattach the DRG, or attach it to another VCN.

**ipsec connection**

After creating the CPE object and DRG, you connect them by creating an IPSec connection, which you can think of as a parent object that represents the Site-to-Site VPN. The IPSec connection has its own *OCID*. When you create this component, you configure the type of routing to use for each tunnel, and you provide any related routing information.

**TUNNEL**

An IPSec tunnel is used to encrypt traffic between secure IPSec endpoints. Oracle creates two tunnels in each IPSec connection for redundancy. Each tunnel has its own *OCID*. Oracle recommends that you configure your CPE device to support both tunnels in case one fails or Oracle takes one offline for maintenance. Each tunnel has configuration information that your network engineer needs when configuring your CPE device. This information includes an IP address and shared secret, as well as ISAKMP and IPSec parameters. You can use the CPE Configuration Helper to gather the information that the network engineer needs. For more information, see Supported IPSec Parameters on page 3821 and Verified CPE Devices on page 3846.

**Access Control for the Components**

For the purposes of access control, when you set up Site-to-Site VPN, you must specify the compartment where you want each of the components to reside. If you're not sure which compartment to use, put all the components in the same compartment as the VCN. Note that the IPSec tunnels always reside in the same compartment as the parent IPSec connection. For information about compartments and restricting access to your networking components, see Access Control on page 3708.

**Component Names and Identifiers**

You can optionally assign a descriptive name to each of the components when you create them. These names don't have to be unique, although it's a best practice to use unique names across your tenancy. Avoid entering confidential information. Oracle automatically assigns each component an OCID. For more information, see Resource Identifiers.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing Site-to-Site VPN, CPE, and DRG connections with NAT device and subnet](image)

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to
match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

About the Tunnel Shared Secret

Each tunnel has a shared secret. By default, Oracle assigns the shared secret to the tunnel unless you provide a shared secret yourself. You can provide a shared secret for each tunnel when you create the IPSec connection, or later after the tunnels are created. For the shared secret, only letters, numbers, and spaces are allowed. If you change an existing tunnel's shared secret, the tunnel goes down while it is being reprovisioned.

For instructions, see Changing the Shared Secret That an IPSec Tunnel Uses on page 4037.

Resources for Configuring the CPE

Your network engineer must configure the CPE at your end of the IPSec connection. To make it easier, Oracle provides these resources:

- **CPE Configuration Helper**: A tool in the Oracle Console that generates a set of content that the network engineer can use when configuring the CPE.
- **A list of verified CPE devices**: For each device, Oracle provides configuration instructions.
- **A list of supported IPSec parameters**: If your CPE is not on the list of verified devices, you can use this list of parameters to configure your CPE.

For more information, also see CPE Configuration on page 3844.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring your connection, Site-to-Site VPN Metrics on page 4042.

What’s Next?

Site-to-Site VPN Quickstart

The Site-to-Site VPN wizard is the quickest way to set up a site-to-site VPN between your on-premises network and your virtual cloud network (VCN). The wizard is a guided, step-by-step process in the Console that sets up the VPN plus related Networking service components.

Other secure VPN solutions include OpenVPN, a Client VPN solution that can be accessed in the Oracle Marketplace. OpenVPN connects individual devices to your VCN, but not whole sites or networks.
# Purpose of the Wizard

Site-to-Site VPN involves setting up and configuring several Networking service components. The wizard sets up those components for you. In general, the wizard does the following:

- Uses a template with assumptions that will help you get started.
- Asks you for some basic network information.
- Sets up the Networking service components for you.
- Lets you generate configuration content for a network engineer to use when configuring your customer-premises equipment (CPE) device.

The wizard is a task within the overall process of setting up Site-to-Site VPN, which is illustrated in the following diagram. The wizard is the shaded box.

<table>
<thead>
<tr>
<th>Step</th>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Get Information from Your Network Engineer</td>
<td>Request information from the network engineer.</td>
</tr>
<tr>
<td>2</td>
<td>Use the Wizard</td>
<td>Use the wizard to set up the Networking components.</td>
</tr>
<tr>
<td>3</td>
<td>Use the CPE Configuration Helper to Generate Content for the Network Engineer</td>
<td>Generate configuration content for the network engineer.</td>
</tr>
<tr>
<td>4</td>
<td>Configure the CPE Device</td>
<td>Configure the CPE device.</td>
</tr>
<tr>
<td>5</td>
<td>Test the Connection</td>
<td>Test the connection.</td>
</tr>
</tbody>
</table>

Notice that the overall process includes work by a network engineer in your organization. That engineer provides information that you, in turn, must supply when running the wizard. The wizard returns information that the network engineer needs when configuring your CPE device. You can use the CPE Configuration Helper to consolidate the necessary information into an organized template for the network engineer.

The following short sections summarize each task.

## Task 1: Information to get from your network engineer

- CPE device's public IP address. (IPv4 required, IPv6 optional)
- CPE vendor, model, and version
- CPE IKE identifier. For more information, see Overview of Site-to-Site VPN Components on page 3812.
- On-premises network routes.
• If you use BGP dynamic routing with the VPN:
  • Your network's BGP ASN
  • For each of the two IPSec tunnels that will be created, the pair of BGP IP addresses (with subnet mask) that you want to use for the inside tunnel interfaces at the ends of each tunnel. For example:
    • Tunnel 1: Inside tunnel interface - CPE: 10.0.0.16/31
    • Tunnel 1: Inside tunnel interface - Oracle: 10.0.0.17/31
    • Tunnel 2: Inside tunnel interface - CPE: 10.0.0.8/31
    • Tunnel 2: Inside tunnel interface - Oracle: 10.0.0.9/31

Task 2: Wizard

You walk through the wizard in the Console. For more information, see these sections:
  • Where to Access the Wizard in the Console on page 3818
  • What the Wizard Creates for You on page 3816

Task 3: Information to give to your network engineer

You use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

The content includes these items:
  • The Oracle VPN IP address and shared secret for each IPSec tunnel.
  • The supported IPSec parameter values.
  • Information about the VCN.
  • CPE-specific configuration information.

Task 4: CPE configuration

Your network engineer takes the information you provide and configures your CPE device.

Task 5: Testing

You and the network engineer test the connection and confirm that traffic is flowing.

Alternative to the Wizard

If you prefer, you can manually set up Site-to-Site VPN yourself. For step-by-step instructions, see Setting Up Site-to-Site VPN on page 3825.

What the Wizard Creates for You

Most Oracle customers who set up Site-to-Site VPN already have a VCN to connect to their on-premises network. In that case, the wizard creates the numbered components in the following diagram. The table describes each component.
<table>
<thead>
<tr>
<th>Number</th>
<th>Component</th>
<th>Description</th>
<th>Can Use Existing One or Create New One?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CPE</td>
<td>A CPE is a <em>virtual representation</em> of your actual CPE device. This virtual representation contains basic information such as the CPE device's public IP address. Yes, you can either use an existing CPE or the wizard creates a new one.</td>
<td></td>
</tr>
<tr>

<td>IPSec tunnels</td>
<td>The wizard creates two <em>IPSec tunnels</em>, each with specific configuration information that you must provide to your network engineer. <strong>Note:</strong> The wizard uses IKEv1 or IKEv2 for the tunnels. For more information on IKEv2, see Using IKEv2 on page 4036. No. The wizard automatically creates the tunnels.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Dynamic routing gateway (DRG)</td>
<td>A DRG is a <em>virtual representation</em> of the actual router at the Oracle end of your Site-to-Site VPN. Yes.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Internet Gateway</td>
<td>If the VCN you select does not already have an <em>Internet Gateway</em> on page 4114, you can choose to let the wizard create one to enable direct connectivity to the internet. Yes, you can either use an existing internet gateway or choose to let the wizard create a new one.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

To create any new resource the service limit for that resource must not already have been reached. Once the service limit for a resource type has been reached, you can either remove unused resources of that type or request a service limit increase.

In addition, during the wizard you specify which subnets in your VCN should be configured with access to the on-premises network. The wizard updates each subnet’s route table and security rules as follows:

- **Route rules:** The wizard adds one or more rules to route VCN traffic to your on-premises network by way of the DRG. There’s one rule per on-premises network route that you provide in the wizard. If the VCN has an internet gateway (or you choose to create one) and a public subnet is selected, the wizard also adds a rule to send remaining traffic (not destined for the on-premises network) to the internet gateway.

- **Security list rules:** The wizard also adds one or more rules to allow all types of traffic from your on-premises network. There’s one rule per on-premises network route that you provide in the wizard. If the VCN has an internet gateway (or you choose to create one) and a public subnet is selected, the wizard also adds a rule to allow SSH over port 22 from the internet.

You can edit the rules and add more if you want.
Networking

After the wizard completes, you can use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

**Where to Access the Wizard in the Console**

**Option 1:**
1. In the Console, click the **Oracle Cloud** icon at the top of the page to go to the Console home page.
   The page has a **Quick Actions** section to take you directly to common tasks.
2. Click the quick action for **Networking: Set up a network with a wizard**.
3. Select **Add Internet Connectivity and Site-to-Site VPN to a VCN**, and then click **Start VPN Wizard**.

**Option 2:**
1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click **Start VPN Wizard**.
3. Select **Add Internet Connectivity and Site-to-Site VPN to a VCN**, and then click **Start VPN Wizard**.

**Option 3:**
1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.
2. Click **Start VPN Wizard**.

**Option 4:**
1. Open the navigation menu and click **Networking**.
2. Click **Overview**.
3. Under **Add Internet Connectivity and Site-to-Site VPN to a VCN** click **Start VPN Wizard**.

**Routing Details for Connections to Your On-Premises Network**

You might use multiple site-to-site connections between your on-premises network and virtual cloud network (VCN) for redundancy or other reasons.

For example, you might use both FastConnect private peering and Site-to-Site VPN to the *dynamic routing gateway (DRG)* attached to your VCN. Or perhaps you use redundant Site-to-Site VPN connections to the DRG (for an example scenario, see **Example Layout with Multiple Geographic Areas** on page 3841). Or perhaps you use FastConnect public peering, FastConnect private peering, and Site-to-Site VPN.

This topic covers important details about route advertisement and path preferences when you have multiple connections.

**DRG Route Advertisements to Your On-Premises Network**

FastConnect private peering and Site-to-Site VPN provide your on-premises network with private access to a VCN. Both types of connections terminate on a single DRG that is attached to the VCN. Remember that Site-to-Site VPN can use either Border Gateway Protocol (BGP) or static routing, or a combination. FastConnect always uses BGP for route advertisements.
For attachments to virtual circuits and IPSec tunnels configured to use dynamic routing, the DRG will advertise all routes contained in their assigned DRG route table.

If an attached VCN is using ingress routing to grant access to Oracle services through the VCN's service gateway, you will be able to observe the route listed as a single mnemonic route using the ListDrgRouteRules API operation. When this route is propagated to another DRG through an RPC or advertised to your on-premises network using BGP, it will appear as a set of literal rules. For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 222.

**Important:**

If you're using Site-to-Site VPN with static routing, and the VCN is configured to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 222.

### Using AS_PATH to prefer routes from Oracle to your on-premises network

This section describes in greater detail how the BGP AS_PATH attribute can be used to influence route selection in the context of a single DRG route table.

If the routes for the different paths are the same, Oracle uses the shortest AS path when sending traffic to your on-premises network, regardless of which path was used to initiate the connection to Oracle. Therefore asymmetric routing is allowed. Asymmetric routing here means that Oracle's response to a request can follow a different path than the request. For example, depending on how your edge device (also called your customer-premises equipment, or CPE) is configured, you could send a request over Site-to-Site VPN, but the Oracle response could come back over FastConnect. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections.

Oracle implements AS path prepending to establish preference on which path to use if your edge device advertises the same route and routing attributes over multiple different connection types between your on-premises network and VCN. The details are summarized in the following table. Unless you're influencing routing in some other way, when the same route is advertised over multiple paths to the DRG at the Oracle end of the connections, Oracle prefers the paths in the following order:

<table>
<thead>
<tr>
<th>Oracle preference</th>
<th>Path</th>
<th>Details of how Oracle prefers the path</th>
<th>Resulting AS path for the route</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FastConnect</td>
<td>Oracle prepends no ASNs to the routes that your edge device advertises, for a total AS path length of 1.</td>
<td>Your ASN</td>
</tr>
<tr>
<td>2</td>
<td>Site-to-Site VPN with BGP routing</td>
<td>Oracle prepends a single private ASN on all the routes that your edge device advertises over Site-to-Site VPN with BGP, for a total AS path length of 2.</td>
<td>Private ASN, Your ASN</td>
</tr>
</tbody>
</table>
Oracle Cloud Infrastructure User Guide

Oracle preference | Path | Details of how Oracle prefers the path | Resulting AS path for the route |
--- | --- | --- | --- |
3 | Site-to-Site VPN with static routing | Oracle prepends 3 private ASNs on the static routes that you've provided (Oracle advertises those routes to the dynamic routing gateway (DRG) at the Oracle end of the IPSec VPN). This results in a total AS path length of 3. | Private ASN, Private ASN, Private ASN |

The preceding table assumes you are sending a single autonomous system number in your AS path. Oracle honors the complete AS path you send. If you use static routing, and also send an AS path that has "Your ASN" plus two or more other ASNs, it can cause unexpected behavior because Oracle's routing preference might change.

While policy-based VPN static routing behavior is documented earlier, Oracle also recommends that if you use FastConnect connections with VPN backup, you employ BGP on your IPSec route-based VPN. This strategy allows you to have full control of failover behavior.

Routing Preferences for Traffic from Your On-Premises Network to Oracle

You can configure your edge device to prefer a specific path when sending traffic from your on-premises network to Oracle. The following section describes a particular situation where you must do that to ensure a consistent traffic path if your on-premises hosts use Oracle services.

Your on-premises network can access public Oracle Services Network services such as Object Storage over multiple paths. You can use public paths, such as the internet or FastConnect public peering. With these public paths, the on-premises hosts communicate with Oracle services by using public IP addresses.

You can also set up your on-premises network with private access to Oracle services through the VCN's service gateway. A service gateway lets hosts in your on-premises network use any of the services listed in Service Gateway: Supported Cloud Services in Oracle Services Network and communicate with those Oracle services from your private IP addresses.

If you've configured your on-premises network with multiple connection paths to Oracle services, your edge device might receive route advertisement of the Oracle services' public IP address routes over multiple paths. Here are the possible paths you can use with your on-premises network:

- Public access paths:
  - Internet service provider (ISP)
  - FastConnect public peering
- Private access paths by way of the VCN's DRG and service gateway:
  - FastConnect private peering
  - Site-to-Site VPN

Your edge device receives route advertisements from the DRG and possibly from routers over public paths. Most of the routes for Oracle services that the DRG advertises have a longer prefix (they are more specific) than the routes for Oracle services that are advertised over the public access paths. Therefore, if you set up your network with both public access and private access to Oracle services, you must configure your edge device to prefer the private access path to the DRG for traffic from the on-premises network to Oracle services. Setting up both public and private access ensures a consistent path for access to Oracle services.

For a list of the public IP ranges advertised over FastConnect public peering, see FastConnect Public Peering Advertised Routes on page 4099.

For a list of the regional public IP ranges advertised over the private paths (for a VCN with a service gateway), see Public IP Addresses for VCNs and the Oracle Services Network on page 222.
Route Filtering

Route filtering allows you to select the routes included in BGP advertisements to your on-premises network. RFC 5291 provides more general information about route filtering and BGP advertisement of routes.

Public virtual circuits over Fastconnect advertise routes according to the selected scope. The options are:

- **Regional** - Advertises all available public routes for this VCN's region to the on-premises network.
- **Market** - Advertises all available public routes for this VCN's region and other regions in the same part of the world to the on-premises network. This is the default setting. The regions available in a market are grouped into tables in FastConnect Public Peering Advertised Routes on page 4099.
- **Global** - Advertises all available public routes for all regions of the Oracle cloud to the on-premises network.
- **Oracle Services Network** - Advertises only public routes used to access Oracle Services Network (OSN) resources to the on-premises network.

Supported IPSec Parameters

This topic lists the supported phase 1 (ISAKMP) and phase 2 (IPSec) configuration parameters for Site-to-Site VPN. Oracle chose these values to maximize security and to cover a wide range of CPE devices. If your CPE device is not on the list of verified devices, use the information here to configure your device.

You can also use the CPE Configuration Helper to gather information that a network engineer uses when configuring the CPE device.

**Important:**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

Supported Encryption Domain or Proxy ID

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 3824.

Supported Parameters for the Commercial Cloud

This section lists the supported parameters if your Site-to-Site VPN is for the commercial cloud. For a list of the commercial cloud regions, see Regions and Availability Domains on page 208.

For some parameters, Oracle supports multiple values, and the recommended one is noted.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

**Phase 1 (ISAKMP)**

<table>

**Supported Parameters for the Government Cloud**

This section lists the supported parameters if your Site-to-Site VPN is for the Government Cloud. For more information, see For All US Government Cloud Customers on page 174.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in **bold text**.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

**Supported Encryption Domain or Proxy ID**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domains for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.
Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

Setting Up Site-to-Site VPN

This topic gives instructions for constructing a Site-to-Site VPN IPSec connection from an on-premises network to your VCN. For general information about Site-to-Site VPN, see Site-to-Site VPN Overview on page 3809.

Before You Get Started

To prepare, do these things first:

- Read this section: Routing for Site-to-Site VPN on page 3810
- Answer these questions:

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is your VCN's CIDR?</td>
<td></td>
</tr>
</tbody>
</table>
**Networking**

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is the public IP address of your CPE device? If you have multiple devices for redundancy, get the IP address for each. <strong>Note:</strong> If your CPE device is behind a NAT device, see <strong>Overview of Site-to-Site VPN Components</strong> on page 3812 and also <strong>Requirements and Prerequisites</strong> on page 3845.</td>
<td></td>
</tr>
<tr>
<td>Will you use port address translation (PAT) between each CPE device and your VCN?</td>
<td></td>
</tr>
<tr>
<td>What type of routing do you plan to use? If you want BGP dynamic routing, list the BGP session IP addresses to use and the ASN of your network. The IP addresses must be part of Site-to-Site VPN's encryption domain. <strong>If you want static routing, what are the static routes for your on-premises network?</strong> See <strong>Routing for Site-to-Site VPN</strong> on page 3810.</td>
<td></td>
</tr>
<tr>
<td>Do you plan to use policy based routing or multiple encryption domains? <strong>See Encryption domains for policy-based tunnels</strong> on page 3824.</td>
<td></td>
</tr>
<tr>
<td>Do you want to provide each tunnel's shared secret or let Oracle assign them? <strong>See Overview of Site-to-Site VPN Components</strong> on page 3812.</td>
<td></td>
</tr>
</tbody>
</table>

- Draw a diagram of your network layout (for examples, see the first task in **Example: Setting Up a Proof of Concept Site-to-Site VPN** on page 3827). Think about which parts of your on-premises network need to communicate with your VCN, and the reverse. Map out the routing and security rules that you need for your VCN.

**Tip:**

If you have an existing Site-to-Site VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.

**Overall Process**

Here's the overall process for setting up Site-to-Site VPN:

1. **Complete the tasks listed in Before You Get Started on page 3825.**
2. **Set up Site-to-Site VPN components** (instructions in **Example: Setting Up a Proof of Concept Site-to-Site VPN** on page 3827):
   a. Create your VCN.
   b. Create a DRG.
   c. Attach the DRG to your VCN.
   d. Create a route table and route rule for the DRG.
   e. Create a security list and required rules.
   f. Create a subnet in the VCN.
   g. Create a CPE object and provide your CPE device's public IP address.
   h. Create an IPSec connection to the CPE object and provide required routing information.
3. **Use the CPE Configuration Helper:** Your network engineer must configure your CPE device with information that Oracle provides during the previous steps. The CPE Configuration Helper generates the information for your
network engineer. For more information, see Using the CPE Configuration Helper on page 3847 and also CPE Configuration on page 3844.

4. Have your network engineer configure your CPE device.

5. Validate connectivity.

If you plan to set up redundant connections, see the Connectivity Redundancy Guide.

**Example: Setting Up a Proof of Concept Site-to-Site VPN**

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is your VCN's CIDR?</td>
<td>172.16.0.0/16</td>

<td>Use 10.0.0.0/16 for the static route for a simple POC.</td>
</tr>
<tr>
<td></td>
<td><strong>Policy-based routing example:</strong></td>
</tr>
<tr>
<td></td>
<td>Use ??? for a simple POC.</td>
</tr>
</tbody>
</table>

**Tip:**

Oracle offers a quickstart workflow to make it easier to set up Site-to-Site VPN. For more information, see Site-to-Site VPN Quickstart on page 3814.

This example scenario shows how to set up a Site-to-Site VPN with a simple layout that you might use for a proof of concept (POC). It follows tasks 1 and 2 in Overall Process on page 3826 and shows each component in the layout being created. For each task, there's a corresponding screenshot from the Console to help you understand what information is needed. For more complex layouts, see Example Layout with Multiple Geographic Areas on page 3841 or Example Layout with PAT on page 3843.

**Task 1: Gather information**
Here's an example diagram for task 1 that uses BGP dynamic routing:

Here's an example diagram for task 1 that uses static routing:

Here's an example diagram for task 1 that uses policy-based routing:

Task 2a: Create the VCN
If you already have a VCN, skip to the next task.

Tip:
When you use the Console to create a VCN, you can create only the VCN, or you can create the VCN with several related resources. This task creates only the VCN, and the subsequent tasks create the other required resources.
1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see **Access Control** on page 3708.

3. Click **Create Virtual Cloud Network**.

4. Enter the following values:
   - **Create in Compartment**: Leave as is.
   - **Name**: A descriptive name for the cloud network. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **CIDR Block**: A single, contiguous CIDR block for the cloud network (for example, 172.16.0.0/16). You can't change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, use a CIDR calculator.
   - **Enable IPv6 Address Assignment**: This option is available only if the VCN is enabled for IPv6. IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

5. You can provide values for the rest of the options, or you can ignore them:
   - **DNS Resolution**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or allow the Console to generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 3781.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Create Virtual Cloud Network**.

The VCN is created and displayed on the page. Ensure that it's done being provisioned before continuing.
Task 2b: Create the DRG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateway.
2. Click Create Dynamic Routing Gateway.
3. Enter the following values:
   - **Create in Compartment**: Leave as is (the VCN’s compartment).
   - **Name**: A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
4. Click Create Dynamic Routing Gateway.

   The DRG is created and displayed on the page. Ensure that it's done being provisioned before continuing.

   **Tip:**
   
   You could also use this DRG as the gateway for Oracle Cloud Infrastructure FastConnect, which is an alternative way to connect your on-premises network to your VCN.

Task 2c: Attach the DRG to the VCN

1. Click the name of the DRG you created.
2. Under Resources, click Virtual Cloud Networks.
3. Click Attach to Virtual Cloud Network.
4. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called transit routing, which is not relevant here.

5. Click Attach.

The attachment is in the Attaching state for a short period before it's ready.

**Task 2d: Create a route table and route rule for the DRG**

Although the VCN comes with a default route table (without any rules), in this task you create a custom route table with a route rule for the DRG. In this example, your on-premises network is 10.0.0.0/16. You create a route rule that takes any traffic destined for 10.0.0.0/16 and routes it to the DRG. When you create a subnet in task 2f, you associate this custom route table with the subnet.

**Tip:**

If you already have an existing VCN with a subnet, you don’t need to create a route table or subnet. Instead you can update the existing subnet's route table to include the route rule for the DRG.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click your VCN.
3. Click Route Tables to see your VCN's route tables.
4. Click Create Route Table.
5. Enter the following values:
   - **Name:** A descriptive name for the route table (for example, MyExampleRouteTable). The name doesn't have to be unique, and it can't be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
   - **Create in compartment:** Leave as is.
   - **Click + Additional Route Rule,** and enter the following:
     - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
     - **Destination CIDR Block:** The CIDR for your on-premises network (10.0.0.0/16 in this example).
     - **Description:** An optional description of the rule.
     - **Tags:** Leave the tag information as is.
6. Click Create Route Table.

The route table is created and displayed on the page. However, the route table doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).
Task 2e: Create a security list

By default, incoming traffic to the instances in your VCN is set to DENY on all ports and all protocols. In this task, you set up two ingress rules and one egress rule to allow basic required network traffic. Your VCN comes with a default security list with a set of default rules. However, in this task you create a separate security list with a more restrictive set of rules focused on traffic with your on-premises network. When you create a subnet in task 2f, you associate this security list with the subnet.

Tip:

Security lists are one way to control traffic in and out of the VCN’s resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

Important:

In the following procedure, ensure that the on-premises CIDR that you specify in the security list rules is the same (or smaller) than the CIDR that you specified in the route rule in the preceding task. Otherwise, traffic will be blocked by the security lists.

1. While still viewing your VCN, click Security Lists on the left side of the page.
2. Click Create Security List.
3. Enter the following values:
   - Name: A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
   - Create in compartment: Leave as is.
4. In the **Allow Rules for Ingress** section, click **Add Ingress Rule** and enter the following values for the ingress rule, which allows incoming SSH on TCP port 22 from your on-premises network:

- **Source Type**: CIDR
- **Source CIDR**: The CIDR for your on-premises network (10.0.0.0/16 in this example)
- **IP Protocol**: TCP.
- **Source Port Range**: Leave as is (the default All).
- **Destination Port Range**: 22 (for SSH traffic).
- **Description**: An optional description of the rule.

5. In the **Allow Rules for Egress** section, click **Add Egress Rule** enter the following values for the egress rule, which allows outgoing TCP traffic on all ports to your on-premises network:

- **Destination Type**: CIDR
- **Destination CIDR**: The CIDR for your on-premises network (10.0.0.0/16 in this example).
- **IP Protocol**: TCP.
- **Source Port Range**: Leave as is (the default All).
- **Destination Port Range**: Leave as is (the default All).
- **Description**: An optional description of the rule.

6. Leave the tag information as is.

7. Click **Create Security List**.

The security list is created and displayed on the page. However, the security list doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).

**Task 2f: Create a subnet**

In this task, you create a subnet in the VCN. Typically a subnet has a CIDR block smaller than the VCN's CIDR. Any instances that you create in this subnet have access to your on-premises network. Oracle recommends using **regional subnets**. Here you create a regional private subnet.

1. While still viewing your VCN, click **Subnets** on the left side of the page.
2. Click **Create Subnet**.
3. Enter the following values:

- **Name**: A descriptive name for the subnet. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Regional or AD-specific subnet**: Select the radio button for **Regional**. Oracle recommends using regional subnets.

- **CIDR Block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). It must be within the cloud network's CIDR block and can't overlap with any other subnets. You can't change this value later. See [Allowed VCN Size and Address Ranges](fn) on page 3606. For reference, use a [CIDR calculator](fn).

- **Enable IPv6 Address Assignment**: This option is available only if the VCN is already enabled for IPv6. IPv6 addressing is supported for all commercial and government regions. For more information, see [IPv6 Addresses](fn) on page 3768.

- **Route Table**: The route table that you created earlier.

- **Private Subnet**: Select this option. For more information, see [Access to the Internet](fn) on page 3609.

- **Use DNS Hostnames in this Subnet**: Leave as is (selected).

- **DHCP Options**: The set of DHCP options to associate with the subnet. Select the default set of DHCP options for the VCN.

- **Security Lists**: The security list that you created earlier.

- **Tags**: Leave as is. You can add tags later if you want. For more information, see [Resource Tags](fn) on page 239.

4. Click **Create Subnet**.

The subnet is created and displayed on the page. The basic VCN in this example is now set up, and you're ready to create the remaining components for Site-to-Site VPN.

**Task 2g: Create a CPE object and provide your CPE device's public IP address**

In this task, you create the CPE object, which is a virtual representation of your CPE device.

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Customer-Premises Equipment**.

2. Click **Create Customer-Premises Equipment**.

3. Enter the following values:

   - **Create in Compartment**: Leave as is (the VCN's compartment).

   - **Name**: A descriptive name for the CPE object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

   - **IP Address**: The public IP address of the CPE device at your end of the VPN (see the list of information to gather in **Before You Get Started** on page 3825).

   - **Tags**: Leave as is. You can add tags later if you want. For more information, see [Resource Tags](fn) on page 239.

4. Click **Create**.
The CPE object is created and displayed on the page.

**Task 2h: Create an IPSec connection to the CPE object**

In this task, you create the IPSec tunnels and configure the type of routing for them (BGP dynamic routing or static routing).

**Tip:**

If you have an existing Site-to-Site VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.

For BGP dynamic routing

In this example, you configure both tunnels to use BGP dynamic routing.

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.
2. Click **Create IPSec Connection**.
3. Enter the following values:
   - **Create in Compartment**: Leave as is (the VCN's compartment).
   - **Name**: Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
   - **Customer-Premises Equipment**: Select the CPE object that you created earlier.
   - **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
   - **Dynamic Routing Gateway**: Select the DRG that you created earlier.
   - **Static Route CIDR**: Leave empty because this IPSec connection uses BGP dynamic routing. You configure the two tunnels to use BGP in subsequent steps.
4. Click **Show Advanced Options**.
5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.

6. On the **Tunnel 1** tab (required):
   - **Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Select the radio button for **BGP Dynamic Routing**.
   - **BGP ASN**: Enter your network's ASN.
   - **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31. The IP address must be part of Site-to-Site VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31. The IP address must be part of Site-to-Site VPN's encryption domain.
   - **Route Filtering**: Choose a Route Filtering option. This selects the routes included in BGP advertisements to your on-premises network.

7. On the **Tunnel 2** tab (required):
   - **Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Select the radio button for **BGP Dynamic Routing**.
   - **BGP ASN**: Enter your network's ASN.
   - **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of Site-to-Site VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of Site-to-Site VPN's encryption domain.
   - **Route Filtering**: Choose a Route Filtering option. This selects the routes included in BGP advertisements to your on-premises network.

8. On the **Tags** tab (optional): Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
9. Click **Create IPSec Connection**.
   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
   The displayed tunnel information includes:
   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.
   - The tunnel's BGP status. At this point, the status is Down. Your network engineer still must configure your CPE device.

To view the tunnel’s shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.

10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure your CPE device.

You can view this tunnel information here in the Console at any time.

You have now created all the components required for Site-to-Site VPN. Next, your network engineer must configure your CPE device before network traffic can flow between your on-premises network and VCN.

For static routing

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.
2. Click **Create IPSec Connection**.
3. Enter the following values:

- **Create in Compartment**: Leave as is (the VCN's compartment).
- **Name**: Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
- **Customer-Premises Equipment**: Select the CPE object that you created earlier.
- **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
- **Dynamic Routing Gateway**: Select the DRG that you created earlier.
- **Static Route CIDR**: Enter at least one static route CIDR (see the list of information to gather in Before You Get Started on page 3825). For this example, enter 10.0.0.0/16. You can enter up to 10 static routes, and you can change the static routes later.

4. Click **Show Advanced Options**.

5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.

6. On the **Tunnel 1** tab (optional):

- **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
- **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type**: Leave the radio button for Static Routing selected.
- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of Site-to-Site VPN's encryption domain.
- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of Site-to-Site VPN's encryption domain.

7. On the **Tunnel 2** tab (optional):

- **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
- **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type**: Leave the radio button for Static Routing selected.
- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of Site-to-Site VPN's encryption domain.
- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of Site-to-Site VPN's encryption domain.

8. **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.
9. Click **Create IPSec Connection**.

The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

The displayed tunnel information includes:

- The Oracle VPN IP address (for the Oracle VPN headend).
- The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.

To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.

10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the CPE device.

You can view this tunnel information here in the Console at any time.

You have now created all the components required for Site-to-Site VPN. Next, your network engineer must configure the CPE device before network traffic can flow between your on-premises network and VCN.

For more information, see **CPE Configuration** on page 3844.

For policy-based routing

Set up Site-to-Site VPN with policy-based routing.

**Note:**

The policy-based routing option is not available in all ADs, and may require creating a new IPSec tunnel.

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.

2. Click **Create IPSec Connection**.

3. Enter the following values:

- **Create in Compartment**: Leave as is (the VCN's compartment).
- **Name**: Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
- **Customer-Premises Equipment**: Select the CPE object that you created earlier.
- **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
- **Dynamic Routing Gateway**: Select the DRG that you created earlier.
- **Static Route CIDR**: Enter at least one static route CIDR (see the list of information to gather in Before You Get Started on page 3825). For this example, enter 10.0.0.0/16. You can enter up to 10 static routes, and you can change the static routes later.

4. Click **Show Advanced Options**.

5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your **CPE is behind a NAT device**, you might need to enter a different value. You can either enter the new value here, or change the value later.
6. On the **Tunnel 1** tab (optional):

- **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
- **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select **IKEv2** if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type**: Select the radio button for **Policy-based** routing.
- **On-premises**: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your on-premises network, with routing determined by the CPE device policies.

  **Note:**

  See [Encryption domains for policy-based tunnels](#) on page 3824 for limitations on how many IPv4 or IPv6 CIDR blocks can be used.

- **Oracle Cloud**: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your VCN.

  **Note:**

  See [Encryption domains for policy-based tunnels](#) on page 3824 for limitations on how many IPv4 or IPv6 CIDR blocks can be used.

- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of one of Site-to-Site VPN's encryption domains.

- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of one of Site-to-Site VPN's encryption domains.

7. On the **Tunnel 2** tab (optional):

- **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
- **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select **IKEv2** if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type**: Select the radio button for **Policy-based** routing.
- **On-premises**: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your on-premises network, with routing determined by the CPE device policies.

  **Note:**

  See [Encryption domains for policy-based tunnels](#) on page 3824 for limitations.

- **Oracle Cloud**: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your VCN.

  **Note:**

  See [Encryption domains for policy-based tunnels](#) on page 3824 for limitations.

- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of one of Site-to-Site VPN's encryption domains.

- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of one of Site-to-Site VPN's encryption domains.
8. **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 239.

9. **Click Create IPSec Connection.**
   
The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

   The displayed tunnel information includes:
   
   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to Shared Secret.

10. **Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location, then deliver it to the network engineer who configures the CPE device.**

    You can view this tunnel information here in the Console at any time.

You have now created all the components required for Site-to-Site VPN. Next, your network engineer must configure the CPE device before network traffic can flow between your on-premises network and VCN.

For more information, see CPE Configuration on page 3844.

**Task 3: Use the CPE Configuration Helper**

Use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

The content includes these items:

- For each IPSec tunnel, the Oracle VPN IP address and shared secret.
- The supported IPSec parameter values.
- Information about the VCN.
- CPE-specific configuration information.

For more information, see Using the CPE Configuration Helper on page 3847.

**Task 4: Have your network engineer configure your CPE**

Provide your network engineer with the following items:

- The content generated by the CPE Configuration Helper.
- The general IPSec parameters that Oracle supports.

**Important:**

Be sure to have your network engineer configure your CPE device to support both of the tunnels in case one fails or Oracle takes one down for maintenance. If you're using BGP, see Routing for Site-to-Site VPN on page 3810.

**Task 5: Validate connectivity**

After the network engineer configures your CPE device, you can confirm that the tunnel's IPSec status is Up and green. Next, you can create a Linux instance in the subnet in your VCN. You should then be able to use SSH to connect to the instance's private IP address from a host in your on-premises network. For more information, see Creating an Instance on page 1023.

**Example Layout with Multiple Geographic Areas**

The following diagram shows an example with this configuration:

- Two networks in separate geographical areas that each connect to your VCN
- A single CPE device in each area
- Two IPSec VPNs (one for each CPE device)
Networking

Notice that each Site-to-Site VPN has two routes associated with it: one for the particular geographical area’s subnet, and a default 0.0.0.0/0 route. Oracle learns about the available routes for each tunnel either through BGP (if the tunnels use BGP), or because you’ve set them as static routes for the IPSec connection (if the tunnels use static routing).

Following are some examples of situations in which the 0.0.0.0/0 route can provide flexibility:

- Assume that the CPE 1 device goes down (see the next diagram). If Subnet 1 and Subnet 2 can communicate with each other, your VCN could still reach the systems in Subnet 1 because of the 0.0.0.0/0 route that goes to CPE 2.
• Assume that your organization adds a new geographical area with Subnet 3 and initially just connects it to Subnet 2 (see the next diagram). If you added a route rule to your VCN’s route table for Subnet 3, the VCN could reach systems in Subnet 3 because of the 0.0.0.0/0 route that goes to CPE 2.

Example Layout with PAT

The following diagram shows an example with this configuration:

• Two networks in separate geographical areas that each connect to your VCN
• Redundant CPE devices (two in each geographical area)
• Four IPSec VPNs (one for each CPE device)
• Port address translation (PAT) for each CPE device

For each of the four connections, the route that Oracle needs to know about is the PAT IP address for the specific CPE device. Oracle learns about the PAT IP address route for each tunnel either through BGP (if the tunnels use
BGP), or because you've set the relevant address as a static route for the IPSec connection (if the tunnels use static routing).

When you set up the route rules for the VCN, you specify a rule for each PAT IP address (or an aggregate CIDR that covers them all) with your DRG as the rule's target.

CPE Configuration

This topic is for network engineers. It explains how to configure the on-premises device (the customer-premises equipment, or CPE) at your end of Site-to-Site VPN so traffic can flow between your on-premises network and virtual cloud network (VCN). See these related topics:

- Networking on page 3604: For general information about the parts of a VCN
- Site-to-Site VPN on page 3808: For various topics about IPSec VPNs
- Verified CPE Devices on page 3846: For a list of CPE devices Oracle has verified
The following figure shows the basic layout of Site-to-Site VPN's IPSec connection.

**Requirements and Prerequisites**

There are several requirements and prerequisites to be aware of before moving forward.

**Routing Considerations**

For important details about routing for your Site-to-Site VPN see Routing for Site-to-Site VPN on page 3810.

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

If you use BGP dynamic routing with your Site-to-Site VPN, you can configure routing so that Oracle prefers one tunnel over the other.

Note that the Cisco ASA policy-based configuration uses a single tunnel.

**Creation of Cloud Network Components**

You or someone in your organization must have already used the Oracle Console to create a VCN and an IPSec connection, which consists of multiple IPSec tunnels for redundancy. You must gather the following information about those components:

- **VCN OCID**: The VCN OCID is a unique Oracle Cloud Infrastructure identifier that has a UUID at the end. You can use this UUID or any other string that helps you identify this VCN in the device configuration and doesn't conflict with other object-group or access-list names.
- **VCN CIDR**
- **VCN CIDR subnet mask**
- For each IPSec tunnel:
  - The IP address of the Oracle IPSec tunnel endpoint (the VPN headend)
  - The shared secret

**Information About Your CPE Device**

You also need some basic information about the inside and outside interfaces of your on-premises device (your CPE). For a list of the required information for your particular CPE, see the links in this list: Verified CPE Devices on page 3846.

Oracle recommends that you disable NAT-T at your CPE when establishing IPSec tunnels with Oracle Cloud Infrastructure. Unless you have multiple CPEs sharing the same NAT IP, NAT-T is not required.

If your CPE is behind a NAT device, you can provide Oracle with your CPE's IKE identifier. For more information, see Overview of Site-to-Site VPN Components on page 3812.
Networking

Route-Based Versus Policy-Based IPSec

The Oracle VPN headends use route-based tunnels, but can work with policy-based tunnels with some caveats. See Encryption domains for policy-based tunnels on page 3824 for full details.

Site-to-Site VPN Best Practices

- **Configure all tunnels for every IPSec connection:** Oracle deploys multiple IPSec headends for all your connections to provide high availability for your mission-critical workloads. Configuring all the available tunnels is a key part of the "Design for Failure" philosophy. (Exception: Cisco ASA policy-based configuration, which uses a single tunnel.)

- **Have redundant CPEs in your on-premises locations:** Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant CPE devices. You add each CPE to the Oracle Cloud Infrastructure Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. Oracle may use any tunnel that is "up" to send traffic back to your on-premises network. For more information, see Routing for Site-to-Site VPN on page 3810.

- **Consider backup aggregate routes:** If you have multiple sites connected via IPSec VPNs to Oracle Cloud Infrastructure, and those sites are connected to your on-premises backbone routers, consider configuring your IPSec connection routes with both the local site aggregate route as well as a default route.

  Note that the DRG routes learned from the IPSec connections are only used by traffic you route from your VCN to your DRG. The default route will only be used by traffic sent to your DRG whose destination IP address does not match the more specific routes of any of your tunnels.

Confirming the Status of the Connection

After you configure the IPSec connection, you can test the connection by launching an instance into the VCN and then pinging it from your on-premises network. For information about launching an instance, see Launching an Instance. To ping the instance, the VCN's security rules must allow ping traffic.

You can get the status of the IPSec tunnels in the API or Console. For instructions, see To view the status and configuration information for the IPSec tunnels on page 4034.

Device Configurations

For links to the specific configuration information for each verified CPE device, see Verified CPE Devices on page 3846.

Verified CPE Devices

The following devices or software have been verified for use with Site-to-Site VPN.

**Note:**

Oracle provides configuration instructions for the vendors and devices in the following table. Make sure to use the configuration instructions for the correct vendor.

If your vendor, device, or software version is not in the following table, your device might still work with Oracle Cloud Infrastructure Site-to-Site VPN. Consult your vendor's documentation for configuration assistance and refer to supported IPSec parameters for supported phase 1 and phase 2 configurations parameters for Site-to-Site VPN.

**Using the CPE Configuration Helper**

After you set up Site-to-Site VPN, your network engineer must configure the customer-premises equipment (CPE) at your end of the connection (for example, a router). The configuration includes details about your virtual cloud network (VCN) and the IPSec tunnels in the Site-to-Site VPN. This topic describes how to use the CPE Configuration Helper in the Oracle Console to generate information that a network engineer uses to configure the CPE. Notice that the CPE Configuration Helper is also referred to as the Helper.

**Overview of the Helper**

For the IPSec tunnels in a Site-to-Site VPN to work, your network engineer must configure your CPE with specific information. The information comes from different sources. Oracle provides some of it in several places within the Oracle Console. The Helper collects the necessary information in one place and then organizes it to make CPE configuration easier for the network engineer. You can copy or download the resulting content to a file.

The configuration information that the network engineer needs depends on which vendor makes the CPE. To ensure that the Helper can produce vendor-specific content, you specify which vendor makes your CPE. See the one-time prerequisite in Using the Helper on page 3848.
In some cases, the Helper might ask for information about your network and include it in the content. If you don't know the answers, you can leave them blank. The resulting content then uses placeholder variables to show where the network engineer needs to provide the answers.

The content that the Helper produces includes these items:

- The Oracle VPN headend for the tunnel (the IP address at the Oracle end)
- The shared secret (pre-shared key) for the tunnel
- Your VCN's CIDR
- BGP information (if you're using BGP dynamic routing for the tunnel)
- The IPSec parameters that Oracle supports
- Other relevant information

**Using the Helper**

One-time prerequisite: Specify the CPE vendor

Edit the CPE and select the vendor. If you're not sure which vendor makes your CPE, or it's not in the list, select Other.

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Customer-Premises Equipment.
2. Select the CPE you're interested in, and then click Edit.
3. For Vendor, select your CPE vendor from the list. If you're not sure which vendor makes your CPE, or it's not in the list, select Other.
4. If prompted, select a value for Platform/Version. Here are guidelines:
   - Oracle recommends using a route-based configuration if possible.
   - If you do not see your specific CPE platform or version in the list, choose the closest platform/version that predates your CPE version.
5. Click Save Changes.

Open the Helper from one of three locations

You can access the Helper from three different locations in the Oracle Console. Where you access the Helper controls the scope of the content it produces:

- **The CPE page:** The Helper produces content for all IPSec connections that terminate on the CPE. Notice that there could be IPSec connections in compartments that you do not have access to. If you don't have permission to view a particular IPSec connection, it is not included in the content.
- **An IPSec connection page:** The Helper produces content for one individual IPSec connection (all tunnels within the connection).
- **A tunnel's page:** The Helper produces content for one tunnel in an IPSec connection.
1. In the navigation menu, click Networking, and then navigate to the resource page you're interested in:
   - The CPE page
   - The IPSec connection page
   - The tunnel page
2. Click Open CPE Configuration Helper.
   The Helper opens on the right side of the page.
   It shows basic information such as the CPE's public IP address and vendor.

Generate the content

The Helper has a Create Content button at the bottom. After you click it and the content is produced, there are buttons to copy or download the content to a file. Give the content to your network engineer, along with the link to the configuration topic for your CPE type (see Verified CPE Devices on page 3846). You can return to the Helper at any time and again generate the configuration content.
Tip:
For certain CPE vendors, the Helper displays fields for vendor-specific information that is used for CPE configuration. The fields might be blank or already have values. You can fill in the blank fields or leave them as is. For blank fields, the resulting content displays placeholder variables to show where the network engineer needs to fill in the values.

Instructions:
1. Review the template of information in the Helper. Optionally fill in any blank fields.
2. Click Create Content at the bottom of the Helper.
   The Helper generates the content.
3. Click either Copy Configuration to Clipboard or Download Configuration (to download it to a file).
4. Click Close.
5. Give the following items to your network engineer:
   - A link to the configuration topic for your CPE type. See Verified CPE Devices on page 3846.
   - The Helper content that you generated.

If You Update Your Site-to-Site VPN

You could change aspects of your Site-to-Site VPN, and after you do, you might want to generate the Helper content again. For example, imagine that you have an IPSec connection that uses static routing, and you decide to change it to use BGP dynamic routing. After updating the Oracle Console with the new routing information, you can generate the Helper content again for the IPSec connection. You can then give that new content to your network engineer to configure the CPE accordingly.

Check Point Configuration Options

Choose the configuration that suits your situation:
- Check Point: Route-Based on page 3849
- Check Point: Policy-Based on page 3874

Check Point: Route-Based

This topic provides a route-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.

This topic is for route-based (VTI-based) configuration. If you instead want policy-based configuration, see Check Point: Policy-Based on page 3874.
Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

![Diagram showing a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels.](image)

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
Routing Protocol Considerations
When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

Other Important CPE Configurations
Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

Caveats and Limitations
This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

Asymmetric Routing
Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

Route-Based or Policy-Based IPSec Connection
The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:
Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.
There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It’s the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the
Networking

- A link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can’t overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing CPE IKE identifier configuration with NAT device]

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration (Route-Based)**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor’s support directly.
The following figure shows the basic layout of the IPSec connection.

![IPSec Connection Diagram](image)

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

If you want to use IKEv2, there’s a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select **IKEv2 only** for the encryption method.

**Configuration Process**

**Redundancy with BGP Over IPSec**

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see Routing Details for Connections to Your On-Premises Network on page 3818.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of Site-to-Site VPN’s encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

Oracle’s BGP ASN in commercial regions is 31898. If you’re configuring Site-to-Site VPN for the Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle’s BGP ASN on page 180.

For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

**Task 1: Install Site-to-Site VPN on Check Point CloudGuard Security Gateway**

**Prerequisite:** Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.
1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.

2. Click OK to save your changes.

Task 2: Create the VTI interface from GAIA

In this task, you configure a VTI interface that passes traffic by using routing rules from the VTI interface to the newly created IPSec tunnel.

1. Log in to the GAIA portal using the Check Point CloudGuard Security Gateway public or private IP address.
2. On the GAIA portal, select the Advanced view.
3. Under Network Management, go to Network Interfaces.
4. Click **Add**, and then click **VPN Tunnel**.
5. Specify the following items:

- **VPN Tunnel ID**: A number that will be added to the VTI interface called \textit{vpnt*}, where the asterisk is the VPN tunnel ID number specified. For VPN tunnel ID = 1, the interface is labeled \textit{vpnt1}.
- **Peer**: The name of the interoperable device that you created earlier for the IPSec tunnel. In this case, the name is \textit{OCI-VPN\_BGP1}.

  \textbf{Important:}

  If the name you specify here does not match the name of the interoperable device, traffic does not flow through the IPSec tunnel.

- **Numbered**: Select \textbf{Numbered} to create a numbered interface.
- **Local Address**: The local IP address that was specified in the Oracle Console as the \textbf{Inside Tunnel Interface - CPE}.
- **Remote Address**: The remote IP address that was specified in the Oracle Console as the \textbf{Inside Tunnel Interface - Oracle}.

6. Click \textbf{OK}.

7. Under \textbf{Network Management}, go to \textbf{IPv4 Static Routes}.

8. Specify the following items:

- **Static route for the Oracle IP address**: Add an IP address with /32 mask for the remote IP address that was specified in the Oracle Console as the \textbf{Inside Tunnel Interface - Oracle}.
- **Static routes to the VCN subnets**: If you're using static routing for this IPSec connection to Oracle, add at least one subnet for the Oracle VCN to be reached through the IPSec tunnel. The following screenshot shows
Networking

a static route to 172.31.2.0/26. If you're using BGP for this IPSec connection to Oracle, skip this item because these routes are learned through BGP (see the next section).

Now all traffic with a specific destination learned from a static route will pass through the newly created IPSec tunnel.

9. Get the interfaces and verify that the VPN tunnel is in the list:
   a. In the Smart Console, go to Gateways & Servers.
   b. Select the Check Point Security Gateways, and double-click.
   c. Under General Properties, on the Network Management page, select Get Interfaces.

   The VPN tunnel interface should appear in the list.

10. To force a route-based VPN to take priority, create an empty group and assign it to the VPN domain:
   a. On the VPN Domain page, select Manually defined, and then select Create empty group.
   b. Click New, select Group, and then select Simple Group.
   c. Enter an Object Name, and then click OK. Do not assign any objects to this empty group.

Task 3: Create an interoperable device

Later, you will create a VPN Community. Before you can, you must create an Interoperable Device that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.
1. Create the new interoperable device.
2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.

3. To force the route-based VPN to take priority, you must create an empty group and assign it to the VPN domain. To do that, on the **Topology** page, in the **VPN Domain** section, select **Manually defined**, and select the empty group.
4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN Communities created.

Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.
5. On the **Link Selection** page, under **Always use this IP address**, select **Main address**, which was the address you specified when creating the interoperable device. If necessary, you can use a specific IP address that will be used as the IKE ID.
6. On the **VPN Advanced** page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2 parameters.

7. Click **OK** to save your changes.

**Task 4: Create a VPN community**

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a **Star Community**.

3. For the star community, add a name.
4. On the Gateways page, select the values for **Center Gateways** and **Satellite Gateways**. This star community acts as a settings template for the interoperable devices you specify in **Center Gateways** and **Satellite Gateways**.

- **Center Gateways**: For the Check Point CloudGuard Security Gateway.
- **Satellite Gateways**: For the CPE that connects to the Oracle DRG for each IPSec tunnel.
5. To allow traffic, go to **Global Properties**, and then **VPN**, and then **Advanced**.
6. Select the check box for **Enable VPN Directional Match in VPN Column**. Later you will create a security policy that uses a directional match condition to allow traffic to pass based on routing rules.

7. Click **OK**.
8. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see **Supported IPSec Parameters** on page 3821.

If you're configuring Site-to-Site VPN for the Government Cloud, see **Required Site-to-Site VPN Parameters for Government Cloud** on page 178.

Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.
9. On the **Tunnel Management** page, select **Set Permanent Tunnels**. Oracle recommends that you:

- Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.
- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an *encryption domain*).

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Oracle VPN headend can support multiple encryption domains, but there are limitations. See Encryption domains for policy-based tunnels on page 3824 for full details.</td>
</tr>
</tbody>
</table>

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see Supported Encryption Domain or Proxy ID on page 3824.
10. On the Shared Secret page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.

11. Click **OK** to save your changes.

Task 5: Create a security policy

1. Go to **Access Control**, and then the **Policy** tab. Create specific security policies by using **Directional Match Condition**, which allows traffic to pass based on route tables. Set up the condition with these settings:
   - **Internal_Clear** > **VPN Community** created
   - **VPN Community** created > **VPN Community** created
   - **VPN Community** created > **Internal_Clear**

   In this case, the **VPN Community** is **OCI-DRG-BGP** and the **Internal_Clear** is predefined by Check Point.

2. Click **OK** to save your changes.
3. Click **Install Policy** to apply the configuration.

Task 1: Enable BGP

   Perform the following steps for each tunnel.

   1. Go to **Advanced Routing**, and then **BGP**.
2. Under BGP Global Settings, click Change Global Settings, and then add a router ID and local ASN.

3. Click Save.

Task 2: Redistribute routes into BGP

1. Go to Advanced Routing, and then Route Distribution.
2. Click **Add Redistribution From**, and then select **Interface**, which is for adding all connected subnets.

3. In the **Add Redistribution from Interface** dialog, configure the following items:
   - **To Protocol**: Select **BGP AS 31898**, which is the Oracle ASN for commercial regions. If you're configuring Site-to-Site VPN for the Government Cloud, see Oracle’s BGP ASN on page 180.
   - **Interface**: Select all to advertise all connected subnets.

4. Click **Save**.
Networking

Now the BGP session should be up and advertising and receiving subnets.

**Verification**

The following CLI command verifies BGP peers and routing.

```
show bgp peers
```

The following command verifies that you're receiving BGP routes.

```
show route bgp
```

The following command verifies the routes that are being advertised. In this example, replace `<remote_IP_address>` with the remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle**

```
show bgp peer <remote_IP_address> advertise
```

The following command verifies the routes that are being received.

```
show bgp peer <remote_IP_address> received
```

Use options 2 and 4 in the following command to verify security associations (SAs).

```
vpn tunnelutil

********** Select Option **********

(1) List all IKE SAs
(2) * List all IPsec SAs
(3) List all IKE SAs for a given peer (GW) or user (Client)
(4) * List all IPsec SAs for a given peer (GW) or user (Client)
(5) Delete all IPsec SAs for a given peer (GW)
(6) Delete all IPsec SAs for a given User (Client)
(7) Delete all IPsec+IKE SAs for a given peer (GW)
(8) Delete all IPsec+IKE SAs for a given User (Client)
(9) Delete all IPsec SAs for ALL peers and users
(0) Delete all IPsec+IKE SAs for ALL peers and users

* To list data for a specific CoreXL instance, append "-i <instance number>" to your selection.

(Q) Quit

***************************************************************************
```

A **Monitoring service** is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see **Site-to-Site VPN Metrics** on page 4042.

If you have issues, see **Site-to-Site VPN Troubleshooting** on page 4044.

**Check Point: Policy-Based**

This topic provides a policy-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.

This topic is for policy-based configuration. If you instead want route-based (VTI-based) configuration, see **Check Point: Route-Based** on page 3849.
Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you’re already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

![Diagram of IPSec connection to Oracle Cloud Infrastructure](image)

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
Routing Protocol Considerations

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.
There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the
Networking

- A network link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
  - Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
  - Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
  - The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
  - An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

CPE Configuration (Policy-Based)

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

If you want to use IKEv2, there's a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select **IKEv2 only** for the encryption method.

Configuration Process

Task 1: Install Site-to-Site VPN on Check Point CloudGuard Security Gateway

**Prerequisite:** Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.
1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.

2. Click **OK** to save your changes.

Task 2: Configure IPSec settings for Check Point CloudGuard Security Gateway

This task covers the most important options used for an IPSec tunnel with Oracle Cloud Infrastructure.

1. On the **Network Management** page, import all the interfaces. You can do this by clicking **Get Interfaces**, which contains options for **Get Interfaces With Topology** and **Get Interfaces Without Topology**. This example uses
**Get Interfaces Without Topology** so that you can define the purpose of each interface as an external or internal network.

All of these interfaces will be used in the **VPN Domain** as subnets advertised by Check Point CloudGuard Security Gateway in the IPSec encryption domain.
2. On the **VPN Domain** page, Oracle recommends that you select the option **for All IP Addresses behind Gateway are based on Topology information**. This option adds all the subnets discovered in **Network Management** to the IPSec Encryption Domain.

You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec encryption domain.
3. If your Check Point CloudGuard Security Gateway uses 1:1 NAT to map private IP addresses to public IP addresses: On the **Link Selection** page, under **Always use this IP address**, select **Statically NATed IP** and specify the IP address that you want to use as your IKE ID.

![Check Point Gateway - gw-security](image)

If you don’t want to use a public IP address as the local IKE ID, you can use another value (such as a private IP address), but the value will not match the one expected on the Oracle DRG. To resolve this, you can change the value that Oracle uses in the Oracle Console (see the instructions that follow).

**To change the CPE IKE identifier that Oracle uses (Oracle Console)**

a. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.

A list of the IPSec connections in the compartment that you’re viewing is displayed. If you don’t see the one you’re looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

b. For the IPSec connection you’re interested in, click the Actions icon (three dots), and then click **Edit**.

The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.

c. Enter your new values for **CPE IKE Identifier Type** and **CPE IKE Identifier**, and then click **Save Changes**.

4. Click **OK** to save your changes.

**Task 3: Create an interoperable device**

Later, you will create a VPN Community. Before you can, you must create a **Interoperable Device** that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.
1. Create the new interoperable device.
2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.
3. On the **Topology** page, Oracle recommends that you create a new topology by clicking **New** and then adding the Oracle VCN subnets to be used for the tunnel.

You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec Encryption Domain.
4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN Communities created.

Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.
5. On the **Link Selection** page, under **Always use this IP address**, select **Main address**, which is the address that you specified when creating the interoperable device. If necessary, you can use a specific IP address that will be used as the IKE ID.
6. On the **VPN Advanced** page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2 parameters.

![VPN Advanced Page](image)

7. Click **OK** to save your changes.

**Task 4: Create a VPN community**

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a Star Community.

3. For the star community, add a name.
4. On the Gateways page, select the values for Center Gateways and Satellite Gateways. This star community acts as a settings template for the interoperable devices you specify in Center Gateways and Satellite Gateways.

- Center Gateways: For the Check Point CloudGuard Security Gateway.
- Satellite Gateways: For the CPE that connects to the Oracle DRG for each IPSec tunnel.

5. If this is a proof of concept (POC) scenario: On the Encrypted Traffic page, select the check box for Accept all encrypted traffic on. The default value for this setting allows the traffic between both center and satellite gateways. This setting is appropriate for a POC scenario. However, for a production scenario, Oracle recommends
that you instead create specific security policies under **Access Control** and on the **Policy** tab. That is covered in the final task in this process.
6. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see [Supported IPSec Parameters](#) on page 3821.

If you're configuring Site-to-Site VPN for the Government Cloud, see [Required Site-to-Site VPN Parameters for Government Cloud](#) on page 178.

Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.

![Encryption Configuration screenshot](image)
7. On the **Tunnel Management** page, select **Set Permanent Tunnels**. Oracle recommends that you:

- Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.
- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an *encryption domain*).

---

**Important:**

The Oracle VPN headend can support multiple encryption domains, but there are limitations. See [Encryption domains for policy-based tunnels](#) for full details.

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see [Supported Encryption Domain or Proxy ID](#) on page 3824.
8. On the Shared Secret page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.

9. Click **OK** to save your changes.

Task 5: Create a security policy (recommended for a production scenario)

If this is a proof of concept (POC) scenario, earlier you selected **Accept all encrypted traffic** on the Encrypted Traffic page. If this is instead a production scenario, Oracle recommends creating security policies.

1. Under Security Policies, click Access Control, and then select the Policy tab.
2. Configure the required values.

3. Click **OK** to save your changes.
4. Click **Install Policy** to apply the configuration.

The IPSec tunnel should now be up.

**Verification**

Use options 2 and 4 in the following command to verify security associations (SAs).

```
vpn tunnelutil
```

```
**********  Select Option  **********
(1)        List all IKE SAs
(2)        * List all IPsec SAs
```
Networking

(3) List all IKE SAs for a given peer (GW) or user (Client)
(4) * List all IPsec SAs for a given peer (GW) or user (Client)
(5) Delete all IPsec SAs for a given peer (GW)
(6) Delete all IPsec SAs for a given User (Client)
(7) Delete all IPsec+IKE SAs for a given peer (GW)
(8) Delete all IPsec+IKE SAs for a given User (Client)
(9) Delete all IPsec SAs for ALL peers and users
(0) Delete all IPsec+IKE SAs for ALL peers and users

* To list data for a specific CoreXL instance, append "-i <instance number>" to your selection.

(Q) Quit

*****************************************************************************

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

Cisco ASA Configuration Options

Choose the configuration based on the ASA software version:

- **9.7.1 or newer:** Route-based configuration
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

**Important:**

Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

**Cisco ASA: Route-Based**

This topic provides a route-based configuration for a Cisco ASA that is running software version 9.7.1 (or newer).

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer:** Route-based configuration (this topic)
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still...
work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
• **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

**Specific to Cisco ASA: Caveats and Limitations**

This section covers important characteristics and limitations that are specific to Cisco ASA.

**Tunnel MTU and Path MTU Discovery**

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- **Option 1: TCP MSS adjustment** on page 3899
- **Option 2: Clear/set the Don't Fragment bit** on page 3899

**Option 1: TCP MSS adjustment**

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration on page 3915 section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```
sysopt connection tcpmss 1387
```

**Option 2: Clear/set the Don't Fragment bit**

Path MTU discovery requires that all TCP packets have the **Don't Fragment** (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- **Set the DF bit (recommended):** Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.

  ```
crypto ipsec df-bit set-df ${outsideInterface}
```

- **Clear the DF bit:** The DF bit is cleared in the packet's IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

  ```
crypto ipsec df-bit clear-df ${outsideInterface}
```
Networking

- **Ignore (copy) the DF bit:** The ASA looks at the original packet's IP header information and copies the DF bit setting.

```plaintext
crypto ipsec df-bit copy-df '${outsideInterface}'
```

**VPN Traffic Might Enter One Tunnel and Exit Another**

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration on page 3915 section.

```plaintext
same-security-traffic permit inter-interface
```

**General Caveats and Limitations**

This section covers general characteristics and limitations of Site-to-Site VPN.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

**Route-Based or Policy-Based IPSec Connections**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.
Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See [Site-to-Site VPN v2 availability](#) on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

**If Your CPE Is Behind a NAT Device**
In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Cisco router running Cisco ASA 9.7.1 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your ASA and your Oracle VCN.
- Identify the IPSec profile used (the following configuration template references this group policy as `oracle-vcn-vpn-policy`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vcn-transform`).
- Identify the virtual tunnel interface names used (the following configuration template references these as variables `${tunnelInterfaceName1}` and `${tunnelInterfaceName2}`).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names or numbers
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

Oracle provides a separate configuration template for IKEv1 versus IKEv2.
Oracle also provides a tool that can generate the template for you, with some of the information automatically filled in. For more information, see Using the CPE Configuration Helper on page 3847.

**IKEv1 Configuration Template**

```plaintext
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! ISAKMP Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! VTI Interface Configuration
! IP Routing (BGP or Static)
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template has various parameters that you must define before applying the configuration.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! PARAMETERS REFERENCED:
! `${OracleInsideTunnelIpAddress1}` = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! `${OracleInsideTunnelIpAddress2}` = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! `${bgpASN}` = Your BGP ASN
! `${cpePublicIpAddress}` = The public IP address for the CPE. This is the IP address of your outside interface
! `${oracleHeadend1}` = Oracle public IP endpoint obtained from the Oracle Console.
! `${oracleHeadend2}` = Oracle public IP endpoint obtained from the Oracle Console.
! `${sharedSecret1}` = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! `${sharedSecret2}` = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! `${outsideInterface}` = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
! `${tunnelInterfaceName1}` = The name of the first VTI used on your ASA.
! `${tunnelInterfaceName2}` = The name of the second VTI used on your ASA.
! `${cpeInsideTunnelIpAddress1}` = The CPE's inside tunnel IP for the first tunnel.
! `${cpeInsideTunnelIpAddress2}` = The CPE's inside tunnel IP for the second tunnel.
! `${cpeInsideTunnelNetmask1}` = The CPE's inside tunnel netmask for the first tunnel.
! `${cpeInsideTunnelNetmask2}` = The CPE's inside tunnel netmask for the second tunnel.
! `${vcnCidrNetwork}` = VCN IP range
! `${vcnCidrNetmask}` = Subnet mask for VCN
! `${onPremCidrNetwork}` = On-premises IP range
! `${onPremCidrNetmask}` = ON-premises subnet mask
!-------------------------------------------------------------------------------------------------------------------------------------------------------------

! ISAKMP Policy

! ISAKMP Phase 1 configuration.
! IKEv1 is enabled on the outside interface.
! IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
```
Networking

```plaintext
! If different parameters are required, modify this template before applying
the configuration.
! WARNING: The IKEv1 group policy is created with a priority of 10. Make
sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev1 enable ${outsideInterface}

crypto ikev1 policy 10
    authentication pre-share
    encryption aes-256
    hash sha
    group 5
    lifetime 28800

! IPSec Configuration

! Create an IKEv1 transform set named 'oracle-vcn-transform' which defines
a combination of IPSec (Phase 2) policy options. Specifically, AES256 for
encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying
the configuration.

crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-
hmac

! A IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created transform set is added to this policy along with
settings for enabling PFS Group 5 and the security association lifetime to
3600 seconds (1 hour).
! If different parameters are required, modify this template before applying
the configuration.

crypto ipsec profile oracle-vcn-vpn-policy
    set ikev1 transform-set oracle-vcn-transform
    set pfs group5
    set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group
defines the pre-shared key used for each respective tunnel.

tunnel-group ${oracleHeadend1} type ipsec-l2l
    ikev1 pre-shared-key ${sharedSecret1}

tunnel-group ${oracleHeadend2} type ipsec-l2l
    ikev1 pre-shared-key ${sharedSecret2}

! VTI Interface Configuration

! A virtual tunnel interface (VTI) is a logical interface representing
the local end of a VPN tunnel to a remote VPN peer. Two VTIS are created
representing two tunnels, one to each Oracle VPN Headend. The IP address
of each VPN headend is provided when you create your IPSec connection in
Oracle Console.
! All traffic routed to a VTI will be encrypted and sent across the tunnel
towards Oracle Cloud Infrastructure.
! Each VTI configuration also references the previously created IPSec
profile 'oracle-vcn-vpn-policy' for its IPSec parameters.

interface ${tunnelInterfaceName1}
    nameif ORACLE-VPN1
```
Networking

```plaintext
ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
tunnel source interface ${outsideInterface}
tunnel destination ${oracleHeadend1}
tunnel mode ipsec ipv4
tunnel protection ipsec profile oracle-vcn-vpn-policy

interface ${tunnelInterfaceName2}
nameif ORACLE-VPN2
ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
tunnel source interface ${outsideInterface}
tunnel destination ${oracleHeadend2}
tunnel mode ipsec ipv4
tunnel protection ipsec profile oracle-vcn-vpn-policy

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding
! commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
!    address-family ipv4 unicast
!        neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
!        neighbor ${OracleInsideTunnelIpAddress1} activate
!        neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
!        neighbor ${OracleInsideTunnelIpAddress2} activate
!        network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
!        no auto-summary
!        no synchronization
!    exit-address-family

! Static Route Configuration
! Each static route references the other VTI by its nameif value.
! Uncomment below line if you want to use static routing.

! route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask}
!  ${OracleInsideTunnelIpAddress1} 1 track
! route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask}
!  ${OracleInsideTunnelIpAddress2} 100

! Configuration for Tunnel Failover

! Uncomment the below IP SLA lines if using static routing.
! Use this IP SLA configuration for static route failover. This IP SLA
! configuration is used for static route failover between the two tunnels.
! Make sure that the SLA monitor and tracking numbers used do not conflict
! with any existing configuration on your ASA.

! sla monitor 10
!    type echo protocol ipIcmpEcho ${oracleHeadend1} interface outside
!    frequency 5
!    sla monitor schedule 10 life forever start-time now

! track 1 rtr 10 reachability
```

IKEv2 Configuration Template

```plaintext
!------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends
! that you configure both tunnels for maximum redundancy.
!------------------------------------------------------------------------------------------------------------------------------------------------------------
```
Networking

The configuration template involves setting up the following:

- IKEv2 Policy
- IPSec Configuration
- IPSec Tunnel Group Configuration
- VTI Interface Configuration
- IP Routing (BGP or Static)

The configuration template has various parameters that you must define before applying the configuration.

PARAMETERS REFERENCED:

- \${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
- \${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
- \${bgpASN} = Your BGP ASN
- \${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface
- \${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
- \${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
- \${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
- \${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
- \${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
- \${(tunnelInterfaceName1)} = The name of the first VTI used on your ASA.
- \${(tunnelInterfaceName2)} = The name of the second VTI used on your ASA.
- \${(cpeInsideTunnelIpAddress1)} = The CPE's inside tunnel IP for the first tunnel.
- \${(cpeInsideTunnelIpAddress2)} = The CPE's inside tunnel IP for the second tunnel.
- \${(cpeInsideTunnelNetmask1)} = The CPE's inside tunnel netmask for the first tunnel.
- \${(cpeInsideTunnelNetmask2)} = The CPE's inside tunnel netmask for the second tunnel.
- \${vcnCidrNetwork} = VCN IP range
- \${vcnCidrNetmask} = Subnet mask for VCN
- \${onPremCidrNetwork} = On-premises IP range
- \${onPremCidrNetmask} = ON-premises subnet mask

IKEv2 Policy

IKEv2 policy is enabled on the outside interface.
IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a lifetime of 28800 seconds (8 hours).
If different parameters are required, modify this template before applying the configuration.
WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

```plaintext
crypto ikev2 enable \${(outsideInterface)}

crypto ikev2 policy 10
  encryption aes-256
  integrity sha
  group 5
  prf sha
  lifetime seconds 28800
```
! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which defines AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
  protocol esp encryption aes-256
  protocol esp integrity sha-1

! An IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created IPSec proposal is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle-vcn-vpn-policy
  set ikev2 ipsec-proposal oracle_v2_ipsec_proposal
  set pfs group5
  set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

group-policy oracle_v2_group_policy internal
  group-policy oracle_v2_group_policy attributes
    vpn-tunnel-protocol ikev2

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group defines the pre-shared key used for each respective tunnel.

tunnel-group ${oracleHeadend1} type ipsec-l2l
  tunnel-group ${oracleHeadend1} general-attributes
    default-group-policy oracle_v2_group_policy
  tunnel-group ${oracleHeadend1} ipsec-attributes
    ikev2 local-authentication pre-shared-key ${sharedSecret1}
    ikev2 remote-authentication pre-shared-key ${sharedSecret1}

tunnel-group ${oracleHeadend2} type ipsec-l2l
  tunnel-group ${oracleHeadend2} general-attributes
    default-group-policy oracle_v2_group_policy
  tunnel-group ${oracleHeadend2} ipsec-attributes
    ikev2 local-authentication pre-shared-key ${sharedSecret2}
    ikev2 remote-authentication pre-shared-key ${sharedSecret2}

! VTI Interface Configuration

! A virtual tunnel interface (VTI) is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Two VTIs are created representing two tunnels, one to each Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.
! All traffic routed to a VTI will be encrypted and sent across the tunnel towards Oracle Cloud Infrastructure.
! Each VTI configuration also references the previously created IPSec profile 'oracle-vcn-vpn-policy' for its IPSec parameters.

interface ${tunnelInterfaceName1}
  nameif ORACLE-VPN1
  ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
  tunnel source interface ${outsideInterface}
  tunnel destination ${oracleHeadend1}
tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

interface ${tunnelInterfaceName2}
  nameif ORACLE-VPN2
  ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
  tunnel source interface ${outsideInterface}
  tunnel destination ${oracleHeadend2}
  tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding
! commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
  ! address-family ipv4 unicast
  !  neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
  !  neighbor ${OracleInsideTunnelIpAddress1} activate
  !  neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
  !  neighbor ${OracleInsideTunnelIpAddress2} activate
  !  network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
  !  no auto-summary
  !  no synchronization
  !  exit-address-family

! Static Route Configuration
! Each static route references the other VTI by its nameif value.
! Uncomment below line if you want to use static routing.

! route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask}
  $(OracleInsideTunnelIpAddress1) 1 track
! route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask}
  $(OracleInsideTunnelIpAddress2) 100

! Configuration for Tunnel Failover

! Uncomment the below IP SLA lines if using static routing.
! Use this IP SLA configuration for static route failover. This IP SLA
! configuration is used for static route failover between the two tunnels.
! Make sure that the SLA monitor and tracking numbers used do not conflict
! with any existing configuration on your ASA.

! sla monitor 10
!  type echo protocol ipIcmpEcho $(oracleHeadend1) interface outside
!  frequency 5
!  sla monitor schedule 10 life forever start-time now

! track 1 rtr 10 reachability

Verification

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to
Cisco's IPSec Troubleshooting document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

show crypto isakmp sa
Use the following command to verify the status of all your BGP connections.

```bash
show bgp summary
```

Use the following command to verify the ASA’s route table.

```bash
show route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

**Cisco ASA: Policy-Based**

This topic provides a policy-based configuration for a Cisco ASA that is running software version 8.5 to 9.7.0.

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer**: Route-based configuration
- **8.5 to 9.7.0**: Policy-based configuration (this topic)
- **Older than 8.5**: Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

**Important:**

Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still...
work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

**Best Practices**

This section covers best practices and considerations for using Site-to-Site VPN.

**Specific to Cisco ASA: VPN filters**

VPN filters let you further filter traffic either before it enters or after it exits a tunnel. Use VPN filters if you need additional granularity for filtering different traffic types or source/destination flows. For more information, see Cisco's [VPN Filter documentation](#).

VPN filter configuration is not included in the configuration template that appears in the CPE Configuration on page 3915 section. To use VPN filters, add the following configuration items manually.

- **Access control list (ACL):** Create an ACL that the VPN filter can use to restrict the traffic permitted through the tunnels. If you have an ACL already used for a VPN filter, do not also use it for an interface access group.

  ```
  access-list ${vpnFilterAclName} extended permit ip ${VcnCidrNetwork} ${VcnCidrNetmask} ${onPremCidrNetwork} ${onPremCidrNetmask}
  ```

- **Group policy:** Apply the VPN filter to your group policy.

  ```
  group-policy oracle-vcn-vpn-policy attributes
  vpn-filter value ${vpnFilterAclName}
  ```

- **Tunnel group:** Apply the group policy to your tunnel group.

  ```
  tunnel-group ${oracleHeadend1} general-attributes
  default-group-policy oracle-vcn-vpn-policy
  ```

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the [Connectivity Redundancy Guide (PDF)](#).

**Routing Protocol Considerations**

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:
Networking

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

- **Policy-based routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

*Specific to Cisco ASA: Caveats and Limitations*

This section covers important characteristics and limitations that are specific to Cisco ASA.

**Tunnel MTU and Path MTU Discovery**

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- **Option 1: TCP MSS adjustment** on page 3912
- **Option 2: Clear/set the Don't Fragment bit** on page 3912

**Option 1: TCP MSS adjustment**

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration on page 3915 section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```
sysopt connection tcpmss 1387
```

**Option 2: Clear/set the Don't Fragment bit**

Path MTU discovery requires that all TCP packets have the **Don't Fragment** (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- **Set the DF bit (recommended)**: Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.

```
crypto ipsec df-bit set-df ${outsideInterface}
```
• **Clear the DF bit:** The DF bit is cleared in the packet's IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

```bash
crypto ipsec df-bit clear-df $outsideInterface
```

• **Ignore (copy) the DF bit:** The ASA looks at the original packet's IP header information and copies the DF bit setting.

```bash
crypto ipsec df-bit copy-df $outsideInterface
```

**VPN Traffic Might Enter One Tunnel and Exit Another**

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration section.

```bash
same-security-traffic permit inter-interface
```

**General Caveats and Limitations**

This section covers general characteristics and limitations of Site-to-Site VPN.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

**Route-Based or Policy-Based IPSec Connection**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

• **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

• **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.
The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

---

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See [Site-to-Site VPN v2 availability](#) on page 4034 for a list of supported regions.
Networking

- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing CPE behind a NAT device](image)

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

![IPSec Connection Diagram]

The configuration template provided is for a Cisco ASA running version 8.5 software (or later).

**Note:**

Cisco ASA versions 9.7.1 and newer support route-based configuration, which is the recommended method to avoid interoperability issues.

If you want tunnel redundancy with a single Cisco ASA device, you must use the route-based configuration. With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.

- Ensure that you permit traffic between your ASA and your Oracle VCN (the following configuration template references this access list with the variable `${outboundAclName}`).

- Identify the internal VPN group policy (the following configuration template references this group policy as `oracle-vcn-vpn-policy`).

- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vcn-transform`).

- Identify the crypto map name and sequence number (the following configuration template references the map name as `oracle-vpn-map-v1` and sequence number 1).

- Identify the operation number for IP SLA continuous ping (the following configuration template uses operation number 1).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. The syntax for each CPE device configuration may be different and depends on the model and software versions. Be sure to compare your CPE model and version to the appropriate configuration template.
Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure that the following values are unique:

- Policy names or numbers
- Crypto map names and sequence numbers
- Interface names
- Access list names or numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

Oracle provides a separate configuration template for IKEv1 versus IKEv2.

Oracle also provides a tool that can generate the template for you, with some of the information automatically filled in. For more information, see Using the CPE Configuration Helper on page 3847.

**IKEv1 Configuration Template**

```plaintext
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of a single IPSec tunnel.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! Access Lists
! ISAKMP Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template has various parameters that you must define before applying the configuration.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface
! ${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = On-premises subnet mask
! ${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.
! ${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
```
Access Lists

! Permit Traffic Between Your ASA and Your Oracle VCN
! Assuming there is an access-list controlling traffic in and out of your
Internet facing interface, you will need to permit traffic between your CPE
and the Oracle VPN Headend
! WARNING: The new ACL entry you add to permit the traffic between your ASA
and VPN headend needs to be above any deny statements you might have in
your existing access-list

access-list ${outboundAclName} extended permit ip host ${oracleHeadend1}
host ${cpePublicIpAddress}

! Crypto ACL
! Create an ACL named ${cryptoMapAclName} which will later be associated
with the IPSec security association using the 'crypto-map' command. This
will define which source/destination traffic needs to be encrypted and sent
across the VPN tunnel.
! Keep this ACL to a single entry. In a policy based configuration each ACL
line will establish a separate encryption domain.
! The encryption domain used in this configuration sample will have a
source/destination of any/VCN CIDR. Refer to the 'Encryption domain for
policy-based tunnels' subsection for supported alternatives.

access-list ${cryptoMapAclName} extended permit ip any ${vcnCidrNetwork}
${vcnCidrNetmask}

! ISAKMP Policy
! ISAKMP Phase 1 configuration.
! IKEv1 is enabled on the outside interface.
! IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared
Key, AES256, SHA1, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800
seconds (8 hours).
! If different parameters are required, modify this template before applying
the configuration.
! WARNING: The IKEv1 group policy is created with a priority of 10. Make
sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev1 enable outside
crypto ikev1 policy 10
   authentication pre-share
   encryption aes-256
   hash sha
   group 5
   lifetime 28800

! Base VPN Policy
! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to
define some basic VPN tunnel settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and
tunnel protocol is set to IKEv1

group-policy oracle-vcn-vpn-policy internal
group-policy oracle-vcn-vpn-policy attributes
   vpn-idle-timeout none
   vpn-session-timeout none
   vpn-tunnel-protocol ikev1

! IPSec Configuration
Create an IKEv1 transform set named 'oracle-vcn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication.

If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-hmac

A crypto map is used to tie together the important traffic that needs encryption (via crypto map ACL) with defined security policies (from the transform set along with other crypto map statements), and the destination of the traffic to a specific crypto peer.

In this configuration example, a single crypto map is created named 'oracle-vpn-map-v1'. This crypto map references the previously created crypto map ACL, the 'oracle-vcn-transform' transform set and further defines PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).

WARNING: Make sure your crypto map name and sequence numbers do not overlap with existing crypto maps.

WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec tunnels: crypto map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vpn-map-v1 1 match address ${cryptoMapAclName}
crypto map oracle-vpn-map-v1 1 set pfs group5
crypto map oracle-vpn-map-v1 1 set peer ${oracleHeadend1}
crypto map oracle-vpn-map-v1 1 set ikev1 transform-set oracle-vcn-transform

crypto map oracle-vpn-map-v1 1 set security-association lifetime seconds 3600

WARNING: The below command will apply the 'oracle-vpn-map-v1' crypto map to the outside interface. The Cisco ASA supports a single crypto map per interface. Make sure no other crypto map is applied to the outside interface before using this command.

crypto map oracle-vpn-map-v1 interface outside

IPSec Tunnel Group Configuration

This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend endpoint.

The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
default-group-policy oracle-vcn-vpn-policy
tunnel-group ${oracleHeadend1} ipsec-attributes
ikev1 pre-shared-key ${sharedSecret1}

IP SLA Configuration

The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the tunnel.

You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all times.

You must allow ICMP on the outside interface.

Make sure that the SLA monitor number used is unique.

sla monitor 1
type echo protocol ipIcmpEcho ${vcnHostIp} interface outside
Networking

```plaintext
frequency 5
sla monitor schedule 1 life forever start-time now

icmp permit any '${outsideInterface}'

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding
commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp '${bgpASN}'
!  address-family ipv4 unicast
!   neighbor '${OracleInsideTunnelIpAddress1}' remote-as 31898
!   neighbor '${OracleInsideTunnelIpAddress1}' activate
!   network '${onPremCidrNetwork}' mask '${onPremCidrNetmask}'
!   no auto-summary
!   no synchronization
!   exit-address-family

! Static Route Configuration
! Uncomment below line if you want to use static routing.

! route outside '${VcnCidrNetwork}' '${VcnCidrNetmask}'
! '${OracleInsideTunnelIpAddress1}'

! Disable NAT for VPN Traffic

! If you are using NAT for traffic between your inside and outside
interfaces, you might need to disable NAT for traffic between your on-
promises network and the Oracle VCN.
! Two objects are created for this NAT exemption. 'obj-OnPrem' represents
the on-promises network as a default route, and 'obj-oracle-vcn-1'
represents the VCN CIDR block used in Oracle Cloud Infrastructure.
! If different address ranges are required, modify this template before
applying the configuration.

! object network obj-onprem
!  subnet 0.0.0.0 0.0.0.0
! object network obj-oracle-vcn-1
!  subnet '${vcnCidrNetwork}' '${vcnCidrNetmask}'
! nat (inside,outside) source static obj-onprem obj-onprem destination
static obj-oracle-vcn-1 obj-oracle-vcn-1

IKEv2 Configuration Template

!----------------------------------------
! IKEv2 Configuration Template
! The configuration consists of a single IPSec tunnel.
!----------------------------------------
! The configuration template involves setting up the following:
! Access Lists
! IKEv2 Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
!----------------------------------------
! The configuration template has various parameters that you must define
before applying the configuration.
```
Parameters Referenced:

- \${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
- \${bgpASN} = Your BGP ASN
- \${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface
- \${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces
- \${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
- \${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
- \${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
- \${vcnCidrNetwork} = VCN IP range
- \${vcnCidrNetmask} = Subnet mask for VCN
- \${onPremCidrNetwork} = On-premises IP range
- \${onPremCidrNetmask} = On-premises subnet mask
- \${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.
- \${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.

Access Lists

- Permit Traffic Between Your ASA and Your Oracle VCN
  - Assuming there is an access-list controlling traffic in and out of your Internet facing interface, you will need to permit traffic between your CPE and the Oracle VPN Headend
  - WARNING: The new ACL entry you add to permit the traffic between your ASA and VPN headend needs to be above any deny statements you might have in your existing access-list

access-list \${outboundAclName} extended permit ip host \${oracleHeadend1} host \${cpePublicIpAddress}

- Crypto ACL
  - Create an ACL named \${cryptoMapAclName} which will later be associated with the IPSec security association using the 'crypto-map' command. This will define which source/destination traffic needs to be encrypted and sent across the VPN tunnel.
  - Keep this ACL to a single entry. In a policy based configuration each ACL line will establish a separate encryption domain.
  - The encryption domain used in this configuration sample will have a source/destination of any/VCN CIDR. Refer to the 'Encryption domain for policy-based tunnels' subsection for supported alternatives.

access-list \${cryptoMapAclName} extended permit ip any \${vcnCidrNetwork} \${vcnCidrNetmask}

- IKEv2 Policy
  - IKEv2 is enabled on the outside interface.
  - IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a lifetime of 28800 seconds (8 hours).
  - If different parameters are required, modify this template before applying the configuration.
  - WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev2 enable outside
crypto ikev2 policy 10
  encryption aes-256
  integrity sha384
  group 5
  prf sha
  lifetime seconds 28800

! Base VPN Policy

! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to
define some basic VPN tunnel settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and
tunnel protocol is set to IKEv2

group-policy oracle-vcn-vpn-policy internal
  group-policy oracle-vcn-vpn-policy attributes
    vpn-idle-timeout none
    vpn-session-timeout none
    vpn-tunnel-protocol ikev2

! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which
defines AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying
the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
  protocol esp encryption aes-256
  protocol esp integrity sha-1

! A crypto map is used to tie together the important traffic that needs
encryption (via crypto map ACL) with defined security policies (from the
IPSec proposal along with other crypto map statements), and the destination
of the traffic to a specific crypto peer.
! In this configuration example, a single crypto map is created named
'oracle-vpn-map-v2' This crypto map references the previously created
crypto map ACL, the 'oracle_v2_ipsec_proposal' IPSec proposal and further
defines PFS Group 5 and the security association lifetime to 3600 seconds
(1 hour).
! WARNING: Make sure your crypto map name and sequence numbers do not
overlap with existing crypto maps.
! WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec
tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The
command is only for tunnels between two Cisco devices. Here's an example
of the command that you should NOT use for the Oracle IPSec tunnels: crypto
map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vpn-map-v2 1 match address ${(cryptoMapAclName)}
crypto map oracle-vpn-map-v2 1 set pfs group5
crypto map oracle-vpn-map-v2 1 set peer ${oracleHeadend1}
crypto map oracle-vpn-map-v2 1 set ikev2 ipsec-proposal
  oracle_v2_ipsec_proposal
  crypto map oracle-vpn-map-v2 1 set security-association lifetime seconds
  3600

! WARNING: The below command will apply the 'oracle-vpn-map-v2' crypto
map to the outside interface. The Cisco ASA supports a single crypto map
per interface. Make sure no other crypto map is applied to the outside
interface before using this command.

crypto map oracle-vpn-map-v2 interface outside

! IPSec Tunnel Group Configuration
This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend endpoint.

The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
default-group-policy oracle-vcn-vpn-policy
tunnel-group ${oracleHeadend1} ipsec-attributes
ikev2 local-authentication pre-shared-key ${sharedSecret1}
ikev2 remote-authentication pre-shared-key ${sharedSecret1}

IP SLA Configuration

The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the tunnel.
You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all times.
You must allow ICMP on the outside interface.
Make sure that the SLA monitor number used is unique.

sla monitor 1
type echo protocol ipIcmpEcho ${vcnHostIp} interface outside
frequency 5
sla monitor schedule 1 life forever start-time now

icmp permit any ${outsideInterface}

IP Routing
Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

Border Gateway Protocol (BGP) Configuration
 Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
! address-family ipv4 unicast
! neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
! neighbor ${OracleInsideTunnelIpAddress1} activate
! network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
! no auto-summary
! no synchronization
! exit-address-family

Static Route Configuration
 Uncomment below line if you want to use static routing.

! route outside ${VcnCidrNetwork} ${VcnCidrNetmask}
 ${OracleInsideTunnelIpAddress1}

Disable NAT for VPN Traffic

If you are using NAT for traffic between your inside and outside interfaces, you might need to disable NAT for traffic between your on-premises network and the Oracle VCN.
Two objects are created for this NAT exemption. 'obj-OnPrem' represents the on-premises network as a default route, and 'obj-oracle-vcn-1' represents the VCN CIDR block used in Oracle Cloud Infrastructure.
If different address ranges are required, modify this template before applying the configuration.

! object network obj-onprem
! subnet 0.0.0.0 0.0.0.0
![object network obj-oracle-vcn-1
! subnet ${vcnCidrNetwork} ${vcnCidrNetmask}
! nat (inside,outside) source static obj-onprem obj-onprem destination
static obj-oracle-vcn-1 obj-oracle-vcn-1

**Verification**

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to Cisco's [IPSec Troubleshooting](#) document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```text
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections.

```text
show bgp summary
```

Use the following command to verify the ASA's route table.

```text
show route
```

A [Monitoring service](#) is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see [Site-to-Site VPN Metrics](#) on page 4042.

If you have issues, see [Site-to-Site VPN Troubleshooting](#) on page 4044.

**Cisco IOS**

This topic provides a route-based configuration for a Cisco IOS device. The configuration was validated using a Cisco 2921 running IOS version 15.4(3)M3.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.
Best Practices

This section covers general best practices and considerations for using Site-to-Site VPN.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.
If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor’s support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet’s source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet’s destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet’s source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It’s the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels
When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

Important:
If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.
Networking

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

CPE Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template was validated using a Cisco 2921 running IOS version 15.4(3)M3. The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.
Networking

The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your CPE and your Oracle VCN.
- Identify the IPSec profile used (the following configuration template references this group policy as oracle-vpn).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as oracle-vpn-transform).

**Important:**

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE**. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Keyrings
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see [Supported IPSec Parameters](#) on page 3821.

There's a separate configuration template for IKEv1 versus IKEv2.

**IKEv1 Configuration Template**

```bash
!------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!------------------------------------------------------------------------------------------------------------------------------------------------------------

! The configuration template involves setting up the following:
! Keyring (Pre-Shared Key)
! Basic ISAKMP Options
! ISAKMP and IPSec Policy Configuration
! IPSec Peers
! Virtual Tunnel Interfaces
! IP Routing (BGP or Static)
! Update Any Internet Facing Access List to Allow IPSec and ISAKMP Packets

!------------------------------------------------------------------------------------------------------------------------------------------------------------

! The configuration template has various parameters that you must define before applying the configuration.

! PARAMETERS REFERENCED:
! `${OracleInsideTunnelIpAddress1}` = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
```
$\{OracleInsideTunnelIpAddress2\} = \text{Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.}\n
$\{bgpASN\} = \text{Your BGP ASN}\n
$\{cpePublicIpAddress\} = \text{The public IP address for the CPE. This is the IP address of your outside interface}\n
$\{oracleHeadend1\} = \text{Oracle public IP endpoint obtained from the Oracle Console.}\n
$\{oracleHeadend2\} = \text{Oracle public IP endpoint obtained from the Oracle Console.}\n
$\{sharedSecret1\} = \text{You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.}\n
$\{sharedSecret2\} = \text{You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.}\n
$\{outsideInterface\} = \text{The public interface or outside of tunnel interface which is configured with the CPE public IP address.}\n
$\{vcnCidrNetwork\} = \text{VCN IP range}\n
$\{vcnCidrNetmask\} = \text{Subnet mask for VCN}\n
$\{onPremCidrNetwork\} = \text{On-premises IP range}\n
$\{onPremCidrNetmask\} = \text{On-premises subnet mask}\n
---

\text{Keyring (Pre-Shared Key)}\n
\text{For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.}\n
\text{Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.}\n
\text{crypto keyring oracle-vpn-$\{oracleHeadend1\}\n\quad local-address $\{cpePublicIpAddress\}\n\quad pre-shared-key address $\{oracleHeadend1\} key $\{sharedSecret1\}\n\text{crypto keyring oracle-vpn-$\{oracleHeadend2\}\n\quad local-address $\{cpePublicIpAddress\}\n\quad pre-shared-key address $\{oracleHeadend2\} key $\{sharedSecret2\}\n
\text{Basic ISAKMP Options}\n
\text{crypto isakmp fragmentation}\n
\text{crypto isakmp keepalive 10 10}\n
\text{The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.}\n
\text{crypto ipsec df-bit clear}\n
\text{crypto ipsec security-association replay window-size 128}\n
\text{ISAKMP and IPSec Policy Configuration}\n
\text{An ISAKMP policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA384, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).}
Networking

! If different parameters are required, modify this template before applying the configuration.

crypto isakmp policy 10
  encri aes 256
  hash sha384
  authentication pre-share
  group 5
  lifetime 28800

! Create an IPSec transform set named 'oracle-vpn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication. This is also where tunnel mode is set for IPSec.

crypto ipsec transform-set oracle-vpn-transform esp-aes 256 esp-sha-hmac
  mode tunnel

! A IPSec profile named 'oracle-vpn' is created.

! The previously created transform set is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).

crypto ipsec profile oracle-vpn
  set pfs group5
  set security-association lifetime seconds 3600
  set transform-set oracle-vpn-transform

! IPSec Peers

! Two ISAKMP profiles are created for each Oracle VPN Headend. An ISAKMP profile is used as a repository for various Phase 1 commands tied to a specific IPSec peer. In this case, we match the previously created keyrings to an Oracle VPN headend.

crypto isakmp profile oracle-vpn-$(oracleHeadend1)
  keyring oracle-vpn-$(oracleHeadend1)
  self-identity address
  match identity address $(oracleHeadend1) 255.255.255.255

crypto isakmp profile oracle-vpn-$(oracleHeadend2)
  keyring oracle-vpn-$(oracleHeadend2)
  self-identity address
  match identity address $(oracleHeadend2) 255.255.255.255

! Virtual Tunnel Interfaces

! Each tunnel interface is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Each tunnel interface represents a single tunnel to a different Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.

! All traffic routed to a tunnel interface will be encrypted and sent across the tunnel towards Oracle Cloud Infrastructure.

! Each tunnel interface configuration also references the previously created IPSec profile 'oracle-vpn' for its IPSec parameters.

! WARNING: When doing static routing you do NOT have to set IPs on the tunnel interfaces unless you have pre-configured inside tunnel interfaces.
Networking

in Oracle Console when creating your IPSec connection. Inside tunnel interfaces are required if using BGP.

interface Tunnel${tunnelNumber1}
ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
tunnel source ${cpePublicIpAddress}
tunnel mode ipsec ipv4
tunnel destination ${oracleHeadend1}
tunnel protection ipsec profile oracle-vpn

interface Tunnel${tunnelNumber2}
ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
tunnel source ${cpePublicIpAddress}
tunnel mode ipsec ipv4
tunnel destination ${oracleHeadend2}
tunnel protection ipsec profile oracle-vpn

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
! neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
! neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
! network ${onPremCidrNetwork} mask ${onPremCidrNetmask}

! Static Route Configuration
! Uncomment below lines if you want to use static routing.
! ip route ${vcnCidrNetwork} ${vcnCidrNetmask} Tunnel${tunnelNumber1}
! ip route ${vcnCidrNetwork} ${vcnCidrNetmask} Tunnel${tunnelNumber2}

! Update Any Internet Facing Access List to Allow IPSec and ISAKMP Packets
! You may need to allow IPSec and ISAKMP packets out your internet facing interface.
! Uncomment below lines to create a new ACL allowing IPSec and ISAKMP traffic and apply it to the outside interface.

! ip access-list extended INTERNET-INGRESS
! permit udp host ${oracleHeadend1} host ${cpePublicIpAddress} eq isakmp
! permit esp host ${oracleHeadend1} host ${cpePublicIpAddress}
! permit udp host ${oracleHeadend2} host ${cpePublicIpAddress} eq isakmp
! permit esp host ${oracleHeadend2} host ${cpePublicIpAddress}
! permit icmp any any echo
! permit icmp any any echo-reply
! permit icmp any any unreachable

! interface ${outsideInterface}
! ip address ${cpePublicIpAddress} $(netmask)

IKEv2 Configuration Template

!-----------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-----------------------------------------------------
! The configuration template involves setting up the following:
! Keyring (Pre-Shared Key)
The configuration template has various parameters that you must define before applying the configuration.

PARAMETERS REFERENCED:

${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.

${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.

${bgpASN} = Your BGP ASN

${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface

${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.

${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.

${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.

${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.

${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.

${vcnCidrNetwork} = VCN IP range

${vcnCidrNetmask} = Subnet mask for VCN

${onPremCidrNetwork} = On-premises IP range

${onPremCidrNetmask} = ON-premises subnet mask

Keyring (Pre-Shared Key)

For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.

Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.

crypto ikev2 keyring oracle-vpn-${oracleHeadend1}
peer oracle_vpn
  address ${oracleHeadend1}
  pre-shared-key local ${sharedSecret1}
  pre-shared-key remote ${sharedSecret1}

crypto ikev2 keyring oracle-vpn-${oracleHeadend2}
peer oracle_vpn
  address ${oracleHeadend2}
  pre-shared-key local ${sharedSecret2}
  pre-shared-key remote ${sharedSecret2}

Optional IPSec settings are included here.

All optional settings included are recommended by Oracle. Remove or comment out any unneeded commands prior to applying this configuration.

WARNING: These settings are global and may impact other IPSec connections.

The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

crypto ipsec df-bit clear
! Increases security association anti-replay window. An increased window size is helpful for scenarios where packets are regularly being dropped due to delays.
crypto ipsec security-association replay window-size 128

! IKEv2 and IPSec Policy Configuration

! An IKEv2 proposal is created and specifies use of a Pre-Shared Key, AES256, SHA384, and Diffie-Hellman Group 5.
! If different parameters are required, modify this template before applying the configuration.
crypto ikev2 proposal oracle_v2_proposal
  encryption aes-cbc-256
  integrity sha384
  group 5
crypto ikev2 policy oracle_v2_policy
  proposal oracle_v2_proposal

! Create an IPSec transform set named 'oracle-vpn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication. This is also where tunnel mode is set for IPSec.
! If different parameters are required, modify this template before applying the configuration.
crypto ipsec transform-set oracle-vpn-transform esp-aes 256 esp-sha-hmac
  mode tunnel

! An IPSec profile named 'oracle_v2_ipsec_profile_tunnel#' is created for each tunnel.
! The previously created transform set is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.
crypto ipsec profile oracle_v2_ipsec_profile_tunnel1
  set ikev2-profile oracle_v2_profile_tunnel1
  set pfs group5
  set security-association lifetime seconds 3600
  set transform-set oracle-vpn-transform
crypto ipsec profile oracle_v2_ipsec_profile_tunnel2
  set ikev2-profile oracle_v2_profile_tunnel2
  set pfs group5
  set security-association lifetime seconds 3600
  set transform-set oracle-vpn-transform

! IPSec Peers

! Two IKEv2 profiles are created for each Oracle VPN Headend.
crypto ikev2 profile oracle-vpn-${oracleHeadend1}
  keyring oracle-vpn-${oracleHeadend1}
  identity local address ${cpePublicIpAddress}
  match identity remote address ${oracleHeadend1} 255.255.255.255
  authentication remote pre-share
  authentication local pre-share
crypto ikev2 profile oracle-vpn-${oracleHeadend2}
keyring oracle-vpn-$(oracleHeadend2)
identity local address $(cpePublicIpAddress)
machine identity remote address $(oracleHeadend2) 255.255.255.255
authentication remote pre-share
authentication local pre-share

! Virtual Tunnel Interfaces

! Each tunnel interface is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Each tunnel interface represents a single tunnel to a different Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.

Verification

The following IOS commands are included for basic troubleshooting.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

`show crypto isakmp sa`

Use the following command to verify the status of all your BGP connections or neighbors.

`show ip bgp summary`

`show ip bgp neighbors`

Use the following command to verify the route table.

`show ip route`

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

FortiGate

This topic provides configuration for a FortiGate that is running software version 6.0.4.

FortiGate experience is recommended. For more details on how to use FortiGate products, visit their official site. For FortiGate documentation for high availability (HA) or manual deployment, see the Fortinet Document Library.

Important:

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.
Networking

Best Practices

This section covers general best practices and considerations for using Site-to-Site VPN.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.
If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

Caveats and Limitations
This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

Asymmetric Routing
Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

Route-Based or Policy-Based Site-to-Site VPN
The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet’s source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:
Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels
If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels
When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPsec connection, or later, by editing the IPsec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPsec Parameters**

For a vendor-neutral list of supported IPsec parameters for all regions, see Supported IPsec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

By default, FortiGate provisions the IPSec tunnel in route-based mode. This topic focuses on FortiGate with a route-based VPN configuration.
If necessary, you can have FortiGate provision the IPSec tunnel in policy-based mode. To enable the feature, go to System, and then to Feature Visiblity. Under Additional Features, enable the Policy-based IPsec VPN feature.

### About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

If you want to use IKEv2, there’s a variation on one of the tasks presented in the next section. Specifically, in task 2, when configuring authentication, select IKE version 2.

### Configuration Process

**Important:**

Before starting, ensure you have a valid license or trial license to configure FortiGate.

**Task 1:** Use the wizard to create the VPN

1. Go to VPN, and then to IPsec Wizard to create a new VPN tunnel.
2. On the **VPN Creation Wizard** page, specify the following items:

   - **Name**: Description used to identify the IPSec tunnel. Avoid entering confidential information.
   - **Template Type**: Site to Site
   - **Remote Device Type**: Cisco
   - **NAT Configuration**: No NAT between sites

3. Click **Next**.

4. On the **Authentication** page, specify the following items:

   - **Remote Device**: IP Address
   - **IP Address**: IP address for the Oracle VPN headend. Oracle generated this value when creating the IPSec tunnel.
   - **Outgoing Interface**: The WAN interface configured for external traffic.
   - **Authentication Method**: Pre-shared Key. Oracle supports only shared secret keys.
   - **Pre-shared Key**: The shared secret. Oracle generated this value when creating the IPSec tunnel.

5. Click **Next**.

6. On the **Policy & Routing** page, specify the following items:

   - **Local Interface**: The LAN interface configured for internal traffic.
   - **Local Subnets**: The subnet used for internal traffic.
   - **Remote Subnets**: The Oracle VCN subnets that will be used for the IPSec tunnel.
   - **Internet Access**: None
7. Click **Create**.

A summary message is shown with details about the configuration. Notice that the wizard automatically creates security policies with the subnets that you specified and adds the required static routes.

<table>
<thead>
<tr>
<th><strong>VPN Creation Wizard</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Summary of Created Objects</strong></td>
</tr>
<tr>

<td><strong>Static Route</strong></td>
</tr>
<tr>
<td><strong>Blackhole Route</strong></td>
</tr>
<tr>
<td><strong>Local to Remote Policy</strong></td>
</tr>
<tr>
<td><strong>Remote to Local Policy</strong></td>
</tr>
</tbody>
</table>

**Task 2: Add Phase 1 and Phase 2 parameters to each IPSec tunnel**

You must convert each newly created IPSec tunnel into a custom tunnel to add the recommended parameters for Phase 1 and Phase 2.

Perform the following steps for each tunnel.

1. Go to **VPN**, and then click **IPsec Tunnels**.
2. Select the tunnel and click **Edit** to view the **Edit VPN Tunnel** page.
3. Click **Convert to Custom Tunnel**.
4. Edit the relevant sections to match the required settings shown in the following screenshots. Remember to click the check mark icon in the top-right corner of each section after making your changes.

The IP address shown in the first screenshot is an example address.

Notice that if you want to use IKEv2, on the Authentication screen, instead select **IKE Version 2**.
5. After configuring all sections, click **OK** to save and close the dialogs.

Task 3: Verify the IPSec connection

At this point, the IPSec tunnel will not be established by default because FortiGate uses the IP address assigned on the WAN interface. In this case, this IP address is a private IP address because Oracle does 1:1 NAT. This private IP address will be used as the local IKE ID and will not match the one expected on the Oracle DRG. To resolve this, you can manually change the local IKE ID on your FortiGate by using the CPE's CLI, or you can change the value that Oracle uses in the Oracle Console (see the instructions that follow). Either way, this fixes the incompatibility and brings up the IPSec tunnel.

To change the CPE IKE identifier that Oracle uses (Oracle Console)
1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.

   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click **Edit**.

   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.

3. Enter your new values for **CPE IKE Identifier Type** and **CPE IKE Identifier**, and then click **Save Changes**.

**Redundancy with BGP Over IPSec**

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see *Routing Details for Connections to Your On-Premises Network* on page 3818.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of Site-to-Site VPN's encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

Oracle's BGP ASN in commercial regions is 31898. If you're configuring Site-to-Site VPN for the Government Cloud, see *Required Site-to-Site VPN Parameters for Government Cloud* on page 178 and also *Oracle's BGP ASN* on page 180.

For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

**Task 1: Edit the tunnel interface**

In the first task, you add the BGP IP address to the newly created FortiGate tunnel interface.

Perform the following steps for each tunnel.

1. Go to **Network**, and then **Interface**.
2. Select the interface you're interested in and click **Edit**.

3. **Configure the following items:**
   - **IP**: Enter the BGP IP address that you assigned to the FortiGate end of the tunnel interface. The following screenshot shows an example value of 192.168.66.2.
   - **Remote IP/Network Mask**: Add the BGP IP address that you assigned to the Oracle end of the tunnel interface. Include either a /30 or /31 mask, depending on how you specified the addresses in the Oracle
Networking

In the following screenshot, 192.168.66.0/30 was used, where 192.168.66.2 is assigned to the FortiGate end, and 192.168.66.1 is assigned to the Oracle end.

- **Ping access** (recommended): In the **Administrative Access** section, enable ping access.

```
<table>
<thead>
<tr>
<th>Interface Name</th>
<th>OCI-IPSEC-BGP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>IP</td>
<td>192.168.66.2</td>
</tr>
<tr>
<td>Network Mask</td>
<td>255.255.255.255</td>
</tr>
<tr>
<td>Remote IP/Network Mask</td>
<td>192.168.66.1/255.255.255.252</td>
</tr>
</tbody>
</table>

**Administrative Access**

- **IPv4**
  - HTTPS
  - HTTP
  - CAPWAP
  - SSH
  - PING
  - SNMP
  - FMG-Access
  - RADIUS Accounting
  - FortiTelemetry

4. Click **OK**.

**Task 2: Add a static route for the Oracle IP address**

For each tunnel, add a /32 static route towards the Oracle IP address through the tunnel, as shown in the following screenshot.

**Task 3: Configure BGP**

Perform the following steps for each tunnel.

1. Go to **Network**, and then **BGP**.
2. Enter the following items:

- **Local AS:** Your BGP ASN. You can use a private ASN. Private ASNs are in the range 64512–65534.
- **Router ID:** A value to provide a unique identity for this BGP router among its peers.
- **Neighbors:** Click **Create New** and enter the BGP IP address for the Oracle end of the tunnel, and the Oracle BGP ASN (31898 for commercial regions). If you're configuring Site-to-Site VPN for connecting to the Government Cloud, see Oracle's BGP ASN on page 180.
- **Networks:** Optionally use this field to advertise a specific subnet over BGP. You can also advertise subnets by using the **Redistribute** section in the **Advanced Options** section.

3. Click **OK**.
Verification

The following CLI command is useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the encryption domain (SPI) identifier, and so on. This kind of information can be critical for determining an issue with the VPN.

```plaintext
diagnose vpn tunnel list
```

The following command indicates a lack of firewall policy, a lack of forwarding route, and policy ordering issues. If there are no communication issues, this command returns blank output.

```plaintext
diagnose debug flow
```

The following command verifies BGP neighbor status information. Remember that an "Active" state doesn't mean that the BGP session is up. "Active" refers to a BGP state message. For more information, see BGP Background and Concepts in the FortiGate documentation.

```plaintext
get router info bgp summary
```

The following command provides more detailed information about a BGP neighbor.

```plaintext
get router info bgp neighbors
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

Furukawa Electric

This configuration was validated using a Furukawa Electric series FITELnet-F220/F221 running Firmware 01.00(00) [0]00.00.0 [2019/07/05 15:00].

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is &quot;up&quot; on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.</td>
</tr>
</tbody>
</table>

Before Starting

Before configuring your CPE, ensure that you:

- Configure your internet provider settings.
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

Supported Encryption Domain or Proxy ID

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 3824.

Parameters from API or Console

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

```plaintext
${vpn-ip#}
```

- Oracle VPN headend IPSec tunnel endpoints. There is one value for each tunnel.
- Example values: 129.146.12.52, 129.146.13.52
Networking

${sharedSecret#}

- The IPSec ISAKMP pre-shared-key. There is one value for each tunnel.
- Example value: EXAMPLEDPfAMkD7nTH3SWr6OFabdT6exXn6enSlsKbE

${cpePublicIpAddress}

- The public IP address for the CPE (previously made available to Oracle via the Console).

${VcnCidrBlock}

- When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.
- Example Value: 10.0.0.0/20

Parameters Based on Current CPE Configuration and State

The following parameters are based on your current CPE configuration.

${tunnelNumber#}

- An interface number to identify the specific tunnel. You need one unused unit number per tunnel.
- Example value: 1, 2

${isakmpPolicy}

- The ISAKMP policy name.
- Example value: isakmp-policy

${ipsecPolicy#}

- The IPSec policy name.
- Example value: ipsec-policy

${isakmpProfile#}

- The ISAKMP profile name. You need one unused ISAKMP profile name per tunnel.
- Example values: OCI-VPN-profile1, OCI-VPN-profile2

${selector}

- The selector name.
- Example value: OCI-VPN-selector

${map#}

- The map name. You need one unused map name per tunnel.
- Example values: OCI-VPN-MAP1, OCI-VPN-MAP2

${customer-bgp-asn}

- Your BGP ASN.
- Example value: 65000

${oracle-bgp-asn#}

- Oracle's BGP ASN.
- Example value: 31898

${customer-interface-ip#}

- The inside tunnel interface for CPE.
- Example value: 10.0.0.16/31

${oracle-interface-ip#}

- The inside tunnel interface for ORACLE.
- Example value: 10.0.0.17/31
${router-id}
- The BGP router ID.
- Example value: 10.0.0.16

**Config Template Parameter Summary**

Each region has multiple Oracle IPSec headends. The following template allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the following table, "User" is you/your company.

<table>
<thead>

Juniper MX

This topic provides configuration for a Juniper MX that is running software version JunOS 15.0 (or newer).

**Important:**

Oracle provides configuration instructions for a set of vendors and devices.
Make sure to use the configuration for the correct vendor.
If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you’re already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor’s documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN’s subnets.
• **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

• **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

### Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

### Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

### Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

### Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

#### Note:

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

• **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet’s destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

• **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.
Networking

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It’s the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

*Important:*

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
Networking

- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing CPE and NAT device configurations](image)

**Note:**
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Juniper MX router running JunOS 15.0 (or newer). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure the Juniper MX public interface (the CPE public IP address is bound to this interface).
- Configure internal routing that routes traffic between the CPE and your local network.
- Configure the tunnel interfaces. See the next section for more information.

**About the Tunnel Interfaces**

In the following configuration template, the tunnel interfaces are referred to with the following variables:

- **msInterface#** - one per tunnel
  - These interfaces correspond to one of the four encryption ASICs on the MS-MPC card.
  - You can distribute load across the ASICs by spreading your tunnels across them.
  - Example values: ms-2/3/0, ms-2/3/1
- **insideMsUnit#** and **outsideMsUnit#** - one pair per tunnel
  - For every tunnel, you need an ms-mpc interface pair of units.
  - One represents the outside of the IPSec tunnel. The other represents the inside of the tunnel.
  - The router forwards packets from your on-premises network to your VCN into the inside unit.
    - The encryption ASIC then encrypts the packets based on the rules and policies.
    - Then the encrypted packet egresses out the outside unit as an ESP packet, ready to be forwarded to the Oracle VPN headend routers.
  - There are over 16,000 possible values for unit numbers.
    - One way to allocate the units is to offset them by 8,000.
    - You can pick values between 0-7999 for insideMsUnit# and 8000-15999 for outsideMsUnit#.
**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword USER_DEFINED in the template.

---

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

You specify the IKE version when defining the IKE policy. In the following configuration, there's a comment showing how to configure the IKE policy for IKEv1 versus IKEv2.

**Configuration Template**

---

```plaintext
# Configuration Template
# The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.

# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE TUNNEL INTERFACES FOR ORACLE
# SETTING THE SERVICES FOR ORACLE.
# SETTING BGP/STATIC ROUTING
# SETTING ROUTING-INSTANCES FOR ORACLE (OPTIONAL).

# The configuration template has various parameters that you must define before applying the configuration.
# Search in the template for the keyword "USER_DEFINED" to find those parameters.

# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle Console.
# connection_presharedkey_1 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# cpe_public_ip_address = The internet-routable IP address that is assigned to the public interface on the CPE. You provide this when creating the CPE object in the Oracle Console.
```

---
# cpe_public_interface = The name of the Juniper interface where the CPE IP address is configured. Eg: ge-0/0/1.0
# msInterface1 = The interface correspond to one of the four encryption ASICs on the MS-MPC card. Eg: ms-2/3/0, ms-2/3/1
# msInterface2 = Second tunnel interface that needs to be configured. Eg: ms-2/3/0, ms-2/3/1
# insideMsUnit1 = The inside interface of the MS-MPC interface pair for tunnel_1
# insideMsUnit2 = The inside interface of the MS-MPC interface pair for tunnel_2
# outsideMsUnit1 = The outside interface of the MS-MPC interface pair for tunnel_1
# outsideMsUnit2 = The outside interface of the MS-MPC interface pair for tunnel_2
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these when creating the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address between the MX and Oracle end points of the inside tunnel interface.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range

# OPTIONAL PARAMETERS:
# customer_on-prem_to_oracle = Name of the routing instance to be defined on the CPE for the tunnel interfaces connecting to the Oracle headends.
# internet_routing_instance = Name of the routing instance to be defined on the CPE for the tunnel interfaces that are connected to the Internet.

# USER_DEFINED: Replace the parameters in the section below as needed.
# If you are using routing-instances on your CPE, you need to make sure you account for them in your configuration. Merge the following configuration into the template provided above.

set routing-instances <customer_on-prem_to_oracle>
interface <msInterface2>.<insideMsUnit2>
set routing-instances <internet_routing_instance>
interface <msInterface2>.<outsideMsUnit2>
set services service-set oracle-vpn-tunnel-tunnel_2 ipsec-vpn-options local-gateway <cpe_public_ip_address> routing-instance <internet_routing_instance>

Verification

Use the following command to verify security associations (SAs).

show services ipsec-vpn ipsec security-associations detail

Use the following command to check the BGP status.

show bgp summary

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure. If you’ve configured the CPE to use routing instances, use the commands with table <table-name> at the end.

show route advertising-protocol bgp <neighbor-address>
show route receive-protocol bgp <neighbor-address>
show route advertising-protocol bgp <neighbor-address> table <table-name>
A **Monitoring service** is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

**Juniper SRX**

This topic provides configuration for a Juniper SRX that is running software version JunOS 11.0 (or newer).

---

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

---

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

---

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your *dynamic routing gateway (DRG)* and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
Routing Protocol Considerations

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.
There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the...
link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.

- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing CPE IKE identifier configuration](image)

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Juniper SRX router running JunOS 11.0 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure the outside tunnel interface (the CPE public IP address is bound to this interface).
- Configure the tunnel interface IDs (referred to as st0.1 and st0.2 in the following configuration template). You need multiple tunnel unit numbers per IPSec connection.
- Configure internal routing that routes traffic between the CPE and your local network.
- Identify the security zone for the outside interface (the following configuration template references this zone as internet_untrust).
- Identify the security zone for the inside interface (the following configuration template references this zone as oracle_trust).
- Identify the security zone for the tunnel interface (the following configuration template references this zone as oracle_vpn).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword USER_DEFINED in the template.
About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

You specify the IKE version when defining the IKE gateway. In the following configuration, there's a comment showing how to configure the IKE gateway for IKEv1 versus IKEv2.

Configuration Template

```plaintext
# Configuration Template
# The configuration consists of two IPSec tunnels. Oracle highly recommends
# that you configure both tunnels for maximum redundancy.

# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE SECURITY ZONES FOR ORACLE
# SETTING THE SECURITY POLICIES FOR ORACLE
# SETTING THE SECURITY SETTING FOR ORACLE
# SETTING BGP/STATIC ROUTING

# The configuration template has various parameters that you must define
# before applying the configuration.
# Search in the template for the keyword "USER_DEFINED" to find those
# parameters.

# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle
# Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle
# Console.
# connection_presharedkey_1 = You provide when you set up the IPSec
# connection in the Oracle Console, or you can use the default Oracle-
# provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec
# connection in the Oracle Console, or you can use the default Oracle-
# provided value.
# outside_public_interface = The public interface or outside of tunnel
# interface which is configured with the CPE public IP address. Example:
# ge-0/0/1.0
# cpe_public_ip_address = The internet-routable IP address that is assigned
to the public interface on the CPE. You provide this when creating the CPE
object in the Oracle Console.
# inside_tunnel_interface = The internal-facing interface for the on-
premises network behind the SRX that needs to reach the Oracle VCN. Example:
# ge-0/0/0.0
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and
Oracle ends of the inside tunnel interface. You provide these when creating
the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address
between the SRX and Oracle end points of the inside tunnel interface.
# internal_network_ip_range = Internal on-premise network behind the SRX
that needs to reach resources in the Oracle VCN.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range

# IPSec Tunnel 1

neighbor <inside_tunnel_interface_ip_address_neighbor> local-as <bgp_asn>
# #5b: Static Route Configuration
# USER_DEFINED: Replace the parameters in the section below as needed
# In case you plan to use static routing to get traffic through the IPSec tunnels, you can point the routes down to the tunnel interfaces. You should redistribute these routes into your on-premises network. Configuration for CPE to VCN static routes:
set routing-options static route <vcn_range> next-hop st0.2

Verification
Use the following command to verify security associations (SAs).

show security ipsec security-associations

Use the following command to check the BGP status.

show bgp summary

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure.

show route advertising-protocol bgp <neighbor-address>
show route receive-protocol bgp <neighbor-address>

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

Libreswan
Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. For an example of setting up a Libreswan host in another cloud provider to connect to your Oracle Cloud Infrastructure virtual cloud network (VCN), see Access to Other Clouds with Libreswan on page 4200.

This topic provides configuration for CPE that is running Libreswan. Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.</td>
</tr>
</tbody>
</table>
If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are an example only.

![Diagram of IPSec connection to Oracle Cloud Infrastructure](image)

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
Networking

- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

**Caveats and Limitations**

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

**Route-Based or Policy-Based Site-to-Site VPN**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term **proxy ID, security parameter index (SPI), or traffic selector** when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.
Networking

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
Networking

- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram](image)

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

CPE Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
Networking

The following figure shows the basic layout of the IPSec connection.

![IPSec Connection Diagram]

**Default Libreswan Configuration Files**

The default Libreswan installation creates the following files:

- **etc/ipsec.conf**: The root of the Libreswan configuration.
- **/etc/ipsec.secrets**: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- **/etc/ipsec.d/**: A directory for storing the .conf and .secrets files for your Oracle Cloud Infrastructure tunnels (for example: oci-ipsec.conf and oci-ipsec.secrets). Libreswan encourages you to create these files in this folder.

The default etc/ipsec.conf file includes this line:

```
include /etc/ipsec.d/*.conf
```

The default etc/ipsec.secrets file includes this line:

```
include /etc/ipsec.d/*.secrets
```

The preceding lines automatically merge all the .conf and .secrets files in the /etc/ipsec.d directory into the main configuration and secrets files that Libreswan uses.

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see **Supported IPSec Parameters** on page 3821.

You specify the IKE version when setting up the IPSec configuration file in task 3 in the next section. In that example file, there’s a comment showing how to configure IKEv1 versus IKEv2.

**Configuration Process**

Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

For details about the specific parameters used in this document, see **Supported IPSec Parameters** on page 3821.

Task 1: Prepare the Libreswan instance
Networking

Depending on the Linux distribution you're using, you might need to enable IP forwarding on your interface to allow clients to send and receive traffic through Libreswan. In the `/etc/sysctl.conf` file, set the following values and apply the updates with `sudo sysctl -p`.

If you're using an interface other than `eth0`, change `eth0` in the following example to your interface (lines 5 and 7).

```
net.ipv4.ip_forward=1
net.ipv4.conf.all.accept_redirects = 0
net.ipv4.conf.all.send_redirects = 0
net.ipv4.conf.default.send_redirects = 0
net.ipv4.conf.eth0.send_redirects = 0
net.ipv4.conf.default.accept_redirects = 0
net.ipv4.conf.eth0.accept_redirects = 0
```

Task 2: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- `${cpeLocalIP}`: The IP address of your Libreswan device.
- `${cpePublicIpAddress}`: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from `${cpeLocalIP}`.
- `${oracleHeadend1}`: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${oracleHeadend2}`: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${vti1}`: The name of the first VTI used. For example, vti1.
- `${vti2}`: The name of the second VTI used. For example, vti2.
- `${sharedSecret1}`: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${sharedSecret2}`: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${vcnCidrNetwork}`: The VCN IP range.

Task 3: Set up the configuration file: `/etc/ipsec.d/oci-ipsec.conf`

Libreswan configuration uses the concept of `left` and `right` to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the `conn` in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **left**: Your local Libreswan CPE
- **right**: The Oracle VPN headend

Use the following template for your `/etc/ipsec.d/oci-ipsec.conf` file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.

```
conn oracle-tunnel-1
left=${cpeLocalIP}
  # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
right=${oracleHeadend1}
authby=secret
tyleftsubnet=0.0.0.0/0
rightsubnet=0.0.0.0/0
auto=start
mark=5/0xffffffff # Needs to be unique across all tunnels
vti-interface=${vti1}
vti-routing=no
```

Important:

If your CPE is behind a 1-1 NAT device, uncomment the `leftid` parameter and set it equal to the `${cpePublicIpAddress}`.
Networking

ikev2=no # To use IKEv2, change to ikev2=insist
ike=aes_cbc256-sha2_384;modp1536
phase2alg=aes_gcm256;modp1536
encapsulation=yes
ike_lifetime=28800s
salifetime=3600s
conn oracle-tunnel-2
  left=${cpeLocalIP} # See preceding note about 1-1 NAT
device
  right=${oracleHeadend2}
  authby=secret
  leftsubnet=0.0.0.0/0
  rightsubnet=0.0.0.0/0
  auto=start
  mark=6/0xffffffff # Needs to be unique across all tunnels
  vti_interface=${vti2}
  vti_routing=no
ikev2=no # To use IKEv2, change to ikev2=insist
ike=aes_cbc256-sha2_384;modp1536
phase2alg=aes_gcm256;modp1536
encapsulation=yes
ike_lifetime=28800s
salifetime=3600s

Task 4: Set up the secrets file: /etc/ipsec.d/oci-ipsec.secrets

Use the following template for your /etc/ipsec.d/oci-ipsec.secrets file. It contains two lines per IPSec connection (one line per tunnel).

$({cpePublicIpAddress}) $({oracleHeadend1}): PSK "$({sharedSecret1})"
$({cpePublicIpAddress}) $({oracleHeadend2}): PSK "$({sharedSecret2})"

Task 5: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service.

Important:

Restarting the Libreswan service may impact existing tunnels.

The following command rereads the config file and restarts the Libreswan service.

service ipsec restart

Task 6: Configure IP routing

Use the following ip command to create static routes that send traffic to your VCN through the IPSec tunnels. If you're logged in with an unprivileged user account, you might need to use sudo before the command.

Important:

Static routes created with the ip route command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.

ip route add $({VcnCidrBlock}) nexthop dev ${vti1} nexthop dev ${vti2}
ip route show

Verification

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.
Networking

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

Checking the Libreswan Status

Check the current state of your Libreswan tunnels by using the following command.

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you're using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

Checking the Tunnel Interface Status

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as tcpdump with the interfaces.

Here's an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>
vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
    inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
    tunnel txqueuelen 1000 (IPIP Tunnel)
    RX packets 0 bytes 0 (0.0 B)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 0 bytes 0 (0.0 B)
    TX errors 10 dropped 0 overruns 0 carrier 10 collisions 0
vti02: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
    inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
    tunnel txqueuelen 1000 (IPIP Tunnel)
    RX packets 0 bytes 0 (0.0 B)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 0 bytes 0 (0.0 B)
    TX errors 40 dropped 0 overruns 0 carrier 40 collisions 0
```

Here's an example of the `ip link show` output:

```
ip link show
<output trimmed>
9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
    state UNKNOWN mode DEFAULT group default qlen 1000
    link/ipip 10.0.0.2 peer 129.213.240.52
10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
    state UNKNOWN mode DEFAULT group default qlen 1000
    link/ipip 10.0.0.2 peer 129.213.240.51
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.
NEC IX Series

This topic provides a route-based Site-to-Site VPN configuration for NEC IX Series devices. This configuration was validated using an IX3315 running Firmware Ver.10.2.16 and IX2106 running Firmware Ver.10.2.16.

| Important: |

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Site-to-Site VPN provides a site-to-site IPSec connection that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.

**Best Practices**

This section covers general best practices and considerations for using Site-to-Site VPN.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
**Routing Protocol Considerations**

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for Site-to-Site VPN on page 3810.

### Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to Routing for Site-to-Site VPN on page 3810.

### Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

### Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for Site-to-Site VPN on page 3810.

### Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI), or traffic selector* when referring to SAs or encryption domains.
Networking

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an **encryption domain**.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

---

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the
Networking

A link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.

- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See Site-to-Site VPN v2 availability on page 4034 for a list of supported regions.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

CPE Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for an IX3315 running Firmware Ver.10.2.16 or IX2106 running Firmware Ver.10.2.16 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure internal routing for traffic between the CPE and your local network.
- Ensure that you permit traffic between your NEC IX Series and your Oracle VCN.
- Identify the IKE policy used (the following configuration template references this IKE policy as $<ikePolicy1> and $<ikePolicy2>).
- Identify the IPSec policy used (the following configuration template references this IPSec policy as $<ipsecPolicy1> and $<ipsecPolicy2>).
- Identify the virtual tunnel interface names used (the following configuration template references these as variables $<tunnelInterfaceNumber1> and $<tunnelInterfaceNumber2>).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword USER_DEFINED in the template.

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2
encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 3821.

You specify the IKE version when defining the IKE gateway. In the following configuration, there's a comment showing how to configure the IKE gateway for IKEv1 versus IKEv2.

IKEv1 Configuration Template

```bash

Openswan

If you want to use Openswan to create Site-to-Site VPN to Oracle Cloud Infrastructure, see Libreswan on page 3980.

How Openswan and Libreswan Are Related

Openswan is a well-known IPSec implementation for Linux. It began as a fork of the now-defunct FreeS/WAN project in 2003. Unlike the FreeS/WAN project, it didn't exclusively target the GNU/Linux operation system, but expanded its use to other operating systems. In 2012, FreeS/WAN renamed itself to The Libreswan Project because of a lawsuit over a trademark of the name openswan.

As a result, when you try to install or query the Openswan package on Oracle Linux, by default the Libreswan package is installed or shown instead. The following yum search query command illustrates this behavior:

```
$ sudo yum search openswan
Loaded plugins: langpacks, ulninfo
Matched: openswan =$-------------------------
NetworkManager--libreswan.x86_64 : NetworkManager VPN plugin for libreswan
NetworkManager--libreswan-gnome.x86_64 : NetworkManager VPN plugin for libreswan-GNOME files
libreswan.x86_64 : IPsec implementation with IKEv1 and IKEv2 keying protocols
```

Libreswan is maintained by The Libreswan Project and has been under active development for over 15 years, going back to the FreeS/WAN Project. For more information, see the project's history.

Palo Alto

This topic provides configuration for a Palo Alto device. The configuration was validated using PAN-OS version 8.0.0.

Palo Alto experience is required.
Important:

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Oracle Cloud Infrastructure offers Site-to-Site VPN, a secure IPSec connection between your on-premises network and a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are only examples.

Best Practices

This section covers general best practices and considerations for using Site-to-Site VPN.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create a Site-to-Site VPN IPSec connection, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec connections that had up to four IPSec tunnels.
The following two routing types are available, and you choose the routing type separately for each tunnel in the Site-to-Site VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

- **Policy-based routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with Site-to-Site VPN, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see [Routing for Site-to-Site VPN](#) on page 3810.

### Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, you may experience asymmetric routing. To allow for asymmetric routing, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support. To configure routing to be symmetric, refer to [Routing for Site-to-Site VPN](#) on page 3810.

### Caveats and Limitations

This section covers general important characteristics and limitations of Site-to-Site VPN to be aware of.

### Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see [Routing for Site-to-Site VPN](#) on page 3810.

### Route-Based or Policy-Based Site-to-Site VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.</td>
</tr>
</tbody>
</table>

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
Networking

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle Site-to-Site VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- Site-to-Site VPN supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- If you had a situation similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.
- Policy-based routing is not available in all regions and depends on VPN Connect v2 connections. See [Site-to-Site VPN v2 availability](#) on page 4034 for a list of supported regions.
• Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
• The CIDR blocks used on the Oracle DRG end of the tunnel can’t overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
• An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as show in the following diagram.

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 3821.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring Site-to-Site VPN for the US Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178 and also Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200.

CPE Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

---

**Important Details About the Configuration Instructions**

- **Commits**: For PAN to activate the configuration, you must perform the commit action after any configuration change.
- **Example IP addresses**: The example configuration uses IP addresses from class A 10.0.0.0/8 (RFC1918) and 198.51.100.0/24 (RFC5735). When you perform the configuration on the CPE, use the correct IP addressing plan for your networking topology.

The example configuration uses the following variables and values:

- **Inside tunnel1 interface - CPE**: 198.51.100.1/30
- **Inside tunnel2 interface - CPE**: 198.51.100.5/30
- **Inside tunnel1 interface - Oracle**: 198.51.100.2/30
- **Inside tunnel2 interface - Oracle**: 198.51.100.6/30
- **CPE ASN**: 64511
- **On-premises network**: 10.200.1.0/24
- **VCN CIDR block**: 10.200.0.0/24
- **CPE public IP address**: 10.200.0.100/24
- **Oracle VPN headend (DRG) IP address 1**: 10.150.128.1/32
- **Oracle VPN headend (DRG) IP address 2**: 10.150.127.1/32
- **Tunnel number 1**: tunnel.1
- **Tunnel number 2**: tunnel.2
- **Exit interface**: ethernet1/1

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see [Supported IPSec Parameters](#) on page 3821.

If you want to use IKEv2, there are special variations of some steps presented in the next section. Here is a summary of the special steps:

- For task 2 (defining the ISAKMP peers), when you add the IKE gateway:
  - On the **General** tab, for the **Version**, select **IKEv2 only mode**.
  - On the **Advanced Options** tab, select the IKE crypto profile associated with the IKEv2 tunnel.
- For task 5 (configuring the IPSec sessions), configure the proxy ID.
**Configuration Process**

The following process includes BGP configuration for the IPSec connection. If you instead want to use static routing, perform tasks 1–5, and then skip to CPE Configuration on page 4002.

Task 1: Configure the ISAKMP Phase 1 policy

In this example, the same ISAKMP policy is used for both tunnels.

1. Go to **Network**, to **IKE Crypto**, and then click **Add**.
2. Configure the parameters as shown in the next screenshot. For a list of the values, see Supported IPSec Parameters on page 3821. If you're configuring Site-to-Site VPN for the Government Cloud, see Required Site-to-Site VPN Parameters for Government Cloud on page 178.

![IKE Crypto Profile](image)

The next screenshot shows the final result for this task:

![IKE Crypto Profile](image)

Task 2: Define the ISAKMP peers

1. Go to **Network**, to **IKE Gateways**, and then click **Add**.
2. For peer 1, configure the parameters as shown in the next screenshots.

   a. On the **General** tab:
      - **Version**: For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2 only mode**. Notice that if you're using IKEv2, later in task 5 you also add proxy IDs.
      - **Interface**: The interface that owns the public IP address on the CPE. Change `ethernet1/1` to the particular value for your networking topology.
      - **Peer IP addresses**: The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your first tunnel.
      - **Pre-shared Key**: The shared secret that Oracle automatically assigned during IPSec tunnel creation. If you want, you can specify a different value. Enter the same value here and in the Oracle Console.
      - **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE's public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the first tunnel.

   ![IKE Gateway Configuration](image)

   b. On the **Advanced Options** tab, ensure that the values are set for the first peer according to the following screenshot.
If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.

![Image of IKE Gateway configuration with IKEv2 settings]
3. For peer 2, configure the parameters as shown in the next screenshots.

a. On the **General** tab:

   - **Version**: For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2 only mode**. For IKEv2, notice that you also need to provide a proxy ID later in task 5.
   - **Interface**: The interface that owns the public IP address on the CPE. Change **ethernet1/1** to the particular value for your networking topology.
   - **Peer IP addresses**: The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your second tunnel.
   - **Pre-shared Key**: The shared secret that Oracle automatically assigned during IPsec tunnel creation. If you want, you can specify a different value. Enter the same value here and in the Oracle Console.
   - **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE’s public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the second tunnel.

   ![IKE Gateway Configuration](image)

b. On the **Advanced Options** tab, ensure that the values are set for the second peer according to this screenshot:
If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.

The next screenshot shows the final result for this task:

Task 3: Define the IPSec Phase 2 policy

In this example, the same IPSec crypto profile is used for both tunnels.
1. Go to Network, to IPSec Crypto, and then click Add.
2. Configure the parameters as shown in the next screenshot.

The next screenshot shows the final result for this task:

Task 4: Configure the virtual tunnel interfaces

1. Go to Network, to Interfaces, to Tunnel, and then click Add.
2. For peer 1, configure the parameters as shown in the next screenshots.

a. On the **Config** tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_tunnel security zone are used.

![Config Tab](image)

b. On the **IPv4** tab, ensure that the values are set for the first peer according to the following screenshot. In this example, the IP address for the tunnel interface is `ipsec_address_static1 = 198.51.100.1/30`. Configure your tunnel IP address according to your networking IP addressing plan.

![IPv4 Tab](image)
3. For peer 2, configure the parameters as shown in the next screenshots.
   
a. On the **Config** tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_tunnel security zone are used.

   ![Tunnel Interface Configuration](image1)

   b. On the **IPv4** tab, ensure that the values are set for the second peer according to the following screenshot. In this example, the IP address for the tunnel interface is `ipsec_address_static2 = 198.51.100.5/30`. Configure your tunnel IP address according to your networking IP addressing plan.

   ![Tunnel Interface IPv4 Configuration](image2)

The next screenshot shows the final result for this task:

![Tunnel Interface Configuration](image3)

Task 5: Configure the IPSec sessions

1. Go to **Network**, to **IPSec Tunnels**, and then click **Add**.
2. For peer 1, configure the parameters on the **General** tab as shown in the next screenshot.

   Notice that if you’re using IKEv1, you do not need to add specific proxy IDs to the **Proxy IDs** tab. They are not needed for an IKEv1 route-based VPN configuration.

   However, for IKEv2, do add proxy IDs to the **Proxy IDs** tab for better interoperability. Ensure that you also configured the IKE gateway to use IKEv2 earlier in task 2.

   ![General tab configuration screenshot](image1)

3. For peer 2, configure the parameters on the **General** tab as shown in the next screenshot.

   If you are using IKEv2, also add proxy IDs on the **Proxy IDs** tab.

   ![General tab configuration screenshot](image2)

**Task 6: Configure BGP over IPSec**

**Note:**

If you want to use static routing instead of BGP, skip task 6 and go to **Configuring Static Routing** on page 4026.

BGP over IPSec requires IP addresses on the tunnel interfaces on both ends.

The screenshots in this example use these subnets for the tunnel interfaces:

- 198.51.100.0/30
- CPE: 198.51.100.1/30
- DRG: 198.51.100.2/30
- 198.51.100.4/30
- CPE: 198.51.100.5/30
- DRG: 198.51.100.6/30

Replace the example values with the BGP IP addresses you specified in the Oracle Console for the inside tunnel interfaces.
Networking

This task consists of three subtasks, each with multiple steps.

Subtask 6-a: Configure the BGP parameters

1. Go to **Network**, to **Virtual Routers**, to **default**, and then to **BGP**. This example uses the default virtual router. Also, the example uses 10.200.1.10 for the router ID and 64511 for the ASN. Use the correct virtual router based on your networking configuration, and use the correct router ID and ASN for your environment.

![BGP Configuration Screenshot]

2. On the **General** tab, configure the parameters as shown in the next screenshot.

![General Tab Screenshot]

3. On the **Advanced** tab, configure the parameters as shown in the next screenshot.

![Advanced Tab Screenshot]
4. On the **Peer Group** tab:

   a. Add the first Peer Group, and under the **Peer Group Name**, add the first session. Add the BGP session with the DRG.

   ![Peer Group Configuration](image)

   b. For the first tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot. Oracle's BGP ASN in commercial regions is 31898. If you're configuring Site-to-Site VPN for the Government Cloud, see Oracle's BGP ASN on page 180.

   ![Addressing Configuration](image)

   c. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.
d. On the **Advanced** tab, configure the parameters as shown in the next screenshot.
c. On the **Peer Group** tab, add the second Peer Group, and under the **Peer Group Name**, add the second session. Add the BGP session with the DRG.

f. For the second tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot.
g. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.
h. On the Advanced tab, configure the parameters as shown in the next screenshot.
The next screenshot shows the final Peer Group configuration:

<table>
<thead>
<tr>
<th>Name</th>
<th>Route</th>
<th>Type</th>
<th>Session</th>
<th>Peer AS</th>
<th>Local Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>D1G1</td>
<td>Yes</td>
<td>nsgp</td>
<td>Session1</td>
<td>31898</td>
<td>198.51.100.2</td>
</tr>
<tr>
<td>D1G2</td>
<td>Yes</td>
<td>nsgp</td>
<td>Session2</td>
<td>31898</td>
<td>198.51.100.6</td>
</tr>
</tbody>
</table>
5. On the **Import** tab, configure the parameters as shown in the next screenshots. Here you configure tunnel.1 as the primary and tunnel.2 as the backup for the VCN route received from the DRG by way of BGP (10.200.0.0/24). From the BGP perspective, both tunnels are in the Established state.

   a. For the first rule, on the **General** tab, configure the parameters as shown in the next screenshot.

   ![General Tab Screenshot]

   b. On the **Match** tab, configure the parameters as shown in the next screenshot.

   ![Match Tab Screenshot]

   c. On the **Action** tab, configure the parameters as shown in the next screenshot.
d. For the second rule, on the **General** tab, configure the parameters as shown in the next screenshot.

![General tab configuration screenshot]

```
Action: Allow
Dampening: None
Local Preference: 500
MED: 0 - 4294967295
Weight: 0 - 65535
Next Hop: 
Origin: Incomplete
AS Path Limit: [1 - 255]
```

```
AS Path
Type: None
Remove
```

```
Community
Type: None
```

```
Extended Community
Type: None
```

```
OK | Cancel
```

e. On the **Match** tab, configure the parameters as shown in the next screenshot.

![Match tab configuration screenshot]
f. On the **Action** tab, configure the parameters as shown in the next screenshot.
6. On the Export tab, configure the parameters as shown in the next screenshots. Here you configure a policy to force the DRG to prefer tunnel.1 for the returning path to the on-premises network CIDR (10.200.1.0/24).

   a. On the General tab, configure the parameters as shown in the next screenshot.

   ![General Tab Screenshot]

   b. On the Match tab, configure the parameters as shown in the next screenshot.

   ![Match Tab Screenshot]

   c. On the Action tab, configure the parameters as shown in the next screenshot.

   ![Action Tab Screenshot]
The next screenshot shows the final Export configuration:

Notice that no configuration is required for the **Conditional Adv** or **Aggregate** tabs.
7. On the **Redist Rules** tab, configure the parameters as shown in the next screenshot. Here you announce the on-premises network CIDR in BGP.

![Image of Redist Rules configuration]

Subtask 6-b: Wait for the BGP sessions to establish and then check the BGP status

1. Go to **Network**, to **IPSec Tunnels**, to the **Virtual Router** column, and then click **Show Routes**.

![Image of IPSec Tunnels configuration]

2. Go to **BGP**, and then to the **Peer** tab to verify that the BGP session is established. Any other value means that the BGP session has not been established successfully and route exchange will not occur.

![Image of BGP Peer configuration]
3. On the **Local RIB** tab: The prefixes are received from the DRG, with tunnel.1 being preferred.

4. On the **RIB Out** tab: The on-premises network CIDR is sent by way of BGP to DRG1 with as_path of 64511, and for DRG2, with an as_path of 64511, 64511. In this way, based on the BGP Best Path Algorithm, the route preferred by the DRG to reach the on-premises network CIDR uses the connection over tunnel.1.

Subtask 6-c: Confirm that the BGP routes have been inserted in the route table

To view the routes, go to **Routing**, and then to the **Route Table** tab.

Configuring Static Routing

Use the instructions here if your CPE does not support BGP over IPSec, or you do not want to use BGP over IPSec.

In this task, you configure static routes to direct traffic through the tunnel interfaces to reach the DRG and finally the VCN hosts.

1. Follow tasks 1–5 in the preceding section.
2. Configure static routes:
   a. Go to **Network**, to **Virtual Routers**, to **default**, to **Static Routes**, and then click **Add**.
   b. For Route 1, configure the parameters as shown in the next image.
   c. For Route 2, configure the parameters as shown in the next image.
### Virtual Router - Static Route - IPv4

<th>Ping Count</th>
</tr>
</thead>
</table>

[Add | Delete]
3. (Recommended) Enable ECMP for traffic sent through the two tunnels. The metric for both routes is set to 10. Here are some important notes about enabling ECMP:

- First check to see if your networking design allows for ECMP.
- Enabling or disabling ECMP on an existing virtual router causes the system to restart the virtual router. The restart might cause existing sessions to be terminated.
- This example uses the default virtual router. Use the correct virtual router for your network environment.

To enable ECMP, go to Network, to Virtual Routers, to default, to Router Settings, to ECMP, and then select the check box for Enable.

Here are screenshots that show the final configuration after this task is complete:

Changing the IKE Identifier

If the CPE is behind a NAT device with a private IP address on the exit interface that the tunnel interfaces use as the source, you must specify the public IP address of the NAT device as the local IKE ID. You can do this by setting the Local Identification value in the IKE Gateway configuration:
Networking

Verification

To verify the IPSec tunnel status:

Use this command to verify the IKE SA:

```
show vpn ike-sa
```

Use this command to verify the IPSec tunnel configuration:

```
show vpn tunnel name <tunnel_name>
```

To verify the BGP status, look for **Established**:

![BGP Status](image)

Oracle Cloud Infrastructure User Guide
To verify the BGP status from the command line:

```
show routing protocol bgp peer peer-name <name>
```

To verify that the routes are installed in the route table:

```
show routing route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your Site-to-Site VPN, see Site-to-Site VPN Metrics on page 4042.

If you have issues, see Site-to-Site VPN Troubleshooting on page 4044.

**WatchGuard**

You can configure a WatchGuard Firebox as your CPE device for Site-to-Site VPN.

To download the configuration instructions, go to the Oracle Bare Metal BOVPN Virtual Interface Integration Guide.

**Yamaha RTX Series**

This configuration was validated using an RTX1210 running Firmware Rev.14.01.28 and RTX830 running Firmware Rev.15.02.03.

**Important:**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

**Before Starting**

Before configuring your CPE:

- Configure your internet provider settings.
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

**Supported Encryption Domain or Proxy ID**

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 3824.

**Parameters from API or Console**

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

```
$[ipAddress#]
```

- Oracle VPN headend IPSec tunnel endpoints. There is one value for each tunnel.
- Example value: 129.146.12.52

```
$[sharedSecret#]
```

- The IPSec IKE pre-shared-key. There is one value for each tunnel.
- Example value: EXAMPLEDPfAMkD7nTH3SWr6OFadbT6exXn6enSlSsKbE

```
${cpePublicIpAddress}
```

- The public IP address for the CPE (previously made available to Oracle via the Console).

```
${VcnCidrBlock}
```

Oracle Cloud Infrastructure User Guide 4031
• When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.
  • Example Value: 10.0.0.0/20

Parameters Based on Current CPE Configuration and State

The following parameters are based on your current CPE configuration.

\$\{tunnelInterface\#\}
  • An interface number to identify the specific tunnel.
  • Example value: 1

\$\{ipsecPolicy\#\}
  • The SA policy to be used for the selected inline interface.
  • Example value: 1

\$\{localAddress\}
  • The public IP address of your CPE.
  • Example value: 146.56.2.52

Config Template Parameter Summary

Each region has multiple Oracle IPSec headends. The following template allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the table, "User" is you/your company.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Source</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>${ipAddress1}</td>
<td>Console/API</td>
<td>129.146.12.52</td>

ip tunnel tcp mss limit auto
tunnel enable 2
ipsec auto refresh on
```
Static Routes Configuration

```bash
ip route $(VcnCidrBlock) gateway tunnel 1 hide gateway tunnel 2 hide
```

Working with Site-to-Site VPN

This topic contains some details about working with Site-to-Site VPN and the related components. Also see these topics:

- Site-to-Site VPN Overview on page 3809
- Site-to-Site VPN Quickstart on page 3814
- Setting Up Site-to-Site VPN on page 3825
- CPE Configuration on page 3844
- Using the CPE Configuration Helper on page 3847
- Site-to-Site VPN FAQ
- Site-to-Site VPN Metrics on page 4042
- Site-to-Site VPN Troubleshooting on page 4044

Updated Site-to-Site VPN service

Site-to-Site VPN v2 improves availability and reliability of IPSec connections and makes possible new functionality. Regions that can provide Site-to-Site VPN v2 are listed in Site-to-Site VPN v2 availability on page 4034. Where available, all newly created IPSec connections are created using Site-to-Site VPN v2. The process for setting up Site-to-Site VPN v2 is identical to setting up Site-to-Site VPN v1.

New functions that depend on Site-to-Site VPN v2 include:

- Multiple encryption domains
- Viewing Your Site-to-Site VPN Log Messages on page 4038

Regions that support Site-to-Site VPN v2 will continue to support Site-to-Site VPN v1. If you have Site-to-Site VPN in one of these regions and want to use one of the added features available for Site-to-Site VPN v2, you will need to create a new connection and end the older connection. There is no migration path to change a v1 connection to a v2 connection currently.

Site-to-Site VPN v2 availability

Site-to-Site VPN v2 is available in all commercial regions with the following exceptions:

- Saudi Arabia West (Jeddah)
- South Korea (Chuncheon) does not support Logging

Viewing Tunnel Status and Configuration

When you successfully create the IPSec connection, Oracle produces important configuration information for each of the resulting IPSec tunnels. For an example, see task 2h in the overall setup process. You can view that information and the status of the tunnels at any time. This includes the BGP status if the tunnel is configured to use BGP dynamic routing.

To view the status and configuration information for the IPSec tunnels

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).

   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

   Each tunnel's details are displayed, including the IPSec status, the BGP status (if the tunnel uses BGP dynamic routing), and the Oracle VPN IP address (the VPN headend).
3. To view a tunnel's shared secret:
   a. Click the tunnel you're interested in.
   b. Next to the Shared Secret field, click Show.

**Using the CPE Configuration Helper**

After you set up Site-to-Site VPN, your network engineer must configure the customer-premises equipment (CPE) at your end of the connection. The configuration includes details about your virtual cloud network (VCN) and the IPSec tunnels in the Site-to-Site VPN. The CPE Configuration Helper generates the information for your network engineer. For more information, see Using the CPE Configuration Helper on page 3847.

**Changing the Static Routes**

You can change the static routes for an existing IPSec connection. You can provide up to 10 static routes.

Remember that an IPSec connection can use either static routing or BGP dynamic routing. You associate the static routes with the overall IPSec connection and not the individual tunnels. If an IPSec connection has static routes associated with it, Oracle uses them for routing a tunnel's traffic only if the tunnel itself is configured to use static routing. If it's configured to use BGP dynamic routing, the IPSec connection's static routes are ignored.

**Important:**
The IPSec connection goes down while it is reprovisioned with your static route changes.

*To edit the static routes*

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click Edit.
   
   The current static routes are displayed.
3. Make your changes and click Save Changes.

**Changing the CPE IKE Identifier That Oracle Uses**

If your CPE is behind a NAT device, you might need to give Oracle your CPE IKE identifier. You can either specify it when you create the IPSec connection, or later edit the IPSec connection and change the value. Oracle expects the value to be an IP address or fully qualified domain name (FQDN). When you specify the value, you also specify which type it is.

**Important:**
The IPSec connection goes down while it is reprovisioned to use your CPE IKE identifier.

*To change the CPE IKE identifier that Oracle uses*

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click Edit.
   
   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.
3. Enter your new values for CPE IKE Identifier Type and CPE IKE Identifier, and then click Save Changes.
Networking

Using IKEv2

Oracle supports Internet Key Exchange (IKE) version 1 and version 2 (IKEv2).

If you want to use IKEv2 and your CPE supports it, you must:

- Configure each IPSec tunnel to use IKEv2 in the Oracle Console. See the following procedures.
- Configure your CPE to use IKEv2 encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see Supported IPSec Parameters on page 3821.

New IPSec connection: using IKEv2

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>

If you create a new IPSec connection manually, you can specify IKEv2 when you create the IPSec connection in the Oracle Console. See the procedure that immediately follows.

If you instead use the VPN quickstart workflow, the IPSec connection is configured to use IKEv1 only. However, after the workflow is complete, you can edit the resulting IPSec tunnels in the Oracle Console and change them to use IKEv2.

To manually set up a new IPSec connection that uses IKEv2:

1. While creating the IPSec connection in the Oracle Console, in the Advanced Options section, click the Tunnel 1 tab.
2. From the IKE Version menu, select IKEv2.
3. Repeat the preceding step for the Tunnel 2 tab.
4. Later when configuring your CPE, configure it to use only IKEv2 and related IKEv2 encryption parameters that the CPE supports.

Existing IPSec connection: upgrading to IKEv2

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
</table>

Oracle recommends performing the following process for one tunnel at a time to avoid disruption in your overall connection. If your connection is not redundant (for example, does not have multiple tunnels), expect downtime while you upgrade to IKEv2.

1. Change the tunnel's IKE version in the Oracle Console:
   a. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   b. Click the IPSec connection you're interested in.
   c. Click the tunnel to view its details.
   d. Click Edit.
   e. From the IKE Version menu, select IKEv2.
   f. Click Save Changes.
2. Update your CPE configuration for the tunnel to use IKEv2 and the related encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see Supported IPSec Parameters on page 3821.
3. If the security associations did not rekey immediately, force a rekey for that tunnel on your CPE. In other words, clear the phase 1 and phase 2 security associations and do not wait for them to expire. Some CPE devices wait for the SAs to expire before rekeying. Forcing the rekey lets you confirm immediately that the IKE version configuration is correct.
4. To verify, ensure that the security associations for the tunnel rekey correctly. If they don't, confirm that the correct IKE version is set in the Oracle Console and on your CPE, and that the CPE is using the desired parameters.

After you've confirmed the first tunnel is up and running again, repeat the preceding steps for the second tunnel.
Changing the Shared Secret That an IPSec Tunnel Uses

When you set up Site-to-Site VPN, by default Oracle provides each tunnel's shared secret (also called the pre-shared key). You might have a particular shared secret that you want to use instead. You can specify each tunnel's shared secret when you create the IPSec connection, or you can edit the tunnels and provide each new shared secret then. For the shared secret, only numbers, letters, and spaces are allowed. Oracle recommends using a different shared secret for each tunnel.

**Important:**

When you change a tunnel's shared secret, both the overall IPSec connection and the tunnel go into the Provisioning state while the tunnel is reprovisioned with the new shared secret. The other tunnel in the IPSec connection remains in the Available state. However, while the first tunnel is being reprovisioned, you cannot change the second tunnel's configuration.

To change the shared secret that an IPSec tunnel uses

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

3. Click the tunnel you're interested in.

4. Next to the Shared Secret field, click Edit.

5. Enter your new value. Only numbers, letters, and spaces are allowed.

6. Click Save Changes.

Changing from Static Routing to BGP Dynamic Routing

If you want to change an existing Site-to-Site VPN from using static routing to using BGP dynamic routing, follow the process in this section.

**Caution:**

When you change a tunnel's routing type, the tunnel's IPSec status does not change during reprovisioning. However, routing through the tunnel is affected. Traffic is temporarily disrupted until your network engineer configures your CPE device in accordance with the routing type change. If your existing Site-to-Site VPN is currently configured to use only a single tunnel, this process will disrupt your connection to Oracle. If your Site-to-Site VPN instead uses multiple tunnels, Oracle recommends reconfiguring one tunnel at a time to avoid disrupting your connection to Oracle.

To change from static routing to BGP dynamic routing

Prerequisites:

- You've read this section: Routing for Site-to-Site VPN on page 3810
- You've gathered the necessary BGP routing information:
  - Your network's ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180.
  - For each tunnel: The BGP IP address for each end of the tunnel (the two addresses for a given tunnel must be a pair from a /30 or /31 subnet, and they must be part of Site-to-Site VPN's encryption domain)

Repeat the following process for each tunnel in the IPSec connection:
1. Reconfigure the tunnel's routing type from static routing to BGP dynamic routing:
   a. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
   b. Click the IPSec connection you're interested in.
      
The tunnels are listed, and the status for each tunnel is shown. The BGP Status for the tunnel you're interested in should show only a hyphen (no value), which means that the tunnel is currently configured to use static routing.
   c. Click the tunnel to view all of its details.
   d. Click Edit.
   e. Do the following:
      
      • **Routing Type**: Select the radio button for BGP Dynamic Routing.
      • **BGP ASN**: Enter your network's BGP ASN.
      • **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31.
      • **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31.
   f. Click Save Changes.
      
The tunnel's BGP Status changes to Down.

2. Have your network engineer update your CPE device's tunnel configuration to use BGP.

3. On your side of the connection, confirm that the tunnel's BGP session is in an established state. If it is not, make sure you've configured the correct IP addresses for the tunnel in the Oracle Console and also for your CPE device.

4. In the Oracle Console, confirm that the tunnel's BGP Status is now Up.

5. Confirm that your CPE device is learning routes from Oracle, and your CPE device is advertising routes to Oracle. If you want to re-advertise the Oracle routes from BGP back to your on-premises network, make sure your CPE device is configured accordingly. Your existing policy to advertise the static routes to your on-premises network may not work for the BGP learned routes.

6. Ping the Oracle BGP IP address from your side of the connection to confirm that traffic is flowing.

After you've confirmed the first tunnel is up and running with BGP, repeat the process for the second tunnel.

---

**Important:**

As noted in Routing for Site-to-Site VPN on page 3810, the static routes that are still configured for the overall IPSec connection do NOT override the BGP routing. Those static routes are ignored when Oracle routes traffic through a tunnel that is configured to use BGP.

Also, you can change a tunnel's routing type back to static routing if necessary. You might do this if the scheduled downtime window for the CPE device is ending soon and you're having trouble establishing the BGP session. When you switch back to static routing, make sure the overall IPSec connection still has your desired static routes configured.

---

**Monitoring Your Site-to-Site VPN**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring your connection, see Site-to-Site VPN Metrics on page 4042.

**Viewing Your Site-to-Site VPN Log Messages**

Access the log messages for Site-to-Site VPN.

You can view the log messages generated for various operational aspects of Site-to-Site VPN such as the negotiations that occur in bringing an IPSec tunnel UP. Enabling and accessing the Site-to-Site VPN log messages can be done via Site-to-Site VPN or the Logging Service.
Networking

To enable message logging

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
2. A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
3. For the IPSec connection you're interested in, click the name of the connection.
   The details page for the connection is displayed.
4. On the left side of the screen under Resources, click on Logs.
   If you do not see this option, the connection has the older Site-to-Site VPN v1 type. Message logging requires Site-to-Site VPN v2.
   Details for the options on the screen are at Enabling Logging for a Resource on page 3363. Logs are handled the same regardless of the resource type generating the log.
6. Click Enable Log.
   The Log detail page is displayed, and the log will be in the process of being created (a "Creating log" message is displayed).

To view log messages

You must already have logging enabled to view the message log. To view the message log:

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
2. A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
3. On the left side of the screen under Resources, click on Logs.
   If you do not see this option, the connection has the older Site-to-Site VPN v1 type. Message logging requires Site-to-Site VPN v2.
4. Click on the Log Name of the log you are interested in. This will open a new browser tab showing the requested log.

See To view the contents of logs on page 3355 for details on using the log display screen.

Disabling or Terminating Site-to-Site VPN

If you want to disable Site-to-Site VPN between your on-premises network and VCN, you can simply detach the DRG from the VCN instead of deleting the IPSec connection. If you're also using the DRG with FastConnect, detaching the DRG would also interrupt the flow of traffic over FastConnect.

You can delete the IPSec connection. However, if you later want to re-establish it, your network engineer would have to configure your CPE device again with a new set of tunnel configuration information from Oracle.

If you want to permanently delete Site-to-Site VPN, you must first terminate the IPSec connection. Then you can delete the CPE object. If you're not using the DRG for another connection to your on-premises network, you can detach it from the VCN and then delete it.

Oracle Cloud Infrastructure User Guide 4039
To delete an IPSec connection

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
2. Click the IPSec connection you're interested in.
3. Click Terminate.
4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

To delete a CPE object

Prerequisite: There must not be an IPSec connection between the CPE object and a DRG.

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Customer-Premises Equipment.
2. For the CPE object that you want to delete, click the Actions icon (three dots), and then click Delete.
3. Confirm the deletion when prompted.

The object will be in the Terminating state for a short period while it's being deleted.

Managing Tags for an IPSec Connection or CPE Object

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

To manage tags for an IPSec connection

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Site-to-Site VPN (IPSec).
2. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

To manage tags for a CPE object

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Customer-Premises Equipment.
2. Click the CPE object you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

Moving an IPSec Connection or CPE Object to a Different Compartment

You can move your resources from one compartment to another. After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. Moving the CPE object to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Working with Compartments on page 3127.

To move a CPE object to a different compartment

1. Open the navigation menu and click Networking. Under Customer Connectivity, click Customer-Premises Equipment.
2. Find the CPE object in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.

**Managing Your DRG**

For tasks related to DRGs, see Dynamic Routing Gateways (DRGs) on page 3793.

**Using the API for Site-to-Site VPN**

This topic lists the Networking service API operations for managing Site-to-Site VPN components.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage your VCN and subnets, use these operations:

- ListVcns
- CreateVcn
- GetVcn
- UpdateVcn
- DeleteVcn
- ChangeVcnCompartment
- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

To manage your DRG, use these operations:

- ListDrgs
- CreateDrg
- GetDrg
- UpdateDrg
- DeleteDrg
- ListDrgAttachments
- CreateDrgAttachment: This operation attaches a DRG to a VCN and results in a `DrgAttachment` object with its own OCID.
- GetDrgAttachment
- UpdateDrgAttachment
- DeleteDrgAttachment: This operation detaches a DRG from a VCN by deleting the `DrgAttachment` object.

To manage routing for your VCN, use these operations:

- ListRouteTables
- GetRouteTable
- UpdateRouteTable
- CreateRouteTable
- DeleteRouteTable

To manage security lists for your VCN, use these operations:

- ListSecurityLists
- GetSecurityList
- UpdateSecurityList
- CreateSecurityList
- DeleteSecurityList
To manage your CPEs, use these operations:

- ListCpes
- CreateCpe
- GetCpe
- UpdateCpe
- DeleteCpe
- ChangeCpeCompartment

To manage your IPSec connections, use these operations:

- ListIPSecConnections
- CreateIPSecConnection: Use this operation to get the configuration information for each tunnel, including the IP address of the DRG (the VPN headend) and the shared secret. See CPE Configuration on page 3844.
- GetIPSecConnection
- UpdateIPSecConnection
- DeleteIPSecConnection
- ChangeIPSecConnectionCompartment
- GetIPSecConnectionDeviceStatus: Use this operation to determine the status of the IPSec tunnels (up or down).
- GetIPSecConnectionDeviceConfig: Use this operation to get the configuration information for each tunnel.

Site-to-Site VPN Metrics

You can monitor the health, capacity, and performance of your Site-to-Site VPN by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

This topic describes the metrics emitted by the metric namespace oci_vpn.

Resources: IPSec connections.

Overview of Metrics: oci_vpn

The available metrics help you determine quickly if your Site-to-Site VPN on page 3808 is up, how much data is flowing over the connection, and if packets are being dropped for unexpected errors.

Site-to-Site VPN includes these resources:

- An IPSec connection, which you can think of as the parent resource (identified by parentResourceId in the following discussion).
- One or more individual tunnels associated with that IPSec connection (each identified by the tunnel's publicIp in the following discussion).

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_vpn

The metrics listed in the following table are automatically available for any Site-to-Site VPN that you create. You do not need to enable monitoring on the resource to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:
**PARENTRESOURCEID**

The **OCID** of the IPSec connection (the parent resource). The connection has multiple individual tunnels.

**PUBLICIP**

Although each tunnel has its own **OCID**, it can be easier to use the **publicIp** dimension to identify a specific IPSec tunnel in the connection. The value is the public IP address of the Oracle end of the tunnel (also known as the *Oracle VPN headend*).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TunnelState</strong></td>
<td>IPSec Tunnel State</td>
<td>Binary (1 or 0)</td>
<td>Whether the tunnel is up (1) or down (0).</td>
<td>parentResourceId</td>
</tr>
<tr>
<td><strong>PacketsReceived</strong></td>
<td>Packets Received</td>
<td>Packets</td>
<td>Number of packets received at the Oracle end of the connection.</td>
<td>publicIp</td>
</tr>
<tr>
<td><strong>BytesReceived</strong></td>
<td>Bytes Received</td>
<td>Bytes</td>
<td>Number of bytes received at the Oracle end of the connection.</td>
<td></td>
</tr>
<tr>
<td><strong>PacketsSent</strong></td>
<td>Packets Sent</td>
<td>Packets</td>
<td>Number of packets sent from the Oracle end of the connection.</td>
<td></td>
</tr>
<tr>
<td><strong>BytesSent</strong></td>
<td>Bytes Sent</td>
<td>Bytes</td>
<td>Number of bytes sent from the Oracle end of the connection.</td>
<td></td>
</tr>
<tr>
<td><strong>PacketsError</strong></td>
<td>Packets with Errors</td>
<td>Packets</td>
<td>Number of packets dropped at the Oracle end of the connection. Dropped packets indicate a misconfiguration in some part of the overall system. Check if there's been a change to the configuration of your VCN, Site-to-Site VPN, or your CPE.</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

*To view default metrics charts for an individual tunnel in an IPSec connection*

1. Open the navigation menu and click **Networking**. Under **Customer Connectivity**, click **Site-to-Site VPN (IPSec)**.
2. Click the IPSec connection to view its details.
3. Click the tunnel you're interested in to view its details and default metrics charts.
For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for all IPSec connections in a compartment

2. For Compartment, select the compartment that contains the IPSec connection you're interested in.
3. For Metric Namespace, select oci_vpn.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Each IPSec tunnel is a single line in a given chart. The tunnel is identified in the chart by the public IP address of the Oracle end of the tunnel.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Site-to-Site VPN Troubleshooting

Create a service request Ask the community

This topic covers the most common troubleshooting issues for Site-to-Site VPN. Some suggestions assume that you are a network engineer with access to your CPE device's configuration.

Log Messages

Viewing log messages generated for various operational aspects of Site-to-Site VPN can be a valuable aid in troubleshooting many of the issues presented during operation. Enabling and accessing the Site-to-Site VPN log messages can be done via Site-to-Site VPN or the Logging service.

- For an overview of the Logging service in general, refer to the Logging Overview on page 3348
- For details on enabling and accessing the Site-to-Site VPN log messages via the logging service, refer to Service Logs on page 3363
- For details on enabling and accessing the Site-to-Site VPN log messages via the Networking service, refer to Viewing Your Site-to-Site VPN Log Messages on page 4038
- For details on the Site-to-Site VPN log message schema, refer to Details for Site-to-Site VPN on page 3400

Tunnel Flapping

Interesting traffic at all times: In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

Multiple IPSEC Connections: You can use two IPSec connections for redundancy. If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

Local IKE identifier: Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to
be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Maximum Transmission Unit (MTU):** The standard internet MTU size is 1500 bytes. For more information on how to determine your MTU please see Overview of MTU on page 4222.

**CPE Configuration**

**Local IKE identifier:** Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 4035.

**Cisco ASA: Policy Based:** Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

**Multiple Tunnels** If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

**Encryption Domain Issues**

The Oracle VPN headends use route-based tunnels, but can work with policy-based tunnels with some caveats. See Encryption domains for policy-based tunnels on page 3824 for full details.

**Stateful security list rules:** If you're using stateful security list rules (for TCP, UDP, or ICMP traffic), you don't need to ensure that your security list has an explicit rule to allow ICMP type 3 code 4 messages because the Networking service tracks the connections and automatically allows those messages. Stateless rules require an explicit ingress security list rule for ICMP type 3 code 4 messages. Confirm that the instance firewalls are set up correctly.

**General Site-to-Site VPN Issues**

**IPSec tunnel is DOWN**

Check these items:
• **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

List of configurations

- **Verified CPE Devices** on page 3846
- **Using the CPE Configuration Helper** on page 3847
- **Checkpoint:**
  - **Check Point: Route-Based** on page 3849
  - **Check Point: Policy-Based** on page 3874
- **Cisco ASA:**
  - **Cisco ASA: Route-Based** on page 3897
  - **Cisco ASA: Policy-Based** on page 3910
- **Cisco IOS** on page 3924
- **FortiGate** on page 3936
- **Furukawa Electric** on page 3950
- **Juniper MX** on page 3954
- **Juniper SRX** on page 3968
- **Libreswan** on page 3980
- **NEC IX Series** on page 3989
- **Openswan** on page 3998
- **Palo Alto** on page 3998
- **WatchGuard** on page 4031
- **Yamaha RTX Series** on page 4031

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair on older connections. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

Connections created after October 2020 in many regions are created using **Site-to-Site VPN v2**, which can support multiple encryption domains.

- **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see **Overview of Site-to-Site VPN Components** on page 3812.

**IPSec tunnel is UP, but no traffic is passing through**

Check these items:
• **Phase 2 (IPSec) configuration:** Confirm that the phase 2 (IPSec) parameters are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

List of configurations

- **Verified CPE Devices** on page 3846
- **Using the CPE Configuration Helper** on page 3847
- **Checkpoint:**
  - **Check Point: Route-Based** on page 3849
  - **Check Point: Policy-Based** on page 3874
- **Cisco ASA:**
  - **Cisco ASA: Route-Based** on page 3897
  - **Cisco ASA: Policy-Based** on page 3910
- **Cisco IOS** on page 3924
- **FortiGate** on page 3936
- **Furukawa Electric** on page 3950
- **Juniper MX** on page 3954
- **Juniper SRX** on page 3968
- **Libreswan** on page 3980
- **NEC IX Series** on page 3989
- **Openswan** on page 3998
- **Palo Alto** on page 3998
- **WatchGuard** on page 4031
- **Yamaha RTX Series** on page 4031
- **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
- **Firewall rules:** Ensure that your firewall rules allow both ingress and egress traffic with the Oracle VPN headend IPs and the VCN CIDR block.
- **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.
- **Cisco ASA:** Do not use the originate-only option with an Oracle Site-to-Site VPN IPSec tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the IPSec tunnels: `crypto map <map name> <sequence number> set connection-type originate-only`

**IPSec tunnel is UP, but traffic is passing in only one direction**

Check these items:

- **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.
- **Single tunnel preferred:** If you want to use only one of the tunnels, ensure that you have the proper policy or routing in place on the CPE to prefer that tunnel.
- **Multiple IPSec connections:** If you have multiple IPSec connections with Oracle, make sure to specify more specific static routes for the preferred IPSec connection.
- **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
- **Firewall rules:** Ensure that your firewall rules allow traffic in both directions with the Oracle VPN headend IPs and the VCN CIDR block.
Troubleshooting Site-to-Site VPN with a Policy-Based Configuration

IPSec tunnel is DOWN

Check these items:

- **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

  List of configurations
  - Verified CPE Devices on page 3846
  - Using the CPE Configuration Helper on page 3847
  - Checkpoint:
    - Check Point: Route-Based on page 3849
    - Check Point: Policy-Based on page 3874
  - Cisco ASA:
    - Cisco ASA: Route-Based on page 3897
    - Cisco ASA: Policy-Based on page 3910
  - Cisco IOS on page 3924
  - FortiGate on page 3936
  - Furukawa Electric on page 3950
  - Juniper MX on page 3954
  - Juniper SRX on page 3968
  - Libreswan on page 3980
  - NEC IX Series on page 3989
  - Openswan on page 3998
  - Palo Alto on page 3998
  - WatchGuard on page 4031
  - Yamaha RTX Series on page 4031

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair on older connections. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

Connections created after October 2020 in many regions are created using Site-to-Site VPN v2, which can support multiple encryption domains.

- **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see Overview of Site-to-Site VPN Components on page 3812.

- **Cisco ASA:** Do not use the originate-only option with an Oracle Site-to-Site VPN IPSec tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the IPSec tunnels: `crypto map <map name> <sequence number> set connection-type originate-only`
**IPSec tunnel is UP but keeps flapping**

Check these items:

- **Initiation of connection:** Ensure that your CPE device is initiating the connection.
- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair on older connections. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

Connections created after October 2020 in many regions are created using [Site-to-Site VPN v2](https://docs.oracle.com/en/cloud/networking/virtual-private-networks/sitedesite-vpn-v2/introduction.html), which can support multiple encryption domains.

- **Interesting traffic at all times:** In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the [Cisco ASA policy-based configuration template](https://docs.oracle.com/en/cloud/networking/virtual-private-networks/cisco-asa-vpn/introduction.html).

**IPSec tunnel is UP but traffic is unsteady**

Check these items:

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair on older connections. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

Connections created after October 2020 in many regions are created using [Site-to-Site VPN v2](https://docs.oracle.com/en/cloud/networking/virtual-private-networks/sitedesite-vpn-v2/introduction.html), which can support multiple encryption domains.

- **Interesting traffic at all times:** In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the [Cisco ASA policy-based configuration template](https://docs.oracle.com/en/cloud/networking/virtual-private-networks/cisco-asa-vpn/introduction.html).
If you had a configuration similar to the example above and only configured three of the six possible IPv4 encryption domains on the CPE side, the link would be listed in a "Partial UP" state since all possible encryption domains are always created on the DRG side.

**BGP Session Troubleshooting for Site-to-Site VPN**

**BGP status is DOWN**

Check these items:

- **IPSec status:** For the BGP session to be up, the IPSec tunnel itself must be up.
- **BGP address:** Verify that both ends of the tunnel are configured with the correct BGP peering IP address.
- **ASN:** Verify that both ends of the tunnel are configured with the correct BGP local ASN and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180.
- **MD5:** Verify that MD5 authentication is disabled or not configured on your CPE device. Site-to-Site VPN does not support MD5 authentication.
- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking the following ports:
  - TCP port 179 (BGP)
  - UDP port 500 (IKE)
  - IP protocol port 50 (ESP)

  If your CPE device's firewall is blocking TCP port 179 (BGP), the BGP neighborship state will always be down. Traffic cannot flow through the tunnel because the CPE device and Oracle router do not have any routes.

**BGP status is flapping**

Check these items:

- **IPSec status:** For the BGP session to be up and not flapping, the IPSec tunnel itself must be up and not flapping.
- **Maximum prefixes:** Verify that you are advertising no more than 2000 prefixes. If you're advertising more, BGP won't be established.

**BGP status is UP, but no traffic is passing through**

Check these items:

- **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
• **Correct routes on both ends:** Verify that you have received the correct VCN routes from Oracle and the CPE device is using those routes. Likewise, verify that you are advertising the correct on-premises network routes over the Site-to-Site VPN, and the VCN route tables use those routes.

**BGP status is UP, but traffic is passing in only one direction**

Check these items:

• **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).

• **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.

• **Asymmetric routing:** Oracle uses asymmetric routing. If you have multiple IPSec connections, ensure that your CPE device is configured for asymmetric route processing.

• **Redundant connections:** If you have redundant IPSec connections, ensure that they’re both advertising the same routes.

**Troubleshooting Redundant IPSec connections**

Remember these important notes:

• FastConnect uses BGP dynamic routing. Site-to-Site VPN IPSec connections can use either static routing or BGP, or a combination.

• For important details about routing and preferred routes when using redundant connections, see Routing for Site-to-Site VPN on page 3810.

• You can use two IPSec connections for redundancy. If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

**IPSec and FastConnect are both set up, but traffic is only passing through IPSec**

Ensure that you use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in Routing for Site-to-Site VPN on page 3810.

**Two on-premises data centers each have an IPSec connection to Oracle, but only one is passing traffic**

Verify that both IPSec connections are up and ensure that you have asymmetric route processing enabled on the CPE.

If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

For more information about this type of setup, see Example Layout with Multiple Geographic Areas on page 3841.

**FastConnect**

The following topics have information about setting up Oracle Cloud Infrastructure FastConnect between your on-premises network and virtual cloud network (VCN):

• FastConnect Overview on page 4052
  • FastConnect Requirements on page 4061
  • FastConnect Redundancy Best Practices on page 4065
  • Routing Details for Connections to Your On-Premises Network on page 3818
  • FastConnect: With an Oracle Partner on page 4072
  • FastConnect: With a Third-Party Provider on page 4080
  • FastConnect: Colocation with Oracle on page 4090
FastConnect Overview

Oracle Cloud Infrastructure FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

Uses for FastConnect

With FastConnect, you can choose to use private peering, public peering, or both.

- **Private peering:** To extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud, or a lift and shift scenario). Communication across the connection is with IPv4 private addresses (typically RFC 1918).
- **Public peering:** To access public services in Oracle Cloud Infrastructure without using the internet. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, or public load balancers in your VCN. Communication across the connection is with IPv4 public IP addresses. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection. For a list of the services available with public peering, see FastConnect Supported Cloud Services. For a list of the public IP address ranges (routes) that Oracle advertises, see FastConnect Public Peering Advertised Routes on page 4099.

In general it's assumed you'll use private peering, and you might also use public peering. Most of this documentation is relevant to both, with specific details called out for private versus public.

If you choose to have multiple paths from your on-premises network to Oracle, see Routing Details for Connections to Your On-Premises Network on page 3818.

IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

Note:

It is possible to connect two VCNs in different regions using FastConnect colocation, with inter-region traffic using that link rather than the Oracle backbone. A Layer 3 device is required to implement this, even for a layer 2 connection. Details of this use case are not available, but are similar to Connecting Oracle Cloud Infrastructure to Amazon VPC with Megaport Cloud Router or Connecting Oracle Cloud Infrastructure to Google Cloud Platform with Equinix Network Edge Cloud Router.

How and Where to Connect

With FastConnect, there are different connectivity models to choose from.

Oracle Partners

- List of Oracle Cloud Infrastructure FastConnect partners
- Port speeds in 1 Gbps, 10 Gbps, or 100 Gbps increments
- Instructions for integrating: FastConnect: With an Oracle Partner on page 4072

Third-Party Provider

- Port speed of 1 Gbps, 10 Gbps, or 100 Gbps per cross-connect
- Instructions for integrating: FastConnect: With a Third-Party Provider on page 4080

Colocation with Oracle in an Oracle Cloud Infrastructure FastConnect Location

- List of Oracle Cloud Infrastructure FastConnect locations
• Port speed of 1 Gbps, 10 Gbps, or 100 Gbps per cross-connect
• Instructions for integrating: FastConnect: Colocation with Oracle on page 4090

The following table summarizes several important requirements for each connectivity model.

<table>
<thead>
<tr>

**Concepts**

Here are some important concepts to understand (also see the following diagrams):

**FastConnect**

The general concept of a connection between your existing network and Oracle Cloud Infrastructure over a private physical network instead of the internet.

**FastConnect location**

A specific Oracle data center where you can connect to Oracle Cloud Infrastructure.

**METRO AREA**

A geographical area (for example, Ashburn) with multiple FastConnect locations. All locations in a metro area connect to the same set of availability domains for resiliency if there is failure in a single location.

**ORACLE PARTNER**

A network service provider that has integrated with Oracle in a FastConnect location. See the list of the Oracle partners in How and Where to Connect on page 4052. If your provider is in the list, see FastConnect: With an Oracle Partner on page 4072.
THIRD-PARTY PROVIDER
A network service provider that is NOT on the list of Oracle partners in How and Where to Connect on page 4052. If you have a third-party provider and want to use FastConnect, see FastConnect: With a Third-Party Provider on page 4080.

COLOCATION
The situation where your equipment is deployed into a FastConnect location. If your network service provider is not on the list of Oracle partners in How and Where to Connect on page 4052, you must collocate.

CROSS-CONNECT
In a colocation or third-party provider scenario, this is the physical cable connecting your existing network to Oracle in the FastConnect location.

CROSS-CONNECT GROUP
In a colocation or third-party provider scenario, this is a link aggregation group (LAG) that contains at least one cross-connect. You can add more cross-connects to a cross-connect group as your bandwidth needs increase. This is applicable only for colocation.

VIRTUAL CLOUD NETWORK (VCN)
Your virtual network in Oracle Cloud Infrastructure. You can use a VCN to extend your infrastructure into the cloud. For more information, see VCNs and Subnets on page 3693.

DYNAMIC ROUTING GATEWAY (DRG)
A virtual edge router attached to your VCN. Necessary for private peering. The DRG is a single point of entry for private traffic coming in to your VCN, whether it's over FastConnect or a Site-to-Site VPN link. After creating the DRG, you must attach it to your VCN and add a route for the DRG in the VCN's route table to enable traffic flow. Instructions for everything are included in the sections that follow.

VIRTUAL CIRCUIT
An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure. Private virtual circuits support private peering, and public virtual circuits support public peering (see Uses for FastConnect on page 4052). Each virtual circuit is made up of information shared between you and Oracle (and also a partner if you're connecting through an Oracle partner). You could have multiple private virtual circuits, for example, to isolate traffic from different parts of your organization (one virtual circuit for 10.0.1.0/24; another for 172.16.0.0/16), or to provide redundancy.

Basic Network Diagrams
The diagrams in this section introduce the basic logical and physical connections involved in FastConnect. Details specific to private versus public peering are called out.
**General Concept of FastConnect**

The following diagram illustrates the two ways to connect to Oracle with FastConnect: either through colocation with Oracle in the FastConnect location, or through an Oracle partner. In both cases, the connection goes between the edge of your existing network and Oracle.

**Connection with Oracle: colocation in data center**

**Connection with Oracle: through Oracle provider**

**Physical Connection**

The next two diagrams give more detail about the physical connections. They also show the metro area that contains the FastConnect location, and a VCN within an Oracle Cloud Infrastructure region.
The first diagram shows the colocation scenario, with your physical connection to Oracle within the FastConnect location.

![Diagram showing colocation scenario]

The next diagram shows a scenario with either an Oracle partner or third-party provider. It shows your physical connection to the provider, and the provider's physical connection to Oracle within the FastConnect location.

![Diagram showing provider scenario]

**Logical Connection: Private Virtual Circuit**

The next two diagrams show a private virtual circuit, which is a single, logical connection between your edge and Oracle Cloud Infrastructure by way of your DRG. Traffic is destined for private IP addresses in your VCN.
Networking

The first diagram shows the colocation scenario.

![Colocation Diagram](image1)

Legend: Private virtual circuit

The next diagram shows the scenario with either an Oracle partner or third-party provider.

![Oracle Partner Diagram](image2)

Legend: Private virtual circuit

**Logical Connection: Public Virtual Circuit**

A public virtual circuit gives your existing network access to Oracle services in Oracle Cloud Infrastructure. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, and public load balancers in your VCN. All communication across a public virtual circuit uses public IP addresses. For a list of services available with FastConnect public peering, see [FastConnect Supported Cloud Services](#). For a list of the public IP address ranges (routes) that Oracle advertises, see [FastConnect Public Peering Advertised Routes](#) on page 4099. You can select the way this access is structured using [Route Filtering](#) on page 3821.
The first diagram shows the colocation scenario with both a private virtual circuit and a public virtual circuit. Notice that the DRG is not involved with the public virtual circuit, only the private virtual circuit.

Here are a few basics to know about public virtual circuits:

- You choose which of your organization's public IP prefixes you want to use with the virtual circuit. All prefix sizes are allowed. Oracle verifies your organization's ownership of each prefix before sending any traffic for it across the connection. Oracle's verification for a given prefix can take up to three business days. You can get the status of the verification of each prefix in the Oracle Console or API. **Oracle begins advertising the Oracle Cloud Infrastructure public IP addresses across the connection only after successfully verifying at least one of your public prefixes.**
- Configure your firewall rules to allow traffic coming from the Oracle public IP addresses.
- Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private...
access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 3818.

- You can add or remove public IP prefixes at any time by editing the virtual circuit. If you add a prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.
- You should consider FastConnect public peering as an untrusted interface, and put in place firewalls and other access controls just like you would for any network interface connected to the Internet. See Security considerations for FastConnect public peering on page 4100 for more information.

Oracle Partner Scenario: BGP Session to Either Oracle or the Oracle Partner

This section is applicable if you're using FastConnect through an Oracle partner. A Border Gateway Protocol (BGP) session is established from your edge, but where it goes depends on which Oracle partner you use.

**Tip:**

For simplicity, the following diagrams show only a private virtual circuit. However, the location of the BGP session is the same for a public virtual circuit.

**To Oracle:** With some of the Oracle partners, the BGP session goes from your edge to Oracle, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are asked to provide basic BGP peering information (see General Requirements on page 4061).

**To the Oracle partner:** With other Oracle partners, your BGP session goes from your edge to the partner's, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are NOT asked for any BGP session.
information. Instead, you share BGP information with your Oracle partner. Notice that there's a separate BGP session that the partner establishes with Oracle.

To use FastConnect if you do not own a Public ASN or Public IP Address

If you use a Public ASN or Public IP Address loaned or leased from a third-party source, your third-party source must provide a Letter of Authorization (LOA) on your behalf before Oracle can allow the completion of FastConnect configuration.

The following additional steps are required to obtain approval when configuring public peering virtual connections:

1. Obtain an LOA from the third-party source that authorizes the Customer to use the Public ASN and or Public IP address. The LOA must contain:
   - Customer Name approved to the use the Public IP Address and Public ASN
   - The range of the Public IP Addresses and or the Public ASN must be explicitly listed
   - The third-party source who owns the Public IP Addresses and or the Public ASN
   - Third-party source authorization authority signatory
   - Contact email, phone number and address of third-party source
   - Your enterprise’s contact email and phone number
   - Date of authorization and validity

2. Using the Console, open a service request on the tenancy and region where you wish to use the third-party provided Public ASN and Public IP Address.

3. Attach the LOA to the service request.

Once the service request is opened and the LOA is approved, Oracle will authorize the use of the Public ASN and or Public IP Address.

FastConnect with Access to Multiple VCNs

You can use a single FastConnect to access multiple VCNs. Different network scenarios are available depending on your needs and which FastConnect connectivity model you use. For more information, see these topics:

- Transit Routing inside a hub VCN on page 3667: This scenario can be used with either FastConnect or Site-to-Site VPN. It involves a single DRG, and multiple VCNs in a hub-and-spoke layout.
- FastConnect with Multiple DRGs and VCNs on page 3689: This scenario can be used only with FastConnect, and only if you’re using a third-party provider or colocated with Oracle. It involves multiple DRGs and private virtual circuits.

What’s Next?

See these topics to get started:

- FastConnect Requirements on page 4061
FastConnect Requirements

This topic covers the requirements for implementing FastConnect.

For general information about FastConnect, see the articles listed for FastConnect on page 4051.

Before Getting Started: Learn and Plan

Here are basic things you need to do before getting started with FastConnect:

- **FastConnect concepts:** Be familiar with the basic concepts covered in FastConnect Concepts.
- **Limits increase:** If you are colocated with Oracle, you must ask Oracle to increase your account limits for cross-connects. By default, these limits are initially set to 0, and a request to create a cross-connect will fail. For instructions, see Requesting a Service Limit Increase on page 245. In your request, indicate the region where you need the resources. It can take a couple of business days for the limit increase to take effect.
- **Hardware and routing requirements:** Review the hardware and routing requirements.
- **Tenancy setup and compartment design:** If you haven't yet, set up your tenancy. Think about who needs access to Oracle Cloud Infrastructure and how. For more information, see "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide. Specifically for FastConnect, see Required IAM Policy on page 4064 to understand the policy required to work with FastConnect components.
- **Cloud network design:** Design your virtual cloud network (VCN), including how you want to allocate your VCN's subnets, define security list rules, define route tables, set up load balancers, and so on. For more information, see Networking on page 3604.
- **Redundancy:** Think through your overall redundancy model to ensure your network can handle planned maintenance by Oracle or your organization, and unexpected failures of the various components. For best practices, see FastConnect Redundancy Best Practices on page 4065.
- **Public IP prefixes:** If you plan to set up a public virtual circuit, get the list of the public IP prefixes that you want to use with the connection. Oracle must validate your organization's ownership of each of the prefixes before advertising each one over the connection.
- **Cloud network setup:** Set up your VCN, subnets, DRG, security lists, IAM policies, and so on, according to your design.

General Requirements

Before getting started with FastConnect, ensure that you meet the following requirements:

- Oracle Cloud Infrastructure account, with at least one user with appropriate Oracle Cloud Infrastructure Identity and Access Management (IAM) permissions (for example, a user in the Administrators group).
- Network equipment that supports Layer 3 routing using BGP.
- For colocation with Oracle: Ability to connect using single mode fiber in your selected FastConnect location. Also see Hardware and Routing Requirements on page 4062.
- For connection to an Oracle partner: At least one physical network connection with the partner. Also see Hardware and Routing Requirements on page 4062.
- For connection to a third-party provider: At least one physical connection with the provider. Also see Hardware and Routing Requirements on page 4062.
- For private peering only: At least one existing DRG set up for your VCN.
- For public peering only: The list of public IP address prefixes that you want to use with the connection. Oracle will validate your ownership of each prefix.
**Important:**

If you intend to collocate with Oracle, you must ask Oracle to increase your account limits for cross-connects. These default limits are initially set to 0, and without a specific request for a limit increase you won't be able to create a valid cross-connect. For instructions on placing this request, see Requesting a Service Limit Increase on page 245. In your request, indicate the region where you need the resources. It can take a couple of business days for the limit increase to take effect.

**Hardware and Routing Requirements**

*If you're using an Oracle partner*

Here are general routing requirements for FastConnect. These are particularly relevant if your BGP session is between your edge and Oracle.

- **IP addressing supported:** IPv4 and IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.
- **P2P IP addresses:**
  - For public virtual circuits, Oracle specifies the IP addresses.
  - For private virtual circuits where your BGP session is between your edge and Oracle, you specify these addresses (/30 or /31, and one pair per virtual circuit). If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.
- **Maximum IP MTU:** 9000
- **Routing protocol:** BGPv4
- **BGP prefix limit:** For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.
- **BGP ASN:** 2-byte or 4-byte ASNs are supported, except for those listed in Special-Purpose Autonomous System (AS) Numbers. Public virtual circuits require a public ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the US Government Cloud, see Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200. BGP ASN 65534 is not available for you to use with FastConnect and VPN. All other private ASNs in the 64512 - 65533 (inclusive) range defined in RFC-6996 can be used normally.
- **BGP MD5 authentication:** Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
- **BGP keep-alive interval:** 60s
- **BGP hold-time interval:** 180s

**Tip:**

By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.
If you’re collocating in a FastConnect location or using a third-party provider

For the cross-connect group and cross-connects:

- **Bandwidth (three choices):**
  - 1 Gbps:
    - 1000Base-LX, 10-km range, 1310 nm
    - You must configure your edge device so that auto-negotiation is OFF
    - Minimum Rx level > -15 dBm
  - 10 Gbps:
    - 10 GbE, LR (10-km range), 1310 nm
    - Minimum Rx level > -12 dBm
  - 100 Gbps (Colocation only):
    - 100GBASE, LR4 QSFP28 (10-km range), WDM optics
    - CrossConnect Groups (LAG/LACP) are not currently supported
    - Minimum Rx level > -12 dBm on each of four lanes

- **General:**
  - Single Mode Fiber
  - Duplex LC connectors

- **Redundancy:**
  - Device redundancy highly recommended
  - In some regions, location redundancy is available and recommended

- **Capacity:**
  - 1 GbE: Minimum 1, Maximum 8
  - 10 GbE: Minimum 1, Maximum 8
  - 100 GbE: 1 only

- **LAG protocol:** LACP with short timers (3 @ 1s). If your router doesn't support LAG, you can set up a single non-LAG cross-connect.

- **VLAN tagging:** 802.1q (single tag)

- **VLAN range:** 100-4094 (you assign the VLANs)

- **Maximum interface MTU:** 9196 (include 4-byte FCS trailer)

For routing:

- **IP addressing supported:** IPv4 and IPv6 addressing is supported for all commercial and government regions. For more information, see IPv6 Addresses on page 3768.

- **P2P IP addresses:**
  - For public virtual circuits, Oracle specifies the IP addresses.
  - For private virtual circuits, you specify the addresses (a /30 or /31). You need one pair of IP addresses per private virtual circuit. If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.

- **Maximum IP MTU:** 9000

- **Routing protocol:** BGPv4

- **BGP prefix limit:** For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.

- **BGP ASN:** 2-byte or 4-byte ASNs are supported, except for those listed in Special-Purpose Autonomous System (AS) Numbers. Public virtual circuits require a public ASN. Oracle's BGP ASN is 31898. For the US Government Cloud, see Oracle's BGP ASN on page 180. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 200

  BGP ASN 65534 is not available for you to use with FastConnect and VPN. All other private ASNs in the 64512 - 65533 (inclusive) range defined in RFC-6996 can be used normally.
- **BGP MD5 authentication**: Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
- **BGP keep-alive interval**: 60s
- **BGP hold-time interval**: 180s

**Tip:**

By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

**Required IAM Policy**

*If you’re using an Oracle partner*

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, and virtual circuits, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions below. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To *only* create and manage a virtual circuit, you would need a policy like this:

```
Allow group VirtualCircuitAdmins to manage drgs in tenancy
Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

*If you’re collocating in a FastConnect location or using a third-party provider*

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, virtual circuits, and cross-connects, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions that follow. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To *only* create and manage cross-connects, cross-connect groups, and virtual circuits, you would need a policy like this:

```
Allow group FastConnectAdmins to manage drgs in tenancy
Allow group FastConnectAdmins to manage cross-connects in tenancy
Allow group FastConnectAdmins to manage cross-connect-groups in tenancy
Allow group FastConnectAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Identifiers for Your FastConnect Resources**

Your resources have several identifiers:

- **Name for the overall connection:** When you create a new FastConnect connection, you can give it a descriptive name of your choice. If you don’t specify one, Oracle automatically assigns a name to the connection.

- **Reference name for each cross-connect:** Each cross-connect has an optional reference name. If you set up a cross-connect, Oracle recommends that you fill in the reference name with the identifier for the cross-connect’s physical fiber cable. That makes it easier for Oracle to help if future troubleshooting is required for the connection. After cabling is done and you have the identifier from the data center, you can add it to the cross-connect's information in the Oracle Console.

- **OCID for each resource:** Each cross-connect group, cross-connect, and virtual circuit has its own unique Oracle-assigned identifier called an OCID.

### What's Next?

Choose the topic that suits your situation:

- FastConnect: With a Third-Party Provider on page 4080
- FastConnect: Colocation with Oracle on page 4090

### FastConnect Redundancy Best Practices

This topic covers best practices for redundancy when implementing FastConnect.

For general information about FastConnect, see FastConnect on page 4051.

#### Overview

In general, you should design your network to achieve high availability (HA). In addition, you should be prepared for these types of disruptions:

- Regularly scheduled maintenance by your organization, your provider (if you're using one), or Oracle.
- Unexpected failures on the part of your networking components, your provider, or Oracle. Failures are rare, but you should plan for them.

For redundancy, Oracle provides:

- Multiple providers for each region
- Two FastConnect locations for each of the following regions (all other regions have a single FastConnect location)
  - Germany Central (Frankfurt)
  - UK South (London)
  - US East (Ashburn)
  - US West (Phoenix)
- Two routers in each FastConnect location
- Multiple physical connections between each Oracle partner and Oracle (for a given region)

The redundancy best practices depend on which connectivity model you use. Also see How and Where to Connect on page 4052.

#### If You Use an Oracle Partner

Connectivity model:

- FastConnect: With an Oracle Partner on page 4072

Oracle handles redundancy of the physical connections between the partner and Oracle, and the redundancy of routers in the FastConnect locations. You should handle redundancy of the physical connection between your existing network and the Oracle partner.

The remaining best practices depend on the partner you're using, and details of the BGP session from your edge:

- For some partners, the BGP session from your edge goes to Oracle. For redundancy best practices, see the next section.
For other partners, the BGP session from your edge goes to the Oracle partner. For redundancy best practices, see Oracle Partner Scenario: Your BGP Session Is to the Oracle Partner on page 4067.

For information about the two scenarios, see Basic Network Diagrams on page 4054.

Oracle Partner Scenario: Your BGP Session Is to Oracle

At a minimum, each Oracle partner has two separate physical connections to Oracle. Set up one virtual circuit on one physical connection (as primary), and the other virtual circuit on another physical connection (as secondary). The following diagram illustrates two virtual circuits, each going to a different router in a single FastConnect location. If the region has a second location, your partner's second physical connection might instead go to that location.

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of two virtual circuits with the same Oracle partner, but in a second FastConnect location in a nearby region. Notice that you must have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
If you also want provider diversity, repeat your entire setup with another provider in each region that you're using.

**Oracle Partner Scenario: Your BGP Session Is to the Oracle Partner**

In this scenario, the BGP session *from your edge* goes to the Oracle partner (as shown in the following diagram). Separate from your BGP session, the Oracle partner has *its own* BGP sessions with Oracle (between the partner's edge and Oracle's edge). The virtual circuit is a logical connection that goes from your edge to the Oracle edge.

The partner has two separate physical connections to Oracle. You create one virtual circuit with the partner. In this scenario, the virtual circuit is automatically designed to be redundant and diverse. The virtual circuit has two separate BGP sessions between the partner and Oracle, each on a different physical connection. The following diagram shows the two separate BGP sessions for the single virtual circuit as dotted lines.
Separately, you must ensure that the connection between your edge and the partner is redundant and diverse.

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of a virtual circuit with the same Oracle partner, but in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
If You Use a Third-Party Provider or Colocate with Oracle

Connectivity models:

- FastConnect: With a Third-Party Provider on page 4080
- FastConnect: Colocation with Oracle on page 4090

Oracle handles redundancy of the Oracle routers in the FastConnect locations. You should handle redundancy of the physical connection between your existing network and Oracle.

To do this, create two physical connections to Oracle, one for each FastConnect location that serves the region. This means that in the Oracle Console, you set up two separate FastConnect connections. You then create two virtual circuits. Set up the first one on the first physical connection (the first FastConnect connection), and the second one on the second physical connection. The following diagram shows the general setup.
You might prefer to connect to only a single FastConnect location because of cost concerns, or if the region has only a single FastConnect location. In that case, create two physical connections and ensure each goes to a different Oracle router in that FastConnect location. You can do this in the Oracle Console when you set up the second physical connection. You can specify the proximity of that connection to other FastConnect connections in that location. For example, the following image shows how to request that your second physical connection (which is a cross-connect group) is created on a different router than your first connection in that FastConnect location (called MyConnection-1).

You must scale the bandwidth of both physical connections evenly, and by using a cross-connect group (LAG) for each connection. Imagine that you have two individual 10 Gbps cross-connects in a single FastConnect location (each to a different Oracle router for redundancy and diversity). If you need to have 20-Gbps bandwidth at a given time, you must ensure that each of your physical connections consists of a cross-connect group (LAG) to contain the cross-connect. Then you need to add another 10 Gbps cross-connect to each LAG, so that each redundant physical connection has two 10 Gbps cross-connects. FastConnect currently does not support equal-cost multi-path routing (ECMP).

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat your setup in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
Oracle recommends using Site-to-Site VPN as a backup for your FastConnect connection. If you do, ensure that the Site-to-Site VPN IPSec tunnels are configured to use BGP routing with a route-based VPN. Within your existing on-premises network, manipulate the routing to prefer routes learned through FastConnect over routes learned through Site-to-Site VPN. For example, use AS_Path Prepend to influence egress traffic from Oracle, and use local preference to influence egress traffic from your network.

If you are using VPN backup, review Oracle's BGP routing behavior in the table shown in Using AS_PATH to prefer routes from Oracle to your on-premises network on page 3819.

The following diagram shows a setup with redundant FastConnect virtual circuits and redundant Site-to-Site VPN tunnels.

What’s Next?

Choose the topic that suits your situation:

- FastConnect: With an Oracle Partner on page 4072
- FastConnect: With a Third-Party Provider on page 4080
- FastConnect: Colocation with Oracle on page 4090

FastConnect: With an Oracle Partner

This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to an Oracle partner. For a summary of the different ways to connect, see the connectivity models.

If you instead want to use a network provider that is not on the list of Oracle partners, see FastConnect: With a Third-Party Provider on page 4080. Or if you want to use FastConnect by collocating with Oracle, see FastConnect: Colocation with Oracle on page 4090.

For general information about FastConnect, see FastConnect on page 4051.
Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan on page 4061. Also see FastConnect Redundancy Best Practices on page 4065 and Hardware and Routing Requirements on page 4062.

You may also need to review information on how to use FastConnect if you do not own a Public ASN or Public IP Address.

Task 2: Set up connection to the Oracle partner

If you haven't already, start the process of ordering the connection from the Oracle partner, setting it up, and then testing it with the partner. It can take some time, depending on the partner.

Task 3: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Also see the sequence diagram in To get the status of your virtual circuit on page 4077.
Instructions:

- Creating a DRG on page 3799
- Attaching a VCN to a DRG on page 3800
- To update rules in an existing route table on page 3705

Summary: Create one or more virtual circuits for your connection in the Oracle Console. If your network design includes more than one virtual circuit, complete the following steps for each one.

Instructions:

Repeat the following steps for each virtual circuit you want to create.

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). The choice of compartment, along with a corresponding IAM policy, controls who has access to the virtual circuit you're about to create.

2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.

   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection.

3. Click Create FastConnect.

4. Select FastConnect Partner and choose the partner from the list.

5. Click Next.

6. Enter the following for your virtual circuit:

   - Name: A friendly name that helps you track your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - Create in Compartment: Leave as is (the compartment you're currently working in).

7. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering...
Networking

(Where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 4052.

- For a private virtual circuit, enter the following:
  - Dynamic Routing Gateway: Select the DRG to route the FastConnect traffic to.
  - Provisioned Bandwidth: Choose a value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4078).
  - Partner Service Key (Optional): Enter the service key provided by your Oracle partner. You can enter this key now or edit the circuit later.

If your BGP session goes to Oracle (see Basic Network Diagrams on page 4054), the dialog box includes other fields for the BGP session:

  - Customer BGP IP Address: The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - Oracle BGP IP Address: The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - Enable IPv6 Address Assignment: IPv6 addressing is supported for all commercial and government regions. See FastConnect and IPv6 on page 3772.
  - Customer BGP ASN: The public or private ASN for your network.
  - Use a BGP MD5 Authentication Key (optional): Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

- For a public virtual circuit, enter the following:
  - Provisioned Bandwidth: Choose a value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4078).
  - Public IP Prefixes: The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
  - Route Filtering: Choose a Route Filtering on page 3821 option. This selects the routes included in BGP advertisements to your on-premises network.
  - Customer BGP ASN: The public ASN for your network. Present only if your BGP session goes to Oracle (see Basic Network Diagrams on page 4054). Oracle specifies the BGP IP addresses for a public virtual circuit.
  - Use a BGP MD5 Authentication Key (optional): Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

8. Click Create.

The virtual circuit is created. Its OCID and a link to the partner's portal are displayed in the resulting confirmation box at the top of the page. The OCID is also available with the other virtual circuit details.

9. Copy and paste the OCID to another location. You give it to your partner in the next task. The virtual circuit is listed on the FastConnect page.

Until you complete the next task and the partner does their provisioning work, the virtual circuit's Lifecycle State is PENDING PROVIDER and the BGP state is DOWN. After the partner does their work, the Lifecycle State switches to PROVISIONED. When the BGP session is established and working, the BGP state changes to UP.

**Tip:**

For a virtual circuit where your BGP session goes to the Oracle partner, the BGP state for the virtual circuit reflects the status of the separate BGP session between the Oracle partner and Oracle. For reference, see Basic Network Diagrams on page 4054.

Also see the diagram in To get the status of your virtual circuit on page 4077.
Task 5: Give the partner information about the virtual circuit

Contact the partner and give the OCID of each virtual circuit that you created, along with any other information the partner requests. Depending on the partner, you might do this in the partner's portal, or over the phone. The partner then configures each virtual circuit on their end to complete the connectivity.

If your partner is AT&T NetBond: After AT&T gives you the service key for your virtual circuit, you can either edit the virtual circuit yourself or create a ticket at My Oracle Support to request provisioning. Include the service key when creating your ticket.

Task 6: Configure your edge

If your BGP session goes to Oracle: (see Basic Network Diagrams on page 4054), configure your edge (your CPE) to use the BGP peering information (see General Requirements on page 4061). Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time. Also configure the router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices on page 4065). After you successfully configure the BGP session, the virtual circuit's BGP session state changes to UP.

If your BGP session instead goes to the Oracle partner: You still need to configure your router if you haven't already. You may need to contact your partner to get the required BGP peering information. This BGP session must be up and running for FastConnect to work. Also configure your edge router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices on page 4065).

Important:

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 3818.

Task 7: Check light levels

Confirm that the light levels are good for each of your physical network connections to the partner. Don't proceed until they are.

Task 8: Confirm your interfaces are up

Confirm your side of the interfaces for the connections to the partner are up. Don't proceed until they are.

BGP Session Goes to Oracle

Task 9a: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

Task 9b: Confirm that the BGP session is established

For each virtual circuit, confirm that the BGP session is in an established state. When it is, the connection is ready to test (see Task 11: Test the connection on page 4077).

BGP Session Goes to the Partner

Task 10a: Ping the partner's edge

For each virtual circuit, ping the partner's edge. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping the partner's edge without errors.
Task 10b: Confirm the BGP session is established

Confirm the BGP session you have with the partner is in an established state. Don't proceed until it is.

Task 10c: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address (which you can get from the partner). Check the error counters and look for any dropped packets. When you can successfully ping this IP address without errors, the connection is ready to test.

Task 11: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance on page 1023. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified at least one of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that only the public prefixes that Oracle has successfully verified so far are advertised on the connection.

Managing Your Virtual Circuit

To get the status of your virtual circuit

1. In the Console, go to Networking, and then click FastConnect to view your list of connections.
2. Click the virtual circuit you're interested in to view its details.

The following diagram shows the different states of the virtual circuit when you're setting it up.
To edit a virtual circuit

You can change these items for a virtual circuit:

- The name
- The bandwidth
- The service key provided by your Oracle partner (for a private virtual circuit)
- Which DRG it uses (for a private virtual circuit)
- The public IP prefixes (for a public virtual circuit)
- Depending on the situation, you might also have access to the BGP session information for the virtual circuit and thus can change it.
Important:

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Edit and make your changes. Avoid entering confidential information.
4. Click Save Changes.

To terminate a virtual circuit

Important:

Also terminate the connection with the partner, or else the partner may continue to bill you.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.

The virtual circuit's Lifecycle State changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Basic Network Diagrams on page 4054.

You can specify your public IP prefixes when you create the virtual circuit. See Task 4: Set up your virtual circuit on page 4074.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 4078. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving a Compartment to a Different Parent Compartment on page 3130.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 3542 for more information.

**Monitoring Your Connection**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring your connection, see FastConnect Metrics on page 4108.

**Troubleshooting**

See FastConnect Troubleshooting on page 4112.

**FastConnect: With a Third-Party Provider**

This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to a third-party network provider of their choice, and not an Oracle partner. For a summary of the different ways to connect, see the connectivity models.

If you are using an Oracle partner, see FastConnect: With an Oracle Partner on page 4072. Or, if you want to use FastConnect by colocating with Oracle, see FastConnect: Colocation with Oracle on page 4090.

For general information about FastConnect, see FastConnect on page 4051.

**Important Points and Responsibilities**

- You can use FastConnect by working with a third-party network service provider or carrier of your choice. The network provider must be capable of connecting to the Oracle routers in one of the FastConnect data center locations over single-mode fiber. For more detailed technical requirements, see Hardware and Routing Requirements on page 4062.
- Your overall connection with the third-party provider includes two parts, as illustrated in the following diagram:
  - **Part 1**: Your physical connection to the third-party provider. The rest of this topic assumes you've already set up this part of the overall connection.
  - **Part 2**: The physical fiber connection (cross-connect) that the third-party provider sets up in the FastConnect location data center on your behalf.

- To obtain the Letter of Authorization (LOA) for the cross-connect, you must use the Oracle Console to set up a cross-connect or cross-connect group. The resulting LOA from Oracle covers part 2 of the connection in the preceding diagram.
- You must forward the LOA to your third-party provider, who is responsible for working with the data center to set up the physical cross-connect on your behalf.
• The third-party provider issues a cross-connect order with the data center facility to run fiber optics to complete the connection from the third-party provider's cage to Oracle's patch panel as described in the LOA. Typically the data center colocation staff are the ones who run the fiber optics to complete the connection.

• Each LOA is valid for only a limited time. If the physical cross-connect is not set up before the LOA's expiration, the LOA is revoked.

• The third-party provider is responsible for charging you for the entire connection (both parts 1 and 2). Oracle does not set up this cross-connect in the data center, does not pay for it, and does not include it in your FastConnect charges.

• The LOA specifies an Oracle demarcation point. If your network provider is located at a different demarcation point in the data center cage, they must set up the cross-connect from their demarcation point to the Oracle demarcation point.

**Getting Started with FastConnect**

The following flow chart shows the overall process of setting up FastConnect.

**Note:**

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.
Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan on page 4061. Also see FastConnect Redundancy Best Practices on page 4065 and Hardware and Routing Requirements on page 4062.

You may also need to review information on how to use FastConnect if you do not own a Public ASN or Public IP Address.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:
- Creating a DRG on page 3799
- Attaching a VCN to a DRG on page 3800
- To update rules in an existing route table on page 3705

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.
You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).

**Instructions:**

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.

2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.

   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection and its components.

3. Click Create FastConnect.

4. Select Colocate with Oracle and click Next. Select this option even though a third-party provider will set up the physical connection to Oracle in the FastConnect location.

5. Enter the following items:

   - **Name:** A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).
   - **Compartment:** Leave as is (the compartment you're currently working in).
   - **Cross-Connect Type:**
     - If your router supports LAG, select Cross-Connect Group. You will create a cross-connect group (a LAG) with at least one cross-connect.
     - If your router does not support link aggregation (LAG), select Single Cross-Connect. You will create a single non-LAG cross-connect with no cross-connect group.
   - **Reference Name:** The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. You might need to get this value from your third-party provider. If you don't have it, you can add it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.
   - **Number of cross-connects:** Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
   - **Port speed:** 1 Gbps, 10 Gbps, or 100 Gbps.
   - **Physical location:** The FastConnect location for this connection.
   - **Specify Router Proximity:** Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.

6. Click Create.

   The new connection is created and listed on the FastConnect page.

7. Click the new connection to see its details.

8. **Print the LOA for each cross-connect:** Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect's details, and then view and print the cross-connect's LOA. In the next task, you forward
it to your third-party provider so they can request cabling at the FastConnect location. The cross-connect's status is PENDING CUSTOMER until you complete the next few tasks.

**Task 4: Forward the LOA to your third-party provider**

Forward the LOA or LOAs from the preceding task to your third-party network provider so they can request cabling at the FastConnect location. Each LOA is valid for a limited time. The details are printed on the LOA.

**Task 5: Check light levels**

After the third-party provider completes setup of the physical cross-connect in the FastConnect location, confirm from your side that the light levels for each physical connection (cross-connect) are good (> -15 dBm). Don't proceed until they are.

In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:

If they are not good, contact your third-party network provider.

**Task 6: Confirm that your interfaces are up**

For each cross-connect's physical fiber cable, confirm your side of the interfaces are up. Don't proceed until they are.

In the Console, you can see the status of Oracle's side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).

If the interfaces are not up, contact your third-party network provider.
**Task 7: Activate each cross-connect**

**Summary:** When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

**Instructions:**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click **Activate**.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click **Edit** and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time. After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

**Task 8: Set up your virtual circuit**

**Summary:** Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

**Important:**

If you want to use a single FastConnect to connect your existing network to multiple DRGs and VCNs, you must set up a different private virtual circuit for each VCN. Each virtual circuit must have a different VLAN and a different set of BGP IP addresses. For more information, see **FastConnect with Multiple DRGs and VCNs** on page 3689.

**Instructions:**

1. In the Console, return to the connection you created earlier. Under **Resources**, click **Virtual Circuits**.
2. Click **Add Virtual Circuit**.
3. Enter the following for your virtual circuit:
   - **Name:** A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment:** Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.
4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering.
Networking

(where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 4052.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway**: Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4097).
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP IP Address**: The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address**: The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment**: Available only in the US Government Cloud. For more information, see FastConnect and IPv6 on page 3772.
  - **Customer BGP ASN**: The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 4097).
  - **Public IP Prefixes**: The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
  - **Route Filtering**: Choose a Route Filtering on page 3821 option. This selects the routes included in BGP advertisements to your on-premises network.
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP ASN**: The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click **Create**.

The virtual circuit is created.

The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

**Task 9: Configure your edge**

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 180. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

**Important:**

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up...
your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 3818.

If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.
- If the third-party provider is performing any media conversion, LACP must be configured on the provider's device instead of your device.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

Task 10: Ping the Oracle BGP IP address

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

Task 11: Confirm that the BGP session is established

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

Task 12: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance on page 1023. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified at least one of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use.
   However, remember that only the public prefixes that Oracle has successfully verified so far are advertised on the connection.

Managing Your Connection

To get the status of your connection

Look at the icon for the particular part of the connection that you're interested in (cross-connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

Cross-Connect: PENDING CUSTOMER

- You need to forward the LOA to your third-party provider so they can request cabling at the FastConnect location. See Task 4: Forward the LOA to your third-party provider on page 4084.
- Or, you need to activate a cross-connect after confirming it's ready to use. See Task 7: Activate each cross-connect on page 4085, but make sure you've performed tasks 5 and 6 first.

Virtual circuit: DOWN

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:

- You need to configure your edge. See Task 9: Configure your edge on page 4086.
• Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).

The following table summarizes the different states of each component involved in the connection at different points during setup:

<table>
<thead>
<tr>
<th>Task in Setup Process</th>
<th>CCG Icon</th>
<th>CC Icon</th>
<th>VC Icon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task 3: Set up your cross-connect group and cross-connect on page 4082</td>
<td>PENDING PROVISIONING</td>
<td>PENDING CUSTOMER</td>
<td>N/A</td>
</tr>
<tr>
<td>Task 7: Activate each cross-connect on page 4085</td>
<td>PROVISIONED</td>
<td>PROVISIONED</td>
<td>N/A</td>
</tr>
<tr>
<td>Task 8: Set up your virtual circuit on page 4085</td>
<td>PROVISIONED</td>
<td>PROVISIONED</td>
<td>PROVISIONING &gt; DOWN</td>
</tr>
<tr>
<td>Task 9: Configure your edge on page 4086</td>
<td>PROVISIONED</td>
<td>PROVISIONED</td>
<td>DOWN &gt; UP</td>
</tr>
</tbody>
</table>

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection to view its details.
   c. Click Add Cross-Connect.
   d. Enter the following items:
      • Name: A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.
      • Reference Name: Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.
   e. Click Add.
      The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.
   f. Print the new cross-connect's LOA. You forward it to your third-party provider in the next step.

2. Perform tasks 4-7 in Getting Started with FastConnect on page 4081. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:
• The name
• The bandwidth
• Which DRG it uses (for a private virtual circuit)
• Which VLAN it uses
• The BGP session information
• The public IP prefixes (for a public virtual circuit)
Important:

Notes About Editing a Virtual Circuit

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Edit** and make your changes. Avoid entering confidential information.
5. Click **Save Changes**.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

Important:

Also terminate the connection with the data center or third-party provider, or else they may continue to bill you.

To terminate a virtual circuit

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Delete**.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the last provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Cross-Connects**, and then click the cross-connect to view its details.
4. Click **Delete**.
5. Confirm when prompted.

The cross-connect's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect group

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.

The cross-connect group's status changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Basic Network Diagrams on page 4054.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit on page 4094.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 4097. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see To move a resource to a different compartment on page 3139.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 3542 for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring your connection, see FastConnect Metrics on page 4108.

Troubleshooting

See FastConnect Troubleshooting on page 4112.

FastConnect: Colocation with Oracle

This topic is for customers who are colocated with Oracle in a FastConnect location. For a summary of the different ways to connect, see the connectivity models.

If you instead have a relationship with an Oracle partner, see FastConnect: With an Oracle Partner on page 4072. Or if you have a relationship with a third-party provider, see FastConnect: With a Third-Party Provider on page 4080.

For general information about FastConnect, see FastConnect on page 4051.
Networking

**Getting Started with FastConnect**

The following flow chart shows the overall process of setting up FastConnect.

**Note:**

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.
Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan on page 4061. Also see FastConnect Redundancy Best Practices on page 4065 and Hardware and Routing Requirements on page 4062.

You may also need to review information on how to use FastConnect if you do not own a Public ASN or Public IP Address.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:

- Creating a DRG on page 3799
- Attaching a VCN to a DRG on page 3800
- To update rules in an existing route table on page 3705

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.

You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).

Instructions:

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.

   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection and its components.
3. Click Create FastConnect.
4. Select Colocate with Oracle and click Next.
5. Enter the following items:
   - Name: A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect
Networking

group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).

- **Compartment**: Leave as is (the compartment you're currently working in).
- **Cross-Connect Type**: 
  - If your router supports LAG, select **Cross-Connect Group**. You will create a cross-connect group (a LAG) with at least one cross-connect.
  - If your router does not support link aggregation (LAG), select **Single Cross-Connect**. You will create a single non-LAG cross-connect with no cross-connect group.
- **Reference Name**: The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. If you don't have it, you can add it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.
- **Number of cross-connects**: Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
- **Port speed**: 1 Gbps, 10 Gbps, or 100 Gbps.
- **Physical location**: The FastConnect location for this connection.
- **Specify Router Proximity**: Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.

6. Click **Create**.

   The new connection is created and listed on the FastConnect page.

7. Click the new connection to see its details.

8. **Print the LOA for each cross-connect**: Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect's details, and then view and print the cross-connect's LOA. In the next task, you submit it with your cabling request at the FastConnect location. The cross-connect's status is PENDING CUSTOMER until you complete the next few tasks.

   ![MyConnection](image)

   **Task 4: Submit LOA and request cabling in the FastConnect location**

   At the FastConnect location, submit each LOA from the preceding task and request cabling for each cross-connect. Each LOA is valid for a limited time. The details are printed on the LOA.

   **Task 5: Check light levels**

   For each cross-connect's physical fiber cable, confirm from your side that the light levels are good (> -15 dBm). Don't proceed until they are.

   In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:
Task 6: Confirm that your interfaces are up

For each cross-connect's physical fiber cable, confirm your side of the interfaces are up. Don't proceed until they are.

In the Console, you can see the status of Oracle's side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).

Task 7: Activate each cross-connect

Summary: When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

Instructions:
