        Type = CreateGroupCursorDetails.TypeEnum.TrimHorizon,
        CommitOnGet = true
    }; CreateGroupCursorRequest createCursorRequest = new CreateGroupCursorRequest
    {
        StreamId = streamId,
        CreateGroupCursorDetails = createGroupCursorDetails
    }; CreateGroupCursorResponse groupCursorResponse = await streamClient.CreateGroupCursor(createCursorRequest);
    return groupCursorResponse.Cursor.Value;
}

private static async Task SimpleMessageLoop(StreamClient streamClient, string streamId, string initialCursor)
{
    string cursor = initialCursor;
    for (int i = 0; i < 10; i++)
    {
        GetMessagesRequest getMessagesRequest = new GetMessagesRequest
        {
            StreamId = streamId,
            Cursor = cursor,
            Limit = 10
        }; GetMessagesResponse getResponse = await streamClient.GetMessages(getMessagesRequest);
        // process the messages
        Console.WriteLine($"Read {getResponse.Items.Count}"stringstream); foreach (Message message in getResponse.Items)
        {
            Console.WriteLine($"(key) : {Encoding.UTF8.GetString(message.Value)}"sstreamstream);
        }
        // getMessages is a throttled method; clients should retrieve sufficiently large message
        // batches, as to avoid too many http requests.
        await Task.Delay(1000);
6. From the \( wd \) directory, run the following command:

```bash
dotnet run
```

7. You should see messages similar to the following:

```
Starting example for OSS Consumer
Starting a simple message loop with a group cursor
Creating a cursor for group exampleGroup, instance exampleInstance-1
Read 10
messagekey-0 : messageValue-0
messagekey-1 : messageValue-1
messagekey-2 : messageValue-2
messagekey-3 : messageValue-3
messagekey-4 : messageValue-4
messagekey-5 : messageValue-5
messagekey-6 : messageValue-6
messagekey-7 : messageValue-7
messagekey-8 : messageValue-8
messagekey-9 : messageValue-9
Read 10
```

**Note:**

If you used the Console to produce a test message, the key for each message is **Null**

---

**Next Steps**

See the following resources for more information:

1. OCI SDK for .NET on GitHub
2. OCI SDK for .NET examples

**SDK for Go Streaming Quickstart**

This quickstart shows you how to use the Oracle Cloud Infrastructure (OCI) SDK for Go on page 5400 and Oracle Cloud Infrastructure Streaming to publish and consume messages.

Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details. For more information about using the OCI SDKs, see the SDK Guides.

**Prerequisites**

1. To use the SDK for Go, you must have the following:
   
   - An Oracle Cloud Infrastructure account.
   
   - A user created in that account, in a group with a policy that grants the required permissions. This user can be yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
   
   - A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. For more information, see SDK configuration file.

2. Collect the Messages endpoint and OCID of a stream. See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. For the purposes of this quickstart, the stream should use a public endpoint...
and let Oracle manage encryption. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream.

3. Go installed locally. Follow these instructions if necessary. Ensure that go is in your PATH.

4. Visual Studio Code (recommended) or any other integrated development environment (IDE) or text editor.

5. Ensure that you have a valid SDK configuration file. For production environments, you should use instance principal authorization.

Producing Messages

1. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd.

2. Create a file named Producer.go in this directory.

3. Add the following code to Producer.go. Replace values of variables ociConfigFilePath, ociProfileName, ociStreamOcid, and ociMessageEndpoint in the following code snippet with the values applicable for your tenancy.

```go
package main

import (  
    "context"  
    "fmt"  
    "strconv"  
    "github.com/oracle/oci-go-sdk/v36/common"  
    "github.com/oracle/oci-go-sdk/v36/example/helpers"  
    "github.com/oracle/oci-go-sdk/v36/streaming"
)

const ociMessageEndpoint = "<stream_message_endpoint>"  
const ociStreamOcid = "<stream_OCID>"  
const ociConfigFilePath = "<config_file_path>"  
const ociProfileName = "<config_file_profile_name>"

func main() {  
    fmt.Println("Go oci oss sdk example producer")  
    putMsgInStream(ociMessageEndpoint, ociStreamOcid)
}

func putMsgInStream(streamEndpoint string, streamOcid string) {
    fmt.Println("Stream endpoint for put msg api is: " + streamEndpoint)

    provider, err :=
        common.ConfigurationProviderFromFileWithProfile(ociConfigFilePath, 
        ociProfileName, 
        )
    helpers.FatalIfError(err)

    streamClient, err :=
        streaming.NewStreamClientWithConfigurationProvider(provider, 
        streamEndpoint)
    helpers.FatalIfError(err)

    // Create a request and dependent object(s).
    for i := 0; i < 5; i++ {
        putMsgReq :=
            streaming.PutMessagesRequest{StreamId:
                common.String(streamOcid),
            PutMessagesDetails: streaming.PutMessagesDetails{
                // we are batching 2 messages for each Put Request
                Messages: []streaming.PutMessagesDetailsEntry{
                    {Key: []byte("key dummy-0-" + strconv.Itoa(i)), 
                        Value: []byte("value dummy-" + strconv.Itoa(i))},
                    {Key: []byte("key dummy-1-" + strconv.Itoa(i)), 
                        Value: []byte("value dummy-" + strconv.Itoa(i))},
                }
            }

        r, err :=
            streamClient.PutMessages(ctx, putMsgReq)
        if err != nil {
            fmt.Println("Failed to put message: " + err)
            continue
        }
    }
}
```
// Send the request using the service client
putMsgResp, err := streamClient.PutMessages(context.Background(), putMsgReq)
helpers.FatalIfError(err)

// Retrieve value from the response.
fmt.Println(putMsgResp)
}

4. Save `Producer.go`.

5. Open the terminal and `cd` to the `wd` directory, run the following commands, in order:
   
a. This command creates the `go.mod` file in the `wd` directory:

   ```
   go mod init oss_producer_example/v0
   ```

   b. This command installs the OCI SDK for Go and for Streaming:

   ```
   go mod tidy
   ```

   c. This command runs the example:

   ```
   go run Producer.go
   ```

6. Use the Console to see the latest messages sent to the stream to verify that production was successful.

**Consuming Messages**

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.

2. Add the following code to `Consumer.go`. Replace values of variables `ociConfigFilePath`, `ociProfileName`, `ociStreamOcid`, and `ociMessageEndpoint` in the following code snippet with the values applicable for your tenancy.

   ```go
   package main
   
   import ("context" "fmt"
            "github.com/oracle/oci-go-sdk/v36/common"
            "github.com/oracle/oci-go-sdk/v36/example/helpers"
            "github.com/oracle/oci-go-sdk/v36/streaming"
            )

   const ociMessageEndpoint = "<stream_message_endpoint>"
   const ociStreamOcid = "<stream_OCID>"
   const ociConfigFilePath = "<config_file_path>"
   const ociProfileName = "<config_file_profile_name>"

   func main() {
   fmt.Println("Go oci oss sdk example for consumer")
   getMsgWithGroupCursor(ociMessageEndpoint, ociStreamOcid)
   }

   func getMsgWithGroupCursor(streamEndpoint string, streamOcid string) {
   client, err := streaming.NewStreamClientWithConfigurationProvider(common.DefaultConfigProvider(), streamEndpoint)
   helpers.FatalIfError(err)
grpCursorCreateReq0 := streaming.CreateGroupCursorRequest{
    StreamId: common.String(streamOcid),
    CreateGroupCursorDetails: streaming.CreateGroupCursorDetails{
        Type: streaming.CreateGroupCursorDetailsTypeTrimHorizon,
        CommitOnGet: common.Bool(true),
        GroupName: common.String("Go-groupname-0"),
        InstanceName: common.String("Go-groupname-0-instancename-0"),
        TimeoutInMs: common.Int(1000),
    }
}

// Send the request using the service client
grpCursorResp0, err := client.CreateGroupCursor(context.Background(),
    grpCursorCreateReq0)
helpers.FatalIfError(err)

// Retrieve value from the response.
fmt.Println(grpCursorResp0)

simpleGetMsgLoop(client, streamOcid, *grpCursorResp0.Value)

func simpleGetMsgLoop(streamClient streaming.StreamClient, streamOcid string, cursorValue string) {
    for i := 0; i < 5; i++ {
        getMsgReq := streaming.GetMessagesRequest{
            Limit: common.Int(3),
            StreamId: common.String(streamOcid),
            Cursor: common.String(cursorValue)}

        // Send the request using the service client
        getMsgResp, err := streamClient.GetMessages(context.Background(),
            getMsgReq)
        helpers.FatalIfError(err)

        // Retrieve value from the response.
        if len(getMsgResp.Items) > 0 {
            fmt.Println("Key : " + string(getMsgResp.Items[0].Key) + ",
                value : " + string(getMsgResp.Items[0].Value) + ", Partition " +
                *getMsgResp.Items[0].Partition)
        }
        if len(getMsgResp.Items) > 1 {
            fmt.Println("Key : " + string(getMsgResp.Items[1].Key) + ",
                value : " + string(getMsgResp.Items[1].Value) + ", Partition " +
                *getMsgResp.Items[1].Partition)
        }
        cursorValue = *getMsgResp.OpcNextCursor
    }
}

3. Save Consumer.go.
4. Open the terminal and cd to the wd directory, run the following commands, in order:
a. This command creates the go.mod file in the wd directory:

    go mod init oss_consumer_example/v0

b. This command installs the OCI SDK for Go and for Streaming:

    go mod tidy

c. This command runs the example:

    go run Consumer.go
5. You should see messages similar to the following:

```python
Go oci oss sdk example for consumer
{ RawResponse={200 OK 200 HTTP/1.1 1 1 map[Access-Control-Allow-Credentials:[true] ... ] }
Key : , value : Example Test Message 0, Partition 0
Key : , value : Example Test Message 0, Partition 0
Key : , value : Example Test Message 0, Partition 0
Key : , value : Example Test Message 0, Partition 0
Key : , value : Example Test Message 0, Partition 0
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you used the Console to produce a test message, the key for each message is Null</td>
</tr>
</tbody>
</table>

See the following resources for more information:

1. OCI SDK for Go on GitHub
2. OCI SDK for Go examples

Developing with Kafka and Streaming

Oracle Cloud Infrastructure Streaming is compatible with most Kafka APIs, allowing you to use applications written for Kafka to send messages to and receive messages from the Streaming service without having to entirely rewrite your code. Usually, modifying configuration values is the only required update.

This section contains quickstart guides showing how to produce and consume messages using the following Kafka clients:

- Kafka Java client
- Kafka .NET client
- Kafka Python client

See Using Streaming with Apache Kafka on page 4898 for more information. Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details.

Kafka Java Client and Streaming Quickstart

This quickstart shows you how to use the Kafka Java client with Oracle Cloud Infrastructure Streaming to publish and consume messages.

See Using Streaming with Apache Kafka on page 4898 for more information. Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details.

**Prerequisites**

1. To use the Kafka Java client with Streaming, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
2. Collect the following details:
   - Stream OCID
   - Messages endpoint
   - Stream pool OCID
   - Stream pool FQDN
   - Kafka connection settings:
     - Bootstrap servers
     - SASL connection strings
     - Security protocol

See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream. Streams correspond to a Kafka topic.

3. JDK 8 or above installed. Ensure that Java is in your PATH.
4. Maven 3.0 or installed. Ensure that Maven is in your PATH.
5. Intellij (recommended) or any other integrated development environment (IDE).
6. Add the latest version of the Maven dependency or jar for Kafka Java SDK to your pom.xml as follows:

   ```xml
   <dependency>
   <groupId>org.apache.kafka</groupId>
   <artifactId>kafka-clients</artifactId>
   <version>2.8.0</version>
   </dependency>
   ```

7. Assuming wd as your working directory for your Java project of this example, your pom.xml will look similar to the following:

   ```xml
   <?xml version="1.0" encoding="UTF-8"?>
   <project xmlns="http://maven.apache.org/POM/4.0.0"
            xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    <modelVersion>4.0.0</modelVersion>
    <groupId>oci.example</groupId>
    <artifactId>StreamsExampleWithKafkaApis</artifactId>
    <version>1.0-SNAPSHOT</version>

    <properties>
      <maven.compiler.source>8</maven.compiler.source>
      <maven.compiler.target>8</maven.compiler.target>
    </properties>

    <dependencies>
      <dependency>
        <groupId>org.apache.kafka</groupId>
        <artifactId>kafka-clients</artifactId>
        <version>2.8.0</version>
      </dependency>
    </dependencies>

   </project>
   ```

8. Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. Refer to Working with Auth Tokens on page 3150 for auth token generation. If you created the stream and stream pool in OCI, you
are already authorized to use this stream according to OCI IAM, so you should create auth tokens for your OCI user.

**Note:**
OCI user auth tokens are visible only at the time of creation. Copy it and keep it somewhere safe for future use.

**Producing Messages**

1. Open your favorite editor, such as Visual Studio Code, from the directory `wd`. You should already have the Kafka SDK dependencies for Java as part of the `pom.xml` of your Maven Java project after you’ve met the prerequisites.

2. Create a new file named `Producer.java` in directory `wd` under the path `/src/main/java/kafka/sdk/oss/example/` with following code. Replace the values of variables in the code as directed by the code comments, namely `bootstrapServers` through `streamOrKafkaTopicName`. These variables are for Kafka connection settings which you gathered in the prerequisites.

```java
package kafka.sdk.oss.example;

import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.StringSerializer;
import java.util.Properties;

public class Producer {
    static String bootstrapServers = "<bootstrap_servers_endpoint>", // usually of the form cell-1.streaming.<region>.oci.oraclecloud.com:9092;
    static String tenancyName = "<OCI_tenancy_name>";
    static String username = "<your_OCI_username>";
    static String streamPoolId = "<stream_pool_OCID>";
    static String authToken = "<your_OCI_user_auth_token>"; // from step 8 of Prerequisites section
    static String streamOrKafkaTopicName = "<topic_stream_name>"; // from step 2 of Prerequisites section

    private static Properties getKafkaProperties() {
        Properties properties = new Properties();
        properties.put("bootstrap.servers", bootstrapServers);
        properties.put("security.protocol", "SASL_SSL");
        properties.put("sasl.mechanism", "PLAIN");
        properties.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG, StringSerializer.class.getName());
        properties.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG, StringSerializer.class.getName());

        final String value = "org.apache.kafka.common.security.plain.PlainLoginModule required
        username="" + tenancyName + "/"
        + username + "/"
        + streamPoolId + "\n"
        + "password="" + authToken + "\";
        properties.put("sasl.jaas.config", value);
        properties.put("retries", 3); // retries on transient errors and load balancing disconnection
        properties.put("max.request.size", 1024 * 1024); // limit request size to 1MB
        return properties;
    }
}
```
public static void main(String[] args) {
    try {
        Properties properties = getKafkaProperties();
        KafkaProducer producer = new KafkaProducer<>(properties);
        for (int i = 0; i < 10; i++) {
            ProducerRecord<String, String> record = new ProducerRecord<
                String, String>(streamOrKafkaTopicName, "messageKey" + i, "messageValue" + i);
            producer.send(record, (md, ex) -> {
                if (ex != null) {
                    System.err.println("exception occurred in producer for review :" + record.value() + ", exception is " + ex);
                    ex.printStackTrace();
                } else {
                    System.err.println("Sent msg to " + md.partition() + " with offset " + md.offset() + " at " + md.timestamp());
                }
            });
        }
        // producer.send() is async, to make sure all messages are sent we use producer.flush()
        producer.flush();
        producer.close();
    } catch (Exception e) {
        System.err.println("Error: exception " + e);
    }
}

3. From the wd directory, run the following command:

```
mvn clean install exec:java -Dexec.mainClass=kafka.sdk.oss.example.Producer
```

4. Use the Console to see the latest messages sent to the stream to verify that production was successful.

Consuming Messages

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.

2. Open your favorite editor, such as Visual Studio Code, from the directory wd under the path /src/main/java/kafka/sdk/oss/example/. You should already have the Kafka SDK dependencies for Java as part of the pom.xml of your Maven Java project after you've met the prerequisites.

3. Create a new file named Consumer.java in directory wd with following code. Replace the values of variables in the code as directed by the code comments, namely bootstrapServers through consumerGroupName.

```java
package kafka.sdk.oss.example;

import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
import java.util.Properties;

public class Consumer {
```
static String bootstrapServers = "<bootstrap_servers_endpoint>", // usually of the form cell-1.streaming.<region>.oci.oraclecloud.com:9092 ;
static String tenancyName = "<OCI_tenancy_name>";
static String username = "<your_OCI_username>";
static String streamPoolId = "<stream_pool_OCID>";
static String authToken = "<your_OCI_user_auth_token>"; // from step 8 of Prerequisites section
static String streamOrKafkaTopicName = "<topic_stream_name>"; // from step 2 of Prerequisites section
static String consumerGroupName = "<consumer_group_name>";

private static Properties getKafkaProperties(){
    Properties props = new Properties();
    props.put("bootstrap.servers", bootstrapServers);
    props.put("group.id", consumerGroupName);
    props.put("enable.auto.commit", "false");
    props.put("session.timeout.ms", "30000");
    props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG, "org.apache.kafka.common.serialization.StringDeserializer");
    props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG, "org.apache.kafka.common.serialization.StringDeserializer");
    props.put("security.protocol", "SASL_SSL");
    props.put("sasl.mechanism", "PLAIN");
    props.put("auto.offset.reset", "earliest");
    final String value = "org.apache.kafka.common.security.plain.PlainLoginModule required username=" + tenancyName + "/"
    + username + "/"
    + streamPoolId + "\n"
    + "password=\n"
    + authToken + "\n";)
    props.put("sasl.jaas.config", value);
    return props;
}

public static void main(String[] args) {
    final KafkaConsumer<Integer, String> consumer = new KafkaConsumer<>(getKafkaProperties());
    consumer.subscribe(Collections.singletonList(streamOrKafkaTopicName));
    ConsumerRecords<Integer, String> records = consumer.poll(10000);
    System.out.println("size of records polled is "+ records.count());
    for (ConsumerRecord<Integer, String> record : records) {
        System.out.println("Received message: (" + record.key() + ", " + record.value() + ") at offset "+ record.offset());
    }
    consumer.commitSync();
    consumer.close();
}

4. From the wc directory, run the following command:

mvn clean install exec:java -Dexec.mainClass=kafka.sdk.oss.example.Consumer
5. You should see messages similar to the following:

```
INFO related maven compiling and building the Java code
size of records polled is 3
Received message: (messageKey0, message value) at offset 1284
Received message: (messageKey0, message value) at offset 1285
Received message: (null, message produced using oci console) at offset 1286
```

**Note:**

If you used the Console to produce a test message, the key for each message is **Null**

**Next Steps**

See the following resources for more information:

1. Using Streaming with Apache Kafka on page 4898 and Using Kafka APIs on page 4899
2. Kafka Producer API Java Docs
3. Kafka Consumer API Java Docs

**Kafka .NET Client and Streaming Quickstart**

This quickstart shows you how to use the Kafka .NET client with Oracle Cloud Infrastructure Streaming to publish and consume messages. These examples use C# language.

See Using Streaming with Apache Kafka on page 4898 for more information. Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details.

**Prerequisites**

```
Note:

In this quickstart, we create and run a simple .NET console application by using Visual Studio Code and the .NET CLI. Project tasks, such as creating, compiling, and running a project are done by using the .NET CLI. If you prefer, you can follow this tutorial with a different IDE and run commands in a terminal.
```

1. To use the Kafka .NET client with Streaming, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.

2. Collect the following details:
   - Stream OCID
   - Messages endpoint
   - Stream pool OCID
   - Stream pool FQDN
   - Kafka connection settings:
     - Bootstrap servers
     - SASL connection strings
     - Security protocol
   
   See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream. Streams correspond to a Kafka topic.

3. Install .NET 5.0 SDK or later. Ensure that dotnet is set in your PATH environment variable.
4. Visual Studio Code (recommended) with the C# extension installed. For information about how to install extensions on Visual Studio Code, see VS Code Extension Marketplace.

5. Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. Refer to Working with Auth Tokens on page 3150 for auth token generation. If you created the stream and stream pool in OCI, you are already authorized to use this stream according to OCI IAM, so you should create auth tokens for your OCI user.

   ![Note]
   OCI user auth tokens are visible only at the time of creation. Copy it and keep it somewhere safe for future use.

6. Install the SSL CA root certificates on the host where you are developing and running this quickstart. The client uses CA certificates to verify the broker's certificate.

   For Windows, download the cacert.pem file distributed with curl (download cacert.pem). For other platforms, refer to Configure SSL trust store.

Producing Messages

1. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd.
2. Open the terminal and cd into the wd directory.
3. Create a C#.NET console application by running the following command in the terminal:

   ```
   dotnet new console
   ```

   You should see a message indicating that the application was created:
   ```
   The template "Console Application" was created successfully.
   ```

   This creates a Program.cs file with C# code for a simple "HelloWorld" application.

4. To reference the confluent-kafka-dotnet library in your new .NET Core project, run the following command in your project's directory wd:

   ```
   dotnet add package Confluent.Kafka
   ```

5. Replace the code in Program.cs in the wd directory with following code. Replace values of variables in the map ProducerConfig and the name of topic with the details you gathered in the prerequisites:

   ```
   using System;
   using Confluent.Kafka;

   namespace OssProducerWithKafkaApi
   {
       class Program
       {
           static void Main(string[] args)
           {
               Console.WriteLine("Demo for using Kafka APIs seamlessly with OSS");
               var config = new ProducerConfig {
                   BootstrapServers = "<bootstrap_servers_endpoint>", //usually of the form cell-1.streaming.
                   SslCaLocation = "<path\to\root\ca\certificate\*.pem>",
                   SecurityProtocol = SecurityProtocol.SaslSsl,
                   SaslMechanism = SaslMechanism.Plain,
                   SaslUsername = "<OCI_tenancy_name>/<your_OCI_username>/<stream_pool_OCID>",
               };
           }
       }
   }
   ```
Streaming

SaslPassword = 
"<your_OCI_user_auth_token">", // use the auth-token you created step 5 of
Prerequisites section

};

Produce("<topic_stream_name>", config); // use the name of the
stream you created

}

static void Produce(string topic, ClientConfig config)
{
    using (var producer = new ProducerBuilder<string,
string>(config).Build())
    {
        int numProduced = 0;
        int numMessages = 10;
        for (int i=0; i<numMessages; ++i)
        {
            var key = "messageKey" + i;
            var val = "messageVal" + i;

            Console.WriteLine("Producing record: {key} {val}");

            producer.Produce(topic, new Message<string, string>
            { Key = key, Value = val },
            (deliveryReport) =>
            {
                if (deliveryReport.Error.Code !=
ErrorCode.NoError)
                {
                    Console.WriteLine("Failed to deliver
message: {deliveryReport.Error.Reason}" );
                }
                else
                {
                    Console.WriteLine("Produced message to:
(deliveryReport.TopicPartitionOffset)" );
                    numProduced += 1;
                }
            });
        }
    }

producer.Flush(TimeSpan.FromSeconds(10));

Console.WriteLine("{numProduced} messages were produced
to topic {topic}" );

}

6. From the wd directory, run the following command:

dotnet run

7. Use the Console to see the latest messages sent to the stream to verify that production was successful.

Consuming Messages

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console
to produce a test message, or use the stream and messages we created in this quickstart.
2. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd.
3. Create a C# .NET console application by running the following command on the terminal:

```bash
dotnet new console
```

You should see a message indicating that the application was created:

```
The template "Console Application" was created successfully.
```

This creates a `Program.cs` file with C# code for a simple "HelloWorld" application.

4. To reference the `confluent-kafka-dotnet` library in your new .NET Core project, run the following command in your project’s directory `wd`:

```bash
dotnet add package Confluent.Kafka
```

5. Replace the code in `Program.cs` in the `wd` directory with following code. Replace values of variables in the map `ProducerConfig` and the name of `topic` with the details you gathered in the prerequisites:

```csharp
using System;
using Confluent.Kafka;
using System.Threading;

namespace OssKafkaConsumerDotnet
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Demo for using Kafka APIs seamlessly with OSS");

            var config = new ConsumerConfig {
                BootstrapServers = "<bootstrap_servers_endpoint>", //usually of the form cell-1.streaming.
                SslCaLocation = "<path\to\root\ca\certificate*.pem>",
                SecurityProtocol = SecurityProtocol.SaslSsl,
                SaslMechanism = SaslMechanism.Plain,
                SaslUsername = "<OCI_tenancy_name>/<your_OCI_username>/<stream_pool_OCID>",
                SaslPassword = "<your_OCI_user_auth_token>", // use the auth-token you created step 5 of Prerequisites section
            };

            Consume("<topic_stream_name>", config); // use the name of the stream you created
        }
        static void Consume(string topic, ClientConfig config)
        {
            var consumerConfig = new ConsumerConfig(config);
            consumerConfig.GroupId = "dotnet-oss-consumer-group";
            consumerConfig.AutoOffsetReset = AutoOffsetReset.Earliest;
            consumerConfig.EnableAutoCommit = true;

            CancellationTokenSource cts = new CancellationTokenSource();
            Console.CancelKeyPress += (_, e) => {
                e.Cancel = true; // prevent the process from terminating.
                cts.Cancel();
            };
```
using (var consumer = new ConsumerBuilder<string, string>(consumerConfig).Build())
{
    consumer.Subscribe(topic);
    try
    {
        while (true)
        {
            var cr = consumer.Consume(cts.Token);
            string key = cr.Message.Key == null ? "Null" :
            cr.Message.Key;
            Console.WriteLine($"Consumed record with key {key} and value {cr.Message.Value}");
        }
    }
    catch (OperationCanceledException)
    {
        //exception might have occurred since Ctrl-C was pressed.
    }
    finally
    {
        // Ensure the consumer leaves the group cleanly and final offsets are committed.
        consumer.Close();
    }
}

6. From the $wd$ directory, run the following command:

dotnet run

7. You should see messages similar to the following:

Demo for using Kafka APIs seamlessly with OSS
Consumed record with key messageKey0 and value messageValue0
Consumed record with key messageKey1 and value messageValue1
Consumed record with key Null and value Example test message

**Note:**
If you used the Console to produce a test message, the key for each message is Null

**Next Steps**

See the following resources for more information:

1. Using Streaming with Apache Kafka on page 4898 and Using Kafka APIs on page 4899
2. OCI SDK for .NET Streaming Quickstart

**Kafka Python Client and Streaming Quickstart**

This quickstart shows you how to use the Kafka Python client with Oracle Cloud Infrastructure Streaming to publish and consume messages.

See Using Streaming with Apache Kafka on page 4898 for more information. Refer to the Streaming Service Overview on page 4860 for key concepts and more Streaming details.
Prerequisites

1. To use the Kafka Python client with Streaming, you must have the following:
   - An Oracle Cloud Infrastructure account.
   - A user created in that account, in a group with a policy that grants the required permissions. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.

2. Collect the following details:
   - Stream OCID
   - Messages endpoint
   - Stream pool OCID
   - Stream pool FQDN
   - Kafka connection settings:
     - Bootstrap servers
     - SASL connection strings
     - Security protocol

   See Listing Streams and Stream Pools on page 4874 for instructions on viewing stream details. Refer to Creating Streams on page 4868 and Creating Stream Pools on page 4870 if you do not have an existing stream. Streams correspond to a Kafka topic.

3. Python 3.6 or later, with PIP installed and updated.

4. Visual Code Studio (recommended) or any other integrated development environment (IDE).

5. Install Confluent-Kafka packages for Python using the following command:

   ```bash
   pip install confluent-kafka
   ```

   Note:
   You can install these packages globally, or within a virtualenv. The librdkafka package is used by the confluent-kafka package and embedded in wheels for the latest confluent-kafka release. For more details, refer to the Confluent Python client documentation.

6. Install the SSL CA root certificates on the host where you are developing and running this quickstart. The client uses CA certificates to verify the broker's certificate.

   For Windows, download the cacert.pem file distributed with curl (download cacert.pem). For other platforms, refer to Configure SSL trust store.

7. Authentication with the Kafka protocol uses auth tokens and the SASL/PLAIN mechanism. Refer to Working with Auth Tokens on page 3150 for auth token generation. If you created the stream and stream pool in OCI, you are already authorized to use this stream according to OCI IAM, so you should create auth tokens for your OCI user.

   Note:
   OCI user auth tokens are visible only at the time of creation. Copy it and keep it somewhere safe for future use.

Producing Messages

1. Open your favorite editor, such as Visual Studio Code, from the empty working directory wd. You should already have confluent-kafka packages for Python installed for your current Python environment after you've met the prerequisites.

2. Create a file named Producer.py in the wd directory with the following code. Replace the config values in the map conf and the name of topic is the name of stream you created.

   ```python
   from confluent_kafka import Producer, KafkaError
   ```
if __name__ == '__main__':
    topic = "<topic_stream_name>"
    conf = {
        'bootstrap.servers': "<bootstrap_servers_endpoint>", # usually of the
        'security.protocol': 'SASL_SSL',
        'ssl.ca.location': '/path/on/your/host/to/your/cert.pem/'  # from
        # optionally instead of giving path as shown above, you can do 1. pip
        # install certifi 2. import certifi and
        # 3. 'ssl.ca.location': certifi.where()
        'sasl.mechanism': 'PLAIN',
        'sasl.username': '<OCI_tenancy_name>/<your_OCI_username>/stream_pool_OCID>',  # from step 2 of Prerequisites section
        'sasl.password': '<your_OCI_user_auth_token>',  # from step 7 of
        Prerequisites section
    }

    # Create Producer instance
    producer = Producer(**conf)
    delivered_records = 0

    # Optional per-message on_delivery handler (triggered by poll() or
    flush())
    # when a message has been successfully delivered or permanently failed
    delivery after retries.
    def acked(err, msg):
        global delivered_records
        # Delivery report handler called on
        # successful or failed delivery of message 

        if err is not None:
            print("Failed to deliver message: {}".format(err))
        else:
            delivered_records += 1
            print("Produced record to topic {} partition {} @ offset
            
            [{}].format(msg.topic(), msg.partition(), msg.offset()))

    for n in range(10):
        record_key = "messageKey" + str(n)
        record_value = "messageValue" + str(n)
        print("Producing record: {}\t{}").format(record_key, record_value)

        producer.produce(topic, key=record_key, value=record_value,
        on_delivery=acked)
        # p.poll() serves delivery reports (on_delivery) from previous
        produce() calls.
        producer.poll(0)

    producer.flush()
    print("{} messages were produced to topic {}!").format(delivered_records,
    topic)

3. From the wd directory, run the following command:

    python Producer.py

4. Use the Console to see the latest messages sent to the stream to verify that production was successful.
**Consuming Messages**

1. First, ensure that the stream you want to consume messages from contains messages. You could use the Console to produce a test message, or use the stream and messages we created in this quickstart.

2. Open your favorite editor, such as Visual Studio Code, from the empty working directory `wd`. You should already have `confluent-kafka` packages for Python installed for your current Python environment after you've met the prerequisites.

3. Create a file named `Consumer.py` in the `wd` directory with following code. Replace the config values in the map `conf` and the name of topic is the name of stream you created.

```python
from confluent_kafka import Consumer

if __name__ == '__main__':
    topic = "<topic_stream_name>"
    conf = {
        'bootstrap.servers': "<bootstrap_servers_endpoint>", #usually of the
        'security.protocol': 'SASL_SSL',
        'ssl.ca.location': '/path/on/your/host/to/your/cert.pem/' # from
        # optionally instead of giving path as shown above, you can do 1. pip
        # install certifi 2. import certifi and
        # 3. 'ssl.ca.location': certifi.where()
        'sasl.mechanism': 'PLAIN',
        'sasl.username': '
        "<OCI_tenancy_name>/<your_OCI_username>/<stream_pool_OCID>"', # from step
        'sasl.password': '
        "<your_OCI_user_auth_token>"', # from step 7 of
        
        # Create Consumer instance
        consumer = Consumer(conf)

        # Subscribe to topic
        consumer.subscribe([topic])

        # Process messages
        try:
            while True:
                msg = consumer.poll(1.0)
                if msg is None:
                    # No message available within timeout.
                    # Initial message consumption may take up to
                    # `session.timeout.ms` for the consumer group to
                    # rebalance and start consuming
                    print("Waiting for message or event/error in poll()")
                    continue
                elif msg.error():
                    print('error: {}'.format(msg.error()))
                else:
                    # Check for Kafka message
                    record_key = "Null" if msg.key() is None else
                    msg.key().decode("utf-8")
                    record_value = msg.value().decode("utf-8")
                    print("Consumed record with key " + record_key + " and
                    value " + record_value)
                except KeyboardInterrupt:
```

Oracle Cloud Infrastructure User Guide 4947
pass
finally:
    print("Leave group and commit final offsets")
    consumer.close()

4. From the wd directory, run the following command:

    python Consumer.py

5. You should see messages similar to the following:

    Waiting for message or event/error in poll()
    Waiting for message or event/error in poll()
    Consumed record with key messageKey0 and value messageValue0
    Consumed record with key messageKey1 and value messageValue1
    Consumed record with key Null and value Example test message

    Note:
    If you used the Console to produce a test message, the key for each
    message is Null

Next Steps

See the following resources for more information:

1. Using Streaming with Apache Kafka on page 4898 and Using Kafka APIs on page 4899
2. Confluent Kafka Python client
3. Confluent Kafka Python client GitHub

Streaming Metrics

You can monitor the health and performance of your streams by using metrics and alarms. For more information, see Monitoring on page 3458.

This topic describes the metrics emitted by the Streaming service using the metric namespace oci_streaming.

Overview of Streaming Metrics

The Streaming service provides metrics showing how the service is performing. These metrics are automatically available.

You can use these metrics to:

- Understand the produce/consume latency for a real-time application.
- Calculate and validate the price of service usage.
- Monitor changes in throughput over time.
- Check the time that the last message was consumed.
To view a default set of metrics charts in the Console, navigate to the Service Metrics page and then select the `oci_streaming` metric namespace.

**Available Metrics**

The following tables describe the available Streaming metrics.
You also can use the Monitoring service to create custom queries. Each metric includes the following dimensions:

**REGION**
- The *REGION* where the stream resides.

**RESOURCEID**
- The *OCID* of the stream.

### Producers

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>

<td>Total failed getMessage requests per stream measured over time.</td>
<td></td>
</tr>
</tbody>
</table>

### Stream Health

A healthy stream is a stream that is active: messages are received and consumed successfully. Writes to the service are durable. If you can produce to your stream, and if you get a successful response, then the stream is healthy.

After data is ingested, it is accessible to consumers for the configured retention period. If GetMessages API calls return elevated levels of internal server errors, the service isn't healthy.

A healthy stream also has healthy metrics:

- **Put Messages Latency** is low.
- **Put Messages Total Throughput** is close to 1 MB per second per partition.
- **Put Messages Throttled Records** is close to 0.
- **Put Messages Failure** is close to 0.
- **Get Messages Latency** is low.
- **Get Messages Total Throughput** is close to 2 MB per second per partition.
- **Get Messages Throttled Requests** is close to 0.
- **Get Messages Failure** is close to 0.

### Suggested Alarms

#### Producers

For producers, consider setting alarms on the following metrics:

- **Put Messages Latency**: An increase in latency means that the messages are taking longer to publish, which could indicate network issues.
• **Put Messages Total Throughput:**
  - An increase in total throughput could indicate that the 1 MB per second per partition limit will be reached, and that event will trigger the throttling mechanism.
  - A decrease could mean that the client producer is having an issue or is about to stop.
• **Put Messages Throttled Records:** It's important to get notified when messages are throttled.
• **Put Messages Failure:** It's important to get notified if put messages start failing.

**Consumers**

For consumers, consider setting similar alarms based on the following metrics:

• Get Messages Latency
• Get Messages Total Throughput
• Get Messages Throttled Requests
• Get Messages Failure

**Using the Console**

To view default producer metrics
1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click a stream to view its details.
3. Under Resources, click Produce Monitoring Charts.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default consumer metrics
1. Open the navigation menu and click Analytics & AI. Under Messaging, click Streaming.
2. Click a stream to view its details.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

• Monitoring API for metrics and alarms
• Notifications API for notifications (used with alarms)

**Troubleshooting Streaming**

This topic covers various issues related to Oracle Cloud Infrastructure Streaming and how you can address them. Details about common API errors that all services return are detailed in API Errors on page 5532.

**Troubleshooting Access and Permissions**

**Request returns a "Processing exception while communicating" message and a -1 error**

When you use the Streaming client to send a request, you might see the following error message:

```
Caused by: com.oracle.bmc.model.BmcException: (-1, null, false) Processing exception while communicating to:
```
This error is related to the client. The Streaming service doesn't send it, which means that the request never made it to the service.

**Request returns a NotAuthorizedOrNotFound message and a 404 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
com.oracle.bmc.model.BmcException: (404, NotAuthorizedOrNotFound,false) Unknown stream ocid1.stream.oc1.phx.exampleuniqueID.
(opc-request-id: <opc_request_id>)
```

A 404 error usually means that the needed resource isn't found or that you don't have access to it. An example is when the stream-push policy is missing, or the stream has been deleted or is not accessible. Ensure that all the permissions are correctly set.

**Request returns a "Not Found" message and a 404 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
compartmentId=ocid1.tenancy.oc1..exampleuniqueID&limit=10&page=&sortBy=TIMECREATED&sortOrder=desc&lifecycleState=",
redirected: false, status: 404, ok: false, statusText: "Not Found", headers: Headers, bodyUsed: false }
```

This error indicates a permission-related issue. Ensure that all the permissions are correctly set.

**Request returns a "The following tag namespaces/keys are not authorized or not found" message**

This error suggests that there is a tag on the stream that your user is not authorized to use. Remove the tag or authorize the user. See Resource Tags on page 239 for more information.

**Request returns a "bad handshake" message and a 104 error**

When you send a request to Streaming, you might see an error message similar to the following:

```
SSLError(SSLError("bad handshake: SysCallError(104, 'ECONNRESET'.))
```

This error typically means that your system doesn't have the CA that the certificates were signed by. You may need to install the ca-certificates package on your host or pull the CA certificate from the target endpoint and import it into your system trust store by using `update-ca-trust` command.

**Troubleshooting Limits and Throttling**

Limits on Streaming Resources on page 4864 describes the service and resource limits that might result in the following scenarios.
Partial failures

Streaming supports partial failures caused by throttling, per partition. When a partial failure occurs, the service returns a 200 status code and indicates the failure in the response payload.

If an entire request is throttled, Streaming returns a 429 status code.

Request returns a "Too many requests message" and a 429 error

When you send a request to Streaming, you might see an error message that includes the following:

(429, Too many requests)

This error is caused by the throttling mechanism in the service. It indicates that too many requests per second per partition are being received.

If this error occurs on the producer side, ensure that the total data write rate of 1 MB per second per partition is not exceeded by:

- Lowering the amount of requests per second.
- Decreasing message size by batching.

If this error occurs on the consumer side, ensure that:

- The cursor uses commitOnGet (true).
- You reduce the number of requests, keeping in mind that the maximum data read rate is 5 GET requests per second per partition per consumer group.
- The limit is set for each GET request.

Request returns a "Request size is limited to 1 MiB" message and a 400 error

When you send a request to Streaming, you might see an error message similar to the following:

Exception in thread "main" com.oracle.bmc.model.BmcException: (400, InvalidParameter, false) Request size is limited to 1 MiB. (opc-request-id: <opc_request_id>)

at com.oracle.bmc.http.internal.ResponseHelper.throwIfNotSuccessful (ResponseHelper.java:124)
  at com.oracle.bmc.streaming.internal.http.PutMessagesConverter$1.apply (PutMessagesConverter.java:54)
  at com.oracle.bmc.streaming.StreamClient.putMessages (StreamClient.java:466)

This error occurs because the PutMessages call sent to the service is too large. The size must be less than or equal to 1 MB.

Stream creation fails with a "You exceed the number of allowed partitions" message

This error occurs when you try to create more partitions than your tenancy is allowed. You can request an increase.
Troubleshooting Production and Consumption

Messages do not appear in the Console after publishing them to a stream

You must click the Refresh button to show the first 100 messages. See Using the Console to show recent messages for more information.

Because streams using private endpoints are not accessible from the internet, their messages do not display in the Console.

Consumers receive a "The cursor is outside the retention period and is now invalid" message and a 400 error

When requesting messages from a stream, a consumer might see an error message like the following:

```
(400, InvalidParameter, false) The cursor is outside the retention period and is now invalid
```

This error means that the offsets stored for one or more of your partitions has fallen behind the trim horizon. Some data loss has occurred, and the data that was produced to the stream is no longer available for consumption. Data that is outside the retention period can’t be recovered. At this point, the administrator must decide the best course of action, given the use case.

This error can happen if you are not committing offsets regularly, or if your consumer falls behind constantly. For more information, see Getting Messages on page 4892.

A manual call to the UpdateGroup method is required to reset the cursor for the instances within a consumer group.

Consumers receive a "Trying to commit unreserved partition" message and a 400 error

When requesting messages from a stream, a consumer that is part of a consumer group might see an error message like the following:

```
(400, InvalidParameter, false) Trying to commit unreserved partition
```

This error means that the consumer tried to commit an offset for a partition that was not reserved for that particular consumer. This error can happen when the consumer appears to have timed out, partitions are rebalanced to another consumer, and then the consumer tries to commit offsets. The default timeout is 30 seconds for a consumer. Timeouts for a consumer can be extended by sending a heartbeat. See Consuming as a Group on page 4894 for more information.

This error can also occur when pipelining (commitOnGet=false) and no commits occurred for a significant amount of time (more than 30 seconds).

Request fails with an "Unable to parse JSON body" message and a 400 error

When you send a request to Streaming, you might see an error message similar to the following:

```
(400, Unable to parse JSON body)
```

This error generally means that the JSON body contains an entry in an invalid format.

Ruby SDK requests fail with an "Unable to parse JSON body" message and a 400 error

When you send a request to Streaming using the Ruby SDK, you might see an error message similar to the following:

```
Unable to parse JSON body, 'status': 400, 'code': 'InvalidParameter'
```
The Ruby SDK doesn't do any encoding. You must use `Base64` to encode the strings that are sent in the key and value fields. For example:

```ruby
msgs <<= OCI::Streaming::Models::PutMessagesDetailsEntry.new(key: Base64.strict_encode64(k), value: Base64.strict_encode64(record.to_json))
if msgs.length > 0
  res = @oss_client.put_messages(@stream_ocid, OCI::Streaming::Models::PutMessagesDetails.new(messages: msgs))
end
```

**Troubleshooting Streaming and Kafka**

**Kafka Connect configuration creation fails**

When you try to create a Kafka Connect configuration, you might see an error message like the following:

```
You are not authorized to create Kafka Connect Configurations
```

To create a Kafka Connect configuration, you need to create the correct IAM policy in your tenancy. For example:

```
Allow group xyz to manage connect-harnesses in tenancy
```

See [Managing Kafka Connect Configurations](#) on page 4903 for more information.
Chapter 46

Tagging

This chapter explains how to use tags to add metadata to your resources.

Tagging

Use Tagging to add metadata to resources, which enables you to define keys and values and associate them with resources. You can use the tags to organize and list resources based on your business needs.

Tagging Overview

Oracle Cloud Infrastructure Tagging allows you to add metadata to resources, which enables you to define keys and values and associate them with resources. You can use the tags to organize and list resources based on your business needs.

Caution:

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

How Tagging Works

The Tagging service provides two ways for you to add tags to resources. Each approach offers a different type of tag for you to work with:
Tagging

- Defined tags - tag administrators manage resource metadata.
- Free-form tags - unmanaged metadata applied to resources by users.

One approach involves a tag administrator creating and managing all the tags that users apply to resources. Use IAM policy to select tag administrators, who can create tags. Grant all others in the tenancy only the ability to apply tags. The benefit to this approach is that you can create and manage the keys and values used to tag resources. You can then avoid typos that weaken automation based on tags and provide better reporting based on tags.

The other approach is to allow users to add tags to resources. Each tag is edited or applied at the resource by you or a user creating or modifying a resource. You can use both types of tags throughout your tenancy.

Most of the Tagging features require defined tags. "Tag" is used generically to refer to defined tags. To create metadata that you can trust to manage resources and collect data, use defined tags. With defined tags, the following scenarios become possible:

- Create default tags that are applied to all resources in compartments. See Managing Tag Defaults on page 4980.
- Specify that users must apply tags to resources to successfully create resources in compartments.
- If you make a typo using defined tags, correct it by editing or even deleting the tag. When you delete a defined tag, Oracle removes the key and any value for that tag from all resources. See Deleting Tag Key Definitions and Namespaces on page 4970.
- Associate a list of predefined values for a defined tag. See Using Predefined Values on page 4978.
- Use system variables to generate values for defined tags or tag defaults automatically. See Using Tag Variables on page 4979.
- Track costs based on tags. Use of defined tags is recommended for this use case.
- Set budgets using cost-tracking tags to be alerted when your spending reaches specified levels. See Using Cost-Tracking Tags on page 4976.

Tagging Concepts

Here's a list of the basic tagging concepts:

**TAG NAMESPACE**

You can think of a tag namespace as a container for your tag keys. It consists of a name and zero or more tag key definitions. Tag namespaces are not case sensitive and must be unique across the tenancy. The namespace is also a natural grouping to which administrators can apply policy. One policy on the tag namespace applies to all the tag definitions contained within that namespace.

**TAG KEY**

The name you use to refer to the tag. Tag keys are case insensitive. For example, "mytagkey" duplicates "MyTagKey". You must create tag keys for defined tags in a namespace. Each tag key must be unique within a namespace.

**TAG VALUE TYPE**

The tag value type specifies the data type allowed for the value. Currently two data types are supported: string and a list of strings.

**KEY DEFINITION**

A key definition defines the schema of a tag and includes a namespace, tag key, and tag value type.

**TAG VALUE**

The tag value is the value that the user applying the tag adds to the tag key. Tag values support two data types: strings and lists of strings. You can define a list of values for the user to select from when you define the tag key, or you can allow the user to enter any value when the tag is applied to the resource. If you select a string tag value when you create the key, the user can leave the value blank when they apply the key.

In the example:

Operations.CostCenter="42"
Tagging

Operations is the namespace, CostCenter is the tag key, and 42 is the tag value.

TAG (OR DEFINED TAG)

A tag is the instance of a key definition that is applied to a resource. It consists of a namespace, a key, and a value. “Tag” is used generically to refer to defined tags.

FREE-FORM TAG

A basic metadata association that consists of a key and a value only. Free-form tags have limited functionality. See Understanding Free-form Tags on page 4975.

COST TRACKING

Cost tracking is a feature available with defined tags. This feature is being deprecated and is currently only relevant for use with Budgets. To understand when you need to designate a tag as a cost-tracking Tag, see Using Cost-Tracking Tags on page 4976.

TAG DEFAULT

Tag defaults let you specify tags that are applied automatically to all resources in a specific compartment at the time of creation, regardless of the permissions of the user who creates the resource. See Managing Tag Defaults on page 4980.

RETIRE

You can retire a tag key definition or a tag namespace. Retired tag namespaces and key definitions can no longer be applied to resources. However, retired tags are not removed from the resources to which they have already been applied. You can still specify retired tags when searching, filtering, reporting, and so on.

REACTIVATE

You can reactivate a tag namespace or tag key definition that has been retired to reinstate its usage in your tenancy.

TAG VARIABLE

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Tag Variables on page 4979.

PREDEFINED VALUES

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Predefined Values on page 4978.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators: Use the following topics to find example of IAM policy for Tagging:

- Required Permissions for Working with Defined Tags on page 4968
- Required Permissions for Working with Tag Defaults on page 4981
- Required Permissions for Working with Free-form Tags on page 4976
Region Availability

Tagging is currently available in all regions.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Limits on Tags

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

- Tags per tenancy: unlimited
- Tags per resource: 10 free-form tags and 64 defined tags
- Tags enabled for cost-tracking: 10 per tenancy (includes both active and retired tags)
- Total tag data size: 5 K (JSON). The total tag data size includes all tag data for a single resource (all applied tags and tag values). Sizing is per UTF-8.
- Number of pre-defined values for a tag key: 100 per list

Tip:

Watch a video to introduce you to the concepts and features of tagging: Introduction to Tagging.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing tag namespaces and tags. For more policy samples specific to working with tags and tag namespaces, see Required Permissions for Working with Defined Tags on page 4968.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

Overview of Tags and Tag Namespaces

Defined tags provide more features and control than free-form tags. Before you create a defined tag key, you first set up a tag namespace for it. You can think of the tag namespace as a container for a set of tag keys. When you create
the tag key definition, you must choose the type of value (which also determines how the user applying the tag adds the value):

- You can leave it empty so that a user can fill in the value.
- You can create a list of values so that the user must choose from those values.

To apply a defined tag to a resource, a user first selects the tag namespace, then the tag key within the namespace, and then they can assign the value. If the tag key contains a blank value, the user can type in a value or leave it blank. If the tag key contains a list, the user must select a value from the list.

Defined tags support policy to allow you to control who can apply your defined tags. The tag namespace is the entity to which you can apply policy. Administrators can control which groups of users are allowed to use each namespace.

The following diagrams illustrate defined tags. Two tag namespaces are set up: Operations and HumanResources. The tag keys are defined in the namespaces. Within each namespace, the tag keys must be unique, but a tag key name can be repeated across namespaces. In the example, both namespaces include a key named "Environment."

![Tagging Diagrams](image)

The first instance is tagged with two tags from the Operations tag namespace, indicating that it belongs to the Operations production environment and the Operations project "Alpha". The second instance is tagged with tags from both the HumanResources tag namespace and the Operations tag namespace, indicating that it belongs to the HumanResources "Production" environment, the HumanResources cost center "42", and also the Operations project "Beta".

**Working with Defined Tags**

You must set up the tag namespace and tag keys in your tenancy before users can apply a defined tag to a resource. As part of the set up process, you must also grant permissions to the user groups that needs to use the namespace.
Tagging

**Note:**

Tag namespaces and tag key definitions beginning with "oci" and "orcl" are reserved for internal use.

Features of defined tags include:

- Consist of a tag namespace, a key, and a value.
- The tag namespace and tag key definition must be set up in your tenancy before users can apply a defined tag to a resource.
- You can create the tag key with either a tag value type of string (for the user to add a value or leave blank) or a list of values (from which the user must choose).
- When applying a defined tag, users select from the list of tag keys.
- Users can apply a defined tag during resource creation or to an existing resource.
- Defined tag keys are case insensitive.
- Defined tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.
- You can use tag variables.
- You can create a list of predefined variables to associate with a tag key. Users that apply the tag to a resource must select a value from the list you create.

**Required Permissions for Working with Defined Tags**

To apply, update, or remove defined tags for a resource, a user must be granted permissions on the resource and permissions to use the tag namespace.

Users must be granted `use` access on the *tag namespace* to apply, update, or remove a defined tag for a resource.

Some example policies for tag namespaces:

To allow a group to simply view the tag namespaces in the tenancy (or in a compartment) requires `inspect` access:

```plaintext
Allow group GroupA to inspect tag-namespaces in tenancy
```

**Important:**

To apply tags to a resource when using the Console, a user must have permissions to `inspect tag-namespaces in tenancy`. If the user does not have this permission, the list of tag namespaces cannot be presented to the user in the dialog menu.

To allow a group to read the tag definitions contained in tag namespaces requires `read` access:

```plaintext
Allow group GroupA to read tag-namespaces in tenancy
```

To allow a group to apply, update, or remove a defined tag for a resource requires the `use` access on the tag namespace:

```plaintext
Allow group GroupA to use tag-namespaces in tenancy
```

To allow usage of a specific tag namespace or namespaces, use a `where` clause with the `target.tag-namespace.name` variable. For example:

```plaintext
Allow group GroupA to use tag-namespaces in tenancy where target.tag-namespace.name='Operations'
```

or to specify multiple tag namespaces:

```plaintext
Allow group GroupA to use tag-namespaces in tenancy where any {target.tag-namespace.name='Operations', target.tag-namespace.name='HumanResources'}
```
To manage tag namespaces and the tag definitions in them, requires manage access:

```
Allow group GroupA to manage tag-namespaces in tenancy
```

In addition to the permissions to work with the tag namespace, to apply or remove defined tags on a resource you must have the update permission for the resource. For many resources, the update permission is granted with the use verb. For example, users who can use instances in CompartmentA can also apply, update, or remove defined tags for instances in CompartmentA.

Some resources don't include the update permission with the use verb. To allow a group to apply, update, or remove defined tags for these resources without granting the full permissions of manage, you can add a policy statement to grant only the `<RESOURCE>_UPDATE` permission from the manage verb. For example, to allow a group NetworkUsers to work with defined tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA
Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_UDPATE'
```

The inspect permission for a resource grants permissions to view defined tags for that resource. For example, users who can inspect instances can also view any defined tags applied to the instance.

For information about resource permissions, see Policy Reference on page 2837.

**Example Scenario**

Your company has an Operations department. Within the Operations department are several cost centers. You want to be able to tag resources that belong to the Operations department with the appropriate cost center.

1. Create a tag namespace definition called Operations.
2. In the Operations namespace, create a tag key definition called CostCenter.

Alice already belongs to the group InstanceLaunchers. Alice can manage instances in CompartmentA. You want Alice and other members of the InstanceLaunchers group to be able to apply the Operations.CostCenter tag to instances in CompartmentA.

To grant the InstanceLaunchers group access to the Operations tag namespace (and only the Operations tag namespace), add the following statements to the InstanceLaunchers policy:

```
Allow group InstanceLaunchers to use tag-namespaces in compartment CompartmentA where target.tag-namespace.name='Operations'
```

Alice can now apply the Operations.CostCenter tag to resources in CompartmentA.

**Inheriting Compartment Tags**

The child compartments and their resources in metering services such as Cost Analysis, Usage Reports, and Budget, inherit the defined tags applied to a compartment. However, if there is a conflict between the inherited tags and the tags applied directly to the resources or the child compartments, the tags applied to the resources take precedence over the inherited tags. You can dynamically apply defined tags to resources in a compartment.

For example, consider a tenancy called TenancyA with `TagKey1=TagValueP` and a compartment called Compartment P with `TagKey3=TagValueQ` and `TagKey4=TagValueS`. You have a compute instance in Compartment P with `TagKey2=TagValueR, TagKey3=TagValueT`. When the tag inheritance logic is applied, the following tags are applied to the Compute instance: `TagKey2=TagValueR, TagKey3=TagValueT, TagKey4=TagValueS`. The resource has inherited `TagKey4=TagValueS` from the parent compartment. However, the `TagKey3` applied to the compute instance overrides the `TagKey3` value applied to the parent compartment.

You can filter using inherited tags in Cost Analysis, create budgets with inherited tags, and view these tags in the Usage Reports.
Retiring Key Definitions and Namespace Definitions

You can retire a tag key definition or a tag namespace definition.

When you retire a tag key definition, you can no longer apply it to resources. However, the tag is not removed from the resources that it was applied to. The tag still exists as metadata on those resources and you can still call the retired tag in operations (such as listing, sorting, or reporting).

**Important:**

Retiring a tag stops cost tracking for the tag, but if you do not disable the cost-tracking option on the tag key definition, the retired tag continues to count against your maximum of 10 cost-tracking tags for your tenancy. Disable cost tracking before you retire the tag key definition. To disable cost-tracking after a tag is retired, you must reactivate the tag key definition. You can't update tag key definitions that are in the retired state.

Reactivating Tag Key Definitions and Namespace Definitions

You can reactivate retired tag key definitions and tag namespace definitions.

- When you reactivate a tag key, it is again available for you to apply to resources.
- When you reactivate a tag namespace, you can create new tag key definitions in that namespace. However, if you want to use any of the tag key definitions that were retired with the namespace, you must explicitly reactivate each tag key definition.

Moving Tag Namespaces to a Different Compartment

You can move a tag namespace to a different compartment. The tag namespace can be active or retired when you move it. When you move the tag namespace, all its tag key definitions are moved along with it.

This functionality is useful if you need to reorganize your compartment hierarchy, or if you need to delete a compartment that contains resources. A retired tag namespace, even though it is retired, is still an existing resource. Moving the retired tag namespace to a different compartment can enable you to delete its original containing compartment.

To move a tag namespace, you must be allowed to manage tag-namespaces in both compartments.

See the procedure To move a tag namespace to a different compartment on page 4971.

Deleting Tag Key Definitions and Namespaces

You can delete tag key definitions and tag namespaces.

When you delete a tag key definition, you begin a process that removes the tag from all resources in your tenancy. These things happen immediately:

- If the tag was a cost-tracking tag, it no longer counts against your 10 cost-tracking tags limit, whether you first disabled it or not.
- If the tag was used with dynamic groups, none of the rules that contain the tag will be evaluated against the tag.

The delete action is asynchronous and initiates a work request. Once you start the delete operation, the state of the tag changes to deleting, and tag removal from resources begins. This process can take up to 48 hours depending on the number of resources that were tagged as well as the regions in which those resources reside. When all tags are removed, the state changes to deleted. You cannot restore a deleted tag. After the tag state changes to Deleted, you can use the same tag name again.

To delete a tag key definition, you must first retire it. To delete a tag namespace, you must first retire the tag namespace. When you retire a tag namespace that contains tag key definitions, all the tag keys in the namespace are retired, allowing you to delete the tag namespace.
Using the Console
Managing Tag Namespaces

To create a tag namespace

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   
   A list of the tag namespaces in your current compartment is displayed.

2. Click Create Namespace Definition.

3. Enter the following:
   
   • Create in Compartment: The compartment in which you want to create the namespace definition.
   • Namespace Definition Name: A unique name for this set of tags. The name must be unique within your tenancy. Tag namespace is case insensitive. You cannot change this value later. Avoid entering confidential information.
   • Description: A friendly description. You can change this value later if you want to.

4. Click Create Namespace Definition.

To update a tag namespace's description

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   
   A list of the tag namespaces in your tenancy is displayed.

2. Click the tag namespace you want to update.
   
   The namespace's details are displayed. The description is displayed under the namespace's name.

3. Click the pencil next to the description.

4. Edit the description and save it. Avoid entering confidential information.

To retire a tag namespace

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   
   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace you want to retire.
   
   The namespace's details are displayed.

3. Click Retire Tag Namespace.

4. Confirm when prompted.

To reactivate a tag namespace

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   
   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace you want to reactivate.
   
   The namespace's details are displayed.

3. Click Reactivate Tag Namespace.

4. Confirm when prompted.

To move a tag namespace to a different compartment

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   
   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace you want to move.
   
   The namespace's details are displayed.
3. Click **Move Tag Namespace**.
4. Select the **Target Compartment** that you want to move the tag namespace to.
5. Click **Move Tag Namespace**.

*To delete a tag namespace*

To delete a tag namespace, you must first *retire it*.

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that you want to delete.
   The namespace’s details are displayed.
3. Click **Delete Tag Namespace**.
   
   **Tip:**
   If the **Delete Tag Namespace** option is unavailable, first *retire* your tag namespace.

4. Confirm when prompted.

*Managing Key Definitions*

**To create a key definition**

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click **Create Tag Key Definition**.
4. Enter the following:
   
   • **Tag Key**: Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   • **Description**: Enter a friendly description.
   • **Cost-tracking**: Select the check box to enable this tag for cost tracking. You have a limit of 10 *Using Cost-Tracking Tags* on page 4976 in your tenancy.
5. Under **Tag Value Type**, choose one of the following:
   
   • **Static Value**: Specifies that the user applying the tag can specify any value for this key.
   • **A List of Values**: Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can’t have blank lines or duplicate values.
6. Click **Create Tag Key Definition**.

**To update a tag key definition**

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click **Edit Tag Key Definition**.

   The edit dialog appears.

   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.

   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.

   You have a limit of 10 Using Cost-Tracking Tags on page 4976 in your tenancy.

5. Make your changes and save it.

To retire a tag key definition

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to retire.

   A list of the tag key definitions is displayed.

3. Select the tag key definition you want to retire. To retire multiple tag key definitions at the same time, select all of the tag key definitions that you want to retire.

   **Important:**

   If the tag is a cost-tracking tag, disable the cost-tracking flag. If you don't disable cost-tracking, this tag will still count against your tenancy maximum of 10 cost-tracking tags, even after it is retired. For more information, see Using Cost-Tracking Tags on page 4976.

4. Click **Retire**.

5. Confirm when prompted.

To reactivate a tag key definition

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to reactivate.

   A list of the tag key definitions is displayed.

3. Select the tag key definition you want to reactivate. To reactivate multiple tag key definitions at the same time, select all of the tag key definitions that you want to reactivate.

4. Click **Reactivate**.

5. Confirm when prompted.

To delete a tag key definition

To delete a tag key definition, you must first retire it.

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to delete.

   A list of the tag key definitions is displayed.

3. Select the retired tag key definition you want to delete. To delete multiple tag key definitions at the same time, select all of the tag key definitions that you want to delete. You can delete up to five tag key definitions at the same time.
4. Click **Delete**.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the <strong>Delete</strong> option is unavailable, first <strong>retire</strong> your tag key definition.</td>
</tr>
</tbody>
</table>

5. Confirm when prompted.

After you confirm, the state changes to Deleting. Track the progress of the operation using the work request.

**To track the progress of the delete operation**

a. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

b. Click the tag namespace that includes the tag key definition you deleted.

   A list of the tag key definitions is displayed.

c. Click **Work Requests**.

   The work requests for deleted tag definitions are displayed.

**To monitor a work request for a deleted tag**

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you deleted.

   A list of the tag key definitions is displayed.

3. Click **Work Requests**.

   The work requests for deleted tag definitions are displayed.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage tag namespaces:

- `GetTagNamespace`
- `ListTagNamespaces`
- `CreateTagNamespace`
- `UpdateTagNamespace` - Use to retire or reactivate a tag namespace.
- `CascadeDeleteTagNamespace` - Use to delete a tag namespace and all of its tag key definitions. You must first retire the tag namespace.
- `DeleteTagNamespace` - Use to delete the tag namespace. You must first delete all of the tag key definitions contained in the tag namespace.
- `ChangeTagNamespaceCompartment`

Use these API operations to manage tag key definitions:

- `GetTag` - gets the tag key definition
- `ListTags` - lists tag key definitions
- `ListCostTrackingTags` - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)
- `CreateTag` - creates a tag key definition
- `UpdateTag` - updates the tag key definition (use this operation to retire or reactivate a tag key)
- `DeleteTag` - deletes the tag key definition
- `BulkDeleteTags` - deletes multiple tag key definitions within a tag namespace
Use these API operations to manage work requests spawned by the DeleteTag operation:

- ListTaggingWorkRequests
- ListTaggingWorkRequestErrors
- ListTaggingWorkRequestLogs
- GetTaggingWorkRequest

**Understanding Free-form Tags**

Oracle Cloud Infrastructure supports two kinds of tags: free-form tags and defined tags. This topic describes free-form tags.

Because free-form tags are limited in functionality, Oracle recommends that you only use them to try out the tagging feature in your system when you are first getting started with tagging. For more information about the features and limitations of free-form tags, see Working with Free-form Tags on page 4975.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for free-form tags. For more policy samples specific to working with free-form tags, see Required Permissions for Working with Free-form Tags on page 4976.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

**Overview of Free-form Tags**

Free-form tags consist of a key and a value, for example:

Environment: Production

where "Environment" is the key and "Production" is the value.

You can apply multiple free-form tags to a single resource, up to the limit.

**Working with Free-form Tags**

Free-form tags consist of a key-value pair and have limited features. To experience the full feature set of tagging, use defined tags.

Features of free-form tags include:

- Consist of a key and a value. Free-form tags do not belong to a namespace.
- You can apply free-form tags during resource creation or to an existing resource.
- Free-form tag keys are case sensitive. For example, "Project" and "project" are distinct keys.
- Free-form tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.

Limitations of free-form tags include:

- When applying a free-form tag, you can't see a list of existing free-form tags, so you don't know what tags and values have already been used.
- You can't see a list of existing free-form tags in your tenancy.
- You can't use free-form tags to control access to resources. That is, you can't include free-form tags in IAM policies.
- You can't use tag variables in free-form tags.
- You can't use predefined values in free-form tags.
**Tagging**

**Required Permissions for Working with Free-form Tags**

To apply, update, or remove free-form tags for a resource, you must have the update permission on the resource. For many resources, the update permission is granted with the use verb. For example, users who can use instances in CompartmentA can also apply, update, or remove free-form tags for instances in CompartmentA.

Some resources do not include the update permission with the use verb. To allow a group to apply, update, or remove free-form tags for these resources without granting the full permissions of manage, you can add a policy statement to grant only the <RESOURCE>_UPDATE permission from the manage verb. For example, to allow a group NetworkUsers to work with free-from tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA
Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_UPDATE'
```

The inspect verb for a resource grants permissions to view free-form tags for that resource. Therefore, users who can inspect instances in CompartmentA can also view any free-form tags applied to the instance.

For information about resource permissions, see Policy Reference on page 2837.

**Using Cost-Tracking Tags**

Cost-tracking tags are only relevant when you set budgets.

- You can only use a cost-tracking tag with defined tags.
- You cannot specify free-form tags as cost-tracking tags.
- You do not have to designate a tag as cost-tracking, in order for it to be exposed in Cost Analysis or Cost and Usage Reports.

**Required IAM Policy**

Cost tracking is a feature of defined tags. To allow users to work with cost tracking, use the same IAM policy for working with tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags on page 4968.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

**Working with Cost-Tracking Tags**

Suppose you have a defined tag key definition called Finance.CostCenter. You enable this tag key definition for cost tracking. You apply the tag with a value of "W1" (Finance.CostCenter="W1") to some resources, and you apply the tag with a value of "C2" (Finance.CostCenter="C2") to other resources. These tags enables the following scenario:

- Create one budget for resources tagged "Finance.CostCenter=W1" and a second budget for resources tagged "Finance.CostCenter=C2". If spending surpasses a certain amount or is forecast to exceed a particular threshold, you can set up alerts that notify you.

**Limits on Cost-Tracking Tags**

- You can have a maximum of 10 tag key definitions enabled for cost-tracking in your tenancy at a time. For example, you could enable the Project tag key as a cost-tracking tag and have 75 different departments, but it only takes up 1 tag.

**Using the Console**

You can enable cost-tracking when you create a tag key definition, or you can update an existing tag key definition to enable cost tracking.
Tagging

To create a key definition
1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click Create Tag Key Definition.
4. Enter the following:
   • Tag Key: Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   • Description: Enter a friendly description.
   • Cost-tracking: Select the check box to enable this tag for cost tracking. You have a limit of 10 Using Cost-Tracking Tags on page 4976 in your tenancy.
5. Under Tag Value Type, choose one of the following:
   • Static Value: Specifies that the user applying the tag can specify any value for this key.
   • A List of Values: Specifies that the user must apply a value from a list you create. When you select this option, the Values box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.
6. Click Create Tag Key Definition.

To update a tag key definition
1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click Edit Tag Key Definition.
   The edit dialog appears.
   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.
   If you chose a list of values, the Values box appears, and you must add at least one value. You can't have blank lines or duplicate values in the Values box.
   You have a limit of 10 Using Cost-Tracking Tags on page 4976 in your tenancy.
5. Make your changes and save it.

Using the API
For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
• ListCostTrackingTags - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)
Using Predefined Values

You can create a list of values and associate that list with a tag key definition. When users then apply the tag to a resource, they must select a value from the list of predefined values. Use lists of predefined values to impose limits on the values that users can apply to tags.

You can use predefined values with defined tags and default tags. You cannot create lists of predefined values for free-form tags.

Required IAM Policy

Predefined values are a feature of defined tags. To allow users to work with predefined values, use the same IAM policy for working with tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags on page 4968.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

Working with Predefined Values

You can update existing tags to use predefined values.

Every list of predefined values that you create must contain at least one value. Lists can't contain duplicate values or blank entries. With predefined values, users applying tags can't set the value of a tag to `null`. For more information, see Using the Console on page 4978.

Predefined Values and Default Tags

You can use predefined values and default tags to impose limits on the values that users can apply to tags.

Here's how it works:

1. You define a list of predefined values for a tag key.
2. You create a default tag that uses the key with the list of predefined values and requires that users who create resources in the compartment add the value to the tag.
3. Oracle prompts all users creating resources in the compartment to enter a tag value. Because the tag key contains a predefined list that you created, the value the user applies is a value that you trust.

These features help to ensure that new resources contain the values you expect. For more information, see Managing Tag Defaults on page 4980.

Using the Console

To create a key definition

1. Open the navigation menu and click Governance & Administration. Under Governance, click Tag Namespaces.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click Create Tag Key Definition.
4. Enter the following:
   - **Tag Key**: Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace. Avoid entering confidential information.
   - **Description**: Enter a friendly description.
   - **Cost-tracking**: Select the check box to enable this tag for cost tracking. You have a limit of 10 Using Cost-Tracking Tags on page 4976 in your tenancy.
5. Under **Tag Value Type**, choose one of the following:

   - **Static Value**: Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values**: Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.

6. Click **Create Tag Key Definition**.

**To update a tag key definition**

1. Open the navigation menu and click **Governance & Administration**. Under **Governance**, click **Tag Namespaces**.

   A list of the tag namespaces in your current compartment is displayed.

2. Click the tag namespace that includes the tag key definition you want to update.

   A list of the tag key definitions is displayed.

3. Click the tag key definition you want to update.

   The key definition's details are displayed.

4. Click **Edit Tag Key Definition**.

   The edit dialog appears.

   You can change the description, the tag value type, and enable or disable cost tracking. Avoid entering confidential information.

   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.

   You have a limit of 10 Using Cost-Tracking Tags on page 4976 in your tenancy.

5. Make your changes and save it.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

- **CreateTag** - creates a tag key definition
- **UpdateTag** - updates the tag key definition (use this operation to retire or reactivate a tag key)

**Using Tag Variables**

You can use a variable to set the value of a defined tag. When you add the tag to a resource, the variable resolves to the data it represents. You can use tag variables in defined tags and default tags. You cannot use tag variables in free-form tags.

**Required IAM Policy**

Tag variables are a feature of defined tags. To allow users to work with tag variables, use the same IAM policy for working with tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags on page 4968.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

**Working with Tag Variables**

Consider the following example:

```
Operations.CostCenter="${iam.principal.name} at ${oci.datetime}"
```
Operations is the namespace, CostCenter is the tag key, and the tag value contains two tag variables
${iam.principal.name} and ${oci.datetime}. When you add this tag to a resource, the variables resolve
to your user name (the name of the principal that applied the tag) and a time date stamp for when you added the tag.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>${iam.principal.name}</td>
<td>The name of the principal that tagged the resource.</td>
</tr>
<tr>
<td>${iam.principal.type}</td>
<td>The type of principal that tagged the resource.</td>
</tr>
<tr>
<td>${oci.datetime}</td>
<td>The date and time that the tag was created.</td>
</tr>
</tbody>
</table>

The variable is replaced with data at the time that you apply the tag. If you later edit the tag, the variable is gone and
only the data remains. You can edit the tag value in all the ways you would edit any other tag value.

To create a tag variable, you must use a specific format.

${<variable>}

Type a dollar sign followed by open and close curly brackets. The tag variable goes between the curly brackets. You
can use tag variables with other tag variables and with string values.

**Supported Tag Variables**

The following tag variables are supported.

Managing Tag Defaults

This topic describes how to you can specify tags to be automatically applied to resources at creation time.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing tag defaults and tag
namespaces. For specific policy information for this feature, see Required Permissions for Working with Tag Defaults
on page 4981.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you
want to dig deeper into writing policies for tagging or other IAM components, see Details for IAM on page 2971.

**Overview of Tag Defaults**

Tag defaults let you specify tags that are applied automatically to all resources at the time of creation in a specific
compartment. This feature allows you to ensure that appropriate tags are applied at resource creation without
requiring the user creating the resource to have access to the tag namespaces. Consider the following example:

Alice is a finance administrator and has access to the restricted tag namespace Finance. Alice can set up a tag default
to apply the Finance.CostCenter tag with a value of W1234 to all resources. Eli can create resources but does not
have access to the Finance tag namespace. When Eli creates a resource, the Finance.CostCenter tag is automatically
applied with a value of W1234. Eli cannot change this tag, and Alice is confident that it is always applied correctly
and not changed by the users who create or edit resources.

Tag defaults allow tenancy administrators to create secure permissions boundaries between users concerned with
governance and users who need to create and administer resources.

**Where to Manage Tag Defaults**

Tag defaults are defined for a specific compartment. In the Console, you manage tag defaults on the Compartment
Details page.
Tagging

Required Permissions for Working with Tag Defaults

To create or edit a tag default for a compartment, you must be granted the following combination of permissions:

- manage tag-defaults access on the compartment where you are adding the tag default
- use tag-namespaces access on the compartment where the tag namespace resides
- inspect tag-namespaces access on the tenancy

For the full mapping of permissions to API operations, see Details for IAM on page 2971.

For example, assume you created a set of tag namespaces in CompartmentA. To give a group named TagAdmins access to add tag defaults to CompartmentA, write a policy with the following statements:

Allow group TagAdmins to manage tag-defaults in compartment CompartmentA
Allow group TagAdmins to use tag-namespaces in compartment CompartmentA
Allow group TagAdmins to inspect tag-namespaces in tenancy

Now assume you also want to allow TagAdmins to create tag defaults in CompartmentA using tag namespaces that reside in CompartmentZ. Add a statement to allow TagAdmins to use tag namespaces in CompartmentZ:

Allow group TagAdmins to use tag-namespaces in compartment CompartmentZ

Now when TagAdmins create tag defaults in CompartmentC, they can use tag namespaces that reside in either CompartmentA or CompartmentZ.

Working with Tag Defaults

You can only use tag defaults with defined tags. Free-form tags are not supported for tag defaults.

You can define up to 5 tag defaults per compartment.

After a tag default is created in a compartment:

- The default tag is applied to any new resources created in that compartment.
- Previously existing resources in the compartment are not tagged retro-actively.
- If you change the default value of the tag default, existing occurrences are not updated.

Deleting Tag Defaults

- If you delete the tag default from the compartment, existing occurrences of the tag are not removed from resources.
• When you delete a tag key definition, existing tag defaults based on that tag key definition are not removed from the compartment. Until you delete the tag default in the compartment, the tag default continues to count against your limit of 5 tag defaults per compartment.

**Required Tag Values**

For tag defaults, you must include a tag value, but you have a choice about how the value is applied.

• Default value
• User-applied value

If you use a default value, then you must create it. This value is applied to all resources.

If you specify that a user-applied value is required, then the user creating the resource must enter the value for the tag at the time of resource creation. Users cannot create resources without entering a value for the tag.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can use predefined values and user-applied values to ensure that users only apply a value that you trust. See Using Predefined Values on page 4978.</td>
</tr>
</tbody>
</table>

**Tag Inheritance**

The default tag is applied to all resources created in the compartment, including child compartments and the resources created in the child compartments.

Example:

• In CompartementA, you create a tag default, TagA.
  Resources (and compartments) created in CompartementA are automatically tagged with TagA.
  • In the subcompartement, CompartementB, you create tag default, TagB.
    Resources and compartments created in CompartementB are automatically tagged with TagA and TagB.
    • In the sub-subcompartement, CompartementC, you create tag default TagC.
      Resources created in CompartementC are automatically tagged with TagA, TagB, and TagC.

This example is illustrated in the following graphic:
Overriding Tag Defaults

Tag defaults can be overridden at the time of resource creation by users who have the appropriate permissions to both create the resource and to use the tag namespace.

Example: CompartmentA has a tag default defined to apply CostCenter.Operations="42". Pradeep belongs to a group that grants him permissions to create instances in CompartmentA and also to use tag namespaces in CompartmentA. He creates an instance in CompartmentA, and in the Create Instance dialog, he applies the tag CostCenter.Operations="50". Because he has the appropriate permissions, when the instance is created, the tag default is overridden, and the instance is tagged with CostCenter.Operations="50".

After a resource is created and tagged, users with the appropriate permissions to both update the resource and to use the tag namespace can modify the default tags that were applied at resource creation.

Tag Defaults and Retired Tags

Retired tags can't be applied to new resources. Therefore, if the tag namespace or tag key specified in a tag default is retired, when new resources are created, the retired tag is not applied. As a best practice, you should delete the tag default that specifies the retired tag.

Tag Defaults and Tag Variables

You can use tag variables in tag defaults. Tag variables dynamically resolve at resource creation time. For example, you enter a tag variable for principal name as the tag default in a particular compartment.

Operations.CostCenter="$\{iam.principal.name\}"

Davis and Garcia each create buckets in that compartment. The buckets that Davis creates include default tags that contain his name as the value, while the buckets that Garcia creates have his name.

Operations.CostCenter="Davis"
Operations.CostCenter="Garcia"

Meanwhile, the tag default still contains the original variables. See Using Tag Variables on page 4979.
Limits on Tag Defaults

A maximum of 5 tag defaults can be defined per compartment.

**Note:**

When you delete a tag key definition, existing tag defaults based on that tag key definition are not removed from the compartment. Until you delete the tag default in the compartment, the tag default continues to count against your limit of 5 tag defaults per compartment.

See Limits on Tags on page 4961 for more limits on tags.

Using the Console

To create a tag default

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.
   
   A list of the compartments that you have access to displays.
2. In the list, click the name of the compartment to which you want to add a tag default.
3. On the compartment details page, click **Tag Defaults**.
   
   The list of existing tag defaults displays.
4. Click **Create Tag Default**.
5. Enter the following (all fields are required):
   
   - **Tag Namespace**: Select the tag namespace for the tag default.
   - **Tag Key**: Select the tag key.
6. Specify the type of value you want this tag to have:
   
   - **Default Value**: Enter the value you want this tag to have.
   - **User-applied Value**: Users that create resources must enter the value as resources are created.
7. Click **Create Tag Default**.

To update the default value of a tag default

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.
   
   A list of the compartments that you have access to displays.
2. In this list, click the name of the compartment that has the tag default that you want to update.
3. On the compartment details page, click **Tag Defaults**.
   
   The list of existing tag defaults displays.
4. Find the tag default you want to update. Go to the the Actions icon (three dots) and click **Edit**.
5. Specify the type of value you want this tag to have:
   
   - **Default Value**: Enter the value you want this tag to have.
   - **User-applied Value**: Users that create resources must enter the value as resources are created.
6. Click **Save Changes**.

To delete a tag default

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.
   
   A list of the compartments that you have access to displays.
2. In the list, click the name of the compartment that has the tag default that you want to delete.
3. On the compartment details page, click **Tag Defaults**.
   
   The list of existing tag defaults displays.
4. Find the tag default that you want to delete. Go to the the Actions icon (three dots) and click **Delete**.
5. Confirm when prompted.
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage tag defaults:

- GetTagDefault
- ListTagDefaults
- CreateTagDefault
- UpdateTagDefault
- DeleteTagDefault

Understanding Automatic Tag Defaults

Use tag defaults to manage resources in your tenancy, including tracking costs by principal name and the date resources are created. In tenancies created after December 17, 2019, two tag defaults are automatically added to the root compartment. These tag defaults apply tags to all resources with the following values:

- Name of the principal that created the resource
- Date the resource was created

Overview of Automatic Tag Defaults

The tag defaults Oracle automatically adds come from a tag namespace called Oracle-Tags, which includes two tag key definitions:

- CreatedBy (Cost-tracking tag)
- CreatedOn

Oracle uses these tags to define two tag defaults in the root compartment of your tenancy. When users create resources in your tenancy, each tag is added to the resource automatically. The values for these tags contain the name of the principal that created the resource and the date and time the resource was created. For more information, see Using Tag Variables on page 4979.

Required IAM Policy

Automatic tag defaults are two tag defaults, automatically created in the root compartment. To allow users to work with these tag defaults, use the same IAM policy for working with tag defaults. For more information, see Required Permissions for Working with Defined Tags on page 4968.

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

Working with Automatic Tag Defaults

You can use the cost-tracking tag feature to check usage and set budgets or to filter resources by date. You can remove and update tags automatically applied to resources as you would any other tag. For more information, see Using Cost-Tracking Tags on page 4976 and Resource Tags on page 239.

If you no longer want these tags applied to resources automatically, you can remove the tag defaults that Oracle created. Although Oracle created the tag defaults, they are ordinary tag defaults that you can manage as you would any other. For more information, see Managing Tag Defaults on page 4980.

Using Tags to Manage Access

This topic describes how you can use tags in policy to scope access based on tags applied to either the requestor or the target of an authorization call.

About Tag-Based Access Control

Using conditions and a set of tag variables, you can write policy to scope access based on the tags that have been applied to a resource. Access can be controlled based on a tag that exists on the requesting resource (group, dynamic
Tagging

Tagging (group, or compartment) or on the target of the request (resource or compartment). Tag-based access control provides additional flexibility to your policies by allowing you to define access policies with tags that span compartments, groups, and resources.

**Caution:**

If your organization chooses to create policies that use tags to manage access, then ensure that you have appropriate controls in place to govern who can apply tags. Also, after policies are in place, keep in mind that applying tags to a group, user, or resource has the potential to confer access to resources.

**Before you create a policy** that specifies a tag on either a target or a requestor, ensure that you are aware of:

- all the potential requestors (users, groups, dynamic groups) that carry the tag
- all the resources that carry the tag

**Before you apply a tag to a resource**, ensure that you are aware of any policies in place that include the tag and could impact who has access to the resource.

### Managing Access Using Tags Applied to the Requesting Resource

You can control access based on the value of a tag applied to:

- a group (of users) requesting access
- a dynamic group (of instances) requesting access
- a compartment that a resource in a dynamic group resides in

By using tags in your policy statements to scope access, you can define access for multiple groups through a single policy statement. You can also confer access and revoke access for groups by applying or removing tags, without changing the original policies.

The basic syntax for each variable is shown in the following table. Note that the syntax is the same for group and dynamic group, but each is presented in a different row. See Supported Operators on page 4989 more usage examples.

<table>
<thead>
<tr>
<th>Tag Applied to Requestor</th>
<th>Variable Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>request.principal.group.tag.&lt;tagNamespace&gt;.&lt;tagKeyDefinition&gt;=&lt;value&gt;</td>
<td>The tags applied to the groups that the user belongs to are evaluated for a match.</td>
</tr>
</tbody>
</table>

Sample policy for user group:

```text
allow any-user to
manage instances in
compartment HR where
request.principal.group.tag.Operations.Project=Prod
```

Any user who belongs to a group that has been tagged with `Operations.Project=Prod` can manage instances in the HR compartment.
Tagging

### Tag Applied to Requestor

<table>
<thead>
<tr>
<th>Tag Applied to Requestor</th>
<th>Variable Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dynamic group</td>
<td>request.principal.group.tag.{tagNamespace}.tagKeyDefinition=value '&lt;value&gt;'</td>
<td>The tags applied to the dynamic groups that the instance belongs to are evaluated for a match.</td>
</tr>
<tr>
<td>compartment</td>
<td>request.principal.compartment.tag.{tagNamespace}.tagKeyDefinition=value '&lt;value&gt;'</td>
<td>The tags applied to the compartment that the requesting resource belongs to are evaluated.</td>
</tr>
</tbody>
</table>

#### Sample policy for dynamic group:

allow dynamic-group InstancesA to manage instances in compartment HR where request.principal.group.tag.Operations.Project='Prod'

Instances that are members of the dynamic group InstancesA and that are also members of a dynamic group tagged with Operations.Project='Prod' can manage instances in the compartment HR.

#### Sample policy:

allow dynamic-group InstancesA to manage instances in tenancy where request.principal.compartment.tag.Operations.Project='Prod'

Instances that are members of the dynamic group InstancesA and that also reside in a compartment tagged with Operations.Project='Prod' can manage instances in the tenancy.

---

**Note:**

Users reside in the root compartment of your tenancy, so tags must be applied to the root compartment for those policy statements to work.

---

### Managing Access Using Tags Applied to the Target Resource

You can control access based on the value of a tag applied to:

- a resource
- a compartment that the target resource resides in

The basic syntax for these variables is shown in the following table. See [Supported Operators](#) on page 4989 for more usage examples.
Tag Applied to Target | Variable Syntax | Description
---|---|---
resource | \texttt{target.resource.tag.\{tagNamespace\}.\{tagKeyDefinition\}='value'} | The tag applied to the target resource of the request is evaluated. There are limitations to the permissions that can be granted in this type of policy. See the following sections in this topic for details.
compartment | \texttt{target.resource.compartment.\{tagNamespace\}.\{tagKeyDefinition\}='value'} | The tag applied to the target compartment of the request is evaluated. See Compartment Hierarchies on page 4991 for details on how access is granted in nested compartments.

**Permissions to List a Resource Must Be Granted Separately**

Policies that scope access based on the tag applied to the target resource can't allow the permissions that enable you to return a list of resources. Therefore, permissions to allow listing a resource must be granted through an additional policy statement. This means that if you have defined a policy like:

```text
allow group GroupA to manage all-resources in compartment Operations where target.resource.tag.Operations.Project= 'Prod'
```

GroupA will not be able to list any of the resources that they are otherwise allowed to manage. Members of GroupA would not be able to use the Console to interact with these resources and users would need to know the OCID of the resource they are attempting to manage, which makes using the SDK and CLI cumbersome, also.

To allow GroupA to list those resources, you need to add another policy statement like:

```text
allow group GroupA to inspect all-resources in compartment Operations
```

This approach improves the tag-based policy because it allows users to use the Console more easily (by allowing them to see the resource they want to manage), but still limits the permissions to only inspect. The members of GroupA cannot take any action on those resources unless they are tagged appropriately. Keep in mind when using tag-based access control that the added flexibility requires this additional potential expansion of access.

Another approach you can use to avoid this limitation is to tag the compartments that contains the resources you want to grant access to. An example policy looks like this:

```text
allow group GroupA to manage all-resources in tenancy where target.resource.compartment.tag.Operations.Project= 'Prod'
```

This policy allows the members of GroupA to manage all resources in the tenancy that are in compartments that are tagged with the Operations.Project='Prod' tag.

**Policies that Require a Tag on the Target Resource Can't Grant Create Permissions**

When you write a policy to scope access based on the value of a tag on the resource, keep in mind that the policy cannot grant create permissions. A request to create an instance would fail because the target resource has not been created yet and therefore does not have the appropriate tag to be evaluated. So a policy like:
allow group GroupA to manage instances in compartment Operations where
target.resource.tag.Operations.Project='Prod'

allows the members of GroupA to use and delete instances that are tagged with Operations.Project='Prod', but they
cannot create instances.

**Supported Operators**

Your policy using these tag variables can include these operators and match types:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>String</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag='sample'</td>
<td>Evaluates to true if any of the groups that the requestor belongs to is</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>tagged with the matching value &quot;sample&quot; for MyTagNamespace.MyTag.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(The value is case insensitive.)</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag=/*sample/</td>
<td>Evaluates to true if any of the values of MyTagNamespace.MyTag ends with</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>&quot;sample&quot;. (Simple case insensitive pattern match.)</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.mytagnamespace.mytag = target.resource.tag.mytagnamespace.mytag</td>
<td>Evaluates to true when the specified resource mytagnamespace.mytag</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>has a value that matches the specified target mytagnamespace.tag.</td>
</tr>
<tr>
<td>!=</td>
<td>String</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag != 'sample'</td>
<td>Evaluates to true if none of the string values of the policy variable</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>equals &quot;sample&quot;. (Simple case insensitive string comparison.)</td>
</tr>
<tr>
<td></td>
<td>Pattern</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag =/*sample/</td>
<td>Evaluates to true if none of the values of MyTagNamespace.MyTag ends with</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>&quot;sample&quot;. (Simple case insensitive pattern match.)</td>
</tr>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.mytagnamespace.mytag != target.resource.tag.mytagnamespace.mytag</td>
<td>Evaluates to true if neither side is a subset of the other.</td>
</tr>
<tr>
<td>Operator</td>
<td>Type</td>
<td>Example</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>----------</td>
<td>----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **In**   | String   | request.principal.group.tag.
     | The clause evaluates to
tag.MyTagNamespace.MyTag in ('sample',
     | true if any of the values of
     | 'sample1')
     | MyTag for any group of the current
     | requesting principal either
     | equals to "sample" or
     | "sample1".                                                   |
|          | Pattern  | request.principal.group.tag.
     | The clause evaluates to
tag.MyTagNamespace.MyTag in (/*sample/, /
     | true if any of the values of
     | sample1*/)                                                    |
|          | Policy variable | request.principal.group.tag.
     | The clause evaluates to
tag.MyTagNamespace.MyTag in (target.resource.tag.mytagnamespace.mytag,
     | true if any of the following
     | 'sample')                                                     |
|          |          |                                             | conditions are met:
|          |          |                                             | 1. Either
|          |          |                                             | request.principal.group.tag.MyTagNamespace.MyTag
|          |          |                                             | or
|          |          |                                             | target.resource.tag.mytagnamespace.mytag is a subset of the other.
|          |          |                                             | 2. Any string values of
|          |          |                                             | request.principal.group.tag.MyTagNamespace.MyTag
|          |          |                                             | equals "sample".                                         |
| **not in** | String   | request.principal.group.tag.
     | The clause evaluates to
tag.MyTagNamespace.MyTag not in ('sample',
     | true if none of the values of
     | 'sample1')                                                  |
|          | Pattern  | request.principal.group.tag.
     | The clause evaluates to
tag.MyTagNamespace.MyTag not in (/*sample/, /
     | true if none of the values of
     | sample1*/)                                                  |

Oracle Cloud Infrastructure User Guide 4990
<table>
<thead>
<tr>
<th>Operator</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Policy variable</td>
<td>request.principal.group.tag.MyTagNamespace.MyTag != target.resource.tag.mytagnamespace.mytag, 'sample'</td>
<td>The clause evaluates to true if all of the following conditions are true: 1. Neither request.principal.group.tag.MyTagNamespace.MyTag nor target.resource.tag.mytagnamespace.mytag is a subset of the other. 2. None of the string values of request.principal.group.tag.MyTagNamespace.MyTag equals &quot;sample&quot;.</td>
</tr>
</tbody>
</table>

**Support for Wildcards**

You can use the * character to match all occurrences of `{tagNamespace}`, `{tagKeyDefinition}` regardless of the value. In the policy, you can place * in single quotes '*' or between backslashes /*/>. For example,

```plaintext
allow group GroupA to use all-resources in compartment HR where target.resource.tag.HR.Project= "*"
```

In this example, GroupA can use all resources in the compartment HR that are tagged with the tag namespace and tag key: HR.Project with any value.

**Limitations on Characters in Tag Namespaces and Tag Key Definitions Used in Policy Variables**

Tag namespaces and tag key definitions support a broader set of characters than are allowed in policy variables. Therefore, to use tag namespaces and tag key definitions in variables, ensure that they only include the characters also supported by policy variables. Supported characters are:
a-z, A-Z, 0-9, _, @, -, :.

If your tag namespaces or tag keys have characters other than these, you cannot use them in policy variables. Tag namespaces and tag keys cannot be renamed, so you will have to create new tag namespaces and tag key definitions.

**Considerations for Case**

When working with tags in policies, be aware that tag values are case insensitive. For example:

```plaintext
request.principal.group.tag.MyTagNamespace.MyTag='sample'
```

is the same as

```plaintext
request.principal.group.tag.MyTagNamespace.MyTag='Sample'
```

**Compartment Hierarchies**

When you write a condition to allow access based on the tag applied to a target compartment, remember that this policy also allows access to all compartments nested inside the tagged compartment. All subcompartments in the tagged compartment are resources in the tagged compartment, and therefore the policy grants access.

For example, in this scenario:
Tagging

The policy:

```
allow group GroupA to use all-resources in tenancy where target.resource.compartment.Operations.Project='ProjectA'
```

allows GroupA to use all the resources in CompartmentA, CompartmentA1, and CompartmentA1.1, even though the tag is applied to CompartmentA only.

**Supported Services**

All Oracle Cloud Infrastructure services support the `request.principal.compartment`, `request.principal.group`, and `target.resource.compartment.tag` policy variables.

Not all services support the `target.resource.tag` policy variable. The following table lists the supported services. If the service is not listed in the table, it is not supported at this time.

Some services have limitations. See the appropriate link in the table.

**Limitations and Additional Policies Needed for Specific Target.Resource.Tag Scenarios**

For some services, not all permissions or resource types are supported. When a permission is not supported, that means that even if the resource is tagged and the permission is included in the verb granting access, that permission is not allowed and authorization fails for the operation governed by the permission. For example, the Block Volume service resource `volume-backups`, does not support tag-based access control for the `VOLUME_BACKUP_COPY` permission. Therefore, this policy:

```plaintext
allow group TestGroup to manage volume-backups in compartment Compartment1
where target.resource.tag.TagNS.TagKey = 'test'
```

does not allow members of the group TestGroup to perform the CopyVolumeBackup operation. To grant that permission to TestGroup, you would need to add another policy statement to cover it.

In addition, some operational scenarios require authorization to access multiple resources. When scoping access to tags that are applied to the target resource, you must include a separate policy for each resource involved in the operation. Also, because of the limitations for listing resources and other service-specific permissions, additional policies (not scoped by tag) are required.

**API Gateway Service Limitations**

In addition to the expected tag-based access control policy for API Gateway resources, you’ll need policy allowing manage permissions for `api-workrequests`. 
Here is an example policy with the additional permissions:

```
allow group TestGroup to manage api-workrequests in compartment Compartment1
```

### Big Data Service Limitations

In addition to the expected tag-based access control policy for Big Data resources, you’ll need policy allowing manage permissions for `cluster-work-requests`.

Here is an example policy with the additional permissions:

```
allow group TestGroup to manage cluster-work.requests in compartment Compartment1
```

### Block Volume Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type with Limitations</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Volume</td>
<td>backup-policy-assignments</td>
<td>BACKUP_POLICY_ASSIGNMENT_DELETE</td>
</tr>
<tr>
<td></td>
<td>volume-backups</td>
<td>VOLUME_BACKUP_COPY</td>
</tr>
</tbody>
</table>

Scenarios requiring additional policy:

**Attach a block volume to a compute instance:**

To attach a block volume to a compute instance, in addition to the tag-based access control policy to allow the `use` verb on volumes and instances, you’ll need some additional permissions.

For example:

```
allow group TestGroup to use volumes in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to use instances in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

These two policies allow members of TestGroup to use volumes and instances in Compartment1, when the resources have the appropriate tag. To allow members to attach a block volume to an instance, you’ll also need policies that allow the permissions shown in the following statements:

```
allow group TestGroup to read instances in compartment Compartment1
allow group TestGroup to manage volume-attachments in compartment Compartment1 where any {request.permission='VOLUME_ATTACHMENT_CREATE', request.permission='VOLUME_ATTACHMENT_DELETE'}
```

### Compute Service Limitations

<table>
<thead>
<tr>

Scenarios requiring additional policy:

**Attach compute instance to subnet:**
Tagging

To manage a compute instance’s subnet attachment, in addition to the expected tag-based access control policy for instances and subnets, shown here:

```plaintext
allow group TestGroup to use subnets in compartment Compartment1 where
    target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to manage instances in compartment Compartment1 where
    target.resource.tag.TagNS.TagKey = 'test'
```

You’ll need additional permissions on vnics:

```plaintext
allow group TestGroup to use vnics in compartment Compartment1 where
    ANY{request.permission='VNIC_ATTACH', request.permission='VNIC_CREATE'}
```

Delete a VNIC from a compute instance:

To delete a VNIC from a compute instance, in addition to the expected tag-based access control policy for instances and subnets shown here:

```plaintext
allow group TestGroup to manage instances in compartment Compartment1 where
    target.resource.tag.TagNS.TagKey = 'test'
allow group TestGroup to use subnets in compartment Compartment1 where
    target.resource.tag.TagNS.TagKey = 'test'
```

You’ll need policy allowing you permissions on vnics:

```plaintext
allow group TestGroup to use vnics in compartment Compartment1 where ANY
    {request.permission='VNIC_DELETE', request.permission='VNIC_DETACH'}
```

## Compute Management Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Management</td>
<td>instance-pools</td>
<td>All permissions</td>
<td>The instance-pools resource type is not supported.</td>
</tr>
<tr>
<td></td>
<td>auto-scaling-configurations</td>
<td>AUTO_SCALING_CONFIGURATION_UPDATE</td>
<td></td>
</tr>
</tbody>
</table>

## Content Management Limitations

In addition to the expected tag-based access control policy for Content Management resources, you’ll need policy allowing manage permissions for `oce-work-requests`.

Here is an example policy with the additional permissions:

```plaintext
allow group TestGroup to manage oce-requests in compartment Compartment1
```

## Database Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>

</tbody>
</table>

Update Tags for ExaData Infrastructure:
Tagging

Not supported at this time using tag-based access control policies.

Scenarios requiring additional policy:

**Delete a DB-System:**

To delete or update a DB-System, in addition to the expected tag-based access control policy for `db-systems`, shown here:

```plaintext
allow group TestGroup to manage db-systems in compartment Compartment1 where
target.resource.tag.TagNS.TagKey= 'test'
```

You'll need policy allowing you permissions for `db-backups`, `db-homes`, `vnics`, `subnets` and `databases`. Here is an example policy showing the additional permissions:

```plaintext
allow group TestGroup to manage db-backups in compartment Compartment1 where
ANY {request.permission='DB_BACKUP_DELETE',
request.permission='DB_BACKUP_INSPECT'}
allow group TestGroup to manage db-homes in compartment Compartment1 where
request.permission='DB_HOME_DELETE'
allow group TestGroup to manage vnics in compartment Compartment1 where
ANY {request.permission='VNIC_DELETE', request.permission='VNIC_DETACH'}
allow group TestGroup to manage subnets in compartment Compartment1 where
request.permission='SUBNET_DETACH'
allow group TestGroup to manage databases in compartment Compartment1
```

**Move a DB-system to another compartment:**

To move a DB-System to another compartment, in addition to the expected tag-based access control policy for `db-systems` shown here:

```plaintext
allow group TestGroup to manage db-systems in compartment Compartment1 where
target.resource.tag.TagNS.TagKey= 'test'
```

You'll need policy allowing you permissions for `databases`, `db-homes`, and `db-backups`. Here is an example policy with the additional permissions:

```plaintext
allow group TestGroup to use databases in compartment Compartment1 where
request.permission='DATABASE_UPDATE'
allow group TestGroup to manage db-backups in compartment Compartment1 where
request.permission='DB_BACKUP_INSPECT'
allow group TestGroup to manage db-homes in compartment Compartment1 where
request.permission='DB_HOME_UPDATE'
```

**Database delete for Exadata DB-System:**

To delete a database resource for an Exadata DB-System, you'll need the expected tag-based access control policy for `db-systems` and `databases` shown here:

```plaintext
allow group TestGroup to manage db-systems in compartment Compartment1 where
target.resource.tag.TagNS.TagKey= 'test'
allow group TestGroup to manage databases in compartment Compartment1 where
target.resource.tag.TagNS.TagKey= 'test'
```

You'll also need permissions for `db-homes` and `db-backups`. Here is an example policy with the additional permissions:

```plaintext
allow group TestGroup to manage db-homes in compartment Compartment1 where
request.permission='DB_HOME_UPDATE'
```
Tagging

allow group TestGroup to manage db-backups in compartment Compartment1 where ANY {request.permission='DB_BACKUP_DELETE', request.permission='DB_BACKUP_INSPECT'}

**Delete Database:**
Deleting a database for a baremetal or virtual machine DB system is not supported using tag-based policies on the target resource.

**Database backup create:**
To create a database backup, you'll need the expected tag-based access control policy for databases:

```
allow group TestGroup to manage databases in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

You'll also need permissions for db-backups. Here is an example policy with the additional permissions:

```
allow group TestGroup to manage db-backups in compartment Compartment1 where request.permission='DB_BACKUP_CREATE'
```

**Database restore:**
To restore a database backup, you'll need the expected tag-based access control policy for databases:

```
allow group TestGroup to manage databases in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

You'll also need permissions for backups, like the one shown here:

```
allow group TestGroup to manage db-backups in compartment Compartment1 where request.permission='DB_BACKUP_INSPECT', request.permission='DB_BACKUP_CONTENT_READ'
```

**Create Data Guard association:**
Creating a Data Guard association is not supported using tag-based policies on the target resource.

**Data Catalog Service Limitations**
In addition to the expected tag-based access control policy for Data Catalog resources, you'll need the following additional policies for data-catalog-family:

```
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'GetWorkRequest'
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'ListWorkRequestErrors'
allow group resource_managers to read data-catalog-family in tenancy where request.operation = 'listworkrequestlogs'
```

**Data Science Service Limitations**
In addition to the expected tag-based access control policy for Data Science resources, you’ll need policy allowing manage permissions for data-science-work-requests.

Here is an example policy with the additional permissions:

```
allow group TestGroup to manage data-science-work-requests in compartment Compartment1
```
Digital Assistant Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digital Assistant</td>
<td>oda-design</td>
<td>All permissions</td>
</tr>
<tr>
<td></td>
<td>oda-insights</td>
<td>All permissions</td>
</tr>
</tbody>
</table>

In addition to the expected tag-based access control policy for the Oracle Digital Assistant resources, you’ll need the following additional policies for oda-instances:

allow group TestGroup to inspect oda-instances in compartment Compartment1
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'GetWorkRequest'
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'ListWorkRequestErrors'
allow group TestGroup to read oda-instances in compartment Compartment1
   request.operation = 'listworkrequestlogs'

Load Balancing Service Limitations

Scenarios requiring additional policy:

Update Load Balancer:
To perform any update to load balancers, in addition to the expected tag-based access control policy for load-balancers:

allow group TestGroup to manage load-balancers in compartment Compartment1
   where target.resource.tag.TagNS.TagKey= 'test'

You’ll need policy that allows the GetWorkRequest API operation. Here is an example policy with the additional permission:

allow group TestGroup to read load-balancers in compartment Compartment1
   where request.operation = 'GetWorkRequest'
   network-security-group

Delete Load Balancer:
To delete a load balancer, in addition to the expected tag-based access control policy for load-balancers, subnets, and network-security-group:

allow group TestGroup to manage load-balancers in compartment Compartment1
   where target.resource.tag.TagNS.TagKey= 'test'
allow group TestGroup to use subnets in compartment Compartment1 where
   target.resource.tag.TagNS.TagKey= 'test'
allow group TestGroup to use network-security-group in compartment
   Compartment1 where target.resource.tag.TagNS.TagKey= 'test'

You’ll need these additional permissions for vnics:

allow group TestGroup to use vnics in compartment Compartment1 where ANY
   {request.permission = 'VNIC_DETACH', request.permission = 'VNIC_DELETE',
   request.permission='VNIC_DISASSOCIATE_NETWORK_SECURITY_GROUP')
Networking Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Networking</td>
<td>private-ips</td>
<td>PRIVATE_IP_UPDATE, PRIVATE_IP_DELETE, VNIC_UNASSIGN, SUBNET_DETACH</td>

<td></td>
</tr>
<tr>
<td></td>
<td>vnics</td>
<td>VNIC_UPDATE, VNIC_DELETE</td>
<td></td>
</tr>
</tbody>
</table>

Removing a route rule is not supported.

Attach service gateway or NAT gateway to a route table:

Attaching a service gateway or a NAT gateway to a route table is not supported using tag-based policies on the target resource.

Scenarios requiring additional policy:

Attach DRG to VCN:

To attach DRG to VCN, in addition to the following expected tag-based access control policy for virtual-network-family and vcns:

```
allow group TestGroup to use virtual-network-family in compartment Compartment1 where target.resource.tag.TagNS.TagKey = 'test'
```

You’ll need policy allowing you manage permissions for drgs. Here is an example policy with the additional permissions:

```
allow group TestGroup to manage drgs in compartment Compartment1
```

NoSQL Database Cloud Service Limitations

Supported resources are: nosql-tables, nosql-rows, and nosql-indexes.

In addition to the expected tag-based access control policy for the NoSQL Database Cloud resources, you’ll need these additional policies:

```
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequests'
```

```
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequestErrors'
```

```
allow group TestGroup to read nosql-tables in compartment Compartment1 where request.operation='ListWorkRequestLogs'
```

Note that the preceding policies are required to navigate the NoSQL Database Cloud resources in the Console.
Tagging

Object Storage Service Limitations

<table>
<thead>
<tr>
<th>Service</th>
<th>Resource Type</th>
<th>Permissions Not Supported with the target.resource.tag Policy Variable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Storage</td>
<td>objects</td>
<td>All permissions related to accessing objects</td>
<td>Objects are not taggable.</td>
</tr>
</tbody>
</table>

Public DNS Limitations

In addition to the expected tag-based access control policy for dns resources, you’ll need policy allowing you manage permissions for dns-records. Here is an example policy with the additional permissions:

```allow group TestGroup to manage dns-records in compartment Compartment1```

Tagging Namespace Limitations

Policy that grants a user access to a tag namespace based on a tag on the namespace does not allow the user to create or delete tag key definitions in that tag namespace.

For example, the policy:

```allow group TestGroup to manage tag-namespaces in compartment Compartment1 where target.resource.tag.TagNS.TagKey='test'```

does not allow the users in TestGroup to create or delete tag key definitions in the tag namespaces tagged with TagNS.TagKey='test'.

WAF Limitations

In addition to the expected tag-based access control policy for the WAF resources, you’ll need policy allowing you manage permissions for waas-work-request. Here is an example policy with the additional permissions:

```allow group TestGroup to manage waas-work-request in compartment Compartment1```

Illustrated Examples

- Illustrated Examples on page 5000
- Example Using Tags Applied to a Target Resource on page 5002

Example Using Tags Applied to a Group

Following is an example that demonstrates how you can use tags applied to user groups to manage access to resources in a compartment.

Assume you have three compartments: ProjectA, ProjectB, and ProjectC

For each compartment, there is an admin group set up: A-Admins, B-Admins, and C-Admins.
Each admin group has full access over their compartment through the following policies:

• allow group A-Admins to manage all-resources in compartment ProjectA
• allow group B-Admins to manage all-resources in compartment ProjectB
• allow group C-Admins to manage all-resources in compartment ProjectC

Your organization has set up the following tag namespace and key to tag each group by its role:

• EmployeeGroup.Role

Some values for this tag are 'Admin', 'Developer', 'Test-Engineer'.

All your admin groups are tagged with EmployeeGroup.Role='Admin'

Now you want to set up a Test compartment for members of the three projects to share. You want to give Admin access to all three of your existing admin groups. To accomplish this, you can write a policy like:

allow any-group to manage all-resources in compartment Test where request.principal.group.tag.EmployeeGroup.Role='Admin'
Tagging

With this policy, all of your existing admin groups with the tag will have access to the Test compartment. Also, any new or existing groups that you tag with EmployeeGroup.Role='Admin' in the future will have access to the Test compartment without having to update the policy statements.

**Example Using Tags Applied to a Target Resource**

In this example, each of your organization's project compartments contains two child compartments: Test and Prod. You want to give your test engineers access to the test compartments across all three projects. To accomplish this, you create a tag:

```
ResourceGroup.Role='Test'
```

and apply this to the Test compartments in each of your project compartments.

```
ResourceGroup.Role='Test'
```

You can then use a policy like:
allow group Testers to use all-resources in tenancy where
target.resource.compartment.tag.ResourceGroup.Role='Test'
to allow your group Testers to access the resources across all three test compartments.

Frequently Asked Questions About Tagging

This topic provides answers to frequently asked questions (FAQ) about Tagging.

What is the difference between free-form tags and defined tags?

Free-form tags are simple (string) key and (string) value pairs that can be set on a resource. Free-form tags cannot be used for applying policies or for authentication, and these tags are not included in metering data. Any user can create and apply free-form tags.

Tag administrators create defined tags for the tenancy, and users can apply these tags to resources. Most of the Tagging features require defined tags. For example, tag rules and policies only reference defined tags. For more information, see How Tagging Works.

How do I decide which kind of tag to use?

Most of the Tagging features require defined tags. Because free-from tags are limited in functionality, Oracle recommends that you only use them to try out the tagging feature in your system when you are first getting started with tagging. For more information, see Tagging Overview.

Are there any tools to help users migrate from free-form tags to defined tags?

Not currently.

Who creates defined tags?

Tag administrators create and manage defined tags, and users apply these tags to resources. Use IAM policy to select tag administrators who can create tags. Grant all other users in the tenancy only the ability to apply tags. For more information, see Working with Defined Tags.

What is the difference between a tag namespace, tag key, and key definition?

See Tagging Concepts.

Can I use Tagging with resources that do not have an OCID?

No. Tagging is only supported with resources that have OCIDs.

What are the allowed characters for tag namespaces and keys?

The allowed characters are printable ASCII, except U+0020 space (" "), and U+002E full stop ("."). Namespace and key names cannot be empty.

Avoid entering confidential information.

Can I use an OCID to name my tag namespace?

No. OCIDs do not follow the required format for tag namespaces.

Do I need to provide a value for compartmentId when making API requests?

No. Because namespaces are unique under tenants, you do not need to provide the compartmentId value. All API requests automatically come with tenancy information.
Can I change the name of my tag namespace?
No. You can retire your tag namespace, but you cannot change its name.

Can I change the name of my tag key definition?
No. You can retire your tag key definition, but you cannot change its name.

What is the base URL of the Tagging service?
Tagging is part of the Identity service. The Tagging service has two parts:

- Handling the creation and management of new tag namespaces and tag key definitions. For these operations, use the Identity Service base URL.
- Applying tags to specific resources by including the tag namespace, key, and value information in requests sent to each supporting service.

When I try to delete a tag key definition, why do I get the error "Can't enable definition <tag definition> in retired namespace <namespace name>"?
You cannot delete a tag key definition in a retired namespace. Reactivate the tag namespace and then retire the tag. For more information, see Managing Tags and Tag Namespaces.
Chapter 47

Vault

This chapter explains how to create vaults, encryption keys, and secrets, and how to manage and use them.

Vault

The Vault service helps you centrally manage the encryption keys that protect your data and the secret credentials that you use to access resources.

Overview of Vault

Oracle Cloud Infrastructure Vault is a managed service that lets you centrally manage the encryption keys that protect your data and the secret credentials that you use to securely access resources. Vaults securely store master encryption keys and secrets that you might otherwise store in configuration files or in code. Specifically, depending on the protection mode, keys are either stored on the server or they are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification.

The key encryption algorithms that the Vault service supports includes the Advanced Encryption Standard (AES), the Rivest-Shamir-Adleman (RSA) algorithm, and the elliptic curve digital signature algorithm (ECDSA). You can create and use AES symmetric keys and RSA asymmetric keys for encryption and decryption. You can also use RSA or ECDSA asymmetric keys for signing digital messages.

You can use the Vault service to create and manage the following resources:
You can use the Vault service to exercise the following lifecycle management features for vaults, master encryption keys, and secrets, helping you to control these resources and access to them:

- Create vaults
- Create or import cryptographic material as master encryption keys
- Create secrets to store secret credentials
- Enable or disable master encryption keys for use in cryptographic operations
- Rotate keys to generate new cryptographic material
- Export key or vault metadata to a backup that you can restore and use again later
- Continuously replicate a vault and its keys to another region in the realm
- Update secrets with new secret contents
- Specify which secret version is currently in use through promotion
- Configure rules to govern the management and use of secrets
- Tag vaults, master encryption keys, or secrets to add metadata to resources
- Delete vaults, keys, or secrets when they're no longer needed

Regarding the use of master encryption keys, you can do the following:

- Use keys for encryption and decryption of data while at rest or in transit
- Use keys to sign messages and verify signed messages
- Assign keys to supported Oracle Cloud Infrastructure resources, including, but not limited to, buckets and file systems
- Generate data encryption keys

The following services integrate with the Vault service to support the use of customer-managed keys to encrypt data in their respective, specified resources:

- Oracle Cloud Infrastructure Block Volume: block and boot volumes
- Oracle Cloud Infrastructure Container Engine for Kubernetes: Kubernetes secrets at rest in the etcd key-value store (when creating new clusters only)
- Oracle Cloud Infrastructure Database: Autonomous Container Databases on dedicated Autonomous Exadata Infrastructure and Exadata Databases (without Oracle Data Guard enabled)
- Oracle Cloud Infrastructure File Storage: file systems
- Oracle Cloud Infrastructure Object Storage: buckets
- Oracle Cloud Infrastructure Streaming: stream pools

In addition, integration with Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who and what services can access which keys and secrets and what they can do with those resources. Oracle Cloud Infrastructure Audit integration gives you a way to monitor key and secret usage. Audit tracks administrative actions on vaults, keys, and secrets.

**Key and Secret Management Concepts**

The following concepts are key to understanding the Vault service.

**VAULTS**

Vaults are logical entities where the Vault service creates and durably stores keys and secrets. The type of vault you have determines features and functionality such as degrees of storage isolation, access to management and encryption, scalability, and the ability to back up. The type of vault you have also affects pricing. You cannot change a vault's type after you create the vault.

The Vault service offers different vault types to accommodate your organization's needs and budget. All vault types ensure the security and integrity of the encryption keys and secrets that vaults store. A virtual
Vault

private vault is an isolated partition on a hardware security module (HSM). Vaults otherwise share partitions on the HSM with other vaults.

Virtual private vaults include 1000 key versions by default. If you don't require the greater degree of isolation or the ability to back up the vault, you don't need a virtual private vault. Without a virtual private vault, you can manage costs by paying for key versions individually, as you need them. (Key versions count toward your key limit and costs. A key always contains at least one active key version. Similarly, a secret always has at least one secret version. However, limits on secrets apply to the tenancy, rather than a vault.)

The Vault service designates vaults as an Oracle Cloud Infrastructure resource.

KEYS

Keys are logical entities that represent one or more key versions, each of which contains cryptographic material. A key's cryptographic material is generated for a specific algorithm that lets you use the key for encryption or in digital signing. When used for encryption, a key or key pair encrypts and decrypts data, protecting the data where the data is stored or while the data is in transit. With an AES symmetric key, the same key encrypts and decrypts data. With an RSA asymmetric key, the public key encrypts data and the private key decrypts data.

You can use AES keys in encryption and decryption, but not in digital signing. RSA keys, however, can be used not only to encrypt and decrypt data, but also to digitally sign data and verify the authenticity of signed data. You can use ECDSA keys in digital signing, but not to encrypt or decrypt data.

When processed as part of an encryption algorithm, a key specifies how to transform plaintext into ciphertext during encryption and how to transform ciphertext into plaintext during decryption. When processed as part of a signing algorithm, together, the private key of an asymmetric key and a message produce a digital signature that accompanies the message in transit. When processed as part of a signature verifying algorithm by the recipient of the signed message, the message, signature, and the public key of the same asymmetric key confirm or deny the authenticity and integrity of the message.

Conceptually, the Vault service recognizes three types of encryption keys: master encryption keys, wrapping keys, and data encryption keys.

The encryption algorithms that the Vault service supports for master encryption keys include AES, RSA, and ECDSA. You can create AES, RSA, or ECDSA master encryption keys by using the Console, CLI, or API. When you create a master encryption key, the Vault service can either generate the key material internally or you can import the key material to the service from an external source. (Support for importing key material depends on the encryption algorithm of the key material.) When you create master encryption keys, you create them in a vault, but where a key is stored and processed depends on its protection mode.

Master encryption keys can have one of two protection modes: HSM or software. A master encryption key protected by an HSM is stored on an HSM and cannot be exported from the HSM. All cryptographic operations involving the key also happen on the HSM. Meanwhile, a master encryption key protected by software is stored on a server and, therefore, can be exported from the server to perform cryptographic operations on the client instead of on the server. While at rest, the software-protected key is encrypted by a root key on the HSM. For a software-protected key, any processing related to the key happens on the server. A key's protection mode affects pricing and cannot be changed after you create the key.

After you create your first symmetric master encryption key, you can then use the API to generate data encryption keys that the Vault service returns to you. Some services can also use a symmetric master encryption key to generate their own data encryption keys.

A type of encryption key that comes included with each vault by default is a wrapping key. A wrapping key is a 4096-bit asymmetric encryption key based on the RSA algorithm. The public and private key pair do not count against service limits. They also do not incur service costs. You use the public key as the key encryption key when you need to wrap key material for import into the Vault service. You cannot create, delete, or rotate wrapping keys.

The Vault service recognizes master encryption keys as an Oracle Cloud Infrastructure resource.
KEY VERSIONS

Each master encryption key is automatically assigned a key version. When you rotate a key, the Vault service generates a new key version. The Vault service can generate the key material for the new key version or you can import your own key material.

Periodically rotating keys limits the amount of data encrypted or signed by one key version. If a key is ever compromised, key rotation thus reduces the risk. A key’s unique, Oracle-assigned identifier, called an Oracle Cloud ID (OCID), remains the same across rotations, but the key version lets the Vault service seamlessly rotate keys to meet any compliance requirements you might have.

Although you can’t use an older key version for encryption after you rotate a key, the key version remains available to decrypt any data that it previously encrypted. If you rotate an asymmetric key, the public key can no longer be used to encrypt data, but the private key remains available to decrypt data previously encrypted by the public key. When you rotate an asymmetric key used in digital signing, you can no longer use the private key version to sign data, but the public key version remains available to verify the digital signature of data previously signed by the older private key version.

For symmetric keys, you do not need to track which key version was used to encrypt what data because the key’s ciphertext contains the information that the service needs for decryption purposes. Through rotations of asymmetric keys, however, you must track which key version was used to encrypt or sign what data. With asymmetric keys, the key’s ciphertext does not contain the information that the service requires for decryption or verification.

With AES symmetric keys, each key version counts as one key version when calculating service limits usage. However, with RSA and ECDSA asymmetric keys, each key version counts as two when calculating usage against service limits because an asymmetric key has both a public key and private key. (Asymmetric keys are also known as key pairs.)

HARDWARE SECURITY MODULES

When you create an AES symmetric master encryption key with the protection mode set to HSM, the Vault service stores the key version within a hardware security module (HSM) to provide a layer of physical security. (When you create a secret, secret versions are base64-encoded and encrypted by a master encryption key, but are not stored within the HSM.) After you create the resources, the service maintains copies of any given key version or secret version within the service infrastructure to provide resilience against hardware failures. Key versions of HSM-protected keys are not otherwise stored anywhere else and cannot be exported from an HSM.

When you create an RSA or ECDSA asymmetric master encryption key with the protection mode set to HSM, the Vault service stores the private key within an HSM and does not allow its export from the HSM. However, you can download the public key.

The Vault service uses HSMs that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. This certification means that the HSM hardware is tamper-evident, has physical safeguards for tamper-resistance, requires identity-based authentication, and deletes keys from the device when it detects tampering.

ENVELOPE ENCRYPTION

The data encryption key used to encrypt your data is, itself, encrypted with a master encryption key. This concept is known as envelope encryption. Oracle Cloud Infrastructure services do not have access to the plaintext data without interacting with the Vault service and without access to the master encryption key that is protected by Oracle Cloud Infrastructure Identity and Access Management (IAM). For decryption purposes, integrated services like Object Storage, Block Volume, and File Storage store only the encrypted form of the data encryption key.

SECRETS

Secrets are credentials such as passwords, certificates, SSH keys, or authentication tokens that you use with Oracle Cloud Infrastructure services. Storing secrets in a vault provides greater security than you might achieve storing them elsewhere, such as in code or configuration files. You can retrieve secrets from the Vault service when you need them to access resources or other services.
You can create secrets by using the Console, CLI, or API. Secret contents for a secret are imported to the service from an external source. The Vault service stores secrets in vaults.

The Vault service supports secrets as an Oracle Cloud Infrastructure resource.

SECRET VERSIONS

Each secret is automatically assigned a secret version. When you rotate secret, you provide new secret contents to the Vault service to generate a new secret version. Periodically rotating secret contents reduces the impact in case a secret is exposed. A secret’s unique, Oracle-assigned identifier, called an Oracle Cloud ID (OCID), remains the same across rotations, but the secret version lets the Vault service rotate secret contents to meet any rules or compliance requirements you might have. Although you can't use an older secret version's contents after you rotate it if you have a rule configured preventing secret reuse, the secret version remains available and is marked with a rotation state other than "current". For more information about secret versions and their rotation states, see Secret Versions and Rotation States on page 5079.

SECRET BUNDLES

A secret bundle consists of the secret contents, properties of the secret and secret version (such as version number or rotation state), and user-provided contextual metadata for the secret. When you rotate a secret, you create a new secret version, which also includes a new secret bundle version.

Regions and Availability Domains

The Vault service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

Unlike some Oracle Cloud Infrastructure services, however, the Vault service does not have one regional endpoint for all API operations. The service has one regional endpoint for the provisioning service that handles create, update, and list operations for vaults. For create, update, and list operations for keys, service endpoints are distributed across multiple independent clusters. Service endpoints for secrets are distributed further still across different independent clusters.

Because the Vault service has public endpoints, you can directly use data encryption keys generated by the service for cryptographic operations in your applications. However, if you want to use master encryption keys with a service that has integrated with Vault, you can do so only when the service and the vault that holds the key both exist within the same region. Different endpoints exist for key management operations, key cryptographic operations, secret management operations, and secret retrieval operations. For more information, see Oracle Cloud Infrastructure API Documentation

The Vault service maintains copies of vaults and their contents to durably persist them and to make it possible for the Vault service to produce keys or secrets upon request, even when an availability domain is unavailable. This replication is independent of any cross-region replication that a customer might configure.

For regions with multiple availability domains, the Vault service maintains copies of encryption keys across all availability domains within the region. Regions with multiple availability domains have one rack for each availability domain, which means that the replication happens across three total racks in these regions, where each rack belongs to a different availability domain. In regions with a single availability domain, the Vault service maintains encryption key copies across fault domains.

For secrets, in regions with multiple availability domains, the Vault service distributes secret copies across two different availability domains. In regions with a single availability domain, the Vault service distributes the copies across two different fault domains.

Every availability domain has three fault domains. Fault domains help provide high availability and fault tolerance by making it possible for the Vault service to distribute resources across different physical hardware within a given availability domain. The physical hardware itself also has independent and redundant power supplies that prevent a power outage in one fault domain from affecting other fault domains.
All of this makes it possible for the Vault service to produce keys and secrets upon request, even when an availability domain is unavailable in a region with multiple availability domains or when a fault domain is unavailable in a region with a single availability domain.

**Private Access to Vault**

The Vault service supports private access from Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as the instances that your encrypted volumes are attached to) access public Oracle Cloud Infrastructure services such as the Vault service without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway on page 4127.

**Resource Identifiers**

The Vault service supports vaults, keys, and secrets as Oracle Cloud Infrastructure resources. Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You will be prompted to enter your cloud tenant, your user name, and your password.

For general information about using the API, see REST APIs on page 5528.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Limits on Vault Resources**

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

For instructions to view your usage level against the tenancy's resource limits, see Viewing Your Service Limits, Quotas, and Usage on page 244. You can also get each individual vault's usage against key limits by viewing key and key version counts in the vault details.

**Managing Vaults**

This topic describes how to create and manage vaults. For information specifically about backing up and restoring vaults, see Backing Up Vaults and Keys on page 5060. For information about configuring cross-region replication for vaults and keys, see Replicating Vaults and Keys on page 5064. For information about what you can do with
Vault keys, see Managing Keys on page 5017. For information about what you can do with secrets, see Managing Secrets on page 5067.

The Vault service lets you create vaults in your tenancy as containers for encryption keys and secrets. If needed, a virtual private vault provides you with a dedicated partition in a hardware security module (HSM), offering a level of storage isolation for encryption keys that’s effectively equivalent to a virtual independent HSM.

Vault management tasks include the following:

- Creating a vault
- Viewing vault configuration details
- Updating the vault name
- Managing vault tags
- Deleting a vault
- Moving a vault to a new compartment

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Moving Resources to a Different Compartment

You can move vaults from one compartment to another. After you move a vault to a new compartment, inherent policies apply immediately and affect access to the vault. Moving a vault doesn't affect access to any keys or secrets that the vault contains. You can move a key or secret from one compartment to another independently of moving the vault it's associated with. For more information, see Managing Compartments on page 3126.

Using the Console

To view vault configuration details

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault you want to view.
3. From the list of vaults in the compartment, click the name of the vault.
4. The console displays the following information:

- **Compartment**: The unique, Oracle-assigned ID of the compartment that contains the vault.
- **OCID**: The unique, Oracle-assigned ID of the vault.
- **Created**: The date and time when you initially created the vault.
- **HSM Key Version Usage**: The number of all key versions across all HSM-protected master encryption keys that the vault contains. A master encryption key comprises one or more key versions, up to the limit allowed by service limits.
- **Software Key Version Usage**: The number of all key versions across all software-protected master encryption keys that the vault contains. This can include one or more key versions for each master encryption key, up to the limit allowed by service limits.
- **Virtual Private**: Whether or not the vault is a virtual private vault.
- **Management Endpoint**: The service endpoint for CreateKey, CreateKeyVersion, EnableKey, DisableKey, UpdateKey, ListKeys, ListKeyVersions, GetKey, GetKeyVersion, ImportKey and ImportKeyVersion operations.
- **Cryptographic Endpoint**: The service endpoint for Encrypt, Decrypt, and GenerateDataEncryptionKey operations.
- **Wrapping Key**: The public RSA wrapping key for the vault.

**To create a new vault**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create the vault.
3. Click **Create Vault**.
4. In the **Create Vault** dialog box, click **Name**, and then enter a display name for the vault. Avoid entering confidential information.
5. Optionally, make the vault a virtual private vault by selecting the **Make it a virtual private vault** check box. For more information about vault types, see Key and Secret Management Concepts on page 5007.

   **Note:**
   You cannot change the vault type after the vault is created.

6. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. When you are finished, click **Create**.

**To change a vault name**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to rename.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Edit Name**.
5. In the **Edit Vault Name** dialog box, click **Name**, and then enter a new display name for the vault. Avoid entering confidential information.
6. When you are finished, click **Save**.

**To manage a vault’s tags**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault for which you want to manage tags.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the Vault Details page, click the Tags tab to view or editing existing tags. Or, click Add Tag(s) to add new ones.

To delete a vault

**Note:**
When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted. If replication is configured, deleting a vault in the source region also deletes the vault and any keys in the vault in the destination region.

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault you want to delete.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the Vault Details page, click Delete.
5. To confirm that you want to delete the vault, type the name of the vault, and then choose the date and time you want the vault to be deleted.
6. When you are finished, click Delete Vault.

To cancel the deletion of a vault

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that's in a pending deletion state.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the Vault Details page, click Cancel Deletion.
5. To confirm that you want to cancel deletion of the vault, click Cancel Deletion.

To move a vault to a different compartment

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under Table Scope, in the Compartment list, choose the compartment that contains the vault that you want to move.
3. Find the vault in the list, click the the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To view vault configuration details

Open a command prompt and run `oci kms management vault get` to view the configuration details for a vault:

```
oci kms management vault get --vault-id <target_vault_id>
```

For example:

```
oci kms management vault get --vault-id ocidi.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5j
```
**To create a new vault**

Open a command prompt and run `oci kms management vault create` to create a new vault:

```
Note:
You cannot change the vault type after the vault is created.
```

```
oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type <vault_type>
```

For example:

```
oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgz2zzum45ibploooqtabwk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE
```

Avoid entering confidential information.

**To create a new vault with resource tags**

Open a command prompt and run `oci kms management vault create` with one or both of the `--defined-tags` and `--freeform-tags` options to create a new vault with resource tags:

```
Note:
You cannot change the vault type after the vault is created.
```

```
oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type <vault_type> --defined-tags <JSON_formatted_defined_tag> --freeform-tags <JSON_formatted_freeform_tag>
```

For example, on a MacOS or Linux machine:

```
oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgz2zzum45ibploooqtabwk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-tags '{"Department":"Finance"}'
```

Or, for example, on a Windows machine:

```
oci kms management vault create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgqmgz2zzum45ibploooqtabwk3zz --display-name vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-tags '{"Department":"Finance"}'
```

Avoid entering confidential information.

**To change a vault name**

Open a command prompt and run `oci kms management vault update` to change a vault's name:

```
oci kms management vault update --vault-id <target_vault_id>
```

For example:
Avoid entering confidential information.

**To delete a vault**

Open a command prompt and run `oci kms management vault schedule-deletion` to delete a vault:

```
oci kms management vault schedule-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault schedule-deletion --vault-id ocid1.vault.region1.sea.exampleaaacu2.exampleexamplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq
```

When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted. If replication is configured, deleting a vault in the source region also deletes the vault and any keys in the vault in the destination region.

**To cancel the deletion of a vault**

Open a command prompt and run `oci kms management vault cancel-deletion` to cancel the pending deletion of a vault:

```
oci kms management vault cancel-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault cancel-deletion --vault-id ocid1.vault.region1.sea.exampleaaacu2.exampleexamplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq
```

**To move a vault to a different compartment**

Open a command prompt and run `oci kms management vault change-compartment` to move a vault from one compartment to another within the same tenancy:

```
oci kms management vault change-compartment --vault-id <target_vault_id> --compartment-id <new_compartment_id>
```

For example:

```
oci kms management vault change-compartment --vault-id ocid1.vault.region1.sea.exampleaaacu2.exampleexamplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq --compartment-id ocid1.compartment.oc1..example1example25qr1po4agcmothkbqgqmmuz2zzm45ibiqpoqtablkwk3zz
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage vaults:

- CancelVaultDeletion
- CreateVault
Managing Keys

This topic describes what you can do with keys and key versions to manage their creation and usage. For information specifically about creating keys with your own key material, see Importing Keys and Key Versions on page 5034. For information about assigning keys to protect supported resources, see Assigning Keys on page 5026. For information about how you can use keys in cryptographic operations, see Using Keys on page 5056. For information about backing up and restoring keys, see Backing Up Vaults and Keys on page 5060. For information about what you can do with vaults where you store keys, see Managing Vaults on page 5011. For information about keys more generally, see Key and Secret Management Concepts on page 5007.

In the context of this topic, management of keys includes the ability to do the following:

- Create keys
- View key details
- View a list of keys
- View a list of key versions for a specific key
- Update a key name
- Manage a key's tags
- Enable keys for use in cryptographic operations
- Rotate keys to generate new cryptographic material
- Disable keys to prevent their usage in cryptographic operations
- Delete keys to permanently prevent their usage in cryptographic operations or assignment to resources
- Move a key to a new compartment

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring the traffic associated with your master encryption keys, see Vault Metrics on page 5080.
Moving Resources to a Different Compartment

You can move keys from one compartment to another. After you move a key to a new compartment, inherent policies apply immediately and affect access to the key and key versions. Moving a key doesn't affect access to the vault that a key is associated with. Similarly, you can move a vault from one compartment to another independently of moving any of its keys. For more information, see Managing Compartments on page 3126.

Using the Console

To create a new master encryption key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create the key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create the key.
   - Create a new vault for the key by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Master Encryption Keys, and then click Create Key.
5. In the Create Key dialog box, choose a compartment from the Create in Compartment list. (Keys can exist outside the compartment the vault is in.)
6. Click Protection Mode, and then do one of the following:
   - To create a master encryption key that is stored and processed on a hardware security module (HSM), choose HSM.
   - To create a master encryption key that is stored and processed on a server, choose Software.
   You cannot change a key's protection mode after you create it. For more information about keys, including information about key protection modes, see Key and Secret Management Concepts on page 5007.
7. Click Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Click Key Shape: Algorithm, and then choose from one of the following algorithms:
   - AES. Advanced Encryption Standard (AES) keys are symmetric keys that you can use to encrypt data at rest.
   - RSA. Rivest-Shamir-Adleman (RSA) keys are asymmetric keys, also known as key pairs consisting of a public key and a private key, that you can use to encrypt data in transit, to sign data, and to verify the integrity of signed data.
   - ECDSA. Elliptic curve cryptography digital signature algorithm (ECDSA) keys are asymmetric keys that you can use to sign data and to verify the integrity of signed data.
9. Depending on what you chose in the previous step, either click Key Shape: Length or Key Shape: Curve ID, and then choose the key length, in bits, for AES and RSA keys, or specify the curve ID for ECDSA keys. For AES keys, the Vault service supports keys that are exactly 128 bits, 192 bits, or 256 bits in length. For RSA keys, the service supports keys that are 2048 bits, 3072 bits, or 4096 bits. With ECDSA keys, you can create keys that have an elliptic curve ID of NIST_P256, NIST_P384, or NIST_P521.
10. Optionally, to apply tags, click Show Advanced Options.
   If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
11. When you are finished, click Create Key.

To view key details

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, and then click the name of the key for which you want to see configuration details. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)

5. The console displays the following information:

   - **OCID**: The unique, Oracle-assigned ID of the key.
   - **Created**: The date and time when you initially created the key.
   - **Compartment**: The unique, Oracle-assigned ID of the compartment that contains the key.
   - **Protection Mode**: Where the key is stored and processed, whether on a hardware security module (HSM) or on a server (software).
   - **Vault**: The unique, Oracle-assigned ID of the vault that contains the key.
   - **Key Version**: The unique, Oracle-assigned ID of the key version.
   - **Algorithm**: The encryption algorithm used by the key.
   - **Length**: The number of bits in the key length (for AES keys and RSA keys).
   - **Curve ID**: The curve ID of the key (for ECDSA keys).

**To view a list of keys**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the keys you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. To see a list of keys in this vault, click **Master Encryption Keys**. You can see keys in other compartments by changing the list scope.

**To view a list of key versions**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, click the name of the key for which you want to see a list of key versions, and then click **Versions**. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)

**To change the name of a key**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rename.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to rename, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Edit Name**.
6. In the **Edit Key Name** dialog box, click **Name**, and then enter a new name. Avoid entering confidential information.
7. When you are finished, click **Update**.

**To manage a key's tags**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key for which you want to manage tags.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to manage, and then click the key name. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)
5. On the **Key Details** page, click the **Tags** tab to view or edit existing tags. Or, click **Add Tags** to add new ones.
To enable a key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you want to enable.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to enable, and then select the check box next to the key name. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Enable.

To rotate a master encryption key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you want to rotate.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to rotate, and then select the check box next to the key name. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Rotate Key. (You can only rotate keys in an enabled state.)
6. In the Confirm dialog box, click Rotate Key.

Cryptographic operations involving objects that were encrypted with the previous version of this key will continue to use the older key version. You can re-encrypt those objects with the current key version if you prefer.

To disable a key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault with the key you want to disable.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to disable, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Disable.

To delete a key

Caution:

When you set a key to the Pending Deletion state, anything encrypted by that key immediately becomes inaccessible. This includes secrets. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault that has the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click Master Encryption Keys, locate the key you want to delete, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the Actions menu, click Delete Key.
6. Confirm that you want to delete the key by clicking the box and then typing the key name.
7. Schedule when you want the Vault service to delete the key. By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days.
8. When you're ready, click **Delete Key**. If needed, you can restore use of the key and access to encrypted resources and data by canceling the scheduled deletion.

**To cancel the deletion of a key**

| Tip: |
| You can only cancel the deletion of a key that's in a Pending Deletion state. |

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**, locate the key you want to delete, and then click the Actions icon (three dots) for that key. (If needed, first change the list scope to the compartment that contains the key.)
5. In the **Actions** menu, click **Cancel Deletion**.
6. Confirm that you want to cancel the key's deletion by clicking **Cancel Deletion**. Access to the key and any resources or data encrypted by the key are restored when key returns to an enabled state.

**To move a key to a different compartment**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **Scope**, in the **Compartment** list, choose the compartment that contains the vault that has the master encryption key that you want to move.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Master Encryption Keys**. Find the key in the list, click the the Actions icon (three dots), and then click **Move Resource**. (If needed, first change the list scope to the compartment that contains the key.)
5. Choose the destination compartment from the list.
6. Click **Move Resource**.
7. If there are alarms monitoring the key, update the alarms to reference the new compartment. See **To update an alarm after moving a resource** on page 3542 for more information.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

| Tip: |
| Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in **To view vault configuration details** on page 5012. |

**To create a new key**

Open a command prompt and run `oci kms management key create` to create a new key:

```bash
oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --key-shape <key_encryption_information> --endpoint <control_plane_url>
```

For example, on a MacOS or Linux machine:

```bash
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmu2zzum45ibploogta4bk3zz
```
--display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com

Or, for example, on a Windows machine:

oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibploogtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com

Avoid entering confidential information.

By default, the service creates a master encryption key protected by an HSM. If you prefer to create a master encryption key protected by software, specify the protection mode with --protection-mode. For example, on a Windows machine:

oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibploogtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --protection-mode SOFTWARE --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com

To create a new key with resource tags

Open a command prompt and run oci kms management key create with one or both of the --defined-tags and --freeform-tags options to create a new key with resource tags:

oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --key-shape <JSON_formatted_key_encryption_information> --defined-tags <JSON_formatted_defined_tag> --freeform-tags <JSON_formatted_freeform_tag> --endpoint <control_plane_url>

For example, on a MacOS or Linux machine:

oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibploogtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --defined-tags '{"Operations": {"CostCenter":"42"}}' --freeform-tags '{"Department":"Finance"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com

Or, for example, on a Windows machine:

oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibploogtabwk3zz --display-name key-1 --key-shape '{"algorithm":"AES","length":"16"}' --defined-tags '{"Operations": {"CostCenter":"42"}}' --freeform-tags '{"Department":"Finance"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com

Avoid entering confidential information.
To view a key's details

Open a command prompt and run `oci kms management key get` to view a specific key's details:

```
oci kms management key get --key-id <key_OCID> --endpoint <control_plane_url>
```

For example:

```
oci kms management key get --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nf6b3zfaux21mqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To view a list of keys

Open a command prompt and run `oci kms management key list` to list keys in a vault:

```
oci kms management key list --compartment-id <target_compartment_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key list --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqmmz2zzum45lbpoqtabw3zz --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To view a list of key versions

Open a command prompt and run `oci kms management key-version list` to view a list of key versions for a specific key:

```
oci kms management key-version list --key-id <key_OCID> --endpoint <control_plane_url>
```

For example:

```
oci kms management key-version list --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nf6b3zfaux21mqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To change the name of a key

Open a command prompt and run `oci kms management key update` to edit a key's name.

```
oci kms management key update --key-id <key_OCID> --display-name <new_key_name> --endpoint <control_plane_url>
```

For example:

```
oci kms management key update --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nf6b3zfaux21mqz2 --display-name key-A --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```
Avoid entering confidential information.

**To enable a key**

Open a command prompt and run `oci kms management key enable` to enable a key:

```
oci kms management key enable --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key enable --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtspuqmo4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To rotate a key**

Open a command prompt and run `oci kms management key rotate` to rotate a key:

```
oci kms management key rotate --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key rotate --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtspuqmo4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Cryptographic operations involving objects that were encrypted with the previous version of this key will continue to use the older key version. You can re-encrypt those objects with the current key version if you prefer.

**To disable a key**

Open a command prompt and run `oci kms management key disable` to disable a key:

```
oci kms management key disable --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key disable --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtspuqmo4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To delete a key**

**Caution:**

When you set a key to the Pending Deletion state, anything encrypted by that key immediately becomes inaccessible. This includes secrets. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.
Open a command prompt and run `oci kms management key schedule-deletion` to schedule a key's deletion:

```
oci kms management key schedule-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key schedule-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpuqmo345cvbu7mgmizcoeu2nfc6b3zfaux2lmqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days. For example:

```
oci kms management key schedule-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpuqmo345cvbu7mgmizcoeu2nfc6b3zfaux2lmqz2 --time-of-deletion 2019-06-30T10:00:00Z --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To cancel the deletion of a key**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only cancel the deletion of a key that's in a Pending Deletion state.</td>
</tr>
</tbody>
</table>

Open a command prompt and run `oci kms management key cancel-deletion` to cancel a key's scheduled deletion:

```
oci kms management key cancel-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key cancel-deletion --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpuqmo345cvbu7mgmizcoeu2nfc6b3zfaux2lmqz2 --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

**To move a key to a different compartment**

Open a command prompt and run `oci kms management key change-compartment` to move a master encryption key from one compartment to another within the same tenancy:

```
oci kms management key change-compartment --key-id <target_key_id> --compartment-id <new_compartment_id>
```

For example:

```
oci kms management key change-compartment --key-id ocid1.key.region1.sea.exampleaaacu2.examplea45c6bgmxgau22lzmqz2 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothhkgqgmu2zzum45ibploogtabwk3zz
```
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage keys:

- CreateKey
- DisableKey
- EnableKey
- GetKey
- UpdateKey
- CreateKeyVersion
- GetKeyVersion
- ListKeys
- ListKeyVersions
- CancelKeyDeletion
- ScheduleKeyDeletion
- ChangeKeyCompartment

Assigning Keys

This topic describes how to assign keys to supported resources and how to remove those key assignments when no longer needed.

Instead of using an encryption key that Oracle manages, you can assign master encryption keys that you manage to block or boot volumes, databases, file systems, buckets, and stream pools. Block Volume, Database, File Storage, Object Storage, and Streaming use the keys to decrypt the data encryption keys that protect the data that is stored by each respective service. By default, these services rely on Oracle-managed master encryption keys for cryptographic operations. When you remove a Vault master encryption key assignment from a resource, the service returns to using an Oracle-managed key for cryptography.

You can also assign master encryption keys to clusters that you create using Container Engine for Kubernetes to encrypt Kubernetes secrets at rest in the etcd key-value store.

For information about managing the creation and usage of master encryption keys and key versions, see Managing Keys on page 5017. For information specifically about creating keys with your own key material, see Importing Keys and Key Versions on page 5034. For information about how you can use keys in cryptographic operations, see Using Keys on page 5056. For information about what you can do with vaults where you store keys, see Managing Vaults on page 5011.

Required IAM Policy

| Caution: |
| Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2816 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2817 in Common Policies on page 2806. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1827 in Creating and Managing Exadata Databases on page 1826. |

Oracle Cloud Infrastructure User Guide 5026
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Using the Console

To assign a key to a new Object Storage bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Under List Scope, in the Compartment list, choose the compartment where you want to create a bucket that's encrypted with a Vault service master encryption key.
3. Click Create Bucket, and then follow the instructions in To create a bucket on page 4301 in Managing Buckets on page 4298.

To assign a key to an existing Object Storage bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Under List Scope, in the Compartment list, choose the compartment that contains the bucket that you want to encrypt with a Vault service master encryption key.
3. From the list of buckets, click the bucket name.
4. Do one of the following:
   • If the bucket already has a key assigned to it, next to Encryption Key, click Edit to assign a different key.
   • If the bucket does not already have a key assigned to it, next to Encryption Key, click Assign.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click Assign or Update, as appropriate.

To assign a key to a new Block Volume

Important:

The Block Volume service does not support encrypting volumes with keys encrypted using the Rivest-Shamir-Adleman (RSA) algorithm. When using your own keys, you must use keys encrypted using the Advanced Encryption Standard (AES) algorithm. This applies to block volumes and boot volumes.

1. Open the navigation menu and click Storage. Under Block Storage, click Block Volumes.
2. Under List Scope, in the Compartment list, choose the compartment where you want to create a block volume that's encrypted with a Vault service master encryption key.
3. Click Create Block Volume, and then follow the instructions in Creating a Volume.

To assign a key to an existing Block Volume

Important:

The Block Volume service does not support encrypting volumes with keys encrypted using the Rivest-Shamir-Adleman (RSA) algorithm. When using your own keys, you must use keys encrypted using the Advanced Encryption Standard (AES) algorithm. This applies to block volumes and boot volumes.

1. Open the navigation menu and click Storage. Under Block Storage, click Block Volumes.
2. Under List Scope, in the Compartment list, choose the compartment that contains the block volume that you want to encrypt with a Vault service master encryption key.
3. From the list of volumes, click the volume name.
4. If the volume is currently attached to an instance, click **Detach from Instance**. Follow the instructions in the **Detach Block Volume** dialog box as appropriate, click **Continue Detachment**, and then click **OK**.

5. Then, do one of the following:
   - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.

6. Choose the vault compartment, vault, key compartment, and key.

7. When you are finished, click **Assign** or **Update**, as appropriate.

**To assign a key to a new file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a file system that's encrypted with a Vault service master encryption key.
3. Click **Create File System**, and then follow the instructions in **Creating File Systems** on page 2557.

**To create a Compute instance with an encrypted boot volume**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create an instance with a boot volume that's encrypted with a Vault service master encryption key.
3. Click **Create Instance**, and then follow the instructions in **Launching an Instance**.

**To assign a key to an existing boot volume**

```
Note:

To assign a key to an existing boot volume, you must first detach the boot volume from any instance. However, you can only detach a boot volume from an instance when the instance is stopped. For more information, see **Detaching a Boot Volume** on page 703 and **Stopping and Starting an Instance** on page 1145.
```

1. Open the navigation menu and click **Storage**. Under **Block Storage**, click **Block Volumes**. In the **Block Storage** menu on the sidebar, click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume that you want to encrypt with a Vault service master encryption key.
3. From the list of volumes, click the volume name.
4. Do one of the following:
   - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click **Assign** or **Update**, as appropriate.

**To create a Kubernetes cluster with encrypted secrets in the etcd key-value store**

```
Note:

These instructions assume you have already followed the steps in **Encrypting Kubernetes Secrets at Rest in Etc** on page 1266 and created:
- a dynamic group including all clusters in the compartment
- a suitable policy to give the dynamic group access to the master encryption key in Vault
```

1. Open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a Kubernetes cluster that has Kubernetes secrets encrypted with a Vault service master encryption key.
3. Click **Create Cluster**, follow the instructions under **Using the Console to create a Cluster with Explicitly Defined Settings in the 'Custom Create' workflow** on page 1236 in **Creating a Kubernetes Cluster** on page 1234, and select the **Encrypt Using Customer-Managed Keys** option.

**To assign a key to a new stream pool**

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Streaming**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a stream pool that's encrypted with a Vault service master encryption key.
3. Click **Create Stream Pool**, and then follow the instructions in **Using the Console** on page 4871 in **Creating Stream Pools** on page 4870.

**To change or remove the master encryption key assigned to an existing stream pool**

1. Open the navigation menu and click **Analytics & AI**. Under **Messaging**, click **Streaming**.
2. Click **Stream Pools**.
3. Click a stream pool to display the stream details page.
4. In **Stream Pool Information**, next to **Encryption Key**, do one of the following:
   - To stop using an Oracle-managed key in favor of a Vault master encryption key that you manage, click **Assign**, select a vault and encryption key you have access to, and then click **Assign**.
   - To select a different Vault master encryption key that you manage, click **Edit**, select a vault and encryption key you have access to, and then click **Update**.
   - Click **Unassign** to remove the assigned Vault master encryption key and let Oracle manage the encryption key, and then click **Unassign** again to confirm the removal of the existing key assignment.

**To remove a key assignment from a bucket**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the bucket from which you want to remove a Vault service key assignment.
3. From the list of buckets, click the bucket name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the bucket.

**To remove a key assignment from a Block Volume**

1. Open the navigation menu and click **Storage**. Under **Block Storage**, click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the block volume from which you want to remove a Vault service key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

**To remove a key assignment from a boot volume**

1. Open the navigation menu and click **Storage**. Under **Block Storage**, click **Block Volumes**. In the **Block Storage** menu on the sidebar, click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume from which you want to remove a Vault service key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

**To change a key assignment for a file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system from which you want to remove or change a Vault service key assignment.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. If you want to use Oracle-managed keys:
   - In Encryption Type, select Encrypt using Oracle-managed keys.
6. If you want to assign a different customer-managed key:
   - In Encryption Type, select Encrypt using customer-managed keys.
   - Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click Save Changes.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Tip:**

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 5012.

To assign a key to an Object Storage bucket

Open a command prompt and run `oci os bucket create` to create a bucket that is encrypted with a Vault service master encryption key:

`oci os bucket create --name <bucket_name> --compartment-id <target_compartment_id> --kms-key-id <target_key_id>`

For example:

`oci os bucket create --name Bucket-1 --compartment-id ocid1.compartment.oc1..example1example25qr1po4agcmothkbqgmu2zzum45ibplooqtabwkw3zz --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmooy4m5cvblugmizcoeu2nfcb3zfaux21mqz22f4 --namespace-name example_namespace`

Avoid entering confidential information.

To update the key assigned to an Object Storage bucket

Open a command prompt and run `oci os bucket update` to update the Vault service master encryption key assigned to a bucket:

`oci os bucket update --name <bucket_name> --namespace-name <your_namespace> --kms-key-id <target_key_id>`

For example:

`oci os bucket update --name Bucket-1 --namespace-name example_namespace --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmooy4m5cvblugmizcoeu2nfcb3zfaux21mqz22f4`
To create a block volume that's encrypted with a Vault key

Open a command prompt and run `oci bv volume create` to create a block volume that is encrypted with a Vault service master encryption key:

```
oci bv volume create --display-name <volume_name> --compartment-id <target_compartment_id> --size-in-gbs <volume_size> --availability-domain <target_availability_domain> --kms-key-id <target_key_id>
```

For example:

```
oci bv volume create --display-name EncryptedBlockVolume --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbggmu2zzum45ibploogtabwk3zz --size-in-gbs 50 --availability-domain AAbC:US-ASHBURN-AD-1 --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux21mqz2
```

Avoid entering confidential information in the volume name.

To update a key assigned to an existing Block Volume

Tip:

If the volume is currently attached to an instance, you must first detach it. To do so, open a command prompt and run `oci compute volume-attachment detach --volume-attachment-id <target_blockvolume-attachment_id>`. For more information, see Oracle Cloud Infrastructure CLI Command Reference.

Open a command prompt and run `oci bv volume-kms-key update` to assign a new Vault service master encryption key to an existing block volume:

```
oci bv volume-kms-key update --volume-id <target_blockvolume_id> --kms-key-id <new_key_id>
```

For example:

```
oci bv volume-kms-key update --volume-id ocid1.volume.oc1.sea.examplerwzq7bnohn5vf6b7k4zkgp54miqfcvg6xsuvkl1gzzw63mfu6z5fa --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux21mqz2
```

To create a boot volume that's encrypted with a Vault key

Open a command prompt and run `oci bv boot-volume create` to create a boot volume that is encrypted with a Vault service master encryption key:

```
oci bv boot-volume create --display-name <volume_name> --compartment-id <target_compartment_id> --size-in-gbs <volume_size> --availability-domain <target_availability_domain> --kms-key-id <target_key_id>
```

For example:

```
oci bv boot-volume create --display-name EncryptedBlockVolume --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbggmu2zzum45ibploogtabwk3zz --size-in-gbs 50 --availability-domain AAbC:US-ASHBURN-AD-1 --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplestpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux21mqz2
```

Avoid entering confidential information in the volume name.
To create a Compute instance with a boot volume that's encrypted with a Vault key

1. First, create the JSON input for configuring the instance and boot volume: Open a command prompt and run `oci compute instance launch --generate-full-command-json-input`.

2. Copy, and then paste the output from the command into a text file for editing. Edit the JSON to provide values appropriate for your tenancy and desired image operating system and instance shape. The following example shows the minimum settings required to create an instance and encrypted boot volume.

   ```json
   {
   "availabilityDomain": "ABcD:US-ASHBURN-AD-1",
   "compartmentId": "ocid1.tenancy.oc1..examplea54hlbsiugecvb4g67tnnth7ouk4iivkpysfAuxcetd55uiunrykhq",
   "displayName": "InstanceWithEncryptedBootVolume",
   "metadata": {
   },
   "shape": "VM.Standard1.1",
   "subnetId": "ocid1.subnet.oc1.iad.exampleaurihk3x3y12vcvb53uz22zgaoujtcwvtbvxvfauxdvsjmdf4dza",
   "sourceDetails": {
   "sourceType": "image",
   "imageId": "ocid1.image.oc1.iad.exampleaeookczfwutjxzcvb2gcdgdx4yk6xls7d5fht1fauxzpaxx5dny4a",
   "kmsKeyId": "ocid1.key.oc1.iad.exampleoaaeug.examplera4sq2vescvbjomwredhewtto7rlfauxhvmee73y7jayx"
   } }
   ```

   Avoid entering confidential information in the instance name.

3. Save the file with a ".json" file extension.

4. In the command prompt, run `oci compute instance launch --from-json file://<file_path>`, providing the location of the file you saved in the previous step. For example:

   ```bash
   oci compute instance launch --from-json file://c:\temp\compute-boot-volume.json
   ```

To update a key assigned to an existing boot volume

Tip:

If the volume is currently attached to an instance, you must first detach the volume. To do so, you must first stop the instance. To stop an instance, open a command prompt and run `oci compute instance action --instance-id <target_instance_id> --action STOP`. Then, to detach the boot volume, run `oci compute boot-volume-attachment detach --boot-volume-attachment-id <target_bootvolume-attachment_id>`. For more information, see the Oracle Cloud Infrastructure CLI Command Reference.

Open a command prompt and run `oci bv boot-volume-kms-key update` to assign a new Vault service master encryption key to an existing boot volume:

   ```bash
   oci bv boot-volume-kms-key update --boot-volume-id <target_bootvolume_id> --kms-key-id <new_key_id>
   ```

For example:

   ```bash
   oci bv boot-volume-kms-key update --boot-volume-id ocid1.bootvolume.oc1.sea.exampleless6hvjs6j6mqwcdv4gfzhtanon3fsqyviegheh522be6wv7x7abz7pq
   ```
To create a Kubernetes cluster with encrypted secrets in the etcd key-value store

Note:

These instructions assume you have already followed the steps in Encrypting Kubernetes Secrets at Rest in Etcd on page 1266 and created:
- a dynamic group including all clusters in the compartment
- a suitable policy to give the dynamic group access to the master encryption key in Vault

Open a command prompt and run `oci ce cluster create` to create a cluster where Kubernetes secrets at rest in the etcd data-store are encrypted with a Vault service master encryption key:

```
oci ce cluster create --name <cluster_name> --compartment-id <target_compartment_id> --vcn-id <target_vcn_id> --kubernetes-version <kubernetes_version> --kms-key-id <target_key_id>
```

For example:

```
oci ce cluster create --name EncryptedCluster --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmu2zzum45ibplooqtabwk3zz --vcn-id ocid1.vcn.oc1.iad.exampleexamplesgwertshdsgfy2muagjhrcmzhtp6c5fplejt3miqvyja --kubernetes-version v1.14.8 --kms-key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoym5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq
```

Avoid entering confidential information in the cluster name.

To remove the key assigned to an Object Storage bucket

Open a command prompt and run `oci os bucket update` to remove the Vault service master encryption key assigned to a bucket:

```
oci os bucket update --name <bucket_name> --namespace-name <your_namespace> --kms-key-id ""
```

For example:

```
oci os bucket update --name Bucket-1 --kms-key-id "" --namespace-name example_namespace
```

To remove a key assigned to a Block Volume

Open a command prompt and run `oci bv volume-kms-key delete` to remove the Vault service master encryption key assigned to an existing block volume:

```
oci bv volume-kms-key delete --volume-id <target_blockvolume_id>
```

For example:

```
oci bv volume-kms-key delete --volume-id ocid1.volume.oc1.sea.exampleerwzq7bnohn5vf6b7k4zkp54miqfcvg6xsuvkllgzzw63mfuu6z5fa
```
To remove a key assigned to a Block Volume boot volume

Open a command prompt and run `oci bv boot-volume-kms-key delete` to remove the Vault service master encryption key assigned to an existing boot volume:

```bash
oci bv boot-volume-kms-key delete --boot-volume-id <target_bootvolume_id>
```

For example:

```bash
oci bv boot-volume-kms-key delete --boot-volume-id
oci1.bootvolume.oicl.sea.exampleless6hvjs6j6mqwcdv4gfzhtanon3fsqyviqeh522be6wv7x7abz7pq
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to assign keys:

Container Engine for Kubernetes

- `CreateCluster`

Core Services

- `LaunchInstance`
- `CreateBootVolume`
- `CreateVolume`
- `UpdateBootVolumeKmsKey`
- `UpdateVolumeKmsKey`
- `DeleteBootVolumeKmsKey`
- `DeleteVolumeKmsKey`

File Storage

- `CreateFileSystem`
- `UpdateFileSystem`

Object Storage

- `CreateBucket`
- `UpdateBucket`

Streaming

- `CreateStreamPool`
- `UpdateStreamPool`

Importing Keys and Key Versions

This topic describes how to import key material that you already have. When you use imported key material, you remain responsible for the key material while allowing the Vault service to use a copy of it. You might want to "bring your own key" (BYOK) if you want to:

- Use key material that is generated by a tool or source based on your requirements.
- Use the same key material that you use on other cloud or on-premise systems.
- Manage the key material, its expiration and deletion in the Vault service.
- Own and manage the key material outside Oracle Cloud Infrastructure for additional durability, and for recovery purposes.
When you create a key or key version, you can import your own key material instead of letting the Vault service generate the key material internally.

You can import the following key types and key shapes into the Vault service:

### Supported Key Types and Key Sizes

<table>
<thead>
<tr>
<th>Key Type</th>
<th>Supported Key Size</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Symmetric Keys:</strong></td>
<td><strong>You can import AES keys having any of the following lengths:</strong></td>
</tr>
</tbody>
</table>
| Advanced Encryption Standard (AES) algorithm-based symmetric keys are used to encrypt or decrypt. | • 128 bits (16 bytes)  
• 192 bits (24 bytes)  
• 256 bits (32 bytes) |
| **Asymmetric Keys:**           | **You can import RSA keys having any of the following lengths:**                   |
| Rivest-Shamir-Adleman (RSA) algorithm-based assymetric keys are used to encrypt, decrypt, sign or verify. | • 2048 bits (256 bytes)  
• 3072 bits (384 bytes)  
• 4096 bits (512 bytes) |

**Note:**

Elliptic Curve Cryptography Digital Signature Algorithm (ECDSA) based asymmetric keys cannot be imported.

The length of the key material must match what you specify at the time you create or import a key. Furthermore, before you can import a key, you must wrap the key material by using the public wrapping key provided with each vault. The vault's wrapping key pair make it possible for the HSM to unwrap and store the key securely. To meet payment card industry (PCI) compliance, you cannot import a key of greater strength than the key that you use to wrap it. Vault wrapping keys are 4096-bit RSA keys. As such, if you want to meet PCI compliance, you cannot import AES keys that are longer than 128 bits.

Also, if you plan to use the command line interface (CLI) to create a new external key or external key version, the key material must be base64-encoded.

### Required IAM Policy

#### Caution:

Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see [Let a user group delegate key usage in a compartment](#) on page 2816 and [Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools](#) on page 2806. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see [Required IAM Policy](#) on page 1827 in [Creating and Managing Exadata Databases](#) on page 1826.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Before You Begin

To bring your own key, you must wrap the key material using RSA - Optimal Asymmetric Encryption Padding (OAEP) before importing it. Transforming the key material provides an additional layer of protection by making it possible for only the hardware security module (HSM) in possession of the private RSA wrapping key to unwrap the key.

The Vault service supports the following wrapping mechanisms based on key type:

<table>
<thead>
<tr>
<th>Key Type</th>
<th>Supported Wrapping Mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symmetric key (AES)</td>
<td>• RSA_OAEP_SHA256 (RSA-OAEP with a SHA-256 hash)</td>
</tr>
<tr>
<td></td>
<td>• RSA_OAEP_AES_SHA256 (RSA-OAEP with a SHA-256 hash and</td>
</tr>
<tr>
<td></td>
<td>a temporary AES key)</td>
</tr>
<tr>
<td>Asymmetric key (RSA)</td>
<td>RSA_OAEP_AES_SHA256 (RSA-OAEP with a SHA-256 hash and a</td>
</tr>
<tr>
<td></td>
<td>temporary AES key)</td>
</tr>
</tbody>
</table>

If you're using MacOS or Linux, you'll need to install the OpenSSL 1.1.1 series to run commands. If you plan to use RSA_OAEP_AES_SHA256 wrapping, then you must also install an OpenSSL patch that supports it, see To configure and patch OpenSSL on page 5038. If you're using Windows, you'll need to install Git Bash for Windows to run commands.

Importing Symmetric Keys

You can import the key or key version by using the Console or the CLI. If you plan to use the CLI, you must also Base64 encode the wrapped key material before you import it.

Using the Console

The following procedures assume that you already have the key material. Use the Console to get the public wrapping key, wrap the AES key material and then import it as a new master encryption key, or as a new key version for an existing master encryption key.

To get the public RSA wrapping key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault for which you want the public RSA wrapping key.
3. From the list of vaults in the compartment, click the name of the vault.
4. Click Create Key under Master Encryption Keys.
5. Select the Import external key check box to see the wrapping key information.
6. Click the Public Wrapping Key value to view the public RSA wrapping key, and then click Copy.
7. Save the copied wrapping key, and then continue To apply RSA-OAEP to wrap the key material on page 5037.
To apply RSA-OAEP to wrap the key material

Open a command prompt and run the following command to wrap the AES material with the public RSA wrapping key associated with the vault. Replace example file names and values as appropriate.

```bash
openssl pkeyutl -encrypt -in <key_material_to_import> -inkey <public_RSA_wrapping_key> -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

For example:

```bash
openssl pkeyutl -encrypt -in "aes_key.bin" -inkey "publickey.pem" -pubin -out "wrappedkey.bin" -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

To import the key material as a new external key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to import key material for a new key.
   - Create a new vault for the key by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Master Encryption Keys, and then click Create Key.
5. In the Create Key dialog box, choose a compartment from the Create in Compartment list. (Keys can exist outside the compartment the vault is in.)
6. Click Protection Mode, and then click HSM.

   **Note:**
   You cannot import key material for keys protected by software.

7. Click Name, and then enter a name to identify the key. Avoid entering confidential information.
8. Click Key Shape: Algorithm, and choose AES.
9. Click Key Shape: Length, and then choose the key length, in bits. For AES keys, the Vault service supports keys that are exactly 128 bits, 192 bits, or 256 bits in length.
10. Select the Import External Key check box.
11. Click Wrapping Algorithm, and then choose one of the following:
   - RSA_OAEP_SHA256
   - RSA_OAEP_AES_SHA256
12. Under External Key Data Source, provide the file that contains the wrapped AES key material.
13. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
14. When you are finished, click Create Key.

To import the key material as a new external key version

**Note:**
Key versions must match the shape of the key to which they're added.

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rotate.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Master Encryption Keys**, and then click the name of the master encryption key that you want to rotate to a new key version.

5. Under **Resources**, click **Versions**, and then, in the list of keys, click **Rotate Key**. (You can only rotate keys in an enabled state.)

6. In the **Confirm** dialog box, select the **Import External Key Version** check box.

7. Under **External Key Data Source**, provide the file that contains the wrapped key material.

8. When you're ready, click **Rotate Key**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 5012.</td>
</tr>
</tbody>
</table>

When using the command line to import key material from outside Oracle Cloud Infrastructure, you can either refer to example scripts or you can run CLI commands individually.

**Individual Commands**

Review the commands in this section if you want to run the CLI commands individually rather than use an example script or if you want to examine the individual steps in the example scripts.

The commands in this section assume that you already generated key material by using the third-party tool of your choice. Once you have the key material, use the CLI to get the public wrapping key that you'll need to wrap the key material. Wrap the key material by applying RSA-OAEP, and then use the CLI again to import the key material as a new master encryption key or a new key version for an existing master encryption key.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you provide complex input, such as JSON, by providing a file that contains the input, rather than formatting the input in the command line.</td>
</tr>
</tbody>
</table>

To get the public RSA wrapping key

Open a command prompt and run `oci kms management wrapping-key get` to get the vault's public RSA wrapping key:

```
oci kms management wrapping-key get --endpoint <control_plane_URL>
```

For example:

```
oci kms management wrapping-key get --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

After you get the public wrapping key, wrap the AES key material by applying RSA-OAEP.

To configure and patch OpenSSL
If you want to wrap your key material using RSA_OAEP_AES_SHA256, then you must patch your CLI with a supported OpenSSL patch.

The OpenSSL -id-aes256-wrap-pad cipher compatible with RSA_AES_KEY_WRAP is not enabled by default in the Command Line Interface (CLI). Patch OpenSSL to allow the envelope wrapping that is needed for the CKM_RSA_AES_KEY_WRAP mechanism.

Perform the following steps to download, compile, and run a new local copy of OpenSSL v1.1.1d using the CLI, without altering the default installation of OpenSSL in the system:

1. Create directories to store the latest OpenSSL binaries in /root/build.

   ```
   mkdir $HOME/build
   mkdir -p $HOME/local/ssl
   cd $HOME/build
   ```

2. Run the following command and note the OpenSSL version:

   ```
   openssl version
   ```

3. Note the latest OpenSSL version at https://www.openssl.org/source/.

4. Download and unpack the libraries.

   Replace `openssl-1.1.1d.tar.gz` with the latest version from step 3 on page 5039.

   ```
   curl -O https://www.openssl.org/source/openssl-1.1.1d.tar.gz
   tar -zxf openssl-1.1.1d.tar.gz
   ```

5. Install the patch, make gcc tools to patch, and then compile the binaries.

   ```
   sudo yum install patch make gcc -y
   ```

6. Run the following commands:

   ```
   Note:
   You might need to update these commands for newer versions of OpenSSL.
   ```

   ```
   cat «-EOF | patch -d $HOME/build/ -p0
   diff -ur orig/openssl-1.1.1d/apps/enc.c openssl-1.1.1d/apps/enc.c
   --- orig/openssl-1.1.1d/apps/enc.c
   +++ openssl-1.1.1d/apps/enc.c
   @@ -533,6 +533,7 @@
   /*
   BIO_get_cipher_ctx (benc, &ctx);
   + EVP_CIPHER_CTX_set_flags (ctx, EVP_CIPHER_CTX_FLAG_WRAP_ALLOW);
   if (!EVP_CipherInit_ex (ctx, cipher, NULL, NULL, NULL, enc)) {
   BIO_printf (bio_err, "Error setting cipher %s\n",
   EOF
   ```

Confirm successful patching if response is similar to the following:

```
[root@ip-172-31-20-119 ~]# cat «-EOF | patch -d $HOME/build/ -p0
diff -ur orig/openssl-1.1.1d/apps/enc.c openssl-1.1.1d/apps/enc.c
--- orig/openssl-1.1.1d/apps/enc.c
+++ openssl-1.1.1d/apps/enc.c
@@ -533,6 +533,7 @@
 */
   BIO_get_cipher_ctx(benc, &ctx);
   + EVP_CIPHER_CTX_set_flags(ctx, EVP_CIPHER_CTX_FLAG_WRAP_ALLOW);
   if (!EVP_CipherInit_ex(ctx, cipher, NULL, NULL, NULL, enc)) {
   BIO_printf(bio_err, "Error setting cipher %s\n",
```
7. Compile the enc.c file.

```
Note:
Compiling might take several minutes for each command.
```

```
cd $HOME/build/openssl-1.1.1d/
./config --prefix=$HOME/local --openssldir=$HOME/local/ssl
make -j$(grep -c ^processor /proc/cpuinfo)
make install
```

You have successfully installed the latest version of OpenSSL. This version is dynamically linked to libraries in the $HOME/local/ssl/lib/ directory, and cannot be run directly. Set the environment variable LD_LIBRARY_PATH to ensure that the associated libraries are available to OpenSSL.

8. Create a script named openssl.sh that loads the $HOME/local/ssl/lib/ path before running the binary. This makes it easier to run OpenSSL multiple times.

```
cd $HOME/local/bin/

echo -e '#!/bin/bash \nenv LD_LIBRARY_PATH=$HOME/local/lib/ $HOME/local/bin/openssl "$@"' > ./openssl.sh
```

9. Set the execute bit on the script.

```
chmod 755 ./openssl.sh
```

10. Start OpenSSL with the following command:

```
$HOME/local/bin/openssl.sh
```

To apply RSA-OAEP to wrap the key material

Open a command prompt and run the following command to wrap the AES key material with the public RSA wrapping key associated with the vault. Replace example file names and values as appropriate.

```
openssl pkeyutl -encrypt -in <key_material_to_import> -inkey <public_RSA_wrapping_key> -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

For example:

```
openssl pkeyutl -encrypt -in "aes_key.bin" -inkey "publickey.pem" -pubin -out "wrappedkey.bin" -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

To import the key material as a new external key
Open a command prompt and run `oci kms management key import` to import the AES key material wrapped with the public RSA wrapping key associated with the vault:

```shell
ox ci kms management key import --wrapped-import-key <wrapped_key_material> --compartment-id <compartment_id> --display-name <key_name> --endpoint <control_plane_URL> --key-shape <key_encryption_information> --protection-mode <key_protection_mode>
```

**Note:**

`protection-mode` indicates how the key persists and where cryptographic operations that use the key are performed. A protection mode of HSM means that the key persists on a hardware security module (HSM) and all cryptographic operations are performed inside the HSM. A protection mode of SOFTWARE means that the key persists on the server, protected by the vault's RSA wrapping key which persists on the HSM. All cryptographic operations that use a key with a protection mode of SOFTWARE are performed on the server. By default, a key's protection mode is set to HSM. You can't change a key's protection mode after the key is created or imported.

For example:

```shell
ox ci kms management key import --wrapped-import-key file:///./wrapped_import_key.json --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgμzzum45ibplooqtabwk3zz --display-name new-external-key --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com --key-shape file:///./key_shape.json --protection-mode HSM
```

To import the key material as a new external key version

Open a command prompt and run `oci kms management key-version import` to import the wrapped AES key material as a new key version for an existing key:

```shell
ox ci kms management key-version import --key-id <key_OCID> --wrapped-import-key <wrapped_key_material>
```

For example:

```shell
ox ci kms management key-version import --key-id ocid1.key.region1.sea.exampleaaacu2.exampleaasmtuqcmoy4r6vblugmizcoeu2nfc6b3zfaux21mqz29 --wrapped-import-key file:///./wrapped_import_key.json
```

**Example Scripts**

Example scripts illustrate how you might fully automate generating the key material, applying RSA-OAEP to wrap the key material, and then creating the new key or key version based on the imported, wrapped key material.

This section includes example scripts for importing AES key material.

Script to import AES key material as a new external key

Automate the import of AES key material as a new key with the following example script.

Open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```bash
#!/usr/bin/env bash
#
# This script is for demonstration purposes only. It provides a functioning set of calls to show how to import AES keys into the Vault service.
#```
set -x

# Import the Key Version by Using the CLI

```bash
oci kms management key-version import --key-id $KEY_ID --wrapped-import-key $WRAPPED_KEY
```

---

## Importing Asymmetric Keys

You can import the key or key version by using the Console or the CLI. If you plan to use the CLI, you must also Base64 encode the wrapped key material before you import it.

### Using the Console

The following procedures assume that you already have the key material. Use the Console to get the public wrapping key, wrap the RSA key material and then import it as a new master encryption key, or as a new key version for an existing master encryption key.

#### To Get the Public RSA Wrapping Key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment that contains the vault for which you want the public RSA wrapping key.
3. From the list of vaults in the compartment, click the name of the vault.
4. Click Create Key under Master Encryption Keys.
5. Select the Import external key check box to see the wrapping key information.
6. Click the Public Wrapping Key value to view the public RSA wrapping key, and then click Copy.
7. Save the copied wrapping key, and then continue To apply RSA-OAEP with AES to wrap the key material on page 5044.

#### To Apply RSA-OAEP with AES to Wrap the Key Material

Open a command prompt and perform the following steps. Replace variables with appropriate values:

1. Generate a temporary AES key:

   ```bash
   openssl rand <AES_key_size> > <AES_key_path>
   ```

2. Wrap the temporary AES key with RSA-OAEP to create the wrapping key:

   ```bash
   openssl pkeyutl -encrypt -in <AES_key_path> -inkey <public_RSA_key> -pubin -out <wrapper_key> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
   ```

3. Wrap your RSA key material with the RSA-OAEP-AES wrapping key:

   ```bash
   openssl pkeyutl -encrypt -in <key_material_to_import> -inkey <wrapper_key> -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
   ```

After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

#### To Import the Key Material as a New External Key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to import key material for a new key.
   - Create a new vault for the key by following the instructions in To Create a New Vault, and then click the name of the vault.

4. Click Master Encryption Keys, and then click Create Key.
5. In the Create Key dialog box, choose a compartment from the Create in Compartment list. (Keys can exist outside the compartment the vault is in.)
6. Click **Protection Mode**, and then click **HSM**.

   **Note:**
   You cannot import key material for keys protected by software.

7. Click **Name**, and then enter a name to identify the key. Avoid entering confidential information.

8. Click **Key Shape: Algorithm**, and choose **RSA**.

9. Click **Key Shape: Length**, and then choose the key length, in bits. For RSA keys, the Vault service supports keys that are exactly 2048 bits, 3072 bits, or 4096 bits in length.

10. Select the **Import External Key** check box.

11. Click **Wrapping Algorithm**, and then choose **RSA_OAEP_AES_SHA256** (RSA-OAEP with a SHA-256 with a temporary AES key).

12. Under **External Key Data Source**, provide the file that contains the wrapped RSA key material.

13. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

14. When you are finished, click **Create Key**.

**To import the key material as a new external key version**

   **Note:**
   Key versions must match the shape of the key to which they're added.

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rotate.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Master Encryption Keys**, and then click the name of the master encryption key that you want to rotate to a new key version.

5. Under **Resources**, click **Versions**, and then, in the list of keys, click **Rotate Key**. (You can only rotate keys in an enabled state.)

6. In the **Confirm** dialog box, select the **Import External Key Version** check box.

7. Under **External Key Data Source**, provide the file that contains the wrapped key material.

8. When you're ready, click **Rotate Key**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see the **Command Line Reference**.

**Tip:**

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in **To view vault configuration details** on page 5012.

When using the command line to import key material from outside Oracle Cloud Infrastructure, you can either refer to example scripts or you can run CLI commands individually.

**Individual Commands**

Review the commands in this section if you want to run the CLI commands individually rather than use an example script or if you want to examine the individual steps in the example scripts.
The commands in this section assume that you already generated key material by using the third-party tool of your choice. Once you have the key material, use the CLI to get the public wrapping key that you'll need to wrap the key material. Wrap the key material by applying RSA-OAEP with AES, and then use the CLI again to import the key material as a new master encryption key or a new key version for an existing master encryption key.

**Tip:**

We recommend that you provide complex input, such as JSON, by providing a file that contains the input, rather than formatting the input in the command line.

To get the public RSA wrapping key

Open a command prompt and run `oci kms management wrapping-key get` to get the vault's public RSA wrapping key:

```
oci kms management wrapping-key get --endpoint <control_plane_URL>
```

For example:

```
oci kms management wrapping-key get --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

After you get the public wrapping key, wrap the RSA key material by applying RSA-OAEP with AES.

To configure and patch OpenSSL

If you want to wrap your key material using `RSA_OAEP_AES_SHA256`, then you must patch your CLI with a supported OpenSSL patch.

The OpenSSL -id-aes256-wrap-pad cipher compatible with `RSA_AES_KEY_WRAP` is not enabled by default in the Command Line Interface (CLI). Patch OpenSSL to allow the envelope wrapping that is needed for the `CKM_RSA_AES_KEY_WRAP` mechanism.

Perform the following steps to download, compile, and run a new local copy of OpenSSL v1.1.1d using the CLI, without altering the default installation of OpenSSL in the system:

1. Create directories to store the latest OpenSSL binaries in `/root/build`.

   ```
   mkdir $HOME/build
   mkdir -p $HOME/local/ssl
   cd $HOME/build
   ```

2. Run the following command and note the OpenSSL version:

   ```
   openssl version
   ```

3. Note the latest OpenSSL version at [https://www.openssl.org/source/](https://www.openssl.org/source/).

4. Download and unpack the libraries.

   Replace `openssl-1.1.1d.tar.gz` with the latest version from step 3 on page 5046.

   ```
   curl -O https://www.openssl.org/source/openssl-1.1.1d.tar.gz
tar -zxf openssl-1.1.1d.tar.gz
   ```

5. Install the patch, make gcc tools to patch, and then compile the binaries.

   ```
   sudo yum install patch make gcc -y
   ```
6. Run the following commands:

```
Note:
You might need to update these commands for newer versions of OpenSSL.
```

```
cat «-EOF | patch -d $HOME/build/ -p0
diff -ur orig/openssl-1.1.1d/apps/enc.c openssl-1.1.1d/apps/enc.c
--- orig/openssl-1.1.1d/apps/enc.c
+++ openssl-1.1.1d/apps/enc.c
@@ -533,6 +533,7 @@
*/
          BIO_get_cipher_ctx(benc, &ctx);
          EVP_CIPHER_CTX_set_flags(ctx, EVP_CIPHER_CTX_FLAG_WRAP_ALLOW);
          if (!EVP_CipherInit_ex(ctx, cipher, NULL, NULL, NULL, enc)) {
             BIO_printf(bio_err, "Error setting cipher %s\n",
EOF
```

Confirm successful patching if response is similar to the following:

```
[root@ip-172-31-20-119 ~]# cat «-EOF | patch -d $HOME/build/ -p0
diff -ur orig/openssl-1.1.1d/apps/enc.c openssl-1.1.1d/apps/enc.c
--- orig/openssl-1.1.1d/apps/enc.c
+++ openssl-1.1.1d/apps/enc.c
@@ -533,6 +533,7 @@
*/
          BIO_get_cipher_ctx(benc, &ctx);
          EVP_CIPHER_CTX_set_flags(ctx, EVP_CIPHER_CTX_FLAG_WRAP_ALLOW);
          if (!EVP_CipherInit_ex(ctx, cipher, NULL, NULL, NULL, enc)) {
             BIO_printf(bio_err, "Error setting cipher %s\n",
EOF
patching file openssl-1.1.1d/apps/enc.c
```

7. Compile the enc.c file.

```
Note:
Compiling might take several minutes for each command.
```

```
cd $HOME/build/openssl-1.1.1d/
./config --prefix=$HOME/local --openssldir=$HOME/local/ssl
make -j$(grep -c ^processor /proc/cpuinfo)
make install
```

You have successfully installed the latest version of OpenSSL. This version is dynamically linked to libraries in the $HOME/local/ssl/lib/ directory, and cannot be run directly. Set the environment variable LD_LIBRARY_PATH to ensure that the associated libraries are available to OpenSSL.

8. Create a script named openssl.sh that loads the $HOME/local/ssl/lib/ path before running the binary. This makes it easier to run OpenSSL multiple times.

```
cd $HOME/local/bin/

echo -e '#!/bin/bash \nenv LD_LIBRARY_PATH=$HOME/local/lib/ $HOME/local/bin/openssl "$@"' > ./openssl.sh
```
9. Set the execute bit on the script.

    chmod 755 ./openssl.sh

10. Start OpenSSL with the following command:

    $HOME/local/bin/openssl.sh

To apply RSA-OAEP to wrap the key material

Open a command prompt and run the following commands to wrap the RSA key material using RSA-OAEP with a temporary AES key. Replace example file names and values as appropriate.

1. Generate a temporary AES key:

    openssl rand <AES_key_size> > <AES_key_path>

2. Wrap the temporary AES key with RSA-OAEP to create the wrapping key:

    openssl pkeyutl -encrypt -in <AES_key_path> -inkey <public_RSA_key>
    -pubin -out <wrapper_key> -pkeyopt rsa_padding_mode:oaep -pkeyopt
    rsa_oaep_md:sha256

3. Wrap your RSA key material with the RSA-OAEP-AES wrapping key:

    openssl pkeyutl -encrypt -in <key_material_to_import> -inkey <wrapper_key>
    -pubin -out <wrapped_key_material> -pkeyopt rsa_padding_mode:oaep -pkeyopt
    rsa_oaep_md:sha256

After you wrap the key, you can then either import the key material by creating a new key or by rotating a key to a new key version.

To import the key material as a new external key

Open a command prompt and run `oci kms management key import` to import the wrapped RSA key material:

    oci kms management key import --wrapped-import-key <wrapped_key_material>
    --compartment-id <compartment_id> --display-name <key_name> --endpoint
    <control_plane_URL> --key-shape <key_encryption_information> --protection-
    mode <key_protection_mode>

**Note:**

`protection-mode` indicates how the key persists and where cryptographic operations that use the key are performed. A protection mode of HSM means that the key persists on a hardware security module (HSM) and all cryptographic operations are performed inside the HSM. A protection mode of SOFTWARE means that the key persists on the server, protected by the vault's RSA wrapping key which persists on the HSM. All cryptographic operations that use a key with a protection mode of SOFTWARE are performed on the server. By default, a key's protection mode is set to HSM. You can't change a key's protection mode after the key is created or imported.

For example:

    oci kms management key import --wrapped-import-key
    file://./wrapped_import_key.json --compartment-id
    ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmu2zzum45ibplooqtabwk3zz
    --display-name new-external-key --endpoint https://exampleaaacu2-
To import the key material as a new external key version

Open a command prompt and run `oci kms management key-version import` to import the wrapped RSA key material as a new key version for an existing key:

```
oci kms management key-version import --key-id <key_OCID> --wrapped-import-key <wrapped_key_material>
```

For example:

```
oci kms management key-version import --key-id ocid1.key.region1.sea.exampleaaacu2.exampleexamplemtspuqmo4m5cvblugmizcoeu2nfc6b3zfaux2lmq2z2 --wrapped-import-key file://./wrapped_import_key.json
```

**Example Scripts**

Example scripts illustrate how you might fully automate generating the key material, applying RSA-OAEP with AES to wrap the key material, and then creating the new key or key version based on the imported, wrapped key material.

This section includes example scripts for importing RSA key material.

**Script to import RSA key material as a new external key**

Automate the import of RSA key material as a new key with the following example script.

Open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```
#!/bin/bash

# This script is for demonstration purposes only. It provides a functioning set of calls to show how to import RSA keys into the Vault service.

set -e;
set -x;
while getopts ":k:w:" opt; do
  case $opt in
  k) key_size="$OPTARG"
    ;;
  w) wrapping_key="$OPTARG"
    ;;
  \?) echo "Invalid option -$OPTARG. Valid options are -k (keySize), -w (Public Wrapping Key)" >&2
    ;;
  esac
done

OPENSSL_PATH="<path_to_OpenSSL>"
WORK_DIR=$(mktemp -d -t kms_XXXX)
BASE64="base64"

echo "Openssl Path: ", ${OPENSSL_PATH}
echo "Work Dir: ", ${WORK_DIR}

# Generate a private key.
private_key_path=${WORK_DIR}/private_key.pem
${OPENSSL_PATH} genrsa -out ${private_key_path} ${key_size}
```

Oracle Cloud Infrastructure User Guide
Script to import RSA key material as a new external key version
Automate the import of AES key material as a new key version of an existing key with the following example script.

Open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```bash
#!/bin/bash

# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to import RSA keys
# into the Vault service.
```
```bash
set -e;
set -x;

while getopts ":k:w:i:" opt; do
  case $opt in
    k) key_size="$OPTARG"
      ;;
    w) wrapping_key="$OPTARG"
      ;;
    i) key_ocid="$OPTARG"
      ;;
    \?) echo "Invalid option -$OPTARG. Valid options are -k (keySize), -w (Public Wrapping Key), -i (Key OCID)" >&2
      ;;
  esac
done

OPENSSL_PATH="<path_to_OpenSSL>"

key_material=${BASE64} ${wrapped_key_material}

##### IMPORT NEW KEY VERSION USING CONSOLE #####
# echo ${key_material} > encoded_key_material.key
```

Oracle Cloud Infrastructure User Guide
Vault

# browser and upload encoded_key_material.key file in console key import section.

##### IMPORT NEW KEY VERSION USING OCI_CLI #####

# echo "{"wrappingAlgorithm": "RSA_OAEP_AES_SHA256", "keyMaterial": "${key_material}" }" > wrapped_import_key.json
# oci kms management key-version import --key-id ${key_ocid} --wrapped-import-key file://wrapped_import_key.json

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to wrap and import keys:

- GetWrappingKey
- ImportKey
- ImportKeyVersion
- ExportKey

Exporting Keys and Key Versions

You can export a software-protected master encryption key or key version if you want to use it to perform cryptographic operations in an application running on a client instead of performing those same operations in the cloud with the Vault service. You can use the key locally, and then discard the key from local memory to protect the key contents. Using an exported key locally improves availability, reliability, and latency.

Required IAM Policy

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2816 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2817 in Common Policies on page 2806. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1827 in Creating and Managing Exadata Databases on page 1826.</td>
</tr>
</tbody>
</table>

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.
Before You Begin

Exporting a key requires you to generate your own RSA key pair to wrap and unwrap the key material. You can use the third-party tool of your choice to generate the RSA key pair.

You can export the key or key version by using the CLI only. We've included example scripts that you can refer to. The scripts include all steps of the export process, from wrapping the key material to exporting the software-protected key or key version.

If you're using MacOS or Linux, you'll need to install the OpenSSL 1.1.1 series to run commands. If you plan to use the RSA encryption algorithm that uses a temporary AES key, then you must also patch OpenSSL with a patch that supports it, see To configure and patch OpenSSL on page 5038. If you're using Windows, you'll need to install Git Bash for Windows and run commands with that tool.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Tip:

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 5012.

This section provides example scripts that you can use to fully automate applying RSA-OAEP to wrap the key material, and then exporting the wrapped key or key version. Choose the appropriate example script for the type of RSA key wrap mechanism, whether you want to use the RSA encryption algorithm (with OAEP padding using SHA-256) that includes a temporary AES key or not. Also ensure that you patch OpenSSL if you plan to use the script that uses a temporary AES key.

The example scripts are based on the oci kms crypto key export command, which exports a software-protected master encryption key:

```
oci kms crypto key export --key-id <key_OCID> --algorithm <encryption_algorithm> --public-key "<public_RSA_wrapping_key>" --endpoint <data_plane_url>
```

To export a software-protected master encryption key by applying RSA-OAEP with a temporary AES key

The following example script invokes the RSA AES key wrap mechanism to generate a temporary AES key that wraps and unwraps the exportable key material. The process by which you transform the temporary AES key is called Optimal Asymmetric Encryption Padding (OAEP). OAEP is commonly used with the RSA encryption algorithm (RSA-OAEP). The Vault service supports RSA-OAEP with a SHA-256 hash.

Applying OAEP with the RSA encryption algorithm (RSA-OAEP) with a SHA-256 hash to wrap the temporary AES key with the provided public RSA wrapping key generates a wrapped temporary AES key. The wrapped temporary AES key and the wrapped exportable key material are concatenated to produce blob output that jointly represents them and which only the possessor of the private RSA wrapping key can decrypt.

To export a software-protected master encryption key, open a command prompt, and then run the following script, replacing example file names and values as appropriate:

```
#!/usr/bin/env bash
```

#
# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to export software-protected
# AES key material
# from the Vault service by using the RSA_OAEP_AES_SHA256 algorithm.
#

set -x

# Trim spaces so that only hexadecimals remain. Convert hexadecimals to data
# and write to file.
wrapped_target_key_data="\$(wrapped_targetKey_array[@]) \ tr -d ' ' \ xxd -p -r"
 eval "\$wrapped_target_key_data > $WRAPPED_SOFTWARE_KEY_PATH"

# Unwrap the wrapped_temp_aes_key by using the private RSA wrapping key.

TEMP_AES_KEY_HEX=$(hexdump -v -e '/1 "%02X"' < $TEMP_AES_KEY_PATH)

# Unwrap the wrapped software-protected key material by using the
# unwrapped temporary AES key. The -id-aes256-wrap-pad OpenSSL cipher value
# specifies the RFC-3394-compliant CKM_RSA_AES_KEY_WRAP mechanism to use for
# unwrapping. As required by RFC 5649, -iv specifies an "alternative initial
# value" that is a 32-bit message length indicator expressed in hexadecimal.
$OPENSSL enc -iv A65959A6 -in $WRAPPED_SOFTWARE_KEY_PATH -d -id-aes256-wrap-pad -k $TEMP_AES_KEY_PATH -out $SOFTWARE_KEY_PATH

To export a software-protected master encryption key by applying RSA-OAEP without a temporary
AES key

The following example script transforms the software-protected master encryption key through a mechanism called
Optimal Asymmetric Encryption Padding (OAEP). OAEP is commonly used with the RSA encryption algorithm
(RSA-OAEP). The Vault service supports RSA-OAEP with a SHA-256 hash.

The script wraps the software-protected master encryption key with the provided public RSA wrapping key, and then
unwraps and exports it with the private RSA wrapping key. Only the possessor of the private RSA wrapping key can
decrypt the wrapped master encryption key.

To export a software-protected master encryption key, open a command prompt, and then run the following script,
replacing example file names and values as appropriate:

#!/usr/bin/env bash

# This script is for demonstration purposes only. It provides
# a functioning set of calls to show how to export software-protected
# AES key material
# from the Vault service by using the RSA_OAEP_SHA256 algorithm.
#
set -x

OPENSSL="<path_to_OpenSSL>" # Use OpenSSL 1.1.1.
KEY_OCID="<key_OCID>" # The Oracle Cloud Identifier (OCID) of the software-
protected master encryption key to export.
ENCRYPTION_ALGORITHM="RSA_OAEP_SHA256"
VAULT_CRYPTO_ENDPOINT="<vault_data_plane_URL>" # The cryptographic endpoint
of the vault that contains the software-protected master encryption key.
PUBLIC_KEY_STRING="<public_RSA_wrapping_key_in_PEM_format>" # The content of
the public key.
PRIVATE_KEY_PATH="<path_to_private_RSA_wrapping_key>" # The location of the
private key.
# Vault

SOFTWARE_KEY_PATH="<path_to_output_exported_key>" # The location for outputting the software-protected master encryption key.
WRAPPED_SOFTWARE_KEY_PATH="<path_to_output_decoded_wrapped_target_key>" # The location for outputting the decoded, wrapped software-protected master encryption key.

# Invoke the CLI to export a software-protected master encryption key.
wrapped_data=$(oci kms crypto key export --key-id ${KEY_OCID} --algorithm ${ENCRYPTION_ALGORITHM} --public-key "${PUBLIC_KEY_STRING}" --endpoint ${VAULT_CRYPTO_ENDPOINT} | grep encrypted-key | cut -d: -f2 | sed 's# "\(.\)\",#\1#g')

# Decode the encoded wrapped data.
echo ${wrapped_data} | base64 -d > ${WRAPPED_SOFTWARE_KEY_PATH}

# Unwrap the wrapped software-protected key material by using the private RSA wrapping key.
${OPENSSL} pkeyutl -decrypt -in ${WRAPPED_SOFTWARE_KEY_PATH} -inkey ${PRIVATE_KEY_PATH} -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256 -pkeyopt rsa_mgf1_md:sha256 -out ${SOFTWARE_KEY_PATH}

## Using Keys

This topic describes what you can do with keys in terms of cryptographic operations and signing operations. For information about managing keys, see Managing Keys on page 5017. For information about exporting keys, see Exporting Keys and Key Versions on page 5052. For information about managing the vaults in which you store keys, see Managing Vaults on page 5011.

Cryptographic operations include the following:

- Encrypting data
- Decrypting data
- Generating data encryption keys
- Signing data
- Verifying signed data

You can use either the command line interface (CLI) or API to perform cryptographic operations.

### Required IAM Policy

**Caution:**

Keys associated with volumes, buckets, file systems, clusters, and stream pools will not work unless you authorize Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment on page 2816 and Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2817 in Common Policies on page 2806. Keys associated with databases will not work unless you authorize a dynamic group that includes all nodes in the DB system to manage keys in the tenancy. For more information, see Required IAM Policy on page 1827 in Creating and Managing Exadata Databases on page 1826.

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.
For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring the traffic associated with your master encryption keys, see Vault Metrics on page 5080.

**Using the Console**

To view the public key of an asymmetric key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where the key exists.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Under Master Encryption Keys, click the name of the key.
5. Under Resources, click Versions.
6. In the list of key versions, find the key for which you want to view the public key, click the Actions menu, and then click View Public Key.
7. Do one of the following:
   - To copy the contents of the public key, click Copy. The contents of the public key are copied to your clipboard.
   - To download the public key, click Download. The file is automatically downloaded to your local computer.
8. When you are finished, click Close.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Tip:**

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details on page 5012.

**To encrypt data by using your Vault master encryption key**

**Note:**

You can use either AES symmetric keys or RSA asymmetric keys to encrypt or decrypt data. ECDSA keys do not support the cryptography required to encrypt or decrypt data. If you want to encrypt data by using an RSA asymmetric key, then you must also provide the --key-version-id of the key. To decrypt the data, you need to provide the same --key-version-id. The need to track key versions exists because, unlike
Vault

symmetric keys, an asymmetric key's ciphertext does not contain the
information that the service needs for decryption purposes.
Open a command prompt and run oci kms crypto encrypt to encrypt data:
oci kms crypto encrypt --key-id <key_OCID> --plaintext <base64_string> -endpoint <data_plane_url>
For example:

oci kms crypto encrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2
--plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= -endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
Optionally, you can include the associated-data option to provide an encryption context that might contain
useful, but non-secret, information about the encrypted data. That information is associated with the encrypted data
such that the data cannot be decrypted without it, providing an extra layer of protection. Associated data must be
properly formatted JSON.
If using an RSA asymmetric key, provide the public key.

oci kms crypto encrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2
--plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4=
--associated-data '{"CustomerId":"12345", "Custom Data":"custom data"}' -endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
To decrypt data by using your Vault master encryption key
Note:
You can use AES symmetric keys or RSA asymmetric keys to encrypt or
decrypt data. ECDSA keys do not support the cryptography required to
encrypt or decrypt data.
Open a command prompt and run oci kms crypto decrypt to decrypt data:
oci kms crypto decrypt --key-id <key_OCID> --ciphertext <base64_string> -endpoint <data_plane_url>
For example:

oci kms crypto decrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2
--ciphertext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4=
--endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
If you want to decrypt data previously encrypted by an RSA asymmetric key, then you must also provide the -key-version-id of the key that encrypted the data. The need to track key versions exists because, unlike
symmetric keys, an asymmetric key's ciphertext does not contain the information that the service needs for decryption
purposes. If the data you want to decrypt had an encryption context associated with it at the time of encryption, the
same encryption context is required to decrypt the data. For example, the --associated-data in the following
sample matches what was provided in the preceding sample command for encrypting data.

oci kms crypto decrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz2

Oracle Cloud Infrastructure User Guide

5058


To generate a data encryption key from your Vault master encryption key

Note:
You can only use AES symmetric keys to generate data encryption keys. You cannot generate data encryption keys from RSA and ECDSA asymmetric keys.

Open a command prompt and run `oci kms crypto generate-data-encryption-key` to generate a data encryption key that you can then use to encrypt and decrypt data:

```
oci kms crypto generate-data-encryption-key --key-id <key_OCID> --key-shape <key_encryption_information> --include-plaintext-key <Boolean_value> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto generate-data-encryption-key --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugizcoeu2nfc6b3zfaux2lmg2 --key-shape file://path/to/json/file --include-plaintext-key true --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

To view the public key of an asymmetric key

Open a command prompt and run `oci kms management key-version get` to view the public key of an asymmetric key:

```
oci kms management key-version get --key-id <key_OCID> --key-version-id <keyversion_OCID> --endpoint <control_plane_url>
```

For example:

```
oci kms management key-version get --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugizcoeu2nfc6b3zfaux2lmg2 --key-version-id ocid1.keyversion.region1.sea.example5aacuu.abbreviation.abbreviation.example.aexample --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To sign data by using your Vault master encryption key

Note:
You can only use RSA or ECDSA asymmetric keys to digitally sign data and verify signed data. AES keys do not support the asymmetric cryptography required to sign data or to verify signed data.

Open a command prompt and run `oci kms crypto signed-data sign` to sign a message:

```
oci kms crypto signed-data sign --key-id <key_OCID> --key-version-id <keyversion_OCID> --message <base64_string> --signing-algorithm <key_algorithm> --endpoint <data_plane_url>
```

For example:
To verify signed data by using your Vault master encryption key

**Note:**

You can only use RSA or ECDSA asymmetric keys to digitally sign data and verify signed data. AES keys do not support the asymmetric cryptography required to sign data or to verify signed data.

Open a command prompt and run `oci kms crypto verified-data verify` to verify the integrity of signed data:

```
oci kms crypto verified-data verify --key-id <key_OCID> --key-version-id <keyversion_OCID> --message <base64_string> --signature <base64_string> --signing-algorithm <key_algorithm> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto verified-data verify --key-id ocid1.key.region1.sea.exampleaaacu2.exampl3510smtspuqmo4m5cvblugmizcoeu2nfc6b3zaux2lmqz245gezevsq --key-version-id ocid1.keyversion.region1.sea.example5aacuu.aumjmafauxaaa.abuwcljt2lolvy7221paefa53mb12022 --message VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsaXZlIGRvZy4= --signing-algorithm SHA_224_RSA_PKCS_PSS --endpoint https://exampleaaacu3-crypto.kms.us-ashburn-1.oraclecloud.com
```

Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the following operations to use keys in cryptographic operations:

- Decrypt
- Encrypt
- GenerateDataEncryptionKey
- ExportKey
- Sign
- Verify

Backing Up Vaults and Keys

This topic describes how to preserve virtual private vaults and encryption keys. You can create backups of these resources to store in a bucket or offline, outside of Oracle Cloud Infrastructure.

Currently, the only type of vault you can back up is a virtual private vault. Similarly, the only type of encryption key that you can back up is a master encryption key protected by a hardware security module (HSM). You cannot back up master encryption keys protected by software. You also cannot back up secrets.

You might want to back up a vault or encryption key before deleting either if you don't need them now, but think you might need to use the key for decryption later. Deleting a vault and key otherwise means losing the ability to...
decrypt any resource or data that the key was used to encrypt. Restoring a key lets you resume using a resource that was previously encrypted by the key.

You might also create a backup of a vault to use in a disaster recovery scenario. You can restore a backup in any region within the realm, making it possible to access encrypted resources even in disaster recovery scenarios where the region of the backed-up resource is no longer available.

Note:

By default, a key backup includes metadata about the vault it's associated with. A vault backup might optionally include key metadata, but you cannot back up secrets, whether independently or as part of a vault backup. You can only back up and restore encryption keys protected by an HSM and virtual private vaults.

For information about creating and managing the use of keys, see Managing Keys on page 5017. For information about what you can do with vaults where you store keys and secrets, see Managing Vaults on page 5011. For information about creating and managing the use of secrets, see Managing Secrets on page 5067.

How It Works

Keys are always associated with the vault where you created them. This relationship persists even as the key is backed up and restored. As a result, restoring a key always requires you to already have the vault associated with the key. You also need the vault because the vault hosts the management and cryptographic endpoints against which you manage and use the key. This might mean that you need to first restore the vault, and then restore the key, if both were backed up and subsequently deleted.

You back up a vault or key by exporting identifying information about the vault or key and what it contains. (The service encrypts the backups, and only the service can restore them.) Vault backups can optionally include keys, assuming the vault has keys and the keys are in a supported lifecycle state when you perform the backup. You can only back up active, enabled, or disabled keys. Backups exclude keys that are deleted or in a transitional state (for example, "Creating" or "Pending Deletion"). Key backups always include vault metadata, in addition to key metadata. Having vault metadata makes it possible to restore the key at all. You can only back up active vaults.

You can back up only one vault or one key at a time. (The exception is when you backup keys as part of a vault backup.) When you perform a key backup, the file includes all associated key versions in an enabled state. Backups exclude key versions in a deleted or pending deletion state.

Backup operations require you to specify where to download the backup. Downloads can be stored in a new or existing Object Storage bucket or a temporary URL that's created specifically for pre-authenticated requests. For more information about pre-authenticated requests, see Using Pre-Authenticated Requests on page 4387. Backups must be stored in buckets in the same region, but you can copy the backup to a different region by using Object Storage.

Backup and restore operations generate work requests to help you track their progress.

You restore a vault or key by importing the backup from storage to where you want it, as long as you restore the vault to the same tenancy and compartment where you originally created the backup. The key also can only be restored to its original tenancy and compartment, which might be a different compartment from the vault. You can, however, restore vaults and keys to a different region if your tenancy spans multiple regions.

You can restore a vault or a key individually. If you included keys in a vault backup, then restoring the vault restores all the keys included in the backup. Restoring a key restores all the key versions included in the backup.

You can restore a vault or key even when the vault or key already exists in the region. Also, at any time, you can take a newer backup of a vault or key if you want to capture changes to the vault, such as a new name or tags, or the keys, such as new key versions. Updating an already restored vault or key reflects those changes. Updates from a backup are always additive. This means that updates can only append new information. For example, any new key versions created in a reference vault are added to its restored key when you update the restored key. But, if you delete a key from a reference vault, and then you update a restored vault from a backup of the reference vault, the update does not result in a corresponding key deletion in the restored vault. Similarly, any keys that you create for a restored vault are independent of any keys associated with the reference vault that you created the backup from. You manage them independently, too.
Most other operations are not allowed while a backup or restore operation is in progress. This prevents you from deleting a key while it’s being backed up, for example. Prohibited operations include attempts to perform simultaneous backup or restore operations on the same resource.

To make it easier to reuse any policies that you created to allow management and use of vaults and keys, when you restore a vault and key, they maintain the same unique Oracle Cloud Identifier (OCID) if they're restored to the region where they were originally backed up. When you restore a vault or key to a different region, you must review and update policies to correspond to new OCIDs.

When you restore a vault or key, especially a key with a lot of key versions, tenancy service limits do apply.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for typical policies that give access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

Depending on where you want to store backups and retrieve them from, you might also need access to an Object Storage bucket. For administrators: for typical policies that gives access to buckets, see Let users write objects to Object Storage buckets on page 2813 and Let users download objects from Object Storage buckets on page 2814.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Using the Console**

**Note:**

Only active virtual private vaults and active, enabled, or disabled keys can be exported to a backup.

**To back up a vault**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that you want to back up.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Back Up Vault**.
5. Choose a source: export a backup to either an Existing Object Storage Bucket (recommended) or a pre-authenticated Object Storage URL for an object that you can write to.
6. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL for an object.
7. Optionally, to back up only the vault without any keys, select the **Back up vault metadata only** check box.
8. When you are finished, click **Back Up Vault**. (Note the compartment so that you can restore this resource to the right compartment later.)

**To back up a key**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the key that you want to back up.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Click **Master Encryption Keys**, and then click the name of the key that you want to back up. (If needed, first change the list scope to the compartment that contains the key, and then click the key name.)

5. On the **Key Details** page, click **Back Up Key**.

6. Choose a source: export a backup to either an **Existing Object Storage Bucket** (recommended) or a pre-authenticated Object Storage **URL** that you can write to.

7. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL to an object.

8. When you are finished, click **Back Up Key**. (Note the compartment so that you can restore this resource to the right compartment later.)

**To restore a vault**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to restore a vault. The compartment must match the compartment of the reference vault at the time of backup.

3. Click **Restore Vault**.

4. Choose a source. You can import a backup from an **Existing Object Storage Bucket** that you have access to or a pre-authenticated Object Storage **URL**. You can also **Upload a File** from your computer or a mapped network location.

5. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL. Include the backup name.
   - In **Choose a file**, drag and drop a file or, to browse for a file, click **select one**.

6. When you are finished, click **Restore Vault**.

**To update a vault from a backup**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that you want to update from a backup.

3. From the list of vaults in the compartment, click the name of the vault.

4. On the **Vault Details** page, click **Update Vault from Backup**.

5. Choose a source. You can import a backup from an **Existing Object Storage Bucket** that you have access to or a pre-authenticated Object Storage **URL**. You can also **Upload a File** from your computer or a mapped network location.

6. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the **Backup Name**. Avoid entering confidential information.
   - Click **Object Storage URL**, and then provide a pre-authenticated URL. Include the backup name.
   - In **Choose a file**, drag and drop a file or, to browse for a file, click **select one**.

7. When you are finished, click **Update Vault**.

**To restore a key**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment of the vault that contains the key that you want to restore.

3. From the list of vaults in the compartment, click the name of the vault. You must choose the same vault where the key was backed up originally. (If needed, also change the list scope to the compartment where the key was at the time of backup.)

4. Click **Master Encryption Keys**, and then click **Restore Key**.
5. Choose a source. You can import a backup from an Existing Object Storage Bucket or a pre-authenticated Object Storage URL that you can write to. You can also Upload a File from your computer or a mapped network location.

6. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the Backup Name. Avoid entering confidential information.
   - Click Object Storage URL, and then provide a pre-authenticated URL to an object.

7. When you are finished, click Restore Key.

To update a key from a backup

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment of the vault that contains the key that you want to update from a backup.
3. From the list of vaults in the compartment, click the name of the vault that contains the key.
4. Click Master Encryption Keys, click the key name, and then click Update Key from Backup. (If needed, change the list scope to the compartment of the key, if the key is in a different compartment from the vault.)
5. Choose a source. You can import a backup from an Existing Object Storage Bucket that you have access to or a pre-authenticated Object Storage URL. You can also Upload a File from your computer or a mapped network location.

6. Do one of the following, depending on what you chose in the previous step:
   - Choose a bucket from the dropdown menu. If needed, you can change the compartment to find a bucket in a different compartment. Then, specify the Backup Name. Avoid entering confidential information.
   - Click Object Storage URL, and then provide a pre-authenticated URL. Include the backup name.

7. When you are finished, click Update Key.

To view a work request for a backup or restore operation

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment of the vault (or the vault of the key) that you're interested in.
3. From the list of vaults in the compartment, click the name of the vault, and then click Work Requests.
4. Optionally, click Master Encryption Keys, click the key name, and then click Work Requests. (If needed, change the list scope to the compartment of the key, if the key is in a different compartment from the vault.)
5. For detailed information about the work request, click the work request name.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to back up and restore virtual private vaults and keys:

- BackupVault
- RestoreVaultFromFile
- RestoreVaultFromObjectStore
- RestoreKeyFromFile
- RestoreKeyFromObjectStore

Replicating Vaults and Keys

This topic describes how to replicate a virtual private vault so that you can read the keys in the vault from a different region within the same realm.
You cannot replicate a vault unless it was created as a virtual private vault. Because virtual private vaults are not included as an Always Free resource, you must request the appropriate service limits in the destination region where you want to replicate the vault before you configure replication.

Cross-region replication helps protect your organization in disaster recovery scenarios and in the use of resources across different regions. You can replicate virtual private vaults from one region to another region to make them and the keys that they contain available to meet compliance requirements or to improve latency.

When you configure cross-region replication for a virtual private vault, the Vault service automatically synchronizes the creation, deletion, update, or move of any keys or key versions between the initiating vault and a vault in one destination region. The vault from which the service replicates data is known as the source vault. The vault in the destination region to which the service replicates data from the source vault is known as the vault replica.

The service supports cryptographic operations against the vault and keys in the destination region. Management operations against the vault and keys in the destination region are not supported. For example, you cannot create keys directly in the vault replica, nor can you back up a vault replica. You can note the cryptographic endpoint of the vault in the destination region by viewing the replica details and begin using that endpoint when needed.

When you want to stop replication, you only need to delete the vault replica. Only one destination vault can exist for a given source vault at any time, so you must delete the existing vault replica if you want to set up replication to a different destination region.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: for a typical policy that gives access to vaults, keys, and secrets, see Let security admins manage vaults, keys, and secrets on page 2816. Besides policies for users and groups, you must also write a policy that gives the Vault service the ability to do everything with vaults so it can create and manage vaults on your behalf during replication. For example, the following policy gives permission to the service in all regions realm-wide:

```
Allow service keymanagementservice to manage vaults in tenancy
```

To restrict permissions to specific compartments, specify the compartment instead. For more information about permissions or if you need to write more restrictive policies, see Details for the Vault Service on page 3043.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Using the Console**

You can only replicate active virtual private vaults and active, enabled, or disabled keys.

**To replicate a vault and its keys**

A given virtual private vault can only have one vault replica and the replica must exist in a different region in the same realm. When you replicate a vault, the service automatically replicates all existing keys. Replication does not include secrets.

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that you want to replicate.

3. From the list of vaults in the compartment, click the name of the vault that you are interested in.

4. Click **Replicate Vault**.

5. In the **Replicate Vault** dialog box, choose a destination region from the list, and then click **Create Replica**.

**To view the details of a vault replicated from another vault**

**Note:**
This procedure describes how to view the details of the vault that is created when replication is configured on a source vault.

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault configured for replication whose details you want to view.

3. From the list of vaults in the compartment, click the name of the source vault.

4. Click **View Replica Details**.

5. The details of the replicated vault include the following:
   - **Destination Region:** The region in which the vault replica exists.
   - **Replication State:** The current state of the vault in the destination region regarding replication. (A vault's replication state is unrelated to its lifecycle state. The lifecycle state of the vault in the destination region matches the lifecycle state of the vault in the source region.)
   - **Creation Date:** The date that you started replicating data to the vault in the destination region.
   - **Destination Vault Name:** The name of the vault in the destination region.
   - **OCID:** The unique, Oracle-assigned ID of the vault in the destination region.
   - **Management Endpoint:** The endpoint to use if you need to begin sending requests for management operations to the vault in the destination region.
   - **Cryptographic Endpoint:** The endpoint to use in the event you need to begin sending requests for cryptographic operations to the vault in the destination region.

To view replicated keys

1. The currently selected region is displayed at the top of the Console. From the **Region** menu, select the region that you chose as the destination region when you configured replication.

2. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

3. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the keys you are interested in.

4. From the list of vaults in the compartment, click the name of the vault.

5. To see a list of keys in this vault, click **Master Encryption Keys**. You can see keys in other compartments by changing the list scope.

**To delete a vault replica**

**Note:**
When you configure replication on a vault, deleting the replicated vault stops replication, but otherwise has no impact on its source.

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with a replica that you want to delete.
3. From the list of vaults in the compartment, click the name of the vault.
4. Click View Replica Details.
5. Click the Actions menu (three dots), and then click Delete Replica.
6. In the Confirm Deletion dialog box, click the box, and then type the name of the vault in the destination region.
7. When you are finished, click Delete Replica.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to work with vault replicas:

- CreateVaultReplica
- DeleteVaultReplica
- ListVaultReplicas

Managing Secrets

This topic describes how to manage secrets. Management of secrets includes the ability to do the following:

- Create secrets
- View secret details
- View a list of secrets
- View a list of secret versions for a specific secret
- Update a secret description
- Create a new secret version (by updating secret contents)
- Promote a secret version to current
- Manage a secret's tags
- View a secret's rules
- Add or edit secret rules
- Delete secrets or secret versions to permanently prevent the use of their secret contents
- Move a secret to a new compartment
- Retrieve secret by name

Before You Begin

Before you begin, we recommend that you first read Rules for Secrets on page 5080 and Secret Versions and Rotation States on page 5079 to better understand the implications of working with rules, secret versions, and secret version rotation states.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators:

- The policy Let security admins manage vaults, keys, and secrets on page 2816 lets the specified group do everything with vaults, keys, and secrets.
- The policy Let security admins manage all secrets in a specific vault in a compartment on page 2817 lets the specified group do everything with secrets in a specific vault.
- The policy Let users read, update, and rotate all secrets on page 2818 lets the specified group read, update, and rotate all secrets in any vault in the tenancy.
• For more information about permissions or if you need to write more restrictive policies for secrets, see Details for the Vault Service on page 3043.

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring the traffic associated with your secrets, see Vault Metrics on page 5080.

Moving Resources to a Different Compartment

You can move secrets from one compartment to another. After you move a secret to a new compartment, inherent policies apply immediately and affect access to the secret and secret versions. Moving a secret doesn't affect access to the vault that a secret is associated with. Similarly, you can move a vault from one compartment to another independently of moving any of its secrets. For more information, see Managing Compartments on page 3126.

Using the Console

To create a new secret

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Under List Scope, in the Compartment list, click the name of the compartment where you want to create a secret.
3. From the list of vaults in the compartment, do one of the following:
   • Click the name of the vault where you want to create a secret.
   • Create a new vault for the secret by following the instructions in To create a new vault, and then click the name of the vault.
4. Click Secrets, and then click Create Secret.
5. In the Create Secret dialog box, choose a compartment from the Create in Compartment list. (Secrets can exist outside the compartment the vault is in.)
6. Click Name, and then enter a name to identify the secret. Avoid entering confidential information.
7. Click Description, and then enter a brief description of the secret to help identify it. Avoid entering any confidential information in this field.
8. Choose the master encryption key that you want to use to encrypt the secret contents while they’re imported to the vault. (The key must belong to the same vault. The key must also be a symmetric key. You cannot encrypt secrets with asymmetric keys.)
9. Specify the format of the secret contents you’re providing by choosing a template type from the Secret Type Template list. (You can provide secret contents in plain-text when you use the Console to create a secret or secret version, but secret contents do need to be base64-encoded before they’re sent to the service. The Console automatically encodes plain-text secret contents for you if you choose this format.)
10. Click Secret Contents, and then enter the secret contents. (The maximum allowable size for a secret bundle is 25 KB.)
11. Optionally, you can apply a rule to manage how secrets are used. You can either create a rule regarding the reuse of secret contents across versions of a secret, or you can create a rule specifying when the secret contents expire. For more information about rules, see Rules for Secrets on page 5080.

- **Rule Type.** You can specify a **Secret Reuse Rule** or a **Secret Expiry Rule**. At most, you can have one of each. If you already have one rule, but want to add another, click **+ Another Rule**.
- Reuse rule configuration: You can either enforce the reuse rule so it applies even to deleted secrets versions, or you can allow reuse of secret contents from deleted secret versions.
- Expiry rule configuration: You can set how frequently you want secret contents to expire and what you want to happen when the secret or secret version expires. Expiration of individual secret versions is represented by a period of 1 to 90 days that you can specify with the arrow buttons or entering a number. Expiration of the secret itself is represented by an absolute time and date between 1 to 365 days from the current time and date. Specify this date by using the date picker. You can configure expiry values for both the secret version and secret or just one of the two. (It’s possible to clear the secret version expiry interval, but you must delete the entire expiry rule and start over if you want to set an absolute time to expire the secret.)

12. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

13. When you are finished, click **Create Secret**.

**To view secret details**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and then click the name of the secret for which you want to see configuration details. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)
5. The console displays the following information:
   - **OCID:** The unique, Oracle-assigned ID of the secret.
   - **Created:** The date and time when you initially created the secret.
   - **Compartment:** The name of the compartment that contains the secret.
   - **Vault:** The name of the vault that contains the secret.

**To view a list of secrets**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secrets you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. To see a list of secrets in this vault, click **Secrets**. You can see secrets in different compartments by changing the list scope.

**To view a list of secret versions**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and then click the name of the secret for which you want to see a list of secret versions. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)
5. Under **Secret Version List**, you can see all versions that exist for the selected secret. For more information about secret versions, see Secret Versions and Rotation States on page 5079.

**To update a secret description**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret with the description you want to update.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and then click the name of the secret you want to edit. (If needed, first change the list scope to the compartment that contains the secret.)
5. Click **Edit**.
6. In the **Edit Secret** dialog box, click **Description**, and then enter a new description. Avoid entering any confidential information in this field.
7. When you are finished, click **Save Changes**.

**To update a secret's contents to create a new secret version**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the secret you want to provide with new secret contents.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and then click the name of the secret with the secret contents you want to update. (If needed, first change the list scope to the compartment that contains the secret.)
5. Click **Create Secret Version**. (You can only create a new secret version for a secret that's not pending deletion.)
6. Specify the format of the secret contents you're providing by choosing a template type from the **Secret Type Template** list. (You can provide secret contents in plain-text when you use the Console to create a secret or secret version, but secret contents do need to be base64-encoded before they're sent to the service. The Console automatically encodes plain-text secret contents for you if you choose this format.)
7. Click **Secret Contents**, and then enter the secret contents. (The maximum allowable size for a secret bundle is 25 KB.)
8. If you don't want to immediately promote the new secret version to current, select the **Set to Pending** check box. Otherwise, this new secret version is automatically promoted as the current version.
9. Click **Create Secret Version**.

**To promote an existing secret version to current**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret that you want to update.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and then click the name of the secret that you want to use a different secret version. (If needed, first change the list scope to the compartment that contains the secret.)
5. Make a different secret version the current secret version by doing one of the following:
   • Click **Edit**, click **Current Version**, and then click the version number you want to promote. When you're ready, click **Save Changes**.
   • Under **Secret Version List**, locate the version number that you want to promote, click the Actions icon (three dots) for that secret version, and then click **Promote to Current**. Confirm the promotion by clicking **Promote to Current**.

**To manage a secret's tags**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to manage tags.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, locate the secret you want to manage, and then click the secret name. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)
5. On the **Secret Details** page, click the **Tags** tab to view or edit existing tags. Or, click **Add Tags** to add new ones.

**To view a secret's rules**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to view configured rules.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret that has rules you want to view. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)

5. On the **Secret Details** page, click **Rules** to view existing rules.

### To edit a secret’s rules

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret for which you want to add or edit rules.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, and then click the name of the secret. (If needed, first change the list scope to the compartment that contains the secret, and then click the secret name.)

5. On the **Secret Details** page, click **Rules**, and then click **Add/Edit Rules**.

   - **Rule Type**. You can specify a **Secret Reuse Rule** or a **Secret Expiry Rule**. At most, you can have one of each. If you already have one rule, but want to add another, click **+ Another Rule**.
   - **Reuse rule configuration**: You can either enforce the reuse rule so it applies even to deleted secrets versions, or you can allow reuse of secret contents from deleted secret versions.
   - **Expiry rule configuration**: You can set how frequently you want secret contents to expire and what you want to happen when the secret or secret version expires. Expiration of individual secret versions is represented by a period of 1 to 90 days that you can specify with the arrow buttons or entering a number. Expiration of the secret itself is represented by an absolute time and date between 1 to 365 days from the current time and date. Specify this date by using the date picker. You can configure expiry values for both the secret version and secret or just one of the two. (It's possible to clear the secret version expiry interval, but you must delete the entire expiry rule and start over if you want to set an absolute time to expire the secret.)

6. If you want to delete a rule while you're configuring them, do one of the following:
   - To delete the secret version rule, clear the days configured.
   - To delete the rule altogether, click the X next to the rule.

7. When you're ready, click **Save Changes**.

### To delete a secret

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a secret is pending deletion, resources or services that rely on that secret immediately become inaccessible. The secret also can't be rotated or otherwise updated. When the secret is deleted, its are irreversibly destroyed. If you want to restore the use of a secret before it is permanently deleted, you can cancel its deletion.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you want to delete.

3. From the list of vaults in the compartment, click the vault name.

4. Click **Secrets**, locate the secret you want to delete, and then click the Actions icon (three dots) for that secret. (If needed, first change the list scope to the compartment that contains the secret.)

5. In the **Actions** menu, click **Delete Secret**.

6. Confirm that you want to delete the secret by clicking the box and then typing the secret name.

7. Schedule when you want Vault to delete the secret. By default, the service schedules secrets for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.

8. When you're ready, click **Delete Secret**. If needed, you can restore use of the secret and access to resources and services that use the contents of that secret by canceling the scheduled deletion and making the secret version current again.
To delete a secret version

Caution:

When a secret version is pending deletion, resources or services that rely on that secret version immediately become inaccessible. The secret version also can't be rotated or otherwise updated. When the secret version is deleted, its contents are irreversibly destroyed. If you want to restore the use of a secret version before it is permanently deleted, you can cancel its deletion.

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret with the secret version you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, and the click the secret name. (If needed, first change the list scope to the compartment that contains the secret.)
5. Under **Secret Versions List**, locate the secret version, and then click the Actions icon (three dots) for that secret version.
6. In the **Actions** menu, click **Delete Secret Version**.
7. Confirm that you want to delete the secret version by clicking the box and then typing the secret version number.
8. Schedule when you want Vault to delete the secret version. By default, the service schedules secret versions for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.
9. When you're ready, click **Delete Secret Version**. If needed, you can restore use of the secret version and access to resources or services that use the contents of that secret version by canceling the scheduled deletion and making the secret version current again.

To cancel the deletion of a secret

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret you no longer want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, locate the secret for which you want to cancel deletion, and then click the Actions icon (three dots) for that secret. (If needed, first change the list scope to the compartment that contains the secret.)
5. In the **Actions** menu, click **Cancel Deletion**.
6. Confirm that you want to cancel the secret's deletion by clicking **Cancel Deletion**. Access to the secret and any resources or services that used the contents of the secret can be restored after the secret returns to active, current use.

To cancel the deletion of a secret version

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that has the secret with the secret version you no longer want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Secrets**, locate the secret with the secret version for which you want to cancel deletion, and then click the secret name. (If needed, first change the list scope to the compartment that contains the secret.)
5. Under **Secret Versions List**, locate the secret version, and then click the Actions icon (three dots) for that secret version.
6. In the **Actions** menu, click **Cancel Deletion**.
7. Confirm that you want to cancel the secret version's deletion by clicking **Cancel Deletion**. Access to the secret version and any resources or services that used its contents can be restored after the secret version returns to active, current use.

To move a secret to a different compartment

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Under **Table Scope**, in the **Compartment** list, choose the compartment that contains the vault that has the secret that you want to move.

3. Click **Secrets**. Find the secret in the list, click the the Actions icon (three dots), and then click **Move Resource**. (If needed, first change the list scope to the compartment that contains the secret.)

4. Choose the destination compartment from the list.

5. Click **Move Resource**.

6. If there are alarms monitoring the secret, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 3542 for more information.

### Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

**Tip:**

Each region has a unique endpoint for create, update, and list operations for secrets. This endpoint is referred to as the control plane URL or secret management endpoint. Each region also has a unique endpoint for operations related to retrieving secret contents. This endpoint is known as the data plane URL or the secret retrieval endpoint. When using the CLI for secret operations, you must provide the appropriate endpoint for the type of operation. For regional endpoints, see the API Documentation.

### To create a new secret

Open a command prompt and run `oci vault secret create-base64` to create a new secret:

**Note:**

You must specify a symmetric key to encrypt the secret during import to the vault. You cannot encrypt secrets with asymmetric keys. Furthermore, the key must exist in the vault that you specify.

```bash
oci vault secret create-base64 --compartment-id <target_compartment_id> --secret-name <secret_name> --vault-id <target_vault_id> --description <secret_description_text> --key-id <encryption_key_id> --secret-content-content <base64_encoded_secret_content> --secret-content-name <unique_content_name> --secret-content-stage <secret_version_rotation_state>
```

For example:

```bash
oci vault secret create-base64 --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbqgmmuz2zzum45ibplooqtabwk3zz --secret-name testSecret --vault-id ocid1.vault.oc1.iad.exampleyaaeuk.examplesuxtdqxczg4ouq2mh223z4o2ojs404q4ghmt6r7 example --description "this is a test secret" --key-id ocid1.key.oc1.iad.exampleyaaeuk.abuwcvbwr2nbfvraqoqmesmhopc74rlqupwyv3byhikd4577rrky7ex --secret-content-content bXlwYXNzd29yZA== --secret-content-name testpassword1 --secret-content-stage CURRENT
```

Avoid entering confidential information.

### To view a secret's details

Open a command prompt and run `oci vault secret get` to view a specific secret's details:

```bash
oci vault secret get --secret-id <secret_OCID>
```
For example:

```bash
oci vault secret get --secret-id
oci1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzq14qmpbrtd7pprafhvcfik6wuitexample
```

To view a list of secrets

Open a command prompt and run `oci vault secret list` to list secrets in a vault:

```bash
oci vault secret list --compartment-id <target_compartment_id>
```

For example:

```bash
oci vault secret list --compartment-id
oci1.compartment.oc1..example1example25qrlo4agcmothkbqgqmu2zzum45ibploogtabwkw3zz
```

To view a list of secret versions

Open a command prompt and run `oci vault secret-version list` to view a list of secret versions for a specific secret:

```bash
oci vault secret-version list --secret-id <secret_OCID>
```

For example:

```bash
oci vault secret-version list --secret-id
oci1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzq14qmpbrtd7pprafhvcfik6wuitexample
```

To update a secret description

Open a command prompt and run `oci vault secret update` to edit a secret's description.

```bash
To update a secret's contents to create a new secret version
```

Open a command prompt and run `oci vault secret update` to edit a secret's description.

```
Caution:
Avoid entering confidential information in the secret description. Also, you
must update the current secret version number, secret contents, and secret
rules independently of one another. Lastly, you can only update secrets in an
Active lifecycle state.
```

```bash
oci vault secret update --secret-id <secret_OCID> --
description <secret_description_text>
```

For example:

```bash
oci vault secret update --secret-id
oci1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqzq14qmpbrtd7pprafhvcfik6wuitexample
--description "this is a new secret description"
```

To update a secret's contents to create a new secret version

Open a command prompt and run `oci vault secret update-base64` to update a secret's contents to create
a new secret version:

```bash
oci vault secret update-base64 --secret-id <target_secret_id> --secret-
content-content <base64_encoded_secret_content>
```
For example:

```bash
oci vault secret update-base64 --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample
--secret-content-content bXluZXdwYXNzd29yZA==
```

### To promote an existing secret version to current

Open a command prompt and run `oci vault secret update` to promote a secret version to current, active use:

```bash
oci vault secret update --secret-id <target_secret_id> --current-version-number <target_secret_version_number>
```

For example:

```bash
oci vault secret update --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample
--current-version-number 3
```

### To manage a secret's tags

Open a command prompt and run `oci vault secret update` to manage a secret's tags:

```bash
oci vault secret update --secret-id <target_secret_id> --defined-tags <defined_tags_in_JSON_format>
```

For example:

```bash
oci vault secret update --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample
--defined-tags '({"ProdSecrets" : {"NodePool" : "10"}})'
```

### To view a secret's rules

Open a command prompt and run `oci vault secret get` to view a secret's configured rules:

```bash
oci vault secret get --secret-id <target_secret_id>
```

For example:

```bash
oci vault secret get --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample
```

### To edit a secret's rules

Open a command prompt and run `oci vault secret update` to edit a secret's configured rules:

```bash
oci vault secret update --secret-id <target_secret_id> --secret-rules <secret_rules_in_JSON_format>
```

For example:

```bash
oci vault secret update --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhivcfik6wuitexample
```
You can specify a secret reuse rule or a secret expiry rule. At most, you can have one of each rule type.

**To delete a secret**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a secret is pending deletion, resources or services that rely on that secret immediately become inaccessible. The secret also can’t be rotated or otherwise updated. When the secret is deleted, secret contents are irreversibly destroyed. If you want to restore the use of a secret before it is permanently deleted, you can cancel its deletion.</td>
</tr>
</tbody>
</table>

Open a command prompt and run `oci vault secret schedule-secret-deletion` to schedule a secret’s deletion:

```bash
oci vault secret schedule-secret-deletion --secret-id <target_secret_id> --time-of-deletion <time_in_rfc3339_format>
```

For example:

```bash
oci vault secret schedule-secret-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhicfik6wuitexample --time-of-deletion 2020-04-30T10:00:00Z
```

By default, the service schedules secrets for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days.

**To delete a secret version**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a secret version is pending deletion, resources or services that rely on that secret version immediately become inaccessible. The secret version also can’t be rotated or otherwise updated. When the secret version is deleted, its contents are irreversibly destroyed. If you want to restore the use of a secret version before it is permanently deleted, you can cancel its deletion.</td>
</tr>
</tbody>
</table>

Open a command prompt and run `oci vault secret-version schedule-deletion` to schedule a secret version’s deletion:

```bash
oci vault secret-version schedule-deletion --secret-id <target_secret_id> --secret-version-number <target_secret_version_number> --time-of-deletion <time_in_rfc3339_format>
```

For example:

```bash
oci vault secret-version schedule-deletion --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhicfik6wuitexample --secret-version-number 1 --time-of-deletion 2020-04-09
```

By default, the service schedules secret versions for deletion 30 days from the current date and time. You can set a range between 1 day and 30 days. In the preceding example, because no time is specified, the time of deletion defaults to midnight Coordinated Universal Time (UTC).
**To cancel the deletion of a secret**

Open a command prompt and run `oci vault secret cancel-secret-deletion` to cancel the scheduled deletion of a secret:

```
oci vault secret cancel-secret-deletion --secret-id <target_secret_id>
```

For example:

```
oci vault secret cancel-secret-deletion --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhvcfik6wuitexample
```

**To cancel the deletion of a secret version**

Open a command prompt and run `oci vault secret-version cancel-deletion` to cancel the scheduled deletion of a secret version:

```
oci vault secret-version cancel-deletion --secret-id <target_secret_id> --secret-version-number <target_secret_version_number>
```

For example:

```
oci vault secret-version cancel-deletion --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhvcfik6wuitexample
--secret-version-number 1
```

**To move a secret to a different compartment**

Open a command prompt and run `oci vault secret change-compartment` to move a secret to a different compartment:

```
oci vault secret change-compartment --secret-id <target_secret_id> --compartment-id <new_compartment_id>
```

For example:

```
oci vault secret change-compartment --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhvcfik6wuitexample
--compartment-id
ocid1.tenancy.oc1..exampleati4wjo6cvbxq4iusld51sdneskcfy7lr4a6wfauxuwrwed5b3xea
```

**To view the contents and properties of the current secret version**

Open a command prompt and run `oci secrets secret-bundle get` to view the contents and properties of the current secret version:

```
oci secrets secret-bundle get --secret-id <target_secret_id> --stage <target_secret_version_rotation_state>
```

For example:

```
oci secrets secret-bundle get --secret-id
ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbqjzql4qmpbrtd7pprafhvcfik6wuitexample
--stage CURRENT
```
You can also query for a secret with its name and vault ID using the following command:

```bash
oci secrets secret-bundle get-secret-bundle-by-name --secret-name target_secret_name --vault-id target_vault_id --stage target_secret_version_rotation_state
```

For example:

```bash
oci secrets secret-bundle get-secret-bundle-by-name --secret-name testSecret --vault-id ocid1.vault.oc1.iad.exampleyaaeuk.examplesuxtdqxcz1vygwk4ouq2mhzr223g0o2oj54q4ghmtddlj --stage CURRENT
```

**Note:**
Alternatively, you can use the GetSecretBundleByName API.

**To view the properties for all versions of a secret**

Open a command prompt and run `oci secrets secret-bundle-version list-versions` to view information about each of a secret's secret versions:

```bash
oci secrets secret-bundle-version list-versions --secret-id <target_secret_id>
```

For example:

```bash
oci secrets secret-bundle-version list-versions --secret-id ocid1.vaultsecret.oc1.iad.exampleaz5qacpqahuecvbjqzql4qmpbrtd7pprafhivcfik6wuitexample
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

**Tip:**

Each region has a unique endpoint for create, update, and list operations for secrets. This endpoint is referred to as the control plane URL or secret management endpoint. Each region also has a unique endpoint for operations related to retrieving secret contents. This endpoint is known as the data plane URL or the secret retrieval endpoint. For regional endpoints, see the API Documentation.

Use the following operations to manage secrets:

- CreateSecret
- GetSecret
- UpdateSecret
- GetSecretVersion
- ListSecrets
- ListSecretVersions
- ScheduleSecretDeletion
- CancelSecretDeletion
- ScheduleSecretVersionDeletion
- CancelSecretVersionDeletion
- ChangeSecretCompartment
Use the following operations to retrieve secrets:

- GetSecretBundle
- ListSecretBundleVersions
- GetSecretBundleByName

**Secret Versions and Rotation States**

This topic explains the relationship between secrets, secret versions, and rotation states. It also discusses the impact of service limits on secret versions. Understanding secret versions and rotation states will help you track and manage secret contents to stay in compliance with any limits, rotation or other rules, or regulations. For a basic definition of secret concepts, including secret versions and rotation states, see Key and Secret Management Concepts on page 5007. For information about working with secret versions, see Managing Secrets on page 5067.

**Secret Versions**

Every secret has at least one secret version. Every time you update the contents of a secret, you create a new secret version. Secret version numbers start at 1 and increment by 1. While every secret has at least one version, you might have multiple versions of a secret at any given time.

In addition to a version number, you can identify a secret version by its version name or rotation state. A secret version's rotation state represents how the secret is being used. Typically, applications need the current version of a secret. Marking a secret version as the 'current' version indicates that it has the secret contents currently used for access to the intended resource. Meaning, if you stored the password to connect to a database as a secret, when you request the current version of that secret, you do so with the knowledge that it’s the password that the database currently expects.

**Rotation States**

Secret versions can have more than one rotation state at a time. Where only one secret version exists, such as when you first create a secret, the secret version is automatically marked as both 'current' and the 'latest'. The 'latest' version of a secret contains the secret contents that were last uploaded to the vault, in case you want to keep track of that.

When you rotate a secret to upload new secret contents, you can mark it as 'pending'. Marking a secret version's rotation state as 'pending' lets you upload the secret contents to the vault without immediately putting them into active use. You can continue using the 'current' secret version until you're ready to promote a pending secret version to 'current' status. This typically happens after you've rotated credentials on the target resource or service first. You don’t want to unexpectedly change a secret version. Changing what secret version is current prevents the application that needs it from retrieving the expected secret version from the vault.

For the purposes of rolling back to a previous version easily, such as when you've made a mistake in updating the secret contents or when you've restored a backup of an older resource and need to resume using older secret contents, secret versions can also be marked as 'previous.' A secret version marked as 'previous' was previously a secret version marked as 'current.' To roll back to a previous version, you update the secret to specify the secret version number you want.

As long as a secret version hasn't been deleted, you can update the secret to use that past secret version. When you update the secret, the secret version number you choose gets marked as 'current.' This has the same effect as promoting a secret version to 'current.'

You can only delete secret versions that have been marked as 'deprecated.' A deprecated secret version is one that’s not marked as 'current,' 'pending,' or 'previous.' This helps to prevent circumstances where you might delete a secret version that you need later (for example, when restoring a database you backed up previously). A secret version that’s marked as anything other than 'deprecated' can be marked as 'current' to return it to active use.
Secret Version Limits

The limits on secret versions applies to both a secret’s versions that are in use and versions that are deprecated, including those that have been scheduled for deletion. For information about limits on the number of versions for a given secret and for secret versions in a tenancy, see Service Limits.

Rules for Secrets

This topic explains how the rules you configure for secrets govern their usage. Configuring rules for secrets can help you meet compliance requirements. For information about how to configure or view rules, see Managing Secrets on page 5067.

When you create a secret, you can configure the following types of rules:

- **Secret Reuse Rule.** This type of rule prevents the reuse of secret contents across different versions of a secret.
- **Secret Expiry Rule.** This type of rule restricts how long the secret contents of a particular secret version can remain in use. This rule can also block the retrieval of secret contents for a secret or secret version past the configured expiration date.

You might want to configure either or both of these secret rules to establish best practices around security. You can improve your security posture by acting on secrets that don’t adhere to the rules or, in the case of expiry rules, are in danger of violating them in due time.

Secrets are protected at rest with the encryption guarantees of a Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification-compliant hardware security module (HSM) that backs the vault where the secret is created and stored. However, while in application memory, a secret could be compromised. Preventing the reuse of secret contents by multiple secret versions serves to limit the scope of affected resources in the event of a security breach involving the stored credentials. When only one resource uses the secret contents of a secret version, that resource is the only one that can be impacted. You can deprecate a secret version and then delete it if you find out you can no longer safely use its secret contents. You can choose whether secret reuse rules apply even to deleted secret versions.

Similarly, configuring an expiry rule to specify a time range for how long a secret version can exist also helps limit the impact of a potential security breach. The longer that a set of credentials are used, the more time an attacker has to try to access or decipher them. Frequently updating a secret with new secret contents helps keep credentials safer from users with malicious intent. Or, it at least makes shorter the period of time during which compromised credentials can unknowingly be used or disseminated. You can configure a secret version to expire after 1 to 90 days, but the secret can also have an absolute expiration date and time ranging from 1 to 365 days after its creation date. You can configure either of these values or both. You can also decide whether the secret contents are blocked past the expiration date.

The timer for a secret’s expiry rule resets according to the configured interval. No mechanism exists to update the secret contents. You must rotate the secret version manually.

Vault Metrics

You can monitor the usage of your Vault service master encryption keys and secrets by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

This topic describes the metrics emitted by the Vault service in the oci_kms_keys and oci_secrets namespace.

Resources: master encryption keys and secrets.

Overview of the Vault Service Metrics

Vault service metrics help you measure the success and error count of cryptographic operations on keys and the success and error count of HTTP responses to get, create, and update (getSecretBundle, listSecretBundleVersions, createSecret, and updateSecret) operations during the selected time range. You can use metrics data to diagnose and troubleshoot problems with keys and secrets.
To view a default set of metrics charts in the Console, navigate to the key or secret that you're interested in, and then click **Metrics**. You also can use the Monitoring service to create custom queries.

**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a *policy* written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_kms_keys**

The metrics listed in the following table are automatically available for any master encryption keys that you create. You do not need to enable monitoring on the resource to get these metrics.

Vault service metrics for keys include the following *dimensions*:

<table>
<thead>
<tr>
<th>RESOURCEDISPLAYNAME</th>
<th>RESOURCEID</th>
<th>RESPONSECODE</th>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encrypt</td>
<td>Encrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Encrypt calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Decrypt</td>
<td>Decrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Decrypt calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>GenerateDataEncryptionKey</td>
<td>GenerateDataEncryptionKey Response Count</td>
<td></td>
<td>HTTP responses received by the service for GenerateDataEncryptionKey calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Available Metrics: oci_secrets**

The metrics listed in the following table are automatically available for any secrets that you create. You do not need to enable monitoring on the resource to get these metrics.

Vault service metrics for secrets include the following *dimensions*:

<table>
<thead>
<tr>
<th>DISPLAYNAME</th>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encrypt</td>
<td>Encrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Encrypt calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
</tr>
<tr>
<td>Decrypt</td>
<td>Decrypt Response Count</td>
<td>count</td>
<td>HTTP responses received by the service for Decrypt calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
</tr>
<tr>
<td>GenerateDataEncryptionKey</td>
<td>GenerateDataEncryptionKey Response Count</td>
<td></td>
<td>HTTP responses received by the service for GenerateDataEncryptionKey calls.</td>
<td>resourceDisplayName, resourceId, responseCode</td>
<td></td>
</tr>
</tbody>
</table>
RESOURCEID

The OCID of the resource to which the metrics apply.

RESPONSECODE

The HTTP response code to the operation to which the metrics apply.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetSecretBundle</td>
<td>GetSecretBundle</td>
<td>count</td>
<td>HTTP responses received by the service for GetSecretBundle calls during the selected time range.</td>
<td>displayName, resourceId, responseCode</td>
</tr>
<tr>
<td>ListSecretBundleVersions</td>
<td>ListSecretBundleVersions</td>
<td>count</td>
<td>HTTP responses received by the service for ListSecretBundleVersions calls during the selected time range.</td>
<td></td>
</tr>
<tr>
<td>CreateSecret</td>
<td>CreateSecret</td>
<td>count</td>
<td>HTTP responses received by the service for CreateSecret calls during the selected time range.</td>
<td></td>
</tr>
<tr>
<td>UpdateSecret</td>
<td>UpdateSecret</td>
<td>count</td>
<td>HTTP responses received by the service for UpdateSecret calls during the selected time range.</td>
<td></td>
</tr>
</tbody>
</table>

Using the Console

To view default metric charts for a single master encryption key

1. Open the navigation menu, click Identity & Security, and then click Vault.
2. Click a vault to view the resources it contains.
3. Click a key name to view its details.
4. Under Resources, click Metrics.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for multiple master encryption keys

2. For Compartment, select the compartment that contains the master encryption keys that you're interested in.
3. For Metric Namespace, select `oci_kms_keys`.
   
The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

   **Tip:**
   
   If there are multiple master encryption keys in the compartment, the charts default to show a separate line for each master encryption key. You can instead show a single line aggregated across all master encryption keys in the compartment by selecting the Aggregate Metric Streams check box.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**To view default metric charts for a single secret**

1. Open the navigation menu, click **Identity & Security**, and then click **Vault**.
2. Click a vault to view the resources it contains.
3. Click **Secrets**.
4. Click a secret name to view its details.
5. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**To view default metric charts for multiple secrets**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the secrets that you're interested in.
3. For **Metric Namespace**, select `oci_secrets`.
   
The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

   **Tip:**
   
   If there are multiple secrets in the compartment, the charts default to show a separate line for each secret. You can instead show a single line aggregated across all secrets in the compartment by selecting the Aggregate Metric Streams check box.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Troubleshooting the Vault Service**

This section covers common issues related to the Vault service and how you can address them:

- Creating a Secret Fails Due to Authorization or Resource Not Found on page 5084
- Operation Fails Due to Conflicting Vault State on page 5084
Creating a Secret Fails Due to Authorization or Resource Not Found

There are several reasons why you might receive the following error when creating a secret, "Either you don't have permission to create this resource or the vault where you want to create it doesn't exist."

You might not have the required permissions. You need permissions for the vault where you want to create the secret and for the master encryption key that you want to use to encrypt the secret. If there's no policy that grants you the permissions you need, then an administrator must create one for you or add you to a group that's already named in a policy. If you're an administrator, refer to the following example policy:

- The policy Let security admins manage vaults, keys, and secrets lets the specified group do everything with vaults, keys, and secrets.

To write more restrictive policies, see Details for the Vault Service on page 3043. If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

It's possible that the vault doesn't exist. You can only create a secret in a vault that exists and only when you have permissions to do so.

Operation Fails Due to Conflicting Vault State

There are several reasons why an operation might result in the following error, "The state of the vault that contains this resource conflicts with the requested operation."

The vault lifecycle state shows that the vault is in a state that prevents the requested operation from proceeding or succeeding. This includes interstitial lifecycle states (for example, "Creating") or terminal states (for example, "Deleted"). Most operations are blocked when a vault is pending deletion.

The service might not recognize the same vault state as seen by a client application. This can happen, for example, if you recently changed the vault lifecycle state. The Vault service is eventually consistent regarding resource state. So, if this is the issue, you can try again later.

Developing with the Vault Service

You can use Oracle Cloud Infrastructure developer resources to perform tasks programmatically with the Vault service.

APIs for Vault

These are the API references for Vault:

- API for key management
- API for secret management
- API for secret retrieval

CLIs for Vault

These are the CLI references for Vault:

- CLI for key management
- CLI for secret management
- CLI for secret retrieval

SDKs, DevOps Tools, and Other Resources

For information about other programmatic resources that you can use to work with Vault, including SDKs, DevOps tools and plugins such as Terraform, and Cloud Shell, see Developer Guide on page 5302.
Get Started with Vault

Oracle Cloud Infrastructure Vault lets you centrally manage the encryption keys that protect your data and the secret credentials that you use to securely access resources.

Benefits

<table>
<thead>
<tr>
<th>Secures your Oracle Cloud Infrastructure resources</th>
<th>Links to get started:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vault integrates with Object Storage, Block Volume, File Storage, and Streaming to support encryption of data in buckets, block or boot volumes, file systems, and stream pools. Container Engine for Kubernetes integrates with the Vault service to support the creation of new clusters with encrypted Kubernetes secrets at rest in the etcd key-value store.</td>

Protection for your keys

Keys are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. The Vault service uses the Advanced Encryption Standard (AES) as its encryption algorithm and its keys are AES symmetric keys.

Simplifies and enhances compliance

Vault integrates with Identity and Access Management (IAM) so you can control permissions on individual keys, secrets, and key vaults, and monitor their lifecycle with using Oracle Audit.
This chapter explains how to set up and manage software-defined data centers (SDDCs) in Oracle Cloud Infrastructure.

Oracle Cloud VMware Solution

Oracle Cloud VMware Solution allows you to create and manage VMware enabled software-defined data centers (SDDCs) in Oracle Cloud Infrastructure.

Solution Highlights

An Oracle Cloud VMware Solution gives you full access to the features of a VMware SDDC, along with the following benefits:

- **High availability**: All VMware components are distributed across different fault domains within the Oracle Cloud Infrastructure region’s availability domains. vSAN converged storage technology replicates data across all of the ESXi hosts in the SDDC.
- **Scalability**: You can start with 3 ESXi hosts and scale up to 64 hosts in a single SDDC.
- **Lift and shift**: Migration of on-premises VMware workloads to a Oracle Cloud VMware Solution is seamless.
- **Full integration**: Because the SDDC resides in a virtual cloud network (VCN), it can be configured to communicate with other Oracle Cloud Infrastructure resources such as Compute instances, DB systems and Autonomous Databases, and so on.
- **Manageability**: The Oracle Cloud Infrastructure Console provides workflows to facilitate SDDC creation and networking configuration.
- **Layer 2 networking**: SDDCs are configured with VLANs, which support applications that need layer 2 networking to run in the public cloud.

**Note:**

Bring your own hypervisor deployment of ESXi on bare metal Compute instances is not supported.

SDDC Details

An Oracle Cloud Infrastructure SDDC base configuration has the following properties:

- From 3 to 64 ESXi hosts on Oracle Cloud Infrastructure bare metal BM.DenseIO2.52 Compute instances
- 156 OPCUs, 2304 GB of physical memory, and 153 TB of NVMe-based raw storage
- A version of VMware software on each ESXi host
- An subnet and VLANs in an Oracle Cloud Infrastructure VCN

Supported Shapes

Currently, the only shape supported for ESXi hosts is a two-socket BM.DenseIO2.52 with two CPUs each running 26 cores. See Dense I/O Shapes on page 977 for more detail.
The following diagram shows how the various components of the Oracle Cloud VMware Solution SDDC are deployed on Oracle Cloud Infrastructure bare metal Compute instances, and how the solution is integrated into the Oracle Cloud Infrastructure environment.

The diagram shows three ESXi hosts of an SDDC that resides in an Oracle Cloud Infrastructure VCN. The center host shows the installed VMware software components for compute (vSphere), network (NSX-T), and storage (vSAN) support. The NSX overlay manages the flow of traffic between the VMs, and between the VMs and the rest of the resources in the solution. The VCN here includes various gateways that allow connectivity between the SDDC and an on-premises network, the internet, and the Oracle Services Network.

When you provision an SDDC, you can enable HCX Manager (not shown in the diagram). HCX is an application mobility platform that simplifies application migration, workload rebalancing, and business continuity across data centers and clouds. For HCX to function properly in your VMware solution, you must have:

- A FastConnect connection for intersite communication
- A NAT gateway as required by HCX Manager for license activation, updates, and VMware enhanced support

**Note:**

HCX Manager requires connectivity to a VMware SaaS portal provided by a NAT gateway. Read more about VMware's requirements for HCX Manager:

**Why does HCX Manager require connectivity for activation and updates?**

**About the VMware Software**

Oracle Cloud Infrastructure's VMware software bundle contains vSphere, vSAN, NSX, vCenter, and HCX components to support compute, storage, and network needs for a fully functional VMware environment.

- **vSphere:** vSphere is VMware's virtualization platform for unified management of the SDDC's CPU, storage, and networking infrastructure. Two key components of vSphere are ESXi hypervisor and vCenter Server.
- **NSX-T:** NSX-T Data Center provides the SDDC with its virtual networking and security capabilities. The NSX-T deployment includes NSX Manager unified appliances with NSX-T Local Manager and NSX-T Controller, and NSX-T Edge nodes.
- **vSAN:** Oracle Cloud VMware Solution SDDCs use VMware's vSAN storage technology, which provides a single shared datastore for compute and network management workloads (VMs).
- **HCX:** The Hybrid Cloud Extension is an application mobility platform that removes complexity from application and workload migration. HCX is optionally installed as a plug-in when you set up your SDDC. You can choose to
install HCX Advanced at no additional cost, or HCX Enterprise as a billed upgrade. See HCX License Types on page 5088 for more information.

The following table shows the available versions of the software bundle, along with the version of each component:

<table>
<thead>
<tr>
<th>Software Version</th>
<th>vSphere</th>
<th>vSAN</th>
<th>NSX-T</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.7 update 3</td>
<td>6.7 U3</td>
<td>6.7 U3</td>
<td>3.1.2</td>
</tr>
<tr>
<td>6.5 update 3</td>
<td>6.5 U3</td>
<td>6.5 U3</td>
<td>3.1.2</td>
</tr>
<tr>
<td>7.0 update 2</td>
<td>7.0 U2</td>
<td>7.0 U2</td>
<td>3.1.2</td>
</tr>
</tbody>
</table>

When you provision the SDDC, you select the version of this software bundle to install on the ESXi hosts. You can change the SDDC’s software version later. When you add ESXi hosts to the SDDC, the version of software installed on new hosts is the version currently associated with the SDDC.

Note:
- If you change the VMware software version after provisioning an SDDC, the new version is used only on ESXi hosts that you add to the SDDC. The software version of existing hosts is not changed.
- Changes that you make to the SDDC by using the Oracle Cloud Infrastructure Console, API, or CLI are not automatically made in vCenter. For example, if you change the software version or the SSH keys, the change applies only to ESXi hosts that you add to the SDDC. To change these properties for existing hosts, you must make the applicable updates in vCenter manually.

Upgrading From vSphere Version 6.5 or 6.7 to 7.0.

Architectural changes to the platform from vSphere version 6.x to 7.x can potentially cause loss of data or connectivity when implementing an in-place upgrade. Oracle doesn't recommend or support an in-place upgrade of a vSphere SDDC from versions 6.5 or 6.7 to vSphere 7.0 or later. Instead, deploy a new vSphere 7.0 SDDC on Oracle Cloud Infrastructure VMware Solution and use workload mobility technologies such as VMware HCX to migrate workloads to the new vSphere 7 SDDC.

For more detail on migrating VMware workloads between SDDC clusters, refer to the playbook Migrate your on-premises VMware workloads to the cloud.

HCX License Types

The Hybrid Cloud Extension (HCX) is an application mobility platform that simplifies application migration, workload rebalancing, and business continuity across data centers and clouds. To run HCX, each physical socket at the destination must have at least one license key assigned. The number of on-premises keys provided depends on the HCX license type you choose:
- **Advanced License**: *(No additional cost: Default option)*
  Includes 3 on-premises connection license keys. Choose this option if you're migrating a few workloads and are tolerant of application downtime.
- **Enterprise License**: *(Billed upgrade)*
  Includes 10 on-premises connection license keys. Choose this option if you're migrating many mission-critical workloads with zero downtime tolerance. HCX Enterprise charges are billed monthly and are independent from host billing intervals. After SDDC provisioning is complete, you can view the HCX Monthly Billing Cycle End Date on the Details page.

After you provision your SDDC, you can change your HCX license type:
• **Upgrading to Enterprise:** Increases the number of on-premises connection keys issued from 3 to 10. The upgrade work request is initiated immediately. The HCX Enterprise billing cycle begins as soon as the work request is complete.

• **Downgrading to Advanced:** Decreases the number of on-premises connection keys from 10 to 3. You must specify 3 license keys to retain after the downgrade. The downgrade request remains in a pending state until the HCX Monthly Billing Cycle End Date. You can cancel the downgrade request as long as it is still in a pending state.

For more information, see To change the HCX license type on page 5099.

### VMware Billing Options

Oracle Cloud Infrastructure's VMware solution bundle offers flexible billing options so you can choose a payment interval that best suits your requirements. Each pricing interval requires a minimum host runtime commitment and offers different pricing advantages. For full pricing information for each option, see Oracle Compute Pricing and Oracle Cost Estimator.

<table>
<thead>
<tr>
<th>Pricing Interval</th>
<th>Required Commitment</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hourly</td>
<td>Hourly pricing requires a minimum of 8 hours of committed host runtime</td>
<td>Use this interval for test projects or short-term high utilization events where extra capacity is required for a very limited time.</td>
</tr>
<tr>
<td>Monthly</td>
<td>Monthly pricing requires a minimum of 1 month of committed host runtime.</td>
<td>This interval is a common option, and is the default selection.</td>
</tr>
<tr>
<td>Yearly</td>
<td>One year pricing requires a minimum of 1 year of committed host runtime.</td>
<td>Use this interval for long-term projects such as workload or application migration to Oracle Cloud Infrastructure.</td>
</tr>
<tr>
<td>Every Three Years</td>
<td>Three year pricing requires a minimum of 3 years of committed host runtime.</td>
<td>Use this interval for very long-term projects or mission-critical workloads that aren't easily migrated.</td>
</tr>
</tbody>
</table>

You select an initial pricing interval when you create an SDDC. Any hosts that are created during the SDDC provisioning are subject to the selected interval commitment. After the SDDC is provisioned, you can create additional hosts in the SDDC cluster with longer or shorter pricing intervals at any time. Hosts don't all have to use the same pricing interval, so you can select a pricing interval that best suits the purpose of the host.

You can change a pricing interval for individual hosts. When you change the pricing interval for a host, *the new pricing interval does not take effect until the date and time that the old interval ends.*

For example, let's say you create a host and choose the pricing interval of Every Three Years. If you later decide the host should have a Monthly pricing interval, the new Monthly pricing interval won't take effect for three years. If you cancel your commitment before the end of the selected pricing interval, *billing continues until the interval ends.*

**Important:**

Carefully consider your workload and billing requirements **before** selecting a pricing interval.

### Working with SDDCs

You use the Oracle Cloud Infrastructure Console, API, or CLI to provision and manage SDDC resources. You use VMware's vCenter utility to create and manage workloads in the SDDC.
See the following topics for information and instructions on how to create and manage Oracle Cloud VMware Solution resources:

- Setting Up an Oracle Cloud VMware Solution SDDC on page 5090
- Managing Oracle Cloud VMware Solution SDDCs on page 5097
- Configuring Networking Connectivity for an SDDC on page 5094
- Managing Layer 2 Networking Resources for an SDDC on page 5101

Additional Documentation Resources

The following Oracle Cloud VMware Solution solution playbooks and white papers are available:

- Deploy Zerto to protect your VMware SDDC in the cloud against disasters
  Learn how to deploy Zerto to protect your Oracle Cloud VMware SDDC data in the cloud.
- Deploy Veeam to protect your VMware SDDC in the cloud against disasters
  Learn how to deploy Veeam to protect your Oracle Cloud VMware SDDC data in the cloud.
- Deploy Actifio to protect your VMware SDDC in the cloud against disasters
  Learn how you can configure Actifio backup and disaster recovery solution for guest VMs in Oracle Cloud VMware Solution.
- Deploy a highly available SDDC to the cloud
  Shows you how to deploy a VMware SDDC on Oracle Cloud Infrastructure and then integrate it with other Oracle services running on Oracle Cloud.
- Migrate your on-premises VMware workloads to the cloud
  Outlines the process of online, or live, migration of your VMware workloads from an on-premises data center environment to Oracle Cloud VMware Solution.
- Build a hybrid SDDC by extending your on-premises VMware deployment to Oracle Cloud
  Describes how to set up a hybrid VMware SDDC between your on-premises environment and Oracle Cloud Infrastructure by using Oracle Cloud VMware Solution.
- Learn about connecting to Oracle Cloud and VMware resources
  Describes several methods for connecting to your Oracle Cloud and VMware resources, plus their benefits, limitations, and how to get started.
- Implement disaster recovery for an Oracle Cloud VMware Solution SDDC on the cloud
  Describes how Oracle Cloud VMware Solution uses VMware Site Recovery Manager (SRM) to implement an automated, reliable, and flexible disaster recovery solution for your VMware SDDC.
- Deploy a multitier application stack on a VMware SDDC connected to an autonomous database
  Shows a 3-tier application stack in Oracle Cloud Infrastructure with the application tier deployed in a VMware SDDC that's created by using Oracle Cloud VMware Solution.

Setting Up an Oracle Cloud VMware Solution SDDC

This topic includes information and instructions for provisioning a software-defined data center (SDDC) by using the Oracle Cloud Infrastructure Console or the API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.
Prerequisites

• An existing VCN with an IP address CIDR of the minimum required size or larger available for running the SDDC. The minimum CIDR size for VMware v6.x is /22. The minimum CIDR size for VMware v7.x is /21.

• We recommend that you set up connectivity between the VCN and your on-premises network before provisioning your SDDC. See Access to Your On-Premises Network on page 4124.

• If you do not plan to use the workflow to create an SDDC, ensure that you configure the SDDC's networking resources with the security rules detailed in Security Rules for Oracle Cloud VMware Solution SDDCs on page 5106. Otherwise, provisioning the SDDC will fail.

If you do not yet have a VCN for your SDDC, you can quickly create one and set up an IPSec connection between your on-premises network and the VCN by using the Site-to-Site VPN workflow. See Site-to-Site VPN Quickstart on page 3814 to learn how.

Using the Console

The Create SDDC workflow can create the required networking resources for you (recommended), or you can create them yourself and then select them in the workflow. If you plan to select existing networking resources for your SDDC, ensure that you create them before you start the workflow. The following networking resources are required:

• A provisioning subnet with a route table and a security list - See To create a subnet on page 3697.

• VLANs - See Managing Layer 2 Networking Resources for an SDDC on page 5101.

To create an SDDC

1. Open the navigation menu, click Hybrid, and then click VMware Solution.

2. Click Create SDDC.

3. Provide basic information for the SDDC:

   • SDDC Name: A descriptive name for the SDDC. This name must be unique among all SDDCs in the creating, active, or updating state across all compartments in the region. Avoid entering confidential information.

     **Note:**

     Unlike most display names in the Oracle Cloud Infrastructure Console, this name has the following additional requirements because it is used by vCenter to build URLs:

     • It must be from 1-16 characters long and must start with a letter
     • It can contain only alphanumerical characters and hyphens (-), and hyphens cannot be next to each other

     This name is not case sensitive. For example, "test" and "Test" are treated as the same name.

     • SDDC Compartment: The compartment in which to create the SDDC. All ESXi hosts for this SDDC will be placed in this compartment.

     • Enable HCX: Select this checkbox to have the workflow install the HCX Manager plugin and integrate it with vCenter in the SDDC. You cannot install this plugin later.

       • Choose the HCX license type to install. For more detail, see HCX License Types on page 5088. You can change the license type after provisioning.

     • VMware Software Version: The version of VMware software to install on the ESXi hosts. While the VMware software bundle includes vSphere, vSAN, NSX, and vCenter components, the version you specify here is the version of vSphere. Compatible versions of the other components are installed with the version of
vSphere you select. See About the VMware Software on page 5087 for details about the vSAN, NSX, or vCenter component versions installed. You can change this software version after provisioning.

- **Pricing Interval:** The pricing interval to apply to the ESXi hosts. See VMware Billing Options on page 5089 for more information about available pricing intervals.

- **Number of ESXi Hosts:** The initial number of ESXi hosts to create. Specify at least 3 and at most 64 hosts.

- **Prefix for ESXi Hosts:** (Optional) You can enter a prefix to use for the names of the ESXi hosts to help identify them. This string has the same criteria as the SDDC name. It must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Avoid entering confidential information.

- **SSH Key:** Provide the public key portion of the SSH key. This key is required for remote connections to the ESXi hosts.

- **Availability Domain:** The availability domain in which to create the SDDC. ESXi hosts in the SDDC are distributed across the fault domains in the availability domain to ensure high availability. The management subnet and VLANs for this SDDC must be in this same availability domain.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click Show Advanced Options. The tags you specify are applied to all of the resources in the SDDC.

4. After you complete the Basic Information page, click Next to advance to the SDDC Networks page.

5. Choose a VCN for the SDDC. The VCN can be in a different compartment than the SDDC and its ESXi hosts.

6. If you enabled HCX in step 3, the selected VCN must have a NAT gateway attached to it.

   - If a NAT gateway already exists for the VCN, the name, compartment, and public IP address information is displayed.
   - If there is no NAT gateway attached to the selected VCN, the workflow creates one for you. Enter a name and select a compartment for the NAT gateway.

7. Select whether the workflow should create the network resources for this SDDC (recommended) or use existing network resources that you specify.

   **To have the workflow create the network resources:**

   a. Click Create New Subnet and VLANs.

   b. Enter an available CIDR block in your selected VCN for the SDDC management CIDR. Depending on the software version you choose, the workflow divides this CIDR into equal segments to use for the provisioning subnet and the required VLANs:

<table>
<thead>
<tr>
<th>VMware Versions</th>
<th>Required SDDC CIDR Block Size</th>
<th>Number of Segments</th>
<th>Segment Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.x</td>
<td>/22</td>
<td>7</td>
<td>/25</td>
</tr>
<tr>
<td>7.x</td>
<td>/21</td>
<td>9</td>
<td>/25</td>
</tr>
</tbody>
</table>

   If you are enabling HCX, the segment for the vSphere VLAN is further divided into two equal segments, one for vSphere and the other for HCX. The size must be at least /22 for version 6.x and /21 for version 7.x to allow the maximum of 64 ESXi hosts to each have their own IP address.

   c. Click Check Availability to ensure that CIDR block is available in the selected VCN. The check scans all subnets and VLANs in all compartments of the VCN.

   d. (Optional) Click Edit Network Details to view or edit the information for the subnet and VLANs the workflow will create. Details include the route table and security list for the subnet, and the route table and
NSG for each VLAN. To update the information for the subnet or a VLAN, click the the Actions icon (three dots) on a row, and choose **Edit Subnet** or **Edit VLAN**.

If you have enabled HCX, an additional route rule is created to allow traffic from the vSphere VLAN to the NAT gateway.

**To use existing network resources:**

a. Click **Select Existing Subnet and VLANs**.

b. Choose the compartment and provisioning subnet for your SDDC's management network. You cannot change the subnet after provisioning.

The CIDR value shown is the private address space for your chosen subnet.

c. Choose the compartment and VLAN for each function of your SDDC's management network.

The VLAN Gateway CIDRs shown are the CIDR blocks from which to derive IP addresses for each VLAN's layer 3 traffic. These CIDR blocks also provide the private IP addresses Oracle uses as attachment objects for public IP addresses when EXSi hosts require internet access.

- **NSX Edge Uplink 1**: Uplink used for communication between the VMware SDDC and Oracle Cloud Infrastructure.
- **NSX Edge Uplink 2**: Reserved for future use to deploy public-facing applications on the VMware SDDC.
- **NSX Edge VTEP**: Used for data plane traffic between the ESXi host and NSX Edge.
- **NSX VTEP**: Used for data plane traffic between ESXi hosts.
- **vMotion**: Used for vMotion (VMware migration tool) management and workload.
- **vSAN**: Used for vSAN (VMware storage) data traffic.
- **vSphere**: Used for management of the SDDC components (ESXi, vCenter, NSX-T, and NSX Edge).

**Note:**

If you checked the **Enable HCX** checkbox, verify that the VLAN selected for vSphere contains a route table rule that allows traffic to the NAT gateway. See [Managing Layer 2 Networking Resources for an SDDC](#) on page 5101 for more information.

- **Replication-Net**: Used for the vSphere Replication engine. (VMware version 7.x only)
- **Provisioning-Net**: Used for virtual machine cold migration, cloning, and snapshot migration.
- **HCX**: Used for HCX traffic. This VLAN appears only if you checked the **Enable HCX** checkbox.

8. (Optional) Provide an SDDC workload CIDR block for the workflow to create an initial logical segment for your VMs. The value must be /30 or larger and must not overlap with the VCN or the SDDC network CIDRs. Note that you can add network segments for the SDDC in NSX Manager after the SDDC is provisioned.

9. Click **Next** to review the summary of settings for creating the SDDC.

If you need to make changes, click **Edit Basic Information** or **Edit SDDC Networks** to return to a page, and update the settings, as applicable.

10. When you are satisfied with the summary information, click **Create SDDC**.

The page shows the provisioning status of each resource.

When provisioning is complete, the SDDC's details page includes a username and an initial password that lets you access the vCenter management utility for the SDDC.

**Note:**

The password value displayed in the Oracle Cloud Infrastructure Console is not updated with your current password after you change it.
11. (Optional) You can check the status of provisioning by viewing its work request item from the SDDC’s details page, under Resources.

Provisioning takes approximately two and a half hours to complete.

If errors occur, you can click Retry Provisioning. Clicking Cancel Provisioning cancels the provisioning process and deletes all resources created for the SDDC.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the CreateSddc API to create a VMware solution.

Use these API operations to create networking infrastructure resources for your VMware solution:

- CreateSubnet
- CreateRouteTable
- CreateSecurityList
- CreateNetworkSecurityGroup
- CreateVlan

**What’s Next?**

After you provisioning your SDDC, you might want to perform some of the following tasks:

- Configure network connectivity between the SDDC and resources in your on-premises network, the Oracle Services Network, the internet through a NAT gateway, or other resources in the VCN. See Configuring Networking Connectivity for an SDDC on page 5094 for information and instructions.
- Modify resources or properties of your SDDC. For example, add ESXi hosts. See Managing Oracle Cloud VMware Solution SDDCs on page 5097.
- Create VMs in your SDDC or perform other VMware tasks. To do so, you can log into vCenter by using the vSphere Client link from the detail page of the SDDC.

**Configuring Networking Connectivity for an SDDC**

This topic covers configuring network connectivity for an Software-Defined Data Center (SDDC) by using quick action workflows in the Oracle Cloud Infrastructure Console.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

**About the SDDC Workflows**

The SDDC quick action workflows make it easy for you to configure connectivity between your SDDC and various network resources within and outside of the VCN. Each workflow determines whether the required networking resources for connectivity already exist, and attempts to create or update them as needed. These networking resources can include gateways, subnets, route tables, rules, and network security groups. To use a workflow successfully, you must have the proper permissions for using and managing the applicable resources. See Details for the Core Services on page 2855 for information about networking resource permissions. Resource creation also relies on your limits and remaining capacity to create more resources.

**Configuring Connectivity to Your On-premises Network**

The workflow for configuring connectivity between your SDDC and an on-premises network does the following:
• Determines whether the VCN has an attached dynamic routing gateway (DRG), and if not, helps you create one.
• Adds the route table, rules, or network security groups needed to enable routing between the DRG and the SDDC's NSX Edge Uplink 1 VLAN.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

Note:
• In the workflow, you are prompted for the CIDR of the on-premises network. If you do not know this value, check with the on-premises network engineer or administrator before you begin. This CIDR value cannot be the same as the SDDC workload CIDR, and cannot overlap with the VCN’s CIDR.
• The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.

To configure connectivity between the SDDC and your on-premises network

1. On the Details page of the SDDC, click Configure connectivity to your on-premises network.
2. Use the Networking wizard to set up the DRG, if needed. After the DRG setup is complete, you can continue with the workflow.
3. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
4. Enter the CIDR of the on-premises network.
5. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink1 VLAN, vSphere Replication Communication (v7.x only), and the DRG.

If you choose to disallow an update, your SDDC might not have connectivity to your on-premises network. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click Show Advanced Options. The tags you specify are applied to all of the new resources created in this workflow.

6. When you are satisfied with the configuration settings, click Apply Configuration.

   The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

Configuring Connectivity to the Oracle Services Network

The workflow for configuring connectivity between your SDDC and the Oracle Services Network does the following:
• Determines whether the VCN has a service gateway, and if not, helps you create one.
• Adds the route table, rules, or network security groups needed to enable routing between the SDDC's NSX Edge Uplink 1 VLAN and the service gateway.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

Note:
The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.
To configure connectivity between the SDDC and Oracle Services Network

1. On the Details page of the SDDC, click **Configure connectivity to Oracle Services Network**.
2. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
3. Click **Next**.
4. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink1 VLAN and the service gateway.
   - If you choose to disallow an update, your SDDC might not have connectivity to Oracle Services Network. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.
   - If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.
5. When you are satisfied with the configuration settings, click **Apply Configuration**.
   - The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

Configuring Connectivity to the Internet Through a NAT Gateway

The workflow for configuring connectivity between your SDDC and the internet through a NAT gateway does the following:

- Determines whether the VCN has a NAT gateway, and if not, helps you create one.
- Adds a default route rule to the SDDC's NSX Edge Uplink1 VLAN's route table to send traffic to the internet through the NAT gateway.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

**Note:**

The workflow adds a required route rule to the VLAN's route table. If you have reached your route rule limits, you are prompted to check your existing rules and delete one to free up capacity.

To configure connectivity to the internet through a NAT gateway

1. On the Details page of the SDDC, click **Configure connectivity to the internet through NAT gateway**.
2. Review the details of the planned updates to your networking resources.
   - If you choose to disallow an update, your SDDC might not have internet connectivity through the NAT gateway. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.
   - If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click **Show Advanced Options**. The tags you specify are applied to all of the new resources created in this workflow.
3. When you are satisfied with the configuration settings, click **Apply Configuration**.
   - The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.
Configuring Connectivity to Other Resources in the VCN

The workflow for configuring connectivity between your SDDC and other resources in the VCN does the following:

- Allows you to select subnets in the VCN that contain resources you want your SDDC to connect to. If the VCN has no subnets, you can use the Networking Wizard from the workflow to create them.
- Adds the route table, rules, or network security groups needed to enable routing between the SDDC's NSX Edge Uplink 1 VLAN and the resources in the selected subnets.

The permissions required to run the workflow successfully depend on the resources the workflow needs to create or update. Before you begin, ensure you have the correct permissions to use and manage these resources.

Note:
The workflow adds required route rules and security rules to the VCN resources. If you have reached your limits, you are prompted to check your existing rules and delete some to free up capacity.

To configure connectivity between the SDDC and other resources in the VCN

1. On the Details page of the SDDC, click Configure connectivity to VCN resources.
2. Enter the SDDC workload CIDR. This CIDR block provides the IP addresses the VMware VMs use to run workloads. The minimum size is /30.
3. Click Select Subnets.
4. Check the check boxes of the subnets that contain resources your SDDC needs to connect to. You filter and sort the list to help you find the subnets you're interested in.
5. Click Save Selection.
6. Click Next.
7. Review the details of the planned updates to your networking resources. The workflow creates or updates route tables and rules that impact the NSX Edge Uplink1 VLAN and the selected subnets.

If you choose to disallow an update, your SDDC might not have connectivity to the resources in a subnet. To complete the configuration, you can either return to the workflow later or make the required resource update manually outside of the workflow.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click Show Advanced Options. The tags you specify are applied to all of the new resources created in this workflow.

8. When you are satisfied with the configuration settings, click Apply Configuration.

The Console displays the status of each operation in the workflow. In an error occurs, you can retry the operation. When you close the Applying Configuration window, you return to the SDDC Details page, which shows a summary of the resources that were updated and allows you to view each one by clicking the applicable link.

Managing Oracle Cloud VMware Solution SDDCs

This topic describes how to manage your Oracle Cloud VMware solution software-defined data center (SDDC) resources by using the Oracle Cloud Infrastructure Console or API. SDDC resources include SDDCs and ESXi hosts. To create and manage VMs on the ESXi hosts, you use VMware’s vCenter utility.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.
Using the Console

The procedures that follow include steps for managing SDDCs and ESXi hosts.

To update basic properties of an SDDC

You can modify basic properties of the SDDC, including the name, the VMware software version, and the SSH keys.

**Note:**

- If you change the VMware software version after provisioning an SDDC, the new version is used only on ESXi hosts that you add to the SDDC. The software version of existing hosts is not changed.
- Changes that you make to the SDDC by using the Oracle Cloud Infrastructure Console, API, or CLI are not automatically made in vCenter. For example, if you change the software version or the SSH keys, the change applies only to ESXi hosts that you add to the SDDC. To change these properties for existing hosts, you must make the applicable updates in vCenter manually.

1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.
2. Click the name of the SDDC to view details about it.
3. Click **Edit SDDC**.
4. Make the applicable changes:
   - **SDDC Name:** Enter a new name for SDDC. This name must be unique among all SDDCs in the creating, active, or updating state across all compartments in the region. Avoid entering confidential information.
     **Note:**
     Unlike most display names in the Oracle Cloud Infrastructure Console this name has the following additional requirements because it is used by vCenter to build URLs:
     - It must be from 1-16 characters long and must start with a letter
     - It can contain only alphanumeric characters and hyphens (-), and hyphens cannot be next to each other
     This name is not case sensitive. For example, "test" and "Test" are treated as the same name.
   - **VMware Software Version:** Select the version of VMware software to install on new ESXi hosts. While the VMware software bundle includes vSphere, vSAN, NSX, and vCenter components, the new version you specify here is the vSphere version only. The update does not impact the versions of the vSAN, NSX, or vCenter components.
   - **SSH Key:** Provide the public key portion of the SSH key. This key is required for remote connections to the ESXi hosts.
5. (Recommended) Click the **vSphere Client** link to go to vCenter, and make the appropriate updates for the SDDC properties you changed in the Console. You can do this task now or after you save your changes.
6. Click **Save Changes**.

To add an ESXi host to an SDDC

1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.
2. Click the name of the SDDC to view details about it.
3. Click **Create ESXi Host**.
4. (Optional) Enter a name for the new host that helps to identify it later. The name must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Hyphens cannot be next to each other. Avoid entering confidential information.
5. **(Optional) Show the ESXi host details to view or modify the following host properties:**
   - VMware software version
   - SSH key
   - VLANs

6. When you are satisfied with the properties for this host, click **Create ESXi Host**.

### To edit an ESXi host
1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.
2. Click the name of the SDDC to view details about it.
3. In the list of ESXi hosts, click the Actions icon (three dots) for the host you want to rename, and then click **Edit**.
   
   You can edit the ESXi Host Name or Pricing Interval:
4. **(Optional)** Enter the new name for the host. The name must be from 1-16 characters long, must start with a letter, and can contain only alphanumeric characters and hyphens (-). Hypens must not be next to each other. Ensure that the name is unique within the SDDC. Avoid entering confidential information.
5. **(Optional)** Choose a new Pricing Interval for the host.

   **Important:**
   
   The new pricing interval doesn't take effect until the previous billing interval's end date and time. If you cancel your commitment before the end of the selected pricing interval, billing continues until the interval ends.

6. Click **Save Changes**.

### To remove ESXi hosts from an SDDC
1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.
2. Click the name of the SDDC to view details about it.
3. In the list of ESXi hosts, click the Actions icon (three dots) for the host you want to remove, and then click **Terminate ESXi Host**.

### To change VLANs the SDDC uses
1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.
2. Click the name of the SDDC to view details about it.
3. Under Resources, click **SDDC Networks**.
4. On the VLANs tab, click **Change VLANs**.
5. Make the applicable changes. See **VLANs Required for an SDDC** on page 5101 for information about VLANs.

   **Note:**
   
   Changes that you make to the SDDC's VLAN assignments by using the Oracle Cloud Infrastructure Console, API, or CLI are not automatically made in vCenter. You must make these updates in vCenter manually.

6. Click **Save Changes**.

### To change the HCX license type
You can change the HCX license type for an SDDC:

- **Upgrading to Enterprise:** Increases the number of on-premises connection keys issued from 3 to 10. The upgrade work request is initiated immediately. The HCX Enterprise billing cycle begins as soon as the work request is complete.
- **Downgrading to Advanced:** Decreases the number of on-premises connection keys from 10 to 3. You must specify 3 license keys to retain after the downgrade. The downgrade request remains in a pending state until the HCX Monthly Billing Cycle End Date. You can cancel the downgrade request as long as it is still in a pending state.

For more information, see **HCX License Types** on page 5088.
1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.

2. Click the name of the SDDC to view details about it.

3. Click the Change link to the right of **HCX License Type**.

4. If you currently have the **Advanced** license installed on the SDDC:
   a. Select **I consent to upgrade to the Enterprise license**(Billed Upgrade)
   b. Click **Save Changes**.

   Charges for the Enterprise license upgrade appear in the next billing cycle.

5. If you currently have the **Enterprise** license installed on the SDDC:
   a. Select **I consent to downgrade to the Advanced license**(No Additional Cost)
   b. Select 3 license keys to remain active after Enterprise features end.
   c. Click **Save Changes**.

   The downgrade request remains in a **PENDING** state until the HCX Monthly Billing Cycle End Date. A notification appears on the SDDC Details page that shows the date that Enterprise features end. To cancel the pending downgrade, click **Cancel Downgrade** to the right of the notification.

**To move an SDDC to a different compartment**

1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.

2. Click the name of the SDDC to view details about it.

3. Click **Move Resource**.

4. Choose the destination compartment from the list.

5. Click **Move Resource**.

**To terminate an SDDC**

SDDC termination automatically removes the SDDC's associated instances and boot volumes. With a failed SDDC, you can opt to also delete all of its associated networking resources. These resources include the subnet and its route table and security list, and the VLANs and their route tables and NSGs. A networking resource cannot be deleted if that resource is used by another SDDC or networking resource. A networking resource in use will remain after the SDDC is terminated.

1. Open the navigation menu, click **Hybrid**, and then click **VMware Solution**.

2. Click the name of the SDDC to view details about it.

3. Click **Terminate**.

   Termination removes the SDDC and its associated resources. Terminated resources cannot be restored.

4. Follow the prompt to confirm termination, and click **Terminate All**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use these API operations to manage VMware solution resources:

- **ListSddcs**
- **GetSddc**
- **UpdateSddc**
- **ChangeSddcCompartment**
- **DeleteSddc**
- **ListEsxiHosts**
- **GetEsxiHost**
- **CreateEsxiHost**
- **UpdateEsxiHost**
- **DeleteEsxiHost**
Managing Layer 2 Networking Resources for an SDDC

This topic describes how to manage layer 2 networking resources for a software-defined data center (SDDC) by using the Oracle Cloud Infrastructure Console or the API.

About SDDC Layer 2 Networking Resources

An Oracle Cloud Infrastructure SDDC requires a management subnet and layer 2 networking resources. The layer 2 networking resources include seven VLANs and their configured external access objects.

When you provision an SDDC by using the Oracle Cloud Infrastructure Console's Create SDDC workflow, you can have the workflow create these required networking resources for you. We recommend that you select this option. If you prefer, you can create them yourself before you start the Create SDDC workflow, and then select the existing subnet and VLANs you created for this purpose.

The requirements for the SDDC CIDR size and segmentation are different for VMware 6.x and 7.x:

· VMware 6x: Oracle recommends that you create a size /22 CIDR network segment in your VCN for the SDDC’s networking resources. Divide this SDDC CIDR into eight segments of size /25 to use for the subnet and the seven required VLANs indicated in this topic.

· VMware 7x: Oracle recommends that you create a size /21 CIDR network segment in your VCN for the SDDC’s networking resources. Divide the SDDC CIDR into ten segments of size /25 to use for the subnet and the nine required VLANs indicated in this topic.

If you are enabling HCX, further divide the segment for the vSphere VLAN into two equal segments, one for vSphere and the other for HCX.

In addition, you must configure the security rules for these networking resources as detailed in Security Rules for Oracle Cloud VMware Solution SDDCs on page 5106. Otherwise, provisioning the SDDC will fail.

**Note:**

You can update VCN, VLAN, and subnet CIDR block information after creation. Ensure that any changes you make to the VCN after the SDDC is provisioned follow the preceding requirements.

For more information about editing your VCN, see VCNs and Subnets on page 3693.

VLANs Required for an SDDC

An SDDC requires VLANs for the following functions:

- **NSX Edge Uplink 1:** Uplink used for communication between the VMware SDDC and Oracle Cloud Infrastructure.
- **NSX Edge Uplink 2:** Reserved for future use to deploy public-facing applications on the VMware SDDC.
- **NSX Edge VTEP:** Used for data plane traffic between the ESXi host and NSX Edge.
- **NSX VTEP:** Used for data plane traffic between ESXi hosts.
- **vMotion:** Used for vMotion (VMware migration tool) management and workload.
- **vSAN:** Used for vSAN (VMware storage) data traffic.
- **vSphere:** Used for management of the SDDC components (ESXi, vCenter, NSX-T, and NSX Edge).
- **Replication-Net:** Used for the vSphere Replication engine. (VMware version 7.x only)
- **Provisioning-Net:** Used for virtual machine cold migration, cloning, and snapshot migration.
- **HCX:** *(Optional)* Used for HCX traffic. Create this VLAN if you plan to enable HCX when you provision the SDDC.

**Note:**

If you allow the Create SDDC workflow to create the VLANs, the workflow divides the SDDC management CIDR you specify into equal...
segments to use for the provisioning subnet and the required VLANs. If
you enable HCX, the workflow further divides the vSphere segment into
two equal parts, one for the vSphere VLAN and the other for the HCX
VLAN. You can follow this model if you choose to create your VLANs
manually.

HCX also requires that the vSphere VLAN has a route table rule that
allows traffic to a NAT gateway attached to the VCN. See VCN Route
Tables on page 3702 for more information.

These VLANs must all be in the same VCN and availability domain you specify when you create the SDDC, but they
can be in different compartments.

External Access to VLAN Resources

You can enable external access to an SDDC's ESXi hosts by creating a private IP object for the VLAN that can be
used as a route target. Additionally, you can enable internet access to hosts in the VLAN by assigning a public IP
address to the VLAN's private IP address object. When you configure external access, you have the option to indicate
that it be accessible as a route target only and, as such, have no associated public IP address. See To add external
access to a VLAN on page 5103 for the steps to configure external access.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access
is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don't have permission or are unauthorized, verify with your administrator what type of access you have and
which compartment to work in.

Using the Console

Use the procedures that follow to create and manage VLANs and external access objects for your SDDCs.

To create a VLAN for an SDDC

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display
   only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For
   more information, see Access Control on page 3708.
3. Click the VCN in which you plan to provision your SDDC.
4. Under Resources, click VLANs.
5. Click Create VLAN.
6. Enter the following:
   • Name: (Optional) A descriptive name for the VLAN. It doesn't have to be unique, and you can change it later. Avoid
     entering confidential information.
   • Create in Compartment: The compartment for the VLAN.
   • VLAN Type: A VLAN can be either Regional or Availability Domain-specific. Regional VLANs are useful
     for high-availability. See Regions and Availability Domains on page 208 for more information.
   • Availability Domain: If you choose to create an availability domain-specific VLAN, select the availability
     domain. The ESXi hosts must be in the same availability domain as the SDDC's VLANs.
   • IEEE 802.1Q VLAN Tag: (Optional) The VLAN uses this unique value to identify a broadcast domain for
     layer 2 traffic. Enter a number from 1 to 4094. If you don't enter a value, Oracle assigns one. You cannot
     change this value later.
   • VLAN Gateway CIDR: This CIDR provides IP addresses used by the VLAN for external layer 3
     communication and routing. This CIDR block also provides the private IP addresses Oracle uses as attachment
objects for public IP addresses when instances require access to internet hosts. You can't change this value later.

**Note:**
This CIDR must be within the VCN's CIDR and cannot overlap with the CIDRs of the other subnets and VLANs in the VCN.

- **Route Table:** The route table contains rules that specify the next hop for traffic from the VLAN to external destinations.

- **Network Security Groups:** Select the NSGs with the security rules to apply to all VNICs in this VLAN. You can select up to 5 NSGs for a VLAN.

You manage NSG membership for VNICs in a VLAN at the VLAN level. You cannot add or remove individual VNICs in a VLAN from an NSG.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. If you don't see the tagging option, click Show Advanced Options.

7. Click **Create VLAN**.

The new VLAN displays in the list of VLANs for the VCN in the selected compartment.

8. Repeat steps 5 through 7 for each VLAN you need for your SDDC. See VLANs Required for an SDDC on page 5101.

**To add external access to a VLAN**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN that contains the VLAN you want to modify.

If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under Resources, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Add External Access**.
6. Specify the type of external access to configure.

   - **Route Target Only:** Select this option to assign a private IP address only for use as a route target for traffic that needs to reach the VMware overlay. The IP address must be within VLAN gateway CIDR block. If you do not specify a name or a private IP address, or both, Oracle generates the needed values for you.

   - **Public Access:** Select this option to also provide a public IP address for internet access to the resources such as VNICs and VMs in the VLAN. The public IP address must be attached to a private IP address to enable internet access.

     - **Private IP Address:** (Optional) Specify a name and/or a private IP address within the VLAN gateway CIDR block. If you do not specify these values, Oracle generates them for you. Note that as with the route target only option, this private IP address can also be used as a route target for non-internet traffic.

     - **Reserved Public IP Address:** (For public access only) Choose whether to specify an existing reserved public IP address or have a new one created for this external access.

If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator. To see the tagging options, click Show Advanced Options.

7. Click **Add External Access**.

**To modify external access to a VLAN**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN that contains the VLAN you want to modify.

   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. In the External Access list, select the external access you want to modify, click the Actions icon (three dots), and then click the **Edit**.

The settings you can modify depend on the external access type. Consider the following:

- You can change the external access type from *route target only* to *public access*, or the other way around.
  
  If you change the type from *public access* to *route target only*, the private IP address will no longer have an associated reserved IP address. Therefore, any host that uses the private IP address will not be accessible from the internet.

  If you change the type from *route target only* to *public access*, you'll need to attach a reserved public IP address to it to enable access from the internet. You can select an existing public IP address or have a new one created for this purpose.

- For both *route target only* and *public access* types, you can rename the private IP address but you cannot change the IP address value itself.

- For a *public access* type, you can rename the reserved public IP address but you cannot change the IP address value itself.

6. When you are done making your updates, click **Save Changes**.

### To remove external access to a VLAN

**Important:**

If an existing route rule targets the private IP address associated with the external access you are removing, the route rule will drop traffic to that private IP address.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to modify.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. In the External Access list, select the external access you want to remove, and click **Remove**.
6. Click **Remove** to complete the action.

### To move a VLAN to a different compartment

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to move.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Move Resource**.
6. Choose the destination compartment from the list.
7. Click **Move Resource**.

### To modify basic properties of a VLAN

You can rename a VLAN, or change its route table or network security groups.

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to modify.
   
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Edit**.
6. Change the applicable settings:
   - **VLAN Name**: Use a descriptive name that helps to identify the VLAN. The name doesn't have to be unique. Avoid entering confidential information.
   - **Route Table**: The route table provides mapping for traffic from the VLAN to external destinations.
     (To select a route table in a different compartment, click **Change Compartment**, and select the compartment the target route table is in.)
   - **Network Security Groups**: Select the NSGs with the security rules to apply to all VNICs in this VLAN. You can select up to 5 NSGs for a VLAN.
7. When you are done making changes, click **Save Changes**.

**To modify the network security groups of a VLAN**
1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to modify.
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Next to **Network Security Groups**, click **Edit**.
6. Make the applicable changes to the list of security groups. The VLAN can be associated with up to 5 security groups.
7. Click **Save Changes**.

**To delete a VLAN**

```
Note:
You cannot delete a VLAN if it has any external access resources. You must first remove all external access. See To remove external access to a VLAN on page 5104.
```

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that contains the VLAN you want to delete.
   If you do not see the VCN listed, ensure that you have the correct compartment selected.
3. Under **Resources**, click **VLANs**.
4. Click the name of the VLAN to view details about it.
5. Click **Delete**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use these API operations to create and manage layer 2 networking resources for an Oracle Cloud VMware solution SDDC:
- **GetVlan**
- **ListVlans**
- **CreateVlan**
- **UpdateVlan**
- **ChangeVlanCompartment**
- **DeleteVlan**

For a list of API operations to create and manage networking resources used by the VLANs in an SDDC, see the following topics:
- **Route tables**
• NSGs
• Private IPs

Security Rules for Oracle Cloud VMware Solution SDDCs

This topic details the security rules the Console’s Create SDDC workflow configures for the new SDDC’s subnet and VLANs. The rules are based on the requirements set by VMware.

| Important: |
| If you do not use the workflow to create an SDDC, ensure that you configure the SDDC’s networking resources with these security rules. Otherwise, provisioning the SDDC will fail. |

Provisioning Subnet

The security lists for the provisioning subnet have the following stateful ingress security rules:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Source</th>
<th>Protocol</th>
<th>Source Port</th>
<th>Destination Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingress</td>
<td>VCN CIDR</td>

This chapter explains how to use Vulnerability Scanning.

Vulnerability Scanning

Oracle Vulnerability Scanning Service helps improve your security posture in Oracle Cloud by routinely checking hosts for potential vulnerabilities. The service generates reports with metrics and details about these vulnerabilities.

- **Get Started**
  - Learn about Scanning
  - Create policies
  - Create a recipe
  - Create a target

- **Reports**
  - View host scans
  - View port scans
  - View benchmarks
  - View vulnerabilities

- **Use Cases**
  - Reference architecture

- **Integration**
  - Scan images in Container Registry
  - Scan hosts with Cloud Guard

- **Troubleshooting**
  - Troubleshoot Scanning

- **Developer Tools**
  - API for Scanning
  - CLI for Scanning
  - SDKs and the CLI
  - Cloud Shell

- **Support**
  - Get help and contact Support
  - Create a service request

**Scanning Overview**

Oracle Vulnerability Scanning Service helps improve your security posture in Oracle Cloud by routinely checking hosts for potential vulnerabilities. The service generates reports with metrics and details about these vulnerabilities.

The Scanning service can identify several types of security issues in your compute instances:

- Ports that are unintentionally left open might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.
- OS packages that require updates and patches to address vulnerabilities
- OS configurations that hackers might exploit
Vulnerability Scanning

- Industry-standard benchmarks published by the Center for Internet Security (CIS).

  The Scanning service checks hosts for compliance with the section 5 (Access, Authentication, and Authorization) benchmarks defined for Distribution Independent Linux.

The Scanning service can scan individual compute instances, or it can scan all compute instances within a compartment and its subcompartments. If you configure the Scanning service at the root compartment, then all compute instances in the entire tenancy are scanned.

The Scanning service detects vulnerabilities in the following platforms:

- Oracle Linux
- CentOS
- Ubuntu
- Windows (no CIS benchmarks)

Concepts
Understand key concepts and components related to the Scanning service.

Scan Recipe
Scanning parameters for a type of cloud resource, including what information to examine and how often.

Target
One or more cloud resources that you want to scan using a specific recipe. Resources in a target are of the same type, such as compute instances.

Host Scan
Metrics about a specific cloud resource that was scanned, including the vulnerabilities that were found, their risk levels, and CIS benchmark compliance.

The Scanning service uses a host agent to detect these vulnerabilities.

Port Scan
Open ports that were detected on a specific cloud resource that was scanned.

The Scanning service can detect open ports using a host agent, or using a network mapper that searches your public IP addresses.

Vulnerabilities Report
Information about a specific type of vulnerability that was detected in one or more targets, like a missing update for an OS package.

Integration with Cloud Guard
You can view security vulnerabilities identified by the Scanning service in Cloud Guard.

Cloud Guard is an Oracle Cloud Infrastructure service that provides a central dashboard to monitor all of your cloud resources for security weakness in configuration, metrics, and logs. When it detects a problem, it can suggest, assist, or take corrective actions, based on your Cloud Guard configuration.

Like the Scanning service, Cloud Guard uses recipes and targets.

- A recipe defines the types of problems that you want Cloud Guard to report
- A target defines the compartments that you want Cloud Guard to monitor, and is associated with a recipe.

A configuration detector recipe consists of detector rules. The default Cloud Guard configuration detector recipe includes rules that check for vulnerabilities and open ports found by the Scanning service.

For more information, see Scanning with Cloud Guard on page 5140.
Resource Identifiers
Scanning resources, like most types of resources in Oracle Cloud Infrastructure, have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID).

For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Vulnerability Scanning
You can access Vulnerability Scanning using the Console (a browser-based interface), the command line interface (CLI), or the REST API. Instructions for the Console, CLI, and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You are prompted to enter your cloud tenant, your user name, and your password.

For a list of available SDKs, see Software Development Kits and Command Line Interface. For general information about using the APIs, see REST API.

Authentication and Authorization
Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, policies control who can create users, create and manage a VCN (virtual cloud network), launch instances, and create buckets.

- If you're a new administrator, see Getting Started with Policies.
- For specific details about writing policies for this service, see Scanning IAM Policies on page 5145.
- For specific details about writing policies for other services, see Policy Reference.

Monitoring
To monitor scanning activity, Vulnerability Scanning integrates with these other services in Oracle Cloud Infrastructure.

- The Audit service automatically records calls to all public Vulnerability Scanning API endpoints as log entries. See Overview of Audit.
- The Monitoring service enables you to monitor your Vulnerability Scanning resources using metrics and alarms. See Scanning Metrics on page 5152.
- The Events service allows your development teams to automatically respond when a Vulnerability Scanning resource changes its state. See Scanning Events on page 5154.

Getting Started
Use the Scanning service to check for security vulnerabilities in the compute instances for a single compartment.

   If you are not an administrator, you must be given access to the Scanning service in a policy (IAM) written by an administrator.
2. Create the Required IAM Policy for Host Scanning on page 5119.
   An administrator must grant the Scanning service permission to activate the Scanning agent on your target compute instances.
3. Open the navigation menu and click Identity & Security. Click Scanning.
4. Click Create Scan Recipe.
   See Creating a Host Scan Recipe on page 5120.
5. Click Create Target.
   See Creating a Host Target on page 5124.
6. Click **View Scan Result**.
   
   Results are typically available 15 minutes after creating a new target, but it can take up to 24 hours.
   
   See **Viewing Host Scans** on page 5128.

7. (Optional) **Scanning with Cloud Guard** on page 5140
   
   If you run into problems, see **Troubleshooting the Scanning Service** on page 5142.

### Managing Host Scan Recipes

Use Oracle Vulnerability Scanning Service to create and manage recipes that scan target compute *instances*, or hosts, for potential security vulnerabilities.

A recipe determines which types of security issues that you want scanned:

- Port scanning: check for open ports using a network mapper that searches your *public IP addresses*
- Agent-based scanning:
  
  - Check for open ports that are not accessible from public IP addresses
  - Check for OS vulnerabilities like missing patches
  - Check for compliance with industry-standard benchmarks published by the Center for Internet Security (CIS)

The Scanning service checks hosts for compliance with the section 5 (Access, Authentication, and Authorization) benchmarks defined for Distribution Independent Linux.

A recipe also defines a schedule, or how often scanning is performed.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a *policy (IAM)* written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which *compartment* you are supposed to work in.

For example, to allow users in the group *SecurityAdmins* to create, update, and delete all Vulnerability Scanning resources in the compartment *SalesApps*:

| Allow group SecurityAdmins to manage vss-family in compartment SalesApps |

See **Scanning IAM Policies** on page 5145.

### Required IAM Policy for Host Scanning

If you enable agent-based scanning in your recipe, then you must give the Scanning service permission to deploy the Oracle Cloud Agent to your target compute instances.

The Scanning service must also be able to read the *VNIC (virtual network interface card)* on your target compute instances.

To grant this permission for all compute instances in the entire tenancy:

| Allow service vulnerability-scanning-service to manage instances in tenancy |
| Allow service vulnerability-scanning-service to read compartments in tenancy |
| Allow service vulnerability-scanning-service to read vnics in tenancy |
| Allow service vulnerability-scanning-service to read vnic-attachments in tenancy |

To grant this permission for all compute instances in a specific compartment:

| Allow service vulnerability-scanning-service to manage instances in compartment <compartment_name> |
| Allow service vulnerability-scanning-service to read compartments in compartment <compartment_name> |
Vulnerability Scanning

Allow service vulnerability-scanning-service to read vnics in compartment <compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <compartment_name>

A VNIC might be in a different compartment from your Compute instance. Either grant VNIC permissions for the entire tenancy or for the specific VNIC compartment:

Allow service vulnerability-scanning-service to read vnics in compartment <vnic_compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <vnic_compartment_name>

To create a host scan target that uses agent-based scanning, the user must have the manage instance permission for the target instances.

Allow group <group_name> to manage instances in compartment <compartment_name>

See Policy Details for the Core Services.

Creating a Host Scan Recipe

Use the Console to create a host scan recipe.

All recipes in the Scanning service are the Compute configuration type.

2. Open the Create Scan Recipe dialog.
   - If no scan recipes exist, the Welcome page is displayed, which includes an introduction to the service.
   - Click Create Scan Recipe, and then select the Compartment in which you want to create the recipe.
   - If scan recipes already exist, select the Compartment in which you want to create the recipe, and then click Create.
3. Enter a Name for the recipe.
   Avoid entering confidential information.
4. Select the level of Port Scanning for this recipe.
   - Standard - Check the 1000 most common port numbers.
   - Light (default) - Check the 100 most common port numbers.
   - None - Do not check for open ports.

The Scanning service uses a network mapper that searches your public IP addresses. See Ports that are Scanned on page 5133.

5. (Optional) Disable Agent Based Scanning if you don't want to activate the Vulnerability Scanning agent plugin on the targets assigned to this recipe.

The Vulnerability Scanning agent runs on the selected targets and checks the OS configuration of targets for vulnerabilities, such as missing patches.

If you enable both Agent Based Scanning and Port Scanning, then the agent also checks for open ports that are not accessible from public IP addresses.

Note:

If you disable both Port Scanning and Agent Based Scanning in this recipe, then the Scanning service doesn't scan any targets assigned to this recipe.
6. (Optional) If **Agent Based Scanning** is enabled, then configure more agent parameters.
   a) Disable **CIS Benchmark Scanning** if you don't want the agent to check targets for compliance with industry-standard benchmarks published by the *Center for Internet Security* (CIS).
   b) If **CIS Benchmark Scanning** is enabled, then select the **CIS Benchmark Profile** for this recipe.
      - **Strict** - If more than 20% of the CIS benchmarks fail, then the target is assigned a risk level of **Critical**.
      - **Medium** (default) - If more than 40% of the CIS benchmarks fail, then the target is assigned a risk level of **High**.
      - **Lightweight** - If more than 80% of the CIS benchmarks fail, then the target is assigned a risk level of **High**.

7. Configure the **Schedule** for the recipe.
   The schedule controls how frequently the targets assigned to this recipe are scanned.
   Choose from **Daily** or **Weekly**.

8. (Optional) Assign tags to the recipe.
   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   To add a defined tag, you must have permissions to use the **Tag Namespace**.
   For more information about tagging, see **Resource Tags**. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

9. Click **Create**.
   After creating a recipe, you can create scan targets and associate them with the recipe. See **Creating a Host Target** on page 5124.

**Updating a Host Scan Recipe**
Use the Console to update an existing host scan recipe.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Scan Recipes**.
2. Select the **Compartment** that contains your recipe.
3. Click the name of the recipe.
4. Click **Edit**.
5. Modify any of these settings for your recipe.
   - **Name** (Avoid entering confidential information)
   - **Port Scanning**
   - **Agent Based Scanning**
   - **CIS Benchmark Scanning**
   - **CIS Benchmark Profile**
   - **Schedule**

The Vulnerability Scanning agent checks the OS configuration of targets for vulnerabilities, such as missing patches. The agent can also check targets for compliance with industry-standard benchmarks published by the *Center for Internet Security* (CIS).

The schedule controls how frequently the targets assigned to this recipe are scanned.

6. Click **Save Changes**
7. (Optional) Click **Tags** if you want to manage the tags for this recipe.
   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   To add a defined tag, you must have permissions to use the **Tag Namespace**.
   For more information about tagging, see **Resource Tags**. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.
Moving a Scan Recipe to a Different Compartment
Use the Console to move a scan recipe from one compartment to another.

2. Select the Compartment that contains your recipe.
3. Click the name of the recipe.
4. Click Move Resource.
5. Choose the destination compartment.
6. Click Move Resource.

After you move the recipe to the new compartment, inherent policies apply immediately and affect access to the recipe through the Console. For more information, see Managing Compartments.

Deleting a Scan Recipe
Use the Console to delete a scan recipe.

To delete a scan recipe, it must not be associated with any scan targets. See Deleting a Target on page 5126.

2. Select the Compartment that contains your recipe.
3. Click the name of the recipe.
4. Click Delete.
5. When prompted for confirmation, click Delete.

Using the CLI
For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list all host scan recipes in a compartment:

```bash
oci vulnerability-scanning host scan recipe list --compartment-id <compartment_ocid>
```

For example:

```bash
oci vulnerability-scanning host scan recipe list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific host scan recipe:

```bash
oci vulnerability-scanning host scan recipe get --host-scan-recipe-id <recipe_ocid>
```

For example:

```bash
oci vulnerability-scanning host scan recipe get --host-scan-recipe-id ocid1.vsshostscanrecipe.oc1..exampleuniqueID
```

To create a host scan recipe:

```bash
oci vulnerability-scanning host scan recipe create --display-name <name> --compartment-id <compartment_ocid> --agent-settings '{"scanLevel": <agent_scan_level>}', --cis-benchmark-settings '{"scanLevel": <CIS_scan_level>}', --port-settings '{"scanLevel": <port_scan_level>}' --schedule '{"type": <daily_or_weekly>}'
```

Oracle Cloud Infrastructure User Guide 5122
For example:

```bash
oci vulnerability-scanning host scan recipe create --display-name MyRecipe --compartment-id ocid1.compartment.oc1..exampleuniqueID --agent-settings '{"scanLevel": "STANDARD"}' --cis-benchmark-settings '{"scanLevel": "MEDIUM"}' --port-settings '{"scanLevel": "STANDARD"}' --schedule '{"type": "DAILY"}'
```

### Using the API

For information about using the API and signing requests, see `/iaas/api/%23/en/iaas/` and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage host scan recipes:

- ListHostScanRecipes
- GetHostScanRecipe
- CreateHostScanRecipe
- UpdateHostScanRecipe
- ChangeHostScanRecipeCompartment
- DeleteHostScanRecipe

**Note:**

The HostEndpointProtectionSettings have no effect and are reserved for future use.

### Managing Host Targets

Use Oracle Vulnerability Scanning Service to create and manage host targets and to assign them to scan recipes. A host target is a collection of compute instances that you want routinely scanned for security vulnerabilities.

**Note:**

The Scanning service detects vulnerabilities in the following platforms:

- Oracle Linux
- CentOS
- Ubuntu
- Windows (no CIS benchmarks)

You have two options when selecting the compute instances for a host target.

- Scan one or more specific compute instances within a compartment.
- Scan all compute instances within a compartment and its subcompartments.

If you create a target for the root compartment, then all compute instances in the entire tenancy are scanned.

The Scanning service saves the results for a compute instance in the same compartment as the instance’s Scanning target.

Consider the following example.

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyInstance are in CompartmentB.

Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a *policy (IAM)* written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which *compartment* you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

```
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
```

See [Scanning IAM Policies](#) on page 5145.

**Required IAM Policy for Host Scanning**

If you enable agent-based scanning in your recipe, then you must give the Scanning service permission to deploy the Oracle Cloud Agent to your target compute instances.

The Scanning service must also be able to read the *VNIC (virtual network interface card)* on your target compute instances.

To grant this permission for all compute instances in the entire tenancy:

```
Allow service vulnerability-scanning-service to manage instances in tenancy
Allow service vulnerability-scanning-service to read compartments in tenancy
Allow service vulnerability-scanning-service to read vnics in tenancy
Allow service vulnerability-scanning-service to read vnic-attachments in tenancy
```

To grant this permission for all compute instances in a specific compartment:

```
Allow service vulnerability-scanning-service to manage instances in compartment <compartment_name>
Allow service vulnerability-scanning-service to read compartments in compartment <compartment_name>
Allow service vulnerability-scanning-service to read vnics in compartment <compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <compartment_name>
```

A VNIC might be in a different compartment from your Compute instance. Either grant VNIC permissions for the entire tenancy or for the specific VNIC compartment:

```
Allow service vulnerability-scanning-service to read vnics in compartment <vnic_compartment_name>
Allow service vulnerability-scanning-service to read vnic-attachments in compartment <vnic_compartment_name>
```

To create a host scan target that uses agent-based scanning, the user must have the `manage instance` permission for the target instances.

```
Allow group <group_name> to manage instances in compartment <compartment_name>
```

See [Policy Details for the Core Services](#).

**Creating a Host Target**

Use the Console to create a host scan target.
At least one host scan recipe must be in your tenancy before creating a target. See Managing Host Scan Recipes on page 5119.

If your host scan recipe is configured for Agent Based Scanning, you must give the Scanning service permission to deploy the agent before creating a target. See Required IAM Policy for Host Scanning on page 5119.

A compute instance is associated with a VCN (virtual cloud network) and a subnet. If a compute instance in your target is on a private subnet or has no public IP address, the VCN must include a service gateway and a route rule for the service gateway. See Access to Oracle Services: Service Gateway.

2. Select the Compartment in which you want to create the target.

   Note: The compute instances that you assign to this target can be in a different compartment than the target.

3. Click Create.

   All targets in the Scanning service are the Compute configuration type.

4. Enter a Name and Description for the target.

   Avoid entering confidential information.

5. Select a Scan Recipe for the target.

6. Select the Target Compartment that contains the compute instances you want to scan.

7. Choose compute instances for this target.

   • All compute instances in the selected target compartment and its subcompartments
   • Specific compute instances in the selected target compartment - Select individual compute instances.

   You can't create a target with a compartment or a compute instance that is already specified in another target. However, multiple targets can scan the same compute instance.

   Note: Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

8. (Optional) Assign tags to the target.

   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.

   To add a defined tag, you must have permissions to use the Tag Namespace.

   For more information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

9. Click Create.

After creating a target, the Scanning service checks your compute instances for security vulnerabilities and open ports based on the parameters and schedule that is configured in the recipe. You can view the results of these scans in reports:

• Host Scans on page 5128
• Host Vulnerabilities Reports on page 5135

You can also use Cloud Guard to view the results of your scans. See Scanning with Cloud Guard on page 5140.

**Updating a Host Target**

Use the Console to update an existing host scan target.

2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Edit**.
5. Modify any of these settings for your target.
   - **Name**
   - **Description**
   - **Scan Recipe**
   - **Target Compartment**

   Avoid entering confidential information.

6. Update the compute instances for this target.
   - **All compute instances in the selected target compartment and its subcompartments**
   - **Specific compute instances in the selected target compartment** - Select individual compute instances

   You can't update a target with a compartment or a compute instance that is already specified in another target. However, multiple targets can scan the same compute instance.

7. Click **Save Changes**
8. (Optional) Click **Tags** if you want to manage the tags for this target.

   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.

   To add a defined tag, you must have permissions to use the **Tag Namespace**.

   For more information about tagging, see **Resource Tags**. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

### Viewing the Compute Instances for a Host Target

Use the Console to view the compute instances associated with an existing host scan target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.

   The **Compute Instances** table displays.
4. Click the name of a specific compute instance to view its details.

### Moving a Target to a Different Compartment

Use the Console to move a scan target from one compartment to another.

Moving a target does not also move the compute instances in the target.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Move Resource**.
5. Choose the destination compartment.
6. Click **Move Resource**.

After you move the target to the new compartment, inherent policies apply immediately and affect access to the target through the Console. For more information, see **Managing Compartments**.

### Deleting a Target

Use the Console to delete a target.

Deleting a target does not delete the compute instances in the target.
1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Targets**.
2. Select the **Compartment** that contains your target.
3. Click the name of the target.
4. Click **Delete**.
5. When prompted for confirmation, click **Delete**.

### Using the CLI

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see **CLI Help**.

To list all host scan targets in a compartment:

```
oci vulnerability-scanning host scan target list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host scan target list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific host scan target:

```
oci vulnerability-scanning host scan target get --host-scan-target-id <target_ocid>
```

For example:

```
oci vulnerability-scanning host scan target get --host-scan-target-id ocid1.vsshostscantarget.oc1..exampleuniqueID
```

To create a host scan target:

```
oci vulnerability-scanning host scan target create --display-name <name> --description "<description>" --compartment-id <create_in_compartment_ocid> --host-scan-recipe-id <recipe_ocid> --target-compartment-id <target_compartment_ocid> --instance-ids <compute_instance_ocids>
```

For example, to scan all compute instances in a compartment:

```
oci vulnerability-scanning host scan target create --display-name MyTarget --description "All instances in compartment ABC" --compartment-id ocid1.compartment.oc1..exampleuniqueID1 --host-scan-recipe-id ocid1.vsshostscanrecipe.oc1..exampleuniqueID --target-compartment-id ocid1.compartment.oc1..exampleuniqueID2
```

### Using the API

For information about using the API and signing requests, see **/iaas/api/%23/en/iaas/** and **Security Credentials**.

For information about SDKs, see **Software Development Kits and Command Line Interface**.

Use the following operations to manage host scan targets:

- **ListHostScanTargets**
- **GetHostScanTarget**
- **CreateHostScanTarget**
- **UpdateHostScanTarget**
- **ChangeHostScanTargetCompartment**
- **DeleteHostScanTarget**
Host Scans

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. Use host scans to identify security vulnerabilities in your compute instances like open ports, critical OS patches, and failed benchmark tests.

At least one host target must exist before any host scans are created. See Managing Host Targets on page 5123.

The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

• The compute instance MyInstance is in CompartmentA.
• MyInstance is specified in Target1.
• Target1 is in CompartmentB.
• All reports related to MyInstance are in CompartmentB.

The Scanning service categorizes problems by these risk levels.

• Critical - the most serious problems detected, which should be your highest priority to resolve.
• High - the next most serious problems.
• Medium - problems that are a bit less serious.
• Low - problems that are still less serious.
• Minor - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

Allow group SecurityAdmins to manage vss-family in compartment SalesApps

See Scanning IAM Policies on page 5145.

Viewing Host Scans

Use the Console to browse and search for host scans.

2. Select the Compartment in which you created the target.
3. (Optional) Click the table columns to sort the host scans by:
   • Type
   • Risk Level
   • Issues Found
   • Operating System
   • Scan Completed date

   All reports in the Scanning service are type Compute.

4. To view the host scan's details, click its name.

A host scan includes metrics, open ports, vulnerabilities, and benchmarks for a specific compute instance.
Vulnerability Scanning

Viewing Metrics for a Host Scan
Use the Console to view the metrics for a specific compute instance that was scanned.

2. Select the Compartment in which you created the target.
3. Click the name of the host scan.
4. Click Metrics if not already selected.
   
   The Vulnerabilities panel shows the number of security vulnerabilities of each risk level that were detected during the most recent scan of this compute instance.

Viewing Open Ports in a Host Scan
Use the Console to view details about the open ports that were detected on a specific compute instance that was scanned.

Ports that are unintentionally left open might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.

2. Select the Compartment in which you created the target.
3. Click the name of the host scan.
4. Click Open Ports.
   
   • The first panel shows the number of open ports that were detected on each Virtual Network Interface Card (VNIC) in this compute instance.
     A VNIC (virtual network interface card) enables a compute instance to connect to a specific VCN (virtual cloud network). You can mousover the name of a VNIC to view its details.
   
   • The second panel shows the specific port numbers that were detected in this compute instance.
5. (Optional) Select one or more VNIC(s) to show only those ports that were detected on the selected VNICs.

Viewing Vulnerabilities in a Host Scan
Use the Console to view details about potential OS vulnerabilities that were detected on a specific compute instance.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

2. Select the Compartment in which you created the target.
3. Click the name of the host scan.
4. Click Vulnerabilities.
   
   The following details are shown for each issue that was detected in this compute instance:
   
   • Issue ID
   • Risk Level
   • Issue Title
   • Last Detected
   • First Detected
   • Hosts Impacted
5. Click an Issue ID to view more details about a specific vulnerability.

Because Oracle Linux and other enterprise Linux distributions back ports security fixes to the version that is included in a given major release, the Scanning service can incorrectly report vulnerabilities on OS packages that have already been fixed. Additionally, the Scanning service can incorrectly report Oracle Linux vulnerabilities that have been fixed by Ksplice. See Troubleshooting the Scanning Service on page 5142.
You can use vulnerabilities reports to browse all vulnerabilities that the Scanning service detected.

**Viewing CIS Benchmarks in a Host Scan**

Use the Console to view the results of CIS benchmark testing on a specific compute instance.

The Center for Internet Security (CIS) publishes best practices for devices and operating systems, which result from the collaboration of cybersecurity professionals and subject matter experts. The Scanning service checks hosts for compliance with the section 5 (Access, Authentication, and Authorization) benchmarks defined for Distribution Independent Linux.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. Click the name of the host scan.
   
   Locate the number of **CIS Benchmarks Passed**.
4. Click **CIS Benchmarks**.

   The following details are shown for each CIS benchmark that the Scanning service tested on this compute instance:

   • **Benchmark ID**
   • **Result** - pass or fail
   • **Summary**
5. You can learn more about a specific benchmark by downloading the document for Distribution Independent Linux.

**Exporting a Host Scan**

Use the Console to export all host scans as a file in comma-separated value (CSV) format for offline analysis.

Example output:

```
resultId,instanceId,compartmentId,highestProblemSeverity,operatingSystem,startDate,endDate,problemCount
ocid1.vsshostscanresult.example123,ocid1.instance.example123,ocid1.compartment.example123,MEDIUM,linux,2020-12-21T17:44:58Z,2020-12-21T17:44:59Z,2
```

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Host Scans**.
2. Select the **Compartment** in which you created the target.
3. Click **Export**.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list all host scans (agent scans, port scans, and CIS benchmark scans) in a compartment:

```
oci vulnerability-scanning host scan result agent list --compartment-id <compartment_ocid>
oci vulnerability-scanning host scan result port list --compartment-id <compartment_ocid>
oci vulnerability-scanning host scan result cis-benchmark list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host scan result agent list --compartment-id ocid1.compartment.oc1..exampleuniqueID
oci vulnerability-scanning host scan result port list --compartment-id ocid1.compartment.oc1..exampleuniqueID
oci vulnerability-scanning host scan result cis-benchmark list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```
To view the details of a specific host agent scan:

```bash
oci vulnerability-scanning host scan result agent get --host-agent-scan-result-id <agent_scan_ocid>
```

For example:

```bash
oci vulnerability-scanning host scan result agent get --host-agent-scan-result-id ocid1.vsshostscanresult.oc1..exampleuniqueID
```

### Using the API

For information about using the API and signing requests, see `/iaas/api/%23/en/iaas/` and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to view host scans, port scans, and CIS benchmark scans:

- ListHostAgentScanResults
- GetHostAgentScanResult
- ExportHostAgentScanResultCsv
- ListHostPortScanResults
- GetHostPortScanResult
- ListHostCisBenchmarkScanResults
- GetHostCisBenchmarkScanResult

**Note:**

The HostEndpointProtectionScanResult APIs have no effect and are reserved for future use.

### Port Scans

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. This service helps identify ports in your compute instances that are unintentionally left open and might be a potential attack vector to your cloud resources, or enable hackers to exploit other vulnerabilities.

The Scanning service performs port scans only if all of the following are true:

- At least one host target exists. See Managing Host Targets on page 5123.
- At least one host target is associated with a scan recipe that enables port scanning. See Updating a Host Scan Recipe on page 5121.

The Scanning service offers two types of port scanning:

- A network mapper searches your public IP addresses for open ports.
- If agent-based scanning is enabled in the scan recipe, then the agent also checks for open ports that are not accessible from public IP addresses.

The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example:

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
All reports related to MyInstance are in CompartmentB.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

```
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
```

See Scanning IAM Policies on page 5145.

**Viewing Port Scans**

Use the Console to view details about the open ports that were detected on a specific compute instance that was scanned.

2. Select the Compartment in which you created the target.
3. (Optional) Click the table columns to sort the port scans by:
   - Name
   - Number of Open Ports
   - Scan Completed date
4. To view the details of a port scan, click its name.
   - The first panel shows the number of open ports that were detected on each Virtual Network Interface Card (VNIC) in this compute instance.
     A VNIC (virtual network interface card) enables a compute instance to connect to a specific VCN (virtual cloud network). You can mouseover the name of a VNIC to view its details.
   - The second panel shows the following details for each port number that was detected in this compute instance.
     - Protocol (TCP or UDP)
     - Typical service that uses this port
     - VNIC
     - Public or private IP address that the port is listening on
5. (Optional) Select one or more VNIC(s) to show only those ports that were detected on the selected VNICS.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list all port scans in a compartment:

```
oci vulnerability-scanning host scan result port list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host scan result port list --compartment-id ocidi.compartment.oc1..exampleuniqueID
```
To view the details of a specific port scan:

```
oci vulnerability-scanning host scan result port get --host-port-scan-result-id <port_scan_ocid>
```

For example:

```
oci vulnerability-scanning host scan result port get --host-port-scan-result-id ocid1.vssportscanresult.oc1..exampleuniqueID
```

**Using the API**

For information about using the API and signing requests, see /iaas/api/%23/en/iaas/ and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to view port scans:

- ListHostPortScanResults
- GetHostPortScanResult

**Ports that are Scanned**

Lists the top 100 and top 1000 ports that Vulnerability Scanning scans.

Host Vulnerabilities Reports

Oracle Vulnerability Scanning Service scans your targets based on the schedule and scanning properties in the recipe assigned to each target. Use vulnerabilities reports to identify security issues in your compute instances like critical OS patches.

At least one host target must exist before any vulnerabilities reports are created. See Managing Host Targets on page 5123.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

The Scanning service saves the results for a compute instance in the same compartment as the instance's Scanning target.

Consider the following example.

• The compute instance MyInstance is in CompartmentA.
• MyInstance is specified in Target1.
• Target1 is in CompartmentB.
• All reports related to MyInstance are in CompartmentB.

The Scanning service categorizes problems by these risk levels.

• Critical - the most serious problems detected, which should be your highest priority to resolve.
• High - the next most serious problems.
• Medium - problems that are a bit less serious.
• Low - problems that are still less serious.
• Minor - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

```
Allow group SecurityAdmins to manage vss-family in compartment SalesApps
```

See Scanning IAM Policies on page 5145.

Viewing Host Vulnerabilities Reports

Use the Console to browse and search for vulnerabilities reports.

1. Open the navigation menu and click Identity & Security. Under Scanning, click Vulnerability Reports.
2. Select the Compartment in which you created the target.
3. (Optional) Click the table columns to sort the reports by:
   • Risk Level
   • Issue Title
   • Last Detected
   • First Detected
   • Hosts Impacted
4. To view details about a vulnerability, click a report's CVE ID.

A vulnerabilities report includes details about the affected hosts and CVEs.
**Viewing the Affected Hosts in a Vulnerabilities Report**

Use the Console to view details about the compute instances on which a specific vulnerability was detected.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.

2. Select the **Compartment** in which you created the target.

3. To view details about a vulnerability, click a report’s **CVE ID**.

   The **Hosts** section lists the compute instances that are affected by the selected vulnerability.
   - To view more details about an affected compute instance, click the instance's name.
   - To view more details about the scanning results for an instance, click the name of a host scan report.

   The Scanning service creates a separate report for each compute instance that you added to your target configurations. The report has the same name as the compute instance.

   A host scan includes **metrics**, **open ports**, and **benchmarks** for a specific compute instance.

**Viewing the CVE in a Vulnerabilities Report**

Use the Console to learn more information about a specific vulnerability, such as the affected OS packages.

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.

2. Select the **Compartment** in which you created the target.

3. To view details about a vulnerability, click a report’s **CVE ID**.

4. From the report’s details, click the **CVE ID** or **Related CVE ID**.

**Exporting a Vulnerabilities Report**

Use the Console to export all vulnerabilities reports as a file in comma-separated value (CSV) format for offline analysis.

Example output:

```
resultId,compartmentId,cveId,severity,state,title,lastDetected,firstDetected,hostCount
```

1. Open the navigation menu and click **Identity & Security**. Under **Scanning**, click **Vulnerability Reports**.

2. Select the **Compartment** in which you created the target.

3. Click **Export**.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see **CLI Help**.

To list all vulnerabilities reports in a compartment:

```
oci vulnerability-scanning host vulnerability list --compartment-id <compartment_ocid>
```

For example:

```
oci vulnerability-scanning host vulnerability list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

To view the details of a specific vulnerability report:

```
oci vulnerability-scanning host vulnerability get --host-vulnerability-id <vulnerability_ocid>
```
For example:

```
oci vulnerability-scanning host vulnerability get --host-vulnerability-id ocid1.vsshostvulnerability.oc1..exampleuniqueID
```

### Using the API

For information about using the API and signing requests, see [/iaas/api/%23/en/iaas/](/iaas/api/%23/en/iaas/) and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to view reports:

- ListHostVulnerabilities
- GetHostVulnerability
- ListHostVulnerabilityImpactedHosts
- ExportHostVulnerabilityCsv

### Scanning Images

Use Oracle Vulnerability Scanning Service to create recipes and targets that scan images in Oracle Cloud Infrastructure Registry for potential security vulnerabilities.

**Note:**

You can configure image scanning and view results using:

- The Container Registry Console
- The Scanning API or CLI

Image scanning is not available from the Scanning Console.

Oracle Cloud Infrastructure Registry makes it easy to share and manage development artifacts like Docker images by storing them in repositories. A repository is a named collection of related images that are grouped for convenience. During the deployment of an application to a Kubernetes cluster, one or more images can be pulled from a repository to start containers on the cluster.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

The results of an image scan include the specific vulnerabilities in the CVE database that were detected in the image repository.

The Scanning service saves the results for an image repository in the same compartment as the repository's Scanning target.

Consider the following example.

- The repository MyRepo in Container Registry is in CompartmentA.
- MyRepo is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyRepo are in CompartmentB.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.
For example, to allow users in the group SecurityAdmins to create, update, and delete all Vulnerability Scanning resources in the compartment SalesApps:

Allow group SecurityAdmins to manage vss-family in compartment SalesApps

See Scanning IAM Policies on page 5145.

**Required IAM Policy for Image Scanning**

You must give the Scanning service permission to pull images from Oracle Cloud Infrastructure Registry.

To grant this permission for all images in the entire tenacy:

allow service vulnerability-scanning-service to read repos in tenancy
allow service vulnerability-scanning-service to read compartments in tenancy

To grant this permission for all images in a specific compartment:

allow service vulnerability-scanning-service to read repos in compartment <compartment-name>
allow service vulnerability-scanning-service to read compartments in compartment <compartment-name>

**Using Oracle Cloud Infrastructure Registry to Scan Images**

Use Oracle Cloud Infrastructure Registry to quickly configure image scanning for your repositories.

When you create a new repository, image scanning is enabled by default on the repository. Every time an image is pushed to the repository, it is scanned for security vulnerabilities in the CVE database. Oracle Cloud Infrastructure Registry automatically rescans any images in the repository that have changed since the previous scan. You can also disable image scanning on a particular repository.

See Scanning Images for Vulnerabilities.

**Using the CLI**

Use the Scanning CLI to scan container images in Oracle Cloud Infrastructure Registry.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

1. Create a container scan recipe.

   ```
   oci vulnerability-scanning container scan recipe create --display-name <name> --compartment-id <compartment_ocid> --scan-settings '{"scanLevel": "STANDARD"}'
   ```

   Example:

   ```
   oci vulnerability-scanning container scan recipe create --display-name MyRecipe --compartment-id ocid1.compartment.oc1..exampleuniqueID --scan-settings '{"scanLevel": "STANDARD"}"
   ```

2. Create a container scan target.

   ```
   oci vulnerability-scanning container scan target create --display-name <name> --compartment-id <create_in_compartment_ocid> --container-scan-recipe-id <recipe_ocid> --target-registry '{"type":
   ```
Vulnerability Scanning

<region_key> is the key for the Oracle Cloud Infrastructure Registry region you're using. See Availability by Region.

For repositories, you can provide a list of repository names. If repositories is not specified, then all repositories in the compartment are scanned.

Example:

```bash
oci vulnerability-scanning container scan target create --display-name "MyTarget" --compartment-id ocid1.compartment.oc1..exampleuniqueID --container-scan-recipe-id ocid1.vsscontainerscanrecipe.oc1..exampleuniqueID --target-registry "{"type": "OCIR", "url": "https://syd.ocir.io", "compartmentId": "ocid1.compartment.oc1..exampleuniqueID", "repositories": ["myrepo"]}
```

3. View a list of all container scan results in a target compartment.

```bash
oci vulnerability-scanning container scan result list --compartment-id <compartment_ocid>
```

Example:

```bash
oci vulnerability-scanning container scan result list --compartment-id ocid1.compartment.oc1..exampleuniqueID
```

4. View the details of a specific container scan result.

```bash
oci vulnerability-scanning container scan result get --container-scan-result-id <container_scan_ocid>
```

Example:

```bash
oci vulnerability-scanning container scan result get --container-scan-result-id ocid1.vsscontainerscanresult.oc1..exampleuniqueID
```

Using the API

Use the Scanning API to scan container images in Oracle Cloud Infrastructure Registry.

For information about using the API and signing requests, see /iaas/api/%23/en/iaas/ and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

1. Create a container scan recipe.

```bash
POST /20210215/containerScanRecipes
Host: <host>
<authorization and other headers>
{
   "displayName": "<recipe_name>",
   "compartmentId": "<recipe_compartment_ocid>",
   "scanSettings": {
      "scanLevel": "STANDARD"
   }
}
```

2. Create a container scan target.

```bash
POST 20210215/containerScanTargets
Host: <host>
```
Vulnerability Scanning

<authorization and other headers>
{
   "displayName": "<target_name>",
   "description": "<target_description>",
   "compartmentId": "<target_compartment_ocid>",
   "containerScanRecipeId": "<recipe_ocid>",
   "targetRegistry": {
      "type": "OCIR",
      "url": "https://<region_key>.ocir.io"
      "compartmentId": "<repository_compartment_ocid>",
      "repositories": "<repository_name>"
   }
}

<region_key> is the key for the Oracle Cloud Infrastructure Registry region you're using. See Availability by Region.

If repositories is not specified, all repositories in the compartment are scanned.

3. View container scan results.

GET 20210215/containerScanResults?
compartmentId=<target_compartment_ocid>&repository=<repository_name>
Host: <host>
<authorization and other headers>

For more information about these operations, refer to the Scanning API.

Scanning with Cloud Guard

Use Cloud Guard to detect and respond to security vulnerabilities identified by Oracle Vulnerability Scanning Service.

Cloud Guard is an Oracle Cloud Infrastructure service that provides a central dashboard to monitor all of your cloud resources for security weaknesses in configuration, metrics, and logs. When it detects a problem, it can suggest, assist, or take corrective actions, based on your Cloud Guard configuration.

Cloud Guard Concepts

Compare the concepts and features of the Scanning service with Cloud Guard.

Like the Scanning service, Cloud Guard supports recipes and targets.

- A Cloud Guard recipe defines the types of resources and problems that you want to monitor
- A Cloud Guard target defines one or more compartments that you want to monitor, and is associated with a Cloud Guard recipe.

A configuration detector recipe consists of detector rules. The default Cloud Guard configuration detector recipe includes rules that check for vulnerabilities and open ports found in reports created by Vulnerability Scanning. You can use this Oracle-managed configuration detector recipe or clone it to create a custom recipe.

You can also modify the default settings for the Scanning detector rules.

- Disallowed port numbers that Cloud Guard reports as a problem
- Allowed port numbers that Cloud Guard ignores
- Vulnerability risk levels (Low, Medium, High, Critical) that Cloud Guard reports as a problem

Using the Cloud Guard Scanning Detector Rules

Configure and use Cloud Guard to monitor security problems detected in Vulnerability Scanning.

Enable Cloud Guard and create at least one Cloud Guard target, if the service is not already enabled. See Getting Started with Cloud Guard and Managing Targets.
Before using Cloud Guard, at least one Scanning target must exist before the Scanning service creates any reports. These reports are used by the Cloud Guard detector. See Managing Host Targets on page 5123.

**Note:**

Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

To view Scanning problems in Cloud Guard:

1. If you created a custom configuration detector recipe in Cloud Guard, verify that the Vulnerability Scanning detector rules are enabled in your recipe.

   All detector rules are automatically enabled in Oracle-managed recipes like [OCI Configuration Detector Recipe](#), and can't be disabled.

   a) From the Cloud Guard console, click **Detector Recipes**.
   b) Click your custom configuration detector recipe.
   c) Under **Detector Rules**, in the **Filter by detector rule** field, enter **scan**.
   d) Select the check boxes for the Vulnerability Scanning rules.

   - **Scanned host has vulnerabilities**
   - **Scanned host has open ports**

   e) If these rules are not already enabled, click **Enable**.

   For more information, see [Modifying a Detector Recipe](#).

2. From the Cloud Guard console, click **Problems**.

3. Click the name of a Vulnerability Scanning problem to view its details.

   - **Scanned host has vulnerabilities**
   - **Scanned host has open ports**

   **Tip:**

   To filter the list of problems, scroll down and locate the **Labels** field. Enter "VSS" (case-sensitive) and click **Apply Filters**.

Vulnerability Scanning problems include links to the corresponding [Host Scans](#) on page 5128 and [Port Scans](#) on page 5131.

If no Vulnerability Scanning problems are displayed in Cloud Guard, then consider the following scenarios.

- The Vulnerability Scanning service did not create any reports yet. The schedule (daily/weekly) is configured in the Scanning target.
- You recently enabled Cloud Guard or the Vulnerability Scanning detector rules and Cloud Guard has not run them yet.

For more information, see [Processing Reported Problems](#) and [Troubleshooting the Scanning Service](#) on page 5142.

**Updating the Scanning Detector Rules**

In Cloud Guard recipes, you can modify the default settings for the Vulnerability Scanning detector rules. These settings control which vulnerabilities are reported as problems in Cloud Guard.

For example, you can configure which vulnerability risk levels are problems, or configure which TCP or UDP open ports are problems.

You can modify some rule settings in an Oracle-managed detector recipe like [OCI Configuration Detector Recipe](#), and you can modify all rule settings in a custom recipe. You can't disable rules in Oracle-managed recipes.

1. From the Cloud Guard console, click **Detector Recipes**.
2. Click your configuration detector recipe.
3. Under Detector Rules, in the Filter by detector rule field, enter scan.
4. Click the Actions icon for the rule Scanned host has vulnerabilities, and then select Edit.
5. After updating the rule's settings, click Save.
6. Repeat this step on the rule Scanned host has open ports.

For more information, see Modifying Rule Settings in a Detector Recipe.

Troubleshooting the Scanning Service

Identify the causes and fixes for common problems with Oracle Vulnerability Scanning Service.

No Scanning Results
Fix general problems that prevent you from seeing any type of Scanning report.

Target was Created Less Than 24 Hours Ago
After you create a target, the Scanning service does not immediately scan the specified target resources (compute instances).

After creating a target that's associated with your recipe, it can take up to 24 hours for the Scanning service to perform the first scan of the target resources. This delay occurs if you configured your recipe with a Daily schedule or a Weekly schedule.

Missing IAM Policy
To view any type of Scanning report, you must be given the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

For example, to allow users in the group SecurityAuditors to view all Scanning resources in the compartment SalesApps:

Allow group SecurityAuditors to read vss-family in compartment SalesApps

See Scanning IAM Policies on page 5145.

Wrong Compartment is Specified
Within the Console, be sure to choose the Compartment that contains the Scanning results for the targets (compute instances) that you want to view.

The Scanning service saves the results for a compute instance in the same compartment as the instance’s Scanning target.

Consider the following example.

- The compute instance MyInstance is in CompartmentA.
- MyInstance is specified in Target1.
- Target1 is in CompartmentB.
- All reports related to MyInstance are in CompartmentB.

All Features in the Recipe are Disabled
If you created a recipe in the Scanning service, but you disabled all scanning options in the recipe, then the Scanning service doesn't scan any targets assigned to this recipe.

See Updating a Host Scan Recipe on page 5121.

No Host Scans
Fix problems that prevent you from seeing the results of host scans.
Vulnerability Scanning

See No Scanning Results on page 5142 for other common issues.

**Agent-Based Scanning is not Enabled**

To create host scans, the Scanning service uses the Oracle Cloud Agent, which runs on the target compute instances. By default, Agent Based Scanning is enabled in a recipe. If you disabled this option in your recipe, then the Scanning service does not create host scans for the targets that are associated with your recipe.

See Updating a Host Scan Recipe on page 5121.

**Scanning Plugin is Disabled on the Agent**

The Oracle Cloud Agent process manages plugins running on the compute instance. The Scanning plugin is used to detect vulnerabilities and to test CIS benchmarks. By default, the Scanning plugin is enabled on all instances running the agent, but the plugin can be disabled.

If you manually disabled the Scanning plugin on the target compute instances, you must enable it. See Managing Plugins with Oracle Cloud Agent.

**Missing IAM Policy to Deploy the Agent**

If the target compute instances are not running the Oracle Cloud Agent, the Scanning service automatically deploys the agent to the instances. However, an administrator must give the Scanning service permission to update your target compute instances.

See Required IAM Policy for Host Scanning on page 5119.

**Instance is Not Running the Latest Agent**

If the target compute instance is running Oracle Cloud Agent version 1.11.0, it might not automatically update itself to the latest version.

Manually update Oracle Cloud Agent on the instance. See:

- Updating the Oracle Cloud Agent Software
- Oracle Cloud Agent version 1.11.0 does not update automatically

**Missing Service Gateway for Hosts with no Public IP Address**

A compute instance is associated with a VCN (virtual cloud network) and a subnet. If a compute instance in your target is on a private subnet or has no public IP address, the VCN must include a service gateway and a route rule for the service gateway. See Access to Oracle Services: Service Gateway.

If the VCN is not configured correctly, the Scanning service is not able to communicate with compute instances on the private subnet and perform a host scan.

**Reported CVE is Already Fixed in Host (False Positive)**

Fix problems that cause host scans to report vulnerabilities that were already fixed.

Common Vulnerabilities and Exposures (CVE) numbers are used by Oracle to identify security vulnerabilities for operating systems and other software, including Critical Patch Updates and Security Alert advisories. CVE numbers are unique, common identifiers for publicly known information about security vulnerabilities.

During a host scan, the Scanning service compares the version of OS packages on the host with the fixed version of the packages in the open source CVE database.

If you're using the OS Management service to update the target hosts, then the following scenario often indicates a false positive:

- The Scanning service report says that a specific CVE number is not fixed in a target host.
- The OS Management service says that there are no security updates to install on the same target host.
Vulnerability Scanning

**CVE Database Inaccuracies**

Oracle Vulnerability Scanning Service is continually working to improve scan results by using the latest Oracle Linux and open source databases, but there can be inaccuracies in these databases, or in the method used by the service to detect the CVE. For example, the Scanning service can report a security issue in a Linux instance even though:

- The issue was recently fixed in the latest Linux distribution
- The issue was fixed in the latest Linux distribution but recently backported to older versions

If you are concerned that a vulnerability detected by the Scanning service might be a false positive, then you can use a CVE number to verify whether the vulnerability is already fixed in your compute instance.

For example, to verify a CVE for Oracle Linux:

1. From Unbreakable Linux Network CVE Summary, search for the CVE number.
2. From the Errata Information in the CVE details, identify the Release Date for the version of Oracle Linux running on the compute instance.
   
   If the version has a release date, then the CVE is fixed in that version.
3. Connect to the compute instance using SSH.
4. Search the package change log for the CVE number.
   
   ```
   rpm -q --changelog package | grep <CVE>
   ```

**CVE Fixed Using Ksplice**

Oracle Ksplice allows you to update Oracle Linux hosts with important security patches without needing to reboot.

If you fixed a CVE using Ksplice and did not reboot the host, the Scanning service might continue to report it as a vulnerability. You can use the CVE number to verify whether the vulnerability is already fixed in your compute instance.

Oracle Autonomous Linux is a self-patching operating system image based on Oracle Linux. It automatically applies patches daily using Oracle Ksplice. Because Oracle Autonomous Linux updates the kernel without rebooting the host, the Scanning service might continue to report a vulnerability even though it was fixed.

**Old Kernel or Package Files**

If old, unused kernel or package files are present on your host's file system, the Scanning service might report these old files as a vulnerability. This scenario can occur if you created backup copies of these files, or the files were not cleaned up properly during an update or uninstall.

Refer to the detected CVE description to identify the list of files associated with the vulnerability. Search your target host for any copies of these files and delete them.

**No Cloud Guard Results**

Fix problems that prevent you from seeing any Scanning problems in Cloud Guard.

Cloud Guard analyzes the results of the Scanning service and reports the following types of problems:

- Scanned host has vulnerabilities
- Scanned host has open ports

Before troubleshooting Cloud Guard, be sure you're able to view host scans and port scans in the Scanning service. If not, see No Scanning Results on page 5142.

For more information about common Cloud Guard problems, see Troubleshooting Cloud Guard.
The Cloud Guard Targets Do Not Include Target Hosts

Cloud Guard targets are separate resources from Scanning targets. To use Cloud Guard to detect problems in Scanning reports, the Scanning target compartment must be the same as the Cloud Guard target compartment, or be a subcompartment of the Cloud Guard target compartment.

Consider this scenario.

- CompartmentA and CompartmentB are siblings (one is not a subcompartment of the other).
- The compute instance MyInstance is in CompartmentA.
- The Scanning target ScanTarget1 is set to CompartmentA.
- The Cloud Guard target CGTarget1 is set to CompartmentB.

In this example, Cloud Guard does not show problems for vulnerabilities detected in MyInstance. Inspect your target settings in Cloud Guard and the Scanning service. If the Cloud Guard target is set to the root compartment for your tenancy, then no change is needed.

To address this issue, create a Cloud Guard target that includes the compartments in your Scanning targets. See Managing Targets.

The Scanning Rules are Disabled

In an Oracle-managed detector recipe like OCI Configuration Detector Recipe, all detector rules are enabled. However, if you created a custom detector recipe and did not enable the Scanning detector rules, Cloud Guard does not report any Scanning problems.

See Using the Cloud Guard Scanning Detector Rules on page 5140.

The Scanning Rule Settings Exclude Your Vulnerabilities

In Cloud Guard detector recipes, the settings for the Scanning detector rules control which vulnerabilities are reported as problems in Cloud Guard.

- Disallowed port numbers that Cloud Guard reports as a problem
- Allowed port numbers that Cloud Guard ignores
- Vulnerability risk levels (Low, Medium, High, Critical) that Cloud Guard reports as a problem

Consider the following examples.

- A port scan in the Scanning service identifies the open ports 111 and 123, but the Scanning detector rules in Cloud Guard are configured to allow ports 111 and 123.
- A host scan in the Scanning service identifies vulnerabilities with the risk level Medium, but the Scanning detector rules in Cloud Guard are configured only to report vulnerabilities that are High or Critical.

Verify the settings for the Scanning detector rules in your configuration detector recipe. See Updating the Scanning Detector Rules on page 5141.

Scanning IAM Policies

Create IAM policies to control who has access to Oracle Vulnerability Scanning Service resources, and to control the type of access for each group of users.

By default, only users in the Administrators group have access to all Scanning resources. If you are new to IAM policies, see Getting Started with Policies.

For a complete list of all policies in Oracle Cloud Infrastructure, see the Policy Reference.

Resource-Types

The following resource types are related to Vulnerability Scanning.

To assign permissions to all Scanning resources, use the aggregate type:

- vss-family
To assign permissions to individual resource types:

- host-scan-recipes
- host-scan-targets
- host-agent-scan-results
- host-port-scan-results
- host-cis-benchmark-scan-results
- host-vulnerabilities
- container-scan-recipes
- container-scan-targets
- container-scan-results
- vss-work-requests

A policy that uses `<verb> vss-family` is equivalent to writing a policy with a separate `<verb> <resource-type>` statement for each of the individual resource types.

**Supported Variables**

Scanning IAM policies support all the general policy variables.

See [General Variables for All Requests](#).

**Details for Verb + Resource-Type Combinations**

Identify the permissions and API operations covered by each verb for Scanning resources.

The level of access is cumulative as you go from `inspect` to `read` to `use` to `manage`.

A plus sign (+) in a table cell indicates incremental access when compared to the preceding cell, whereas no extra indicates no incremental access.

### Policy Examples

Learn about Scanning IAM policies using examples.

#### Basic Policy Examples

- Allow users in the group `SecurityAdmins` to create, update, and delete all Scanning resources in the entire tenancy:

  ```plaintext
  Allow group SecurityAdmins to manage vss-family in tenancy
  ```

- Allow users in the group `SecurityAdmins` to create, update, and delete all Scanning resources in the compartment `SalesApps`:

  ```plaintext
  Allow group SecurityAdmins to manage vss-family in compartment SalesApps
  ```

- Allow users in the group `SecurityAuditors` to view all Scanning resources in the compartment `SalesApps`:

  ```plaintext
  Allow group SecurityAuditors to read vss-family in compartment SalesApps
  ```

- Allow users in the group `SecurityAdmins` to create, update, and delete host scan recipes in the entire tenancy:

  ```plaintext
  Allow group SecurityAdmins to manage host-scan-recipes in tenancy
  ```

- Allow users in the group `SecurityAuditors` to view all host scanning results in the compartment `SalesApps`:

  ```plaintext
  Allow group SecurityAuditors to read host-agent-scan-results in compartment SalesApps
  Allow group SecurityAuditors to read host-port-scan-results in compartment SalesApps
  Allow group SecurityAuditors to read host-cis-benchmark-scan-results in compartment SalesApps
  Allow group SecurityAuditors to read host-vulnerabilities in compartment SalesApps
  ```
Host Scanning Policy Examples

To use agent-based host scanning, then you must also:

- Grant the Scanning service permission to deploy the Oracle Cloud Agent to your target compute instances.
- Grant the Scanning service permission to read the VNIC (virtual network interface card) on your target compute instances.
- Grant users permission to manage the target compute instances.

Examples:

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning in the entire tenancy:

<table>
<thead>
<tr>
<th>Allow group SecurityAdmins to manage vss-family in tenancy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group SecurityAdmins to manage instances in tenancy</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to manage instances in tenancy</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read compartments in tenancy</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read vnic-attachments in tenancy</td>
</tr>
</tbody>
</table>

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning on instances in the compartment SalesApps:

<table>
<thead>
<tr>
<th>Allow group SecurityAdmins to manage vss-family in compartment SalesApps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group SecurityAdmins to manage instances in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to manage instances in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read compartments in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read vnic-attachments in compartment SalesApps</td>
</tr>
</tbody>
</table>

- Allow the Scanning service and users in the group SecurityAdmins to perform agent-based scanning on instances in the compartment SalesApps. The VNICs of these instances are in the compartment SalesNetwork:

<table>
<thead>
<tr>
<th>Allow group SecurityAdmins to manage vss-family in compartment SalesApps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group SecurityAdmins to manage instances in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to manage instances in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read compartments in compartment SalesApps</td>
</tr>
<tr>
<td>Allow service vulnerability-scanning-service to read vnic-attachments in compartment SalesNetwork</td>
</tr>
</tbody>
</table>

For more information about compute and network policies, see Policy Details for the Core Services.

Scanning Metrics

You monitor the health, capacity, and performance of Oracle Vulnerability Scanning Service by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_vss.
Overview
Metrics help you monitor the vulnerabilities that the Vulnerability Scanning service detects in your cloud resources.

Namespace
A namespace is a container for metrics. The namespace identifies the service sending the metrics. The namespace for the Scanning service is `oci_vss`.

Metrics
Metrics are the fundamental concept in telemetry and monitoring. Metrics define a time-series set of datapoints. Each metric has a namespace, metric name, compartment identifier, one or more dimensions, and a unit of measure. Each datapoint has a timestamp, value, and count associated with it.

Dimensions
A dimension is a key-value pair that defines the characteristics associated with the metric. For example, `resourceId` is the OCID of the resource that was scanned.

Statistics
Statistics are metric data aggregations over specified periods of time. Aggregations are done using the namespace, metric name, dimensions, and the data point unit of measure within the time period specified.

Alarms
Alarms are used to automate operations monitoring and performance. An alarm tracks changes that occur over a specific time period and performs one or more defined actions, based on the rules defined for the metric.

Required IAM Policy
To monitor resources in Oracle Cloud Infrastructure, you must be given the required type of access in a policy (IAM) written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool.

The policy must give you access to the monitoring services and the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you were granted and which compartment you are supposed to work in.

For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics
Scanning metrics include the following dimensions:

- `resourceId`: The OCID of the cloud resource that was scanned, such as a compute instance (Compute).
- `resultId`: The OCID of the host scan in the Scanning service.
- `riskLevel`: The risk level of the cloud resource that was scanned.

The Scanning service categorizes problems by these risk levels:

- **Critical** - the most serious problems detected, which should be your highest priority to resolve.
- **High** - the next most serious problems.
- **Medium** - problems that are a bit less serious.
- **Low** - problems that are still less serious.
- **Minor** - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SecurityVulnerability</td>
<td>Security Vulnerability</td>
<td>count</td>
<td>Total number of vulnerabilities found in a scan of a cloud resource.</td>
</tr>
</tbody>
</table>
**Using the Console**

View the metric charts for the Scanning service.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the **Scanning target** that you're interested in.
3. For **Metric Namespace**, select **oci_vss**.

The **Service Metrics** page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

**Using the API**

Use the following APIs for monitoring.

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

For information about using the API and signing requests, see `/iaas/api/%23/en/iaas/` and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

**Scanning Events**

Oracle Cloud Infrastructure Events allows your development teams to automatically respond when a resource changes its state. Oracle Vulnerability Scanning Service resources emit the following events.

See Getting Started with Events.

**Host Scan Recipe Event Types**

These are the event types that host scan recipes emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostScanRecipe - Create</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - Update Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscanrecipe.begin</td>
</tr>
<tr>
<td>HostScanRecipe - Update End</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscanrecipe.end</td>
</tr>
<tr>
<td>HostScanRecipe - Delete</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscanrecipe</td>
</tr>
<tr>
<td>HostScanRecipe - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changecompartmenthostscanrecipe</td>
</tr>
</tbody>
</table>

This is a reference event for host scan recipes.

```json
{
  "eventType":"com.oraclecloud.vulnerabilityscanning.createhostscanrecipe",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
...}
```
**Host Scan Target Event Types**

These are the event types that host scan targets emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostScanTarget - Create Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Create End</td>
<td>com.oraclecloud.vulnerabilityscanning.createhostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostscantarget</td>
</tr>
<tr>
<td>HostScanTarget - List</td>
<td>com.oraclecloud.vulnerabilityscanning.listhostscantarget</td>
</tr>
<tr>
<td>HostScanTarget - Update Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Update End</td>
<td>com.oraclecloud.vulnerabilityscanning.updatehostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - Delete Begin</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscantarget.begin</td>
</tr>
<tr>
<td>HostScanTarget - Delete End</td>
<td>com.oraclecloud.vulnerabilityscanning.deletehostscantarget.end</td>
</tr>
<tr>
<td>HostScanTarget - ChangeCompartment</td>
<td>com.oraclecloud.vulnerabilityscanning.changehostscantarget</td>
</tr>
</tbody>
</table>

This is a reference event for host scan targets.

```json
{}
```
Host Agent Scan Result Event Types

These are the event types that host agent scan results emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostAgentScanResult - Get</td>
<td>com.oraclecloud.vulnerabilityscanning.gethostagentscanresult</td>

  }
}
```
Web Application Firewall

This chapter explains how to make your endpoints more secure by monitoring and filtering out potentially malicious traffic.

Overview of Web Application Firewall on page 5161

Get a high-level overview of the WAF service.

Getting Started

Follow a guided journey to set up WAF.

Frequently Asked Questions on page 5294

Find answers to frequently asked questions about WAF.

Features

Origin Management

An origin is an endpoint (typically an IP address) of the application protected by the WAF. An origin can be an Oracle Cloud Infrastructure load balancer public IP address which can be used for high availability to an origin. When you create a WAF policy, you define a default origin and optional HTTP headers. An origin must be defined in your WAF policy in order to set up protection rules or other features. The details for the origin can be modified later in the Settings of the WAF policy. In the Origin Settings you can modify or set up HTTP headers for outbound traffic from the WAF to the origin server. These name value pairs are then available to the application.

See Origin Management on page 5176 for more information.
**Bot Management**

Bot Management enables you to mitigate undesired bot traffic from your site using CAPTCHA and JavaScript detection tools, while enabling known published bot providers to bypass these controls.

Non-human traffic makes up most of the traffic to sites. Bot Manager is designed to detect and block, or otherwise direct, non-human traffic that may interfere with site operations. The Bot Manager features mitigate bots that conduct content and price scraping, vulnerability scanning, comment spam, brute force attacks, and application-layer DDoS attacks. You can also allowlist good bots.

See [Bot Management](#) on page 5180 for more information.

**WAF Protection Rules**

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met. Protection Rule Settings allow you to define the parameters for enforcement any time a protection rule is matched. Recommendations aid in the optimization of your WAF security profile. The Security Operations team proactively monitors all events to provide recommendations about the action of a specific ruleset.

See [WAF Protection Rules](#) on page 5187 for more information.

**Access Control**

As a WAF administrator you can define explicit actions for requests that meet various conditions. Conditions use various operations and regular expressions. A rule action can be set to log and allow, detect, block, redirect, bypass, or show a CAPTCHA for all matched requests. You can also use the IP Whitelist tab to manage whitelists containing trusted IP addresses that bypass all rules and challenges.

See [Access Control](#) on page 5267 for more information.

**Caching Rules**

Caching rules allow you to selectively cache requested content on Oracle Cloud Infrastructure's edge servers, such as web pages or certain file types.

See [Caching Rules](#) on page 5273 for more information.

**Overview of Web Application Firewall**

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based, Payment Card Industry (PCI) compliant, global security service that protects applications from malicious and unwanted internet traffic. WAF can protect any internet facing endpoint, providing consistent rule enforcement across a customer's applications.

WAF provides you with the ability to create and manage rules for internet threats including Cross-Site Scripting (XSS), SQL Injection and other OWASP-defined vulnerabilities. Unwanted bots can be mitigated while tactically allowed desirable bots to enter. Access rules can limit based on geography or the signature of the request.

The global Security Operations Center (SOC) will continually monitor the internet threat landscape acting as an extension of your IT infrastructure.

**Web Application Firewall Service Components**

**WEB APPLICATION FIREWALL POLICY**

WAF policies encompass the overall configuration of your WAF service, including origin management, protection rule settings, and bot detection features.

**ORIGIN**

Your web application's origin host server. An origin must be defined in your WAF policy in order to set up protection rules or other features.
PROTECTION RULES

Protection rules can be configured to either allow, block, or log network requests when they meet the specified criteria of a protection rule. The WAF will observe traffic to your web application over time and suggest new rules to apply. To view a list of available WAF rules, see Supported Protection Rules.

BOT MANAGEMENT

The WAF service includes several features that allow you to detect and either block or allow identified bot traffic to your web applications. Bot management features include: JavaScript Challenge, CAPTCHA Challenge, and GoodBot whitelists. For more information, see Bot Management.

Ways to Access the WAF Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface), command line interface (CLI), or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Note About The API

The WAF service is powered by the Oracle Cloud Infrastructure Web Application Acceleration and Security (WAAS) API. All WAF related calls must be made using the WAAS API. To create a WAF configuration using the API, you must first create a WAAS policy with a defined origin and domain using the API. For the purposes of access control, you must provide the OCID of the compartment where you want the service to reside. For information about access control and compartments, see Overview of the IAM Service.

WAF Service Capabilities and Limits

The WAF service is limited to 50 policies per tenant. See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

The WAF service allows a total run time of 20 minutes for upload and download processes through the WAF.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given access in a policy for waas-policy. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Policy examples:
• To allow a specific user group to manage policies in the WAF:

  Allow group <GroupName> to manage waas-policy in compartment <CompartmentName>

  Allow group <GroupName> to read waas-work-request in compartment <CompartmentName>

• To allow a specific user group to manage certificates in the WAF:

  Allow group <GroupName> to manage waas-certificate in compartment <CompartmentName>

• To allow a specific user group view policies in the WAF

  Allow group <GroupName> to read waas-policy in tenancy <TenancyName>

If you’re new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service on page 3049.

Moving WAF Policies to a Different Compartment

You can move WAF policies from one compartment to another. After you move a WAF policy to the new compartment, inherent policies apply immediately and affect access to the WAF policies through the Console, SDK or CLI. For more information, see Managing Compartments on page 3126.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about available WAF service metrics and how to view them, see WAF Metrics on page 5288.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Getting Started with WAF

If you’re new to Oracle Cloud Infrastructure WAF, this topic gives guidance on how to proceed.

Before You Begin

Refer to the Overview of Web Application Firewall on page 5161 for important concepts about WAF.

To begin using the WAF service, you must have the following available:

• Ensure that you have the Required IAM Service Policy on page 5162 permissions.
• We recommended that you use a separate compartment for your WAF policy so that management is easier and more secure.
• A main webapp domain.
• IP address of the LBaaS or other public facing endpoint of the application.
Web Application Firewall

- Ability to update DNS records for the domain.
- The WAF service only supports traffic on ports 80/443. Ensure that your application is not running on other ports.

Also, if you plan to run your site on HTTPS/443, you will need:

- Public certificate for the fully qualified domain name (FQDN) of the application.
- Corresponding private key for the site.
- Certificate in PEM format.
- Full chain certificate (that is, Root, Intermediate, Origin Server)

| Note: |
| SSL certificates can only be applied to the main application of the policy. |

Initial Setup of Your WAF Policy

1. Create a Policy to Route Traffic Through the WAF

To begin, create a policy to route traffic through the WAF without rules enabled. Creating a policy without rules enabled ensures that there are no regressions by having a reverse proxy in front of the application.

To create a policy

1. Select the region and compartment where the policy should be maintained (there is no constraint around the WAF co-existing with Load Balancing or other application resources in Oracle Cloud Infrastructure.
3. Click Create WAF Policy.
4. In the Create WAF Policy dialog box, enter the following:
   - Name: A unique name for the policy. Avoid entering confidential information.
   - Domains:
     - Primary Domain: The fully qualified domain name (FQDN) of the application where the policy will be applied.
     - Additional Domains: (Optional) Subdomains where the policy will be applied.

| Note: |
| Wildcard domains are accepted, however, only as additional domains and only through the API and CLI. |

- WAF Origin: The host or IP address of the public internet facing application that is being protected by the application.
- Origin Name: A unique name for the origin.
- URI: Enter the public facing endpoint (IPv4 or FQDN) of the application.
- HTTPS Port: The port used for secure HTTP connection. The default port is 443.
- HTTP Port: The HTTP port the origin listens on. The default port is 80.
- Headers: (Optional)
  - Header Name: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
  - Header Value: Specifies the data requested by the header.
- Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click Create WAF Policy. The WAF Policy overview appears. Expect the policy to become active within 15 minutes of creation.

See Managing WAF Policies on page 5173 for more information.
2. Update Origin Keep Alive Timeout

WAF requires that your origin's (load balancer or web server) keep alive timeouts are maintained for 301 seconds or more, as our upstream timeout value is 300 seconds. The additional second is to ensure that the connection has enough time to renegotiate when our nodes create connections and avoid connectivity issues. This applies to API calls, as we use our OCI Network Multiplexing technology that helps to reduce network bottlenecks and improve performance by optimizing TCP protocol.

To test the upstream keep alive timeout

HTTP check:
1. Make the request against the origin or upstream server. Run the following command:

   ```
   time telnet www-origin.example.com 80
   ```

   Example output:

   ```
   Trying 12.34.56.78...
   Connected to lb65-soc-191485947.us-east-1.elb.amazonaws.com.
   Escape character is '^]'.
   ```

2. Make a GET request by entering the following HTTP headers:

   ```
   GET / HTTP/1.1
   Host: www.example.com
   Connection: keep-Alive
   ```

3. Press ENTER twice and wait for the session to close or disconnect.

HTTPS check:
1. Initiate the request against the Origin or Upstream Server. Run the following command:

   ```
   time openssl s_client -connect www-origin.example.com:443
   ```

2. Make a GET request by entering the following HTTP headers:

   ```
   GET / HTTP/1.1
   Host: www.example.com
   Connection: keep-Alive
   ```

3. Press ENTER twice and wait for the session to close or disconnect.

You will receive the following output. In this example, the real section shows the actual time the session was alive (5.1 minutes (301 seconds)):

```
HTTP/1.1 200 OK
Content-Type: text/html; charset=UTF-8
 ...
<!DOCTYPE html>
<html>
 ...
</html>
Connection closed by foreign host.
real 5m1.962s
user 0m0.011s
sys 0m0.009s
```

See Origin Management for more information.
3. Upload Your Certificate and Key

This step assumes that your site runs on HTTPS/443.

To upload your certificate and key:

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of your WAF Policy. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **General Settings**.
5. Click **Edit**.
6. In the **Edit Settings** dialog box, enter the following:
   - **Enable HTTPS Support**: Click this check box to enable all communications between the browser and web application to be encrypted.
   - **Certificate Source**: Choose one of the following methods:
     - **Choose Certificate**: Select an existing certificate from the drop-down menu. Click **Change Compartment** to select a certificate from another compartment.
     - **Upload or Paste Certificate and Private Key**
       - Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:
         ```plaintext
         -----BEGIN CERTIFICATE-----
         <Base64_encoded_certificate>
         -----END CERTIFICATE-----
         -----BEGIN CERTIFICATE-----
         <Intermediate_Base64_encoded_certificate>
         -----END CERTIFICATE-----
         ```
     - **Private Key**: Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:
         ```plaintext
         -----BEGIN PRIVATE KEY-----
         <Base64_encoded_private_key>
         -----END PRIVATE KEY-----
         ```
     - **Self Signed Certificate**: Enable this field when using a self-signed certificate to show an SSL warning in the browser.
   - **HTTP to HTTPS Redirect**: When enabled, all HTTP traffic is automatically redirected to HTTPS.
   - **TLS Protocols Support**: Select a TLS protocol from the drop-down list.
     - **Caution**: TLS versions 1 and 1.1 have been deprecated and cannot be used in policy configurations. If you use these versions, a validation error might occur. Use versions 1.2 or 1.3 instead.
   - **Enable SNI**: Server Name Indication (SNI) is an extension of the TLS protocol, which allows multiple secure hostnames to be served from a single IP address.
   - **Advanced Options**
     - **Enable Response Buffering**: Enable or disable buffering of the response from the origin.
     - **Cache Control Respected**: Enable or disable automatic content caching based on the response cache-control header.
     - **Behind CDN**: Enable this to allow the collection of IP addresses from the client request if WAF is connected to a CDN.
7. Click **Save Changes**. Updates to your WAF policy appear in the list to be published in Unpublished Changes.
8. In the WAF Policy overview, under **Unpublished Changes**, click **View**.
9. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
10. Click **Publish All**.  
11. In the Publish Changes dialog box, click **Publish All**.  
   See [Certificates](#) on page 5279 for more information.

### 4. Test Your Application (Before Deploying it to Production)

In this step, you ensure that requests are being routed to the WAF and that your application continues to function normally with a reverse proxy in the topology.

**Test your application through a terminal command**

1. Open a terminal.
   
   Run the following command for HTTP:
   
   ```bash
   curl -lvk http://<OCI_WAF_CNAME> -H "Host: <WEBAPP_DOMAIN>" -so /dev/null
   ```
   
   Run the following command for HTTPS:
   
   ```bash
   curl -lvk https://<OCI_WAF_CNAME> -H "Host: <WEBAPP_DOMAIN>" -so /dev/null
   ```
   
2. You can also run a DNS query against the `<OCI_WAF_CNAME>` for your WAF policy and copy one of the IP addresses from the resulting output.
   
   • To run a DNS query you can use one of the following commands:
   
   ```bash
dig <OCI_WAF_CNAME>
   
   nslookup <OCI_WAF_CNAME>
   ```
   
   • Copy any of the IP addresses from the output.
   
3. Run the following command. Replace `<WEBAPP_DOMAIN>` with your WAF policy domain. Use port 80 or 443. Replace `<OCI_NODE_IP>` with the IP address from `<OCI_WAF_CNAME>`.
   
   ```bash
   Query curl -vso/dev/null --resolve <WEBAPP_DOMAIN>:<PORT_80_OR_443>:<OCI_NODE_IP> https://<WEBAPP_DOMAIN>
   ```
   
   A 200, 301, 302, or any other expected HTTP response code is returned.

   **Note:**
   
   If you receive a 5XX HTTP error, ensure that you have updated your firewall setting to allow our IP addresses. If you are still experiencing an issue, open a service request with My Oracle Support. In the support request, provide your compartment OCID, policy OCID, explanation about the issue you are experiencing, a HAR file, and a time when the issue started.

**Test your application through a web browser**

To test your application using a hosts file, you need an IP address where you could point your application. Under the policy, you should see the CNAME which is assigned to you. You can get the IP address where you can point your application.

1. Open a terminal.
2. Run a DNS query using any of the following commands:
   
   ```bash
dig <OCI_WAF_CNAME>
   
   nslookup <OCI_WAF_CNAME>
   ```
3. Copy one of three IP addresses from a dig command output Answer section and paste it to a hosts file with your domain name.

4. After you save your hosts file, open your application in a browser and verify it is working as expected. A 200, 301, 302, or any other expected HTTP response code is returned.

**Note:**

If you receive a 5XX HTTP error, ensure that you have updated your firewall setting to allow our IP addresses. If you are still experiencing an issue, open a service request with My Oracle Support. In the support request, provide your compartment OCID, policy OCID, explanation about the issue you are experiencing, a HAR file, and a time when the issue started.

---

**Test your SSL**

The following useful command line tools can be used to validate certificates on a given web application:

```bash
echo | openssl s_client -showcerts -servername <Domain> -connect <Domain>:443 2>/dev/null | openssl x509 -inform pem -noout -text
```

Pay special attention to the certificate validity dates and expiration dates that might cause connection issues:

---

Signature Algorithm: sha256WithRSAEncryption
Issuer: C = US, O = Let's Encrypt, CN = Let's Encrypt Authority X3
Validity
   Not Before: Jun  5 03:15:10 2020 GMT
   Not After : Sep  3 03:15:10 2020 GMT
Subject: CN = www.example.com
Subject Public Key Info:
...

---

You can also check the certificate from third-party websites such as SSL Shoooper or SSL labs and perform the validation there.

---

**5. Update DNS to Enable WAF**

After confirming your web application works flawless through WAF, you can now proceed to update the DNS globally.

In this step, you update the CNAME for your zone to route requests from internet clients to WAF. Use the following instructions to make this DNS change in the Console. If your DNS setup resides with another provider, refer to their documentation for instructions.

**To update the CNAME for your zone**

1. In the Policy Information tab of the WAF Policy overview, select the CNAME Target.
2. Copy the CNAME target to your clipboard.
3. Open the navigation menu and click Networking. Under DNS Management, click Overview.
4. Click the Zone Name of the primary domain where you want to update the record. Zone details and a list of records appear.
5. Select the check box for the CNAME record and select Edit from the Actions drop-down menu.
6. In the Edit Record dialog box, update the Target field with the CNAME Target from your clipboard.
7. Click Submit.
8. Click Publish Changes.
9. In the confirmation dialog box, click Publish Changes.
6. Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges.

**CIDR Ranges**
- 129.146.12.128/25
- 129.146.13.128/25
- 129.146.14.128/25
- 129.148.156.0/22
- 129.213.0.128/25
- 129.213.2.128/25
- 129.213.4.128/25
- 130.35.0.0/20
- 130.35.112.0/22
- 130.35.116.0/25
- 130.35.120.0/21
- 130.35.128.0/20
- 130.35.144.0/20
- 130.35.16.0/20
- 130.35.176.0/20
- 130.35.192.0/19
- 130.35.224.0/22
- 130.35.232.0/21
- 130.35.240.0/20
- 130.35.48.0/20
- 130.35.64.0/19
- 130.35.96.0/20
- 130.35.228.0/22
- 132.145.0.128/25
- 132.145.2.128/25
- 132.145.4.128/25
- 134.70.16.0/22
- 134.70.24.0/21
- 134.70.32.0/22
- 134.70.56.0/21
- 134.70.64.0/22
- 134.70.72.0/22
- 134.70.76.0/22
- 134.70.8.0/21
- 134.70.80.0/22
- 134.70.84.0/22
- 134.70.88.0/22
- 134.70.92.0/22
- 134.70.96.0/22
- 138.1.0.0/20
- 138.1.104.0/22
- 138.1.128.0/19
- 138.1.16.0/20
- 138.1.160.0/19
- 138.1.192.0/20
- 138.1.208.0/20
- 138.1.224.0/19
- 138.1.32.0/21
- 138.1.40.0/21
- 138.1.48.0/21
- 138.1.64.0/20
- 138.1.80.0/20
- 138.1.96.0/21
- 138.1.112.0/20
- 140.204.0.128/25
- 140.204.12.128/25
- 140.204.16.128/25
- 140.204.20.128/25
- 140.204.24.128/25
- 140.204.4.128/25
- 140.204.8.128/25
- 140.91.10.0/23
- 140.91.12.0/22
- 140.91.22.0/23
- 140.91.24.0/22
- 140.91.28.0/23
- 140.91.30.0/23
- 140.91.32.0/23
- 140.91.34.0/23
- 140.91.36.0/23
- 140.91.38.0/23
- 140.91.4.0/22
- 140.91.40.0/23
- 140.91.8.0/23
- 147.154.0.0/18
- 147.154.128.0/18
- 147.154.192.0/20
- 147.154.208.0/21
- 147.154.224.0/19
- 147.154.64.0/20
- 147.154.80.0/21
- 147.154.96.0/19
- 192.157.18.0/24
- 192.157.19.0/24
- 192.157.19.0/20
- 192.157.128.0/21
- 192.157.138.0/23
- 192.157.144.0/21
- 192.157.152.0/22

• 199.195.6.0/23
• 205.147.88.0/21

Enable WAF to Passively Detect Rules

WAF protection rules add extra CPU cycles to each transaction, therefore, we recommended enabling only the rules designed for your web application topology. WAF offers a set of recommended rules that will not harm your site performance and work with most of the web application. The WAF bot protection feature makes your web application fully secured to threats.

If you need help with setting up WAF, you can open a service request with My Oracle Support requesting OCI WAF tuning help. An expert will guide you through the process.

To view Protection Rule Recommendations

2. Click the name of the WAF Policy you want to view protection rule recommendations for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Recommendations tab. This list is generated based on the traffic the WAF detects flowing through the WAF. If nothing appears in this list, keep testing the FQDN of your application and check back later.
5. Select the protection rules with a Detect recommended action and then click Accept Recommendations.

**Tip:**
You can use the Recommended Action filter to locate a recommendation by Detect.

To enable WAF Protection Rules to detect mode

2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Use the Protection Rules table to locate the rules you want to detect.
5. Enter the Rule IDs you located from the table into the Rule ID filter. For this example, enter 941140 (Cross-Site Scripting) in the Rule ID filter.
6. Select Detect from the Actions drop-down menu for the protection rules you filtered.

See WAF Protection Rules on page 5187 for more information.

To enable WAF Access Rules to detect mode

2. Click the name of the WAF Policy you want to configure access rules for. The WAF Policy overview appears.
3. Click Access Control.
4. Click **Add Access Rule**.
5. In the Add Access Rule dialog box, enter the following:
   a. **Name:** DetectRequestsFromMySpecificBrowser
   b. **Rule Action:** Select **Detect Only**.
   c. **Conditions:** Select **IP Address** is from the menu and enter the IP address you copied to your clipboard while testing your application in the **IP Address** field.
   d. Click **+Additional Condition**.
   e. **Condition:** Select **User Agent** is from the menu and enter the agent value you copied to your clipboard while testing your application in the **User Agent Header** field.

   
   **Note:** Both the IP Address and the User Agent in the preceding example must match for the rule to be triggered. If a different User Agent is used to test your application, the request will not be detected.

6. Click **Add Access Rule**.
7. Click **Unpublished Changes**.
8. Click **Publish All**.

See **Access Control** on page 5267 for more information.

**To enable WAF BOT rules to detect mode (JavaScript Challenge)**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click **Edit JavaScript Challenge**.
5. In the JavaScript Challenge dialog box, select the **Enable JavaScript Challenge** check box.
6. In the JavaScript Challenge Action section, select **Detect Only**.
7. Enter the following information:
   - **Enable Conditions:** When enabled, conditions must match for a set action to be taken. See **Access Control** on page 5267 for more information about conditions and rules.
   - **Action Threshold (number of requests):** Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - **Action Expire Time (seconds):** Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Follow Redirects:** When enabled, redirect responses from the origin will also be challenged.
   - **Enable NAT Support:** When enabled, the user is identified not only by the IP address but also by a unique additional hash, which prevents blocking visitors with shared IP addresses. It is recommended that this NAT support is disabled for high-load apps (200+RPS).
8. Click **Save Changes**.

The JavaScript Challenge is added to the list of changes to be published.

See **Bot Management** on page 5180 for more information.

**To enable WAF BOT rules to detect mode (Human Interaction Challenge)**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Human Interaction Challenge** tab.
5. Click **Edit Human Interaction Challenge**.
6. In the Edit Human Interaction Challenge dialog box, select the **Enable Human Interaction Challenge** check box.
7. In the Human Interaction Action section, select **Detect Only**.
8. Enter the following information:
   - **Action Threshold (number of requests)**: Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - **Threshold Expiry Period (seconds)**: The number of seconds before the threshold expires.
   - **Action Expire Time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of the client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Interaction Threshold (number of interactions)**: Number of interactions before the threshold expires.
   - **Recording Period (seconds)**: The period of time to record the user's events.
   - **NAT Support**: When enabled, the user is identified not only by the IP address but also by an unique additional hash, which prevents blocking visitors with shared IP addresses. It's recommended to disable the support for the high-load apps (200+ RPS).
9. Click **Save Changes**.

   The Human Interaction Challenge is added to the list of changes to be published.

See **Bot Management** on page 5180 for more information.

See **Managing WAF Policies** on page 5173 for the order of processing of WAF.

### Test the Rules

When the policy is active, you can test that your rules are detected by WAF.

**To initiate requests**

1. Use the same browser you used when you tested your application to do the following:
   - Request the FQDN of your application with the following query parameter appended:
     ```
     ?id=<script>alert("TEST");</script>
     ```
2. Use a different browser on the same machine and repeat the preceding requests. All requests should go through the application.

**To verify that WAF is detecting requests**

To verify that WAF is detecting requests identified as a risk:

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click **Logs**. Logs for the WAF policy appear.
4. Select the **Detect** check box from the **Actions** filter.
5. Verify that there are two entries for the protection rule triggered by the Cross-Site Scripting request and one entry for detecting the User Agent and IP Address.

### Managing WAF Policies

The Oracle Cloud Infrastructure WAF service enables you to create a WAF policy and origin.

**Order of Processing**

The order in which rules and handlers are processed is:

1. IP Whitelists/Blacklists/Good Bot Whitelists
Using the Console

Create and Manage WAF Policies
To create a WAF policy
2. Click Create WAF Policy.
3. In the Create WAF Policy dialog box, enter the following:
   - **Name**: Optional. A unique name for the policy. Avoid entering confidential information.
   - **Domains**:
     - **Primary Domain**: The fully qualified domain name (FQDN) of the application where the policy will be applied.
     - **Additional Domains**: (Optional) Subdomains where the policy will be applied.
   - **WAF Origin**: The host or IP address of the public internet facing application that is being protected by the application.
     - **Origin Name**: A unique name for the origin. Avoid entering confidential information.
     - **URI**: The IPv4 address or fully qualified domain name (FQDN) of the origin. The URI can be a full URI, not just a host/IP.
     - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
     - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
   - **Header(s)**: (Optional)
     - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
     - **Header Value**: Specifies the data requested by the header.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

   **Note:**
   You can add multiple origins to your WAF policy and load balance them accordingly using the origins and originGroups field of the UpdateWaasPolicy operation in the WAAS API.

4. Click Create WAF Policy. The WAF Policy overview appears. You can access Origin Management, Access Control, WAF, Bot Management, Alerts, and any unpublished changes. While the policy is being created, no changes can be made until the process has completed. Expect the policy to become active within 15 minutes of creation.

   A CNAME target is generated for each policy. The CNAME target is a hyphenated version of your FQDN within the Oracle Cloud Infrastructure domain (for example, myapp-mydomain-com.oraclecloud.net).
5. In your DNS zone, update the CNAME record entry with the value of the CNAME target that is generated. This enables traffic to be routed through the WAF before the application. This value is presented soon after you publish your policy the first time on the main page of the policy.

To update a WAF policy

2. Click the name of the WAF Policy you want to update. The WAF Policy overview appears.

   Tip:
   You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

3. Click Edit.
4. In the Edit WAF Policy dialog box, make the needed changes and then click Save Changes.

To delete a WAF policy

2. Select the check box for the policy you want to delete.

   Tip:
   You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

3. Click Delete.
4. In the confirmation dialog box, click Delete.

   The status of the policy changes from Active to Deleting. Deleted policies are maintained for a short time before they are unavailable in the Console.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click Unpublished Changes.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click Publish All.
4. In the Publish Changes dialog box, click Publish All.

To manage tags for a WAF policy

2. Click the name of the WAF Policy you want to view. The WAF Policy overview appears.
3. Click the Tags tab to view or edit existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 239.

To move a WAF policy to a different compartment

2. In the Scope section, select a compartment.
3. Find the WAF policy in the list, click the the Actions icon (three dots), and then click Move Resource to a Different Compartment.
4. Choose the destination compartment from the list.
5. Click Move Resource.
Using the CLI

Open a command prompt and run the following command to get the details of a WAAS policy:

```
oci waas waas-policy get --waas-policy-id <policy_ocid>
```

This can be useful in retrieving the necessary information when opening a ticket with Oracle Cloud Infrastructure support. For more information about how to access and use the CLI, see Command Line Interface (CLI).

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy
- DeleteWaasPolicy
- ChangeWaasPolicyCompartment

Origin Management

An origin is an endpoint (typically an IP address) of the application protected by the WAF. An origin can be an Oracle Cloud Infrastructure load balancer public IP address which can be used for high availability to an origin. When you create a WAF policy, you define a default origin and optional HTTP headers. An origin must be defined in your WAF policy to set up protection rules or other features. The details for the origin can be modified later in the Settings of the WAF policy. In the Origin Settings, you can modify or set up HTTP headers for outbound traffic from the WAF to the origin server. These name-value pairs are then available to the application.

Origin Groups

Multiple origins can be defined for a WAF policy using Origin Groups. When at least two origins are configured, load balancing is enabled. You can group multiple origins in an origin group. An origin group can include origin servers and their weights. The weight of each origin in the origin group determines the priority when load balancing across origins in this group. Origins with higher weights receive larger proportions of client requests. Under origin groups, all origins are active. The grouping is for visual purposes only.

Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges.

Using the Console

To add an origin or origin group

2. Click the name of the WAF Policy you want to add an origin to. The WAF Policy overview appears.
3. Click Settings.
4. Click Origin Groups. If there is more than one origin for the WAF policy, the origins and its group appear.
5. Click Edit. If there is only one origin defined for the WAF policy, the origin belongs to a default origin group.
6. Optionally, you can edit the name of the existing default group or add another group to group multiple origins.
   You can use origin groups to specify the default origin that will be used in your WAF policy.
7. Click + Additional Origin below the origin group where you want to add an origin.
8. Enter the following:
   - **Name**: A unique name for the origin. Avoid entering confidential information.
   - **Default Origin**
     - **Name**: A unique name for the origin.
     - **URI**: The IPv4 address or FQDN of the origin.
     - **HTTP Port**: The HTTP port on the origin that the web application listens on. The default port is 443.
     - **HTTPS Port**: The HTTPS port on the origin that the web application listens on. The default port is 80.
     - **Weight**: The weight of the origin within the group is used for load balancing purposes. Origins with higher weights receive larger proportions of client requests.

9. Click **Save Changes**.
   The changes must be published before they take effect. See To publish changes on page 5177.

**To edit an origin group**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to edit the origin for. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **Origin Groups**. If there is more than one origin for the WAF policy, the origins and its group appear.
5. Click **Edit**. If there is only one origin defined for the WAF policy, the origin belongs to a default origin group.
6. Edit the name of the existing default group or add another group to group together multiple origins. You can use origin groups to specify the default origin that will be used in your WAF policy.
7. Click **Save Changes**.
   The changes must be published before they take effect. See To publish changes on page 5177.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. After you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

- **CreateWaasPolicy**
- **GetWaasPolicy**
- **UpdateWaasPolicy** To remove an origin from the policy using the API, use the **UpdateWaasPolicy** method and leave the origin field empty upon update.

**API Examples**

Each origin has a unique name (key). The name of the origin to be used by the WAF must be referenced in the wafConfig portion of the settings. For example, if you have the following origins in your configuration:

```json
{
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "lifecycleState":"ACTIVE",
   "displayName":"myWAFprotectedApp",
   "origins":{
      "primaryorigin":{
         "httpPort":80,
```
Then within the \texttt{wafConfig}, the origin in use is referred to by name. In this example, the WAF is actively using \texttt{secondaryorigin}.

\texttt{
"wafConfig": {
  "deviceFingerprintChallenge": {
    "isEnabled": false
  },
  "origin": "secondaryorigin",
  "whitelists": []
}}

Using the API, you can define multiple origins for the \texttt{WaasPolicy.origins} field, however, only one of those defined origins can be used in the \texttt{WaasPolicy.wafConfig.origin} field. The following example shows multiple origins defined for the \texttt{WaasPolicy.origins} field, however, only one of these defined origins is used in the \texttt{WaasPolicy.wafConfig.origin} field, as only one origin can be active for a policy.

\texttt{
"origins": {
  "origin1": {
    "uri": "6.6.6.6",
    "httpPort": 80
  },
  "origin2": {
    "uri": "1.1.1.2",
    "httpPort": 80
  }
},
"wafConfig": {
  "origin": "origin1"
}}

The following is an example of origin groups being used to specify the weight of each origin:

\texttt{
{"originGroup1": {
  "origins": [
  {
    "origin": "origin1",
  },
  {
    "origin": "origin2",
  }
  ]
}}

---

Oracle Cloud Infrastructure User Guide
Health Checks

Health checks can be enabled when multiple origins are specified.

Default Settings

- Check URL: / (root/home page)
- Interval: 10 seconds (how often the check is performed)
- Timeout: 5 seconds (timeout after which the check is marked as failed)
- Fail count: 2 (number of failed checks for the origin to be considered down)
- Rise count: 2 (number of successful checks for the origin to be considered up)
- Successful responses: 2xx, 3xx, 4xx, 5xx

Custom health checks can also be configured. The following options are available:

- Enable response text checking (heath checks are looking for the text entered under "Expected response text").
- Specify a host header.

To configure health checks

2. Click the name of the WAF Policy where you want to edit the origin. The WAF Policy overview appears.
3. Click Settings.
4. Click the Origin Settings tab.
5. Click Edit.
6. In Origin Management Settings, make the necessary changes:

- **Enable Health Checks**: Optional. Click the check box to enable Health Checks, then enter the following:
  - **Request and URL**: The type of request and the specific path to visit on the origin when performing the check.
  - **Host Header**: The value of the host header in the HTTP health check request. If this field is left blank, the policy domain is used instead.
  - **User-Agent**: The value of the user agent header in the HTTP health check request.
  - **Expected Response Code Group**: The HTTP response codes that signify the health state.
  - **Check Interval (seconds)**: Interval (in seconds) between health checks to the origin.
  - **Response Timeout (seconds)**: Enter the time to wait for a reply before marking the health check as failed.
  - **Healthy Threshold (number of times)**: Number of successful health checks after which the origin server is marked up.
  - **Unhealthy Threshold (number of times)**: Number of failed health checks after which the origin server is marked down.
  - **Enable Response Text Checking**: Enable this field to check for predefined text in addition to the response code.
  - **Expected Response Text**: Optional. Health checks search for the given text in a case-sensitive manner within the response body and fail if the text is not found.

**Load Balancing Methods**

- **IP_HASH**: All of the incoming requests from the same client IP address should go to the same content origination server. IP_HASH load balancing method uses origin weights when choosing which origin should the hash be assigned to initially.
- **ROUND_ROBIN**: Forwards requests sequentially to the available origin servers. The first request is to the first origin server, the second request is to the next origin server, and so on. After it sends a request to the last origin server, it starts again with the first origin server. When using weights on origins, Weighted Round Robin assigns more requests to origins with a greater weight. Over time, origins receive a number of requests in proportion to their weight.
- **STICKY_COOKIE**: Adds a session cookie to the first response from the origin server and identifies the server that sent the response. The client's next request contains the cookie value, and NGINX routes the request to the origin server that responded to the first request. STICKY_COOKIE load balancing method falls back to Round Robin for the first request.

7. **Enable Origin Compression**: Optional. Enable or disable GZIP compression of origin responses.
8. **Custom Headers**: Optional. Enter the custom HTTP headers to set or override in requests to origin servers.
9. Click **Save Changes**.

The changes must be published before they take effect. See **To publish changes** on page 5177.

**Bot Management**

Bot Management enables you to mitigate undesired bot traffic from your site using CAPTCHA and JavaScript detection tools, while enabling known published bot providers to bypass these controls.
Non-human traffic makes up most of the traffic to sites. Bot Manager is designed to detect and block, or otherwise
direct, non-human traffic that may interfere with site operations. The Bot Manager features mitigate bots that conduct
content and price scraping, vulnerability scanning, comment spam, brute force attacks, and application-layer DDoS
attacks. You can also allowlist good bots.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you enable Bot Management, you incur a higher rate on requests to the WAF.</td>
</tr>
</tbody>
</table>

**JavaScript Challenge**

JavaScript Challenge validates that the client can accept JavaScript with a binary decision. JavaScript Challenge
is generally the first level of bot mitigation, but not sufficient with more advanced bot tools, which require more
advanced challenges. Additional functionality, like detecting Network Address Translation (NAT) traffic, can
mitigate the risk of blocking legitimate user traffic from users behind a shared IP address.

The **Action Threshold** parameter defines the number of requests that fail the challenge before the action is taken. The
requests that fail under this threshold are not logged. For example, if you set the JavaScript challenge action to **Block**
and the **Action Threshold** to 10, and a client that doesn't accept JavaScript makes 11 requests within the **Action
Expire Time**, the first 10 requests will be allowed through to origin (assuming there are no other rules) and logs will
show one **Block** entry action taken for the JavaScript Challenge.

**Human Interaction Challenge**

Human Interaction Challenge is an advanced countermeasure that looks for natural human interactions such as
mouse movements, time on site, and page scrolling to identify bots. When an EDGE server receives requests from a
client, instead of instantly reporting with the requested content, the human interaction challenge checks various event
listeners in the user's browser to determine if there is a human user making a request.

**Device Fingerprint Challenge**

The device fingerprint challenge generates hashed signatures of both virtual and real browsers to identify and block
malicious bots.

**CAPTCHA Challenge**

If a specific URL should be accessed only by a human, you can control it with CAPTCHA protection. You can
customize the comments for the CAPTCHA Challenge for each URL. Bots are kept from accessing protected
web application functionality using CAPTCHA images designed to be out of reach of computer vision and OCR
technologies.

**Good Bot Whitelist**

Good Bots provides the list of bots managed by known providers, such as Baidu or Google. You can allow the access
from a specific good bot, or block the bot if they serve no business purpose. Allowed good bots from this section are
allowlisted.

Allowlisted bots are flagged with a Bypass action in the WAF policy Logs. You can select the **Bypass** check box from the **Action** filter in Logs to search for the traffic allowed from these rules. Logged good bot events are
categorized as a Threat Intelligence Leads log type, however, they are not a threat when the action taken is to Bypass.

The list of good bots on this menu are managed and continuously updated. Additional good bots can be added as a
new access control rule in Access Control.

**Using the Console**

**To configure JavaScript Challenge settings**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.

3. Click Bot Management.
4. Click Edit JavaScript Challenge.
5. In the JavaScript Challenge dialog box, select the Enable JavaScript Challenge check box.
6. In the JavaScript Challenge Action section, choose one of the following methods:
   - Detect Only: Select this option if you want to be alerted for every matched request.
   - Block: Select this option to block requests by returning a response code, error page, or CAPTCHA.
     - Block Action: Select the action that will be taken when a matching request is blocked.
     - Show CAPTCHA
       - CAPTCHA Title: Enter the text for the CAPTCHA page title.
       - CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
       - CAPTCHA Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
       - CAPTCHA submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
     - Set Response Code: Select a status code to return in response to blocked requests.
     - Show Error Page
       - Block Error Page Message: Defines the error or error code.
       - Block Error Page Description: Provides more details about the error, including the cause and further instructions.
       - Block Error Page Code: The error code that is displayed with the error.
7. Enter the following information:
   - Enable Conditions: When enabled, conditions must match for a set action to be taken. See Access Control on page 5267 for more information about conditions and rules.
   - Action Threshold (number of requests): Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - Action Expire Time (seconds): Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - Follow Redirects: When enabled, redirect responses from the origin will also be challenged.
   - Enable NAT Support: When enabled, the user is identified not only by the IP address but also by a unique additional hash, which prevents blocking visitors with shared IP addresses. It is recommended that this NAT support is disabled for high-load apps (200+RPS).
8. Click Save Changes.

The JavaScript Challenge is added to the list of changes to be published.

To edit JavaScript Challenge settings
2. Click the name of the WAF Policy you want to edit JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click Edit JavaScript Challenge.
5. In the Edit JavaScript Challenge dialog box, make the needed changes.
6. Click Save.

To configure Human Interaction Challenge settings
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Human Interaction Challenge tab.
5. Click Edit Human Interaction Challenge.
6. In the Edit Human Interaction Challenge dialog box, select the Enable Human Interaction Challenge check box.
7. In the Human Interaction Action section, choose one of the following methods:
   - **Detect Only**: Select this option if you want to be alerted for every matched request.
   - **Block**: Select this option to block requests by returning a response code, error page, or CAPTCHA.
   - **Block Action**: Select the action that will be taken when a matching request is blocked.
     - **Show CAPTCHA**
       - **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
       - **CAPTCHA Header**: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
       - **CAPTCHA Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
       - **CAPTCHA submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
   - **Set Response Code**: Select a status code to return in response to blocked requests.
   - **Show Error Page**
     - **Block Error Page Message**: Defines the error or error code.
     - **Block Error Page Description**: Provides more details about the error, including the cause and further instructions.
     - **Block Error Page Code**: The error code that is displayed with the error.
8. Enter the following information:
   - **Action Threshold (number of requests)**: Specify the number of failed requests before taking action. Because of the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - **Threshold Expiry Period (seconds)**: The number of seconds before the threshold expires.
   - **Action Expire Time (seconds)**: Enter the number of seconds between challenges to the same IP address. Because of client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3,600 seconds for apps with desktop users only.
   - **Interaction Threshold (number of interactions)**: Number of interactions before the threshold expires.
   - **Recording Period (seconds)**: The period of time to record the user's events.
   - **NAT Support**: When enabled, the user is identified not only by the IP address but also by an unique additional hash, which prevents blocking visitors with shared IP addresses. It's recommended to disable the support for the high-load apps (200+ RPS).
9. Click Save Changes.

The Human Interaction Challenge is added to the list of changes to be published.

**To edit Human Interaction Challenge settings**

2. Click the name of the WAF Policy you want to configure Human Interaction Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Human Interaction Challenge tab.
5. Click Edit Human Interaction Challenge.
6. Update the Human Interaction Challenge and then click Save Changes.
To configure Device Fingerprint Challenge settings

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure Device Fingerprint Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Device Fingerprint Challenge** tab.
5. Click **Edit Device Fingerprint Challenge**.
6. In the Device Fingerprint Challenge dialog box, select the **Enable Device Fingerprint Challenge** check box.
7. In the Device Fingerprint Action section, choose one of the following methods:
   - **Detect Only**: Select this option if you want to be alerted for every matched request.
   - **Block**: Select this option to block requests by returning a response code, error page, or CAPTCHA.
     - **Block Action**: Select the action that will be taken when a matching request is blocked.
       - **Show CAPTCHA**
         - **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
         - **CAPTCHA Header**: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
         - **CAPTCHA Footer Text**: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
         - **CAPTCHA submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").
       - **Set Response Code**: Select a status code to return in response to blocked requests.
       - **Show Error Page**
         - **Block Error Page Message**: Defines the error or error code.
         - **Block Error Page Description**: Provides more details about the error, including the cause and further instructions.
       - **Block Error Page Code**: The error code that is displayed with the error.
8. Enter the following information:
   - **Action Threshold (number of requests)**: Specify the number of failed requests before taking action. Due to the asynchronous request from the browser during page loading, it is recommended to set a threshold of 10 for web applications with basic ajax usage, and 100 for apps with heavy ajax usage.
   - **Threshold Expiry Period (seconds)**: The number of seconds before the threshold expires.
   - **Action Expire Time (seconds)**: Enter the number of seconds between challenges to the same IP address. Due to client IP address changes, it is recommended that the expiry time is set to 120 seconds for apps with mobile users and 3600 seconds for apps with desktop users only.
   - **Max Address Count (IP addresses)**: The maximum number of IP addresses that are added to the list before the specified action is taken.
   - **Max Address Count Expiration (seconds)**: The number of seconds an IP address is kept in the list before it is removed.
9. Click **Save Changes**.

To edit Device Fingerprint Challenge settings

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Device Fingerprint Challenge** tab.
5. Click **Edit Device Fingerprint Challenge**.
6. Update the Device Fingerprint Challenge and then click **Save Changes**.
To add a CAPTCHA Challenge

2. Click the name of the WAF Policy you want to edit CAPTCHA challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Click Add CAPTCHA Challenge.
6. In the Add CAPTCHA Challenge dialog box, enter the following information:
   - CAPTCHA Title: Enter the text for the CAPTCHA page title.
   - CAPTCHA URL Path: Enter the URL path challenged by CAPTCHA.
   - Session Duration: Enter the number of seconds after which the CAPTCHA challenge cannot be resubmitted to the same user.
   - CAPTCHA Header: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
   - Footer Text: Enter the text that will be shown after the CAPTCHA input box and before the submit button.
   - Incorrect CAPTCHA Text: Enter the text that will appear when incorrect text is entered (for example, "The CAPTCHA was incorrect. Please try again.").
   - Submit button: Enter the text for the Submit button (for example, "Yes, I am human.").
7. Click Preview CAPTCHA to preview the CAPTCHA challenge in a new tab.
8. Click Add.

To edit a CAPTCHA Challenge

2. Click the name of the WAF Policy you want to edit CAPTCHA Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Select the check box for the CAPTCHA you want to edit.
6. Select Edit from the Actions drop down menu.
7. Update the CAPTCHA Challenge and then click Save.

To delete a CAPTCHA Challenge

2. Click the name of the WAF Policy you want to delete CAPTCHA Challenge settings for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the CAPTCHA Challenge tab.
5. Select the check box for the CAPTCHA Challenge you want to delete.
6. Click Delete.
7. In the Confirm dialog box, click Delete.

To manage the Good Bot Whitelist

2. Click the name of the WAF Policy you want to configure Bot Management for. The WAF Policy overview appears.
3. Click Bot Management.
4. Click the Good Bot Whitelist tab.
5. Select each bot you want to designate as a good bot.

The designated good bots are added to the list of changes to be published.
To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click Publish All.
4. In the Publish Changes dialog box, click Publish All.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click Discard.
5. In the Discard Change dialog box, click Discard.

Using the CLI

You can use the CLI to enable rate limiting, device fingerprinting, and human interaction challenges.

To enable rate limiting

Open a command prompt and run the following command to enable rate limiting:

```
oci waas address-rate-limiting update-waf --is-enabled true --allowed-rate-per-address 1 --max-delayed-count-per-address 2 --waas-policy-id <policy_ocid>
```

This default rate limit setting will allow one request per second before starting to delay. It will delay for two requests until the traffic falls within the threshold boundaries. It will use the default error response code of 503.

To enable device fingerprinting to detect

Open a command prompt and run the following command to enable device fingerprinting to detect:

```
```

To enable the human interaction challenge to detect

Open a command prompt and run the following command to enable the human interaction challenge to detect:

```
oci waas human-interaction-challenge update --is-enabled true --waas-policy-id <policy_ocid>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
• GetDeviceFingerprintChallenge
• UpdateDeviceFingerprintChallenge
• GetHumanInteractionChallenge
• UpdateHumanInteractionChallenge
• GetWafAddressRateLimiting
• UpdateWafAddressRateLimiting

WAF Protection Rules

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met. Protection Rule Settings allow you to define the parameters for enforcement any time a protection rule is matched. Recommendations aid in the optimization of your WAF security profile. The Security Operations team proactively monitors all events to provide recommendations about the action of a specific ruleset. See Supported Protection Rules on page 5199 for additional information.

Using the Console

To apply an action to a protection rule

2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Rules tab.
5. Find the protection rule you want to apply an action to.

| Tip: |
| You can use the Rule ID or Rule Action filters to locate a protection rule. |

6. Click the Actions icon (three dots) and select one of the following options:
   • Detect: Matching requests generate an alert and the request is proxied.
   • Block: Matching requests are blocked.
   • Off: The rule is disabled.
   • Exclusions: Exclusions are set to specify the types of request that are to be bypassed by the protection rule(s). If a request matches any of the set exclusions, the protection rule(s) will not be executed for that request.
     a. In the Exclusions dialog box, enter the following criteria:
        • Exclusion: Select request cookie values, request cookie names, request parameters, or request parameter names.
        • Value: Enter the value for the selected exclusion.
     b. Click Save Changes.

The protection rule action is added to the list to be published.

To edit rule settings

2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Settings tab.
5. Click Edit Rule Settings.
6. In the Edit Rule Settings dialog box, enter the following:

- **Block Action**: The action taken on malicious requests blocked by WAF.
- **Block Response Code**: Provides information indicating why the request was blocked.
- **Max Number of Arguments**: The maximum number of arguments allowed in the request. The recommended setting is 255.
- **Max Length of Argument**: The maximum argument length allowed in the request. The recommended setting is 400.
- **Max Total Argument Length**: The maximum argument length for all arguments in the request. The recommended setting is 64000.
- **Recommendations Period**: The period in days to analyze for recommended actions.
- **Allowed HTTP Methods**: The list of allowed HTTP protocol methods.

7. Click **Save Changes**.

The accepted protection rules are added to the list to be published.

**To accept recommendations**

Recommendations will begin appearing once sufficient traffic has gone through the WAF to profile the right security posture.

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab.
5. Select the protection rules you want to accept.

**Tip:**

You can use the **Recommended Action** filter to locate a recommendation by **Detect** or **Block**.

6. Click **Accept Recommendations**.

The accepted protection rules are added to the list to be published.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
- GetProtectionRule
- ListProtectionRules

- AcceptRecommendations

### Listing and Accepting Protection Rule Recommendations

Use the following operations to get the list of recommended rules:

- ListRecommendations

```json
{
    "name": "SQL authentication bypass attempts",
    "action": "OFF",
    "description": "Detects basic SQL authentication bypass attempts.",
    "exclusions": [],
    "key": "981244",
    "tags": "SQL Injections, Recommended"
},

{
    "modSecurityRuleIds": [
        "950001",
        "959070",
        "959071",
        "959072",
        "950908",
        "959073"
    ],
    "name": "Common SQL Injections",
    "action": "OFF",
    "description": "Detects common SQL injection attacks",
    "exclusions": [],
    "key": "950001",
    "tags": "SQL Injections, WASCTC, OWASP, A1, PCI, Recommended"
}
```

Using the key values from the output of the GET call above, you can accept one or more of the recommendations using the following operation passing an array of the keys:

- AcceptRecommendations

Body:

```
[  
    "981244",
    "950001"
]
```

### Protection Rule Specific Settings

Several protection rule settings are settings for specific protection rules.
Web Application Firewall

<table>
<thead>
<tr>
<th>Setting</th>
<th>Rule ID</th>
<th>Rule Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allowed HTTP Methods</td>
<td>911100</td>
<td>Restrict HTTP Request Methods</td>
</tr>
<tr>
<td>Max Total Argument Length</td>
<td>960341</td>
<td>Total Arguments Limits</td>
</tr>
<tr>
<td>Max Number of Arguments</td>
<td>960335</td>
<td>Number of Arguments Limits</td>
</tr>
<tr>
<td>Max Length of Argument</td>
<td>960208</td>
<td>Values Limits</td>
</tr>
</tbody>
</table>

The term "Arguments" refers to either query parameters or body parameters in a PUT/POST request. For instance, if the Max Number of Arguments is 2 and RuleID 960335 is set to BLOCK, any of the following requests would be blocked:

- GET /myapp/path?query=one&query=two&query=three
- POST /myapp/path with Body{"arg1":"one","arg2":"two","arg3":"three"}
- POST /myapp/path?query=one&query=two with Body{"arg1":"one"}

Max Length of Argument is the length of either a name or the value of the argument. Total Argument Length refers to the sum of the name and value length.

Exclusions

Sometimes a protection rule can trigger a false positive. You can configure an exception if the request(s) generating the false positive have a particular argument or cookie that can be used to identify that request be excluded from the action normally taken on the rule. Exclusions have to be created through the API. The following exclusion parameters can be used:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQUEST_COOKIES</td>
<td>Cookie Value</td>
</tr>
<tr>
<td>REQUEST_COOKIES_NAMES</td>
<td>Cookie Name (value is irrelevant)</td>
</tr>
<tr>
<td>ARGS</td>
<td>Argument (Query Parameter or POST/PUT data)</td>
</tr>
<tr>
<td>ARGS_NAMES</td>
<td>Query Parameter Name (value is irrelevant)</td>
</tr>
</tbody>
</table>

Example

In this example, a block is applied to WAF Rule 911100 (Restrict HTTP Request Methods) with an exception to allow requests with an argument that contains “passthrough”.

PUT / waasPolicies /<policy_ocid>/wafConfig/protectionRules

With the body:

```json
[
  {
    "key": "911100",
    "action": "BLOCK",
    "exclusions":
      [
        {
          "target": "REQUEST_COOKIES",
          "exclusions": ["yourcompany.com", "Wed, 21 Oct 2015 07:28:00 GMT", "12345", "219ffwef9w0f"]
```
This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

**Protection Rules Tuning**

This basic WAF tuning guide outlines the fundamentals of rule tuning, log inspection, and setting up rule exclusions. Tuning a WAF policy can be beneficial for the following reasons:

- Reduces the chance of blocking a legitimate request.
- Protects against standard web application attacks.
- Protects against specific web application attacks.
- Reduces the amount of scanning, which leads to better performance.

**Definitions**

**TUNING**

The process in which an engineer or analyst modifies protection rules and actions to allow the application server to be protected but remain functional. There is a balance between locking down the application server and allowing the application server to perform its duties. The best tuning takes an intimate knowledge of the application server being protected and protection rules available to protect that application server.

**FALSE POSITIVE**

A false positive occurs when a protection rule is matched against an HTTP transaction and the HTTP transaction is a legitimate (non-malicious) transaction.

**EXCLUSION**

A modification to a protection rule that allows the value or value name of a cookie or HTTP argument to be ignored.

**ORACLE RECOMMENDATION ENGINE (ORE)**

The ORE aids in the optimization of your WAF security profile by letting you enable all rules that do not trigger during an initial recommendation period.

Protection rules can be matched by non-malicious or legitimate parts of an HTTP transaction, also called false positives. Reducing the frequency of false positive rule matching is one goal of tuning. The ORE aids in the optimization of your WAF security profile. After traffic is routed to WAF, recommendations appear in the Console after a configurable recommendation period. Rules with a recommended tag appear in this section. After a recommended rule has been turned on in detect mode, if there were no matches in the configured recommendation period, the ORE will provide a set of rules to block, leaving only the rules that require action in detect mode.

**Overview of WAF Protection Rules**

WAF protects your web applications against threats. WAF is cloud-based and supports over 500 rule sets, and rule sets for the Open Web Application Security Project (OWASP). Use these rules to protect your critical web applications against malicious cyberattacks. These rules are compared against incoming requests to determine if the request contains an attack payload. If it determines that the request is an attack, WAF blocks or alerts you to that
request. These attacks are varied and include threats such as SQL injection, cross-site scripting, and HTML injection—all of which can be detected and blocked by the WAF rule sets.

**How WAF Protection Rules Work**

WAF protection is a toolkit designed for real-time web application monitoring, logging, and access control. The toolkit lets you decide how you want to take advantage of all the protection rules available instead. This flexibility is a core element of WAF protection rules, as we are constantly pushing updates to increase the security scope of our rules.

To identify and defend web applications against attacks, WAF protection rules run checks on any request to the webserver and all associated responses from the server against the set of rules. After the checks succeed, the HTTP request is sent to the website to retrieve the relevant content. If checks fail instead, the appropriate predefined actions are initiated.

The core principles of WAF protection rules are as follows:

- **Passiveness:** You decide which rules are required, therefore you have full control.
- **Flexibility:** WAF protection rules were created by a security expert who provided over 250 rules and the capacity to introduce custom protection rules.
- **Quality not quantity:** WAF protection rules are a dedicated module designed to inspect HTTP traffic that works with the other WAF features (for example, access control and bot management).
- **Predictability:** Having full control of the WAF protection rules allows you to control the results expected. You can define and tune your protection rules and leave the setup unattended, knowing that it keeps working as it was configured.

**Onboarding and Initial Tuning**

First, you need to have some knowledge about the web application for the tuning process. Otherwise, you might enable Linux-specific rules for your Windows server or origin and rules unnecessarily scan your traffic causing performance degradation. The ORE helps you by providing a solid and secure set of protection rules. The recommendation period is a configurable setting with a default of 10 days. We recommend increasing this value to 15 days to get a large sample of logs for normal traffic on the web application. Approximately twenty-four hours after your WAF policy is created, protection rule recommendations will appear in the recommendations tab. The recommendations are rules picked by WAF experts to cover the OWASP Top Ten. These recommended rules have been selected because they typically produce the least number of false positives and still provide good protection.

**Changing the Recommendation Period and Accepting the Recommendations**

By following the steps below, you enable the recommended rules in detect mode. After the rules are in detect mode, we advise waiting 15 days before changing them to block mode.

**Note:**

During the assessment period, all the rules are in detect mode. Detect mode means that there will not be any blocking by protection rules. We recommend performing user acceptance testing and normal application use to help with the tuning process by generating logs. Review logs and check for false positives while the rules are in detect mode. By checking logs that trigger for protection rules, it gives you an idea of what traffic would cause a block when the rules are turned to block mode. During the assessment period, the application should receive as close to normal or production-like traffic as possible. Normal traffic shows you which rules trigger through logs, and false positives can be filtered out.

To change the recommendations period

1. Open the navigation menu and click **Identity & Security.** Under **Web Application Firewall,** click **Policies.**
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules.**
4. Click the Settings tab.
5. Click Edit Rule Settings.
6. In the Edit Rule Settings dialog box, increased the **Recommendations Period** from 10 to 15 days.
7. Click Save Changes.

**To accept the recommendations**
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab.
5. Click **Accept Recommendations**.
6. Click **Unpublished Changes**.
7. Click **Publish All**.
8. In the Publish Changes dialog box, click **Publish All**.

**Using the API to Query for Specific Logs**
The API provides the most options for filtering rules. The following are examples of how to use the CLI to filter logs.

- To filter logs by protection rule ID:
  
  ```bash
  oci waas waf-log list --waas-policy-id <WAFS Policy OCID> --protection-rule-key <protection rule id number>
  ```

- To filter logs by rule type (for example, protection or access rule types):
  
  ```bash
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --log-type PROTECTION_RULES
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --log-type ACCESS
  ```

- To filter logs by request URL:
  
  ```bash
  oci waas waf-log list --waas-policy-id <WAAS Policy OCID> --request-url <request url>
  ```

**Setting Up Logging Analytics**
Logging Analytics helps you to narrow down the protection rules that require attention. Use the following guides to set up the Logging Analytics service with WAF. See [Security Insights for your web apps with OMC Log Analytics](#) and [How to send OCI WAF Logs to OCI Logging Analytics and get Security Insights](#) for more information.

**Note:**
The Security Operations Center (SOC) team can provide you with an OCI Protection Rules tuning proposal based on your WAF policy traffic. The proposal is delivered within 15 days, depending on the complexity of the request.

**Creating Exclusions in Protection Rules**
Reviewing logs is a critical part of the tuning process. Logs show us which rule was matched and what part of the HTTP transaction it was matched against. Refer to the following table for samples of logs and how to use them to create an exclusion.

- The `protectionRuleDetections` object in `WafLog` provides a map of protection rule keys to detection message details. The following table shows four possible exclusions that can be set up for a protection rule.
## Sample Exclusions with Logs

The following section provides raw log samples and examples of what the exclusion value should be for each rule.

**• Rule ID 9411000 - ARGS**

In this example, the **Matched Data** was found within the `ARGS:foo` argument. The exclusion is for rule id 9411000. The exclusion to create is for **Request Parameters** with a value of `foo`.

```json
"protection-rule-detections": { 
  "9411000": { 
    "Message": "detected XSS using libinjection.",
    "Message details": "Matched Data: found within ARGS:foo: <script>xss"
  },
}
```

**• Rule ID 9411000 - ARGS_NAMES**

In this example, the **Matched Data** was found within the `ARGS_NAMES` argument. The exclusion is for rule id 9411000. The exclusion to create is for **Request Parameters Names** with a value of `<script>xss`.

```json
"protection-rule-detections": { 
  "9411000": { 
    "Message": "detected XSS using libinjection.",
    "Message details": "Matched Data: found within ARGS_NAMES:<script>xss: <script>xss"
  },
}
```

**• Rule ID 9411100**

In this example, the **Matched Data** was found within the `REQUEST_COOKIES:a` argument. The exclusion is for rule id 9411100. The exclusion to create is for **Request Cookie Values** with a value of `a`.

```json
"protection-rule-detections": { 
  "9411100": { 
    "Message": "Pattern match "(?i)(<\xef\xbc\x9c]script[^>\xef\xbc\x9e]*[>\xef\xbc\x9e][\\s\\S]*?)" at REQUEST_COOKIES:a.",
    "Message details": "Matched Data: <script> found within REQUEST_COOKIES:a: <script>xss"
  },
}
```

To create exclusions

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Rules** tab.
5. Find the protection rule you want to apply an action to.
6. Click the Actions icon (three dots) and select **Exclusions**. Include the exclusions using the information you obtain from the preceding Sample Exclusions with Logs section.
7. Click **Save Changes**.
8. Click **Unpublished Changes**.
9. Click **Publish All**.
10. In the Publish Changes dialog box, click **Publish All**.

### More Information on Protection Rules

#### Individual Protection Rules Versus Collaborative Protection Rules

To limit false positives, there are special protection rules that are tagged as "collaborative". These rule groups operate differently than the rest of the protection rules, as they use a scoring and threshold system to evaluate traffic. Individual rules work by matching elements of the HTTP transaction against the rule signature. If a match is made, the rule performs its action (for example, detecting or blocking). Each of the collaborative protection rules uses a group of individual rules. The collaborative protection rules require multiple matches of elements of the HTTP transaction against individual rules to perform its action (for example, detecting or blocking). For a collaborative rule to perform its action, at least three elements of the HTTP transaction must match against the individual rules in the collaborative group. After the exclusion is added within the collaborative protection rule group, it will apply to all the rules within it. The following is a list of the collaborative protection rule IDs.

**Collaborative Protection Rule IDs**

- 9300000 - Local File Inclusion (LFI) Collaborative Group - LFI Filter Categories
- 9320000 - Remote Code Execution (RCE) Collaborative Group - UNIX RCE Filter Categories
- 9330000 - PHP Injection Attacks Collaborative Group - PHP Filters Categories
- 9410000 - Cross-Site Scripting (XSS) Collaborative Group - XSS Filters Categories
- 9420000 - SQL Injection (SQLi) Collaborative Group - SQLi Filters Categories

**Request Body Inspection Rule IDs**

The following rules require response body inspection to be enabled. Remember that response body inspection delays the transaction, as it scans all the information within it. Enable only the required rules.

970014, 90005, 120133, 970008, 970016, 981080, 920020, 920006, 920008, 920010, 920012, 920014, 920016, 920018, 90017, 90018, 90020, 90019, 90014, 90021, 90015, 90016, 920021, 920022, 920023, 90024, 90022, 90023, 970013, 970011, 981177, 981000, 981001, 981003, 970018, 970004, 970005, 970010, 970118, 2100090, 970012, 970903, 970009, 970015, 970902, 981005, 981004, 981007, 981006, 970003, 970002, 950110, 950921, 950922, 90002, 90025, 970021, 970007

**No Exception Rules**

The following rules create different raw log values than ARGS, ARGS_NAMES, REQUEST_COOKIE, and REQUEST_COOKIE_VALUE. Exclusions do not exist for these rules, since the rules are based on if the element is present or not. For example, if the content-type header is present, the only option to exclude this rule is to open a service request with My Oracle Support to ask for a custom WAF rule that excludes any of the following rules.

960020, 960015, 960009, 950103

These rules are easily spotted, as the log values are REQUEST_URI, REQUEST_PROTOCOL, and REQUEST_HEADERS.

**Other Protection Rules**

The following is a list of protection rules that are "noisy", with some descriptions and recommendations which help you understand what the rule is trying to match. Exclusions cannot be applied to some of these rules.
<table>
<thead>
<tr>
<th>Rule ID</th>
<th>Rule Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>981318</td>
<td>String Termination/Statement Ending</td>
<td>This rule is important, as it alerts for any escaping character detected within any input field and queryString [ARGS] or cookie. Review the validations taken at the application side and ensure it only allows the proper input characters, for example, letters and numbers. If another input value is required, an exclusion to the rule can be applied in the WAF and let it through.</td>
</tr>
<tr>
<td>960015</td>
<td>Missing Accept Header</td>
<td>Even when requests without accept headers do not mean a violation of the HTTP protocol, requests without accept headers are most often not genuine requests. The rule might be alerting for API or custom application requests. To avoid scanning API or custom application requests, collect a list of the well-known applications that send traffic through and request custom rules. For more information, see RFC 7231, section-5.3.2.</td>
</tr>
<tr>
<td>960021</td>
<td>Missing Accept Header</td>
<td></td>
</tr>
<tr>
<td>960007</td>
<td>Missing Host Header</td>
<td>As described in RFC 7230, section-5.4 &quot;A server must respond with a 400 (Bad Request) status code to any HTTP/1.1 request message that lacks a Host header field and to any request message that contains more than one Host header field or a Host header field with an invalid field-value.&quot; This is an essential method of protection and at the same time ensures that WAF servers properly identify which WAF policy the request is intended for. Since WAF requires a host header to pass traffic to the proper origin, this rule might cause a high rate of false positives.</td>
</tr>
<tr>
<td>960008</td>
<td>Missing Host Header</td>
<td></td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>960009</td>
<td>Missing User-Agent Header</td>
<td>This rule prevents unidentified users from accessing your web application. User-Agent is one of the request headers defined in various RFCs that provides user information. Even when a request contains a user agent, it does not imply it comes from a real human. This rule works as a first level of mitigation for &quot;dummy&quot; attacks that originate from possible bots or &quot;non-RFC compliant&quot; applications. Note: Some APIs might not include the User-Agent header. If API requests are expected, ensure you add the API IP address to the allowlist or have a custom WAF rule that excludes this traffic from being inspected. For more information, see RFC 7231, section-5.5.3. This rule is an indicator of bad or malicious traffic, but it is possible legitimate applications do not have a User-Agent. Ask application owners to use User-Agents when applicable.</td>
</tr>
<tr>
<td>960006</td>
<td>GET/HEAD Requests Validation</td>
<td>As described in RFC 7231, section-4.3.1 and section-4.3.2, HEAD and GET are HTTP methods intended to retrieve information from the origin server. Even when not forbidden by the RFC, sending body or payload through these types of methods is not a common practice. Usually it is caused by improperly defined applications not following the best practices of the RFC and can be used by malicious users as a bypass technique. It is also defined in RFC 2616, section-4.3 &quot;if the request method does not include defined semantics for an entity-body, then the message-body should be ignored when handling the request.&quot;</td>
</tr>
<tr>
<td>960011</td>
<td>GET/HEAD Requests Validation</td>
<td></td>
</tr>
<tr>
<td>Rule ID</td>
<td>Rule Name</td>
<td>Notes</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>960904</td>
<td>Missing Content-Type Header</td>
<td>As defined under RFC 2616, section-7.2.1, &quot;Any HTTP/1.1 message containing an entity-body should include a Content-Type header field defining the media type of that body.&quot; If this best practice is not followed, it could lead to MIME-type sniffing attacks.</td>
</tr>
<tr>
<td>960032</td>
<td>Allowed HTTP methods</td>
<td>The default allowed HTTP methods are GET, HEAD, POST, and OPTIONS. OPTIONS is known as an insecure method because it is highly used by attackers to gather up information from the origin server. This method is also required by some applications to work properly. If this method is not required, create a service request with My Oracle Support to disable it. Other methods can also be added as required with a service request.</td>
</tr>
<tr>
<td>960335</td>
<td>Max amount of arguments</td>
<td>RFC does not enforce the number of arguments that a request must have, but using many arguments could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum number of ARGs allowed per request. The default value is 255.</td>
</tr>
<tr>
<td>960208</td>
<td>Max length of an argument</td>
<td>RFC does not enforce the length per argument that a request must have, but using large argument length could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum length of ARGs allowed per request. The default value is 400.</td>
</tr>
</tbody>
</table>
Web Application Firewall

<table>
<thead>
<tr>
<th>Rule ID</th>
<th>Rule Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>960341</td>
<td>Max total argument length</td>
<td>RFC does not enforce the total (combined) argument size that a request must have, but large combined argument values could be a method used by malicious users attempting to overflow a web application. To protect against these types of attacks, we recommend limiting the maximum combined argument value allowed per request. The default value is 64000.</td>
</tr>
<tr>
<td>92035032</td>
<td>Host Header Is IP Address</td>
<td>This rule does not usually trigger, as WAF needs a host header to send traffic to the origin.</td>
</tr>
<tr>
<td>941120</td>
<td>Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 2</td>
<td>This rule takes a long time to process if there is a large payload. For example, a payload with 64,005 bytes takes around 32 seconds to process.</td>
</tr>
</tbody>
</table>

Supported Protection Rules

The Oracle Cloud Infrastructure WAF service supports many protection rule types. The following list provides a brief explanation of the purpose of each protection rule type.

**Protection Rules**

<table>
<thead>
<tr>
<th>Rule ID/Key</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>90001</td>
<td>Filter Profanity</td>
<td>Detects profanity used in request headers and body.</td>
</tr>
<tr>
<td>90002</td>
<td>United States Social Security Number Leakage</td>
<td>Detects leakage of US SSN in C3 body and headers.</td>
</tr>
<tr>
<td>90004</td>
<td>Executable file upload attempt</td>
<td>Detects attempts to upload executable files through input forms.</td>
</tr>
<tr>
<td>90005</td>
<td>Brazilian Social Security Number (CPF) Leakage</td>
<td>Detects leakage of Brazilian CPF in response body and headers.</td>
</tr>
<tr>
<td>90006</td>
<td>Credit card leakage in request: GSA SmartPay</td>
<td>Detects GSA SmartPay credit card numbers in user input.</td>
</tr>
<tr>
<td>90007</td>
<td>Credit card leakage in request: MasterCard</td>
<td>Detects MasterCard credit card numbers in user input.</td>
</tr>
<tr>
<td>90008</td>
<td>Credit card leakage in request: Visa</td>
<td>Detects Visa credit card numbers in user input.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>90009</td>
<td>Credit card leakage in request: American Express</td>
<td>Detects American Express credit card numbers in user input.</td>
</tr>
<tr>
<td>90010</td>
<td>Credit card leakage in request: Diners Club</td>
<td>Detects Diners Club credit card numbers in user input.</td>
</tr>
<tr>
<td>90011</td>
<td>Credit card leakage in request: enRoute</td>
<td>Detects enRoute credit card numbers in user input.</td>
</tr>
<tr>
<td>90012</td>
<td>Credit card leakage in request: Discover</td>
<td>Detects Discover credit card numbers in user input.</td>
</tr>
<tr>
<td>90013</td>
<td>Credit card leakage in request: JCB</td>
<td>Detects JCB credit card numbers in user input.</td>
</tr>
<tr>
<td>90014</td>
<td>Credit card leakage in response: GSA SmartPay</td>
<td>Detects GSA SmartPay credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90015</td>
<td>Credit card leakage in response: MasterCard</td>
<td>Detects MasterCard credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90016</td>
<td>Credit card leakage in response: Visa</td>
<td>Detects Visa credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90017</td>
<td>Credit card leakage in response: American Express</td>
<td>Detects American Express credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90018</td>
<td>Credit card leakage in response: Diners Club</td>
<td>Detects Diners Club credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90019</td>
<td>Credit card leakage in response: enRoute</td>
<td>Detects enRoute credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90020</td>
<td>Credit card leakage in response: Discover</td>
<td>Detects Discover credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90021</td>
<td>Credit card leakage in response: JCB</td>
<td>Detects JCB credit card numbers sent from site to user.</td>
</tr>
<tr>
<td>90022</td>
<td>Credit card Track 1 data leakage</td>
<td>Detects credit card track 1 data in the response body.</td>
</tr>
<tr>
<td>90023</td>
<td>Credit card Track 2 data leakage</td>
<td>Detects credit card track 2 data in the response body.</td>
</tr>
<tr>
<td>90024</td>
<td>Credit card PAN leakage</td>
<td>Detects credit card primary account number in the response body.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>90025</td>
<td>visitorTracker_isMob malware detection</td>
<td>Detects and/or blocks visitorTracker_isMob malware.</td>
</tr>
<tr>
<td>120133</td>
<td>Canadian Social Identification Number (SIN) leakage</td>
<td>Detects leakage of Canadian SIN in response body and headers.</td>
</tr>
<tr>
<td>900032</td>
<td>HTTP Parameter Polution (HPP) detection</td>
<td>Rule Detects requests that have multiple arguments with the same name indicative of HPP attack.</td>
</tr>
<tr>
<td>911100</td>
<td>Restrict HTTP Request Methods</td>
<td>Allows only request methods specified by the configurable &quot;Allowed http methods&quot; parameter.</td>
</tr>
<tr>
<td>920021, 920022, 920023</td>
<td>Credit card PAN leakage</td>
<td>Detects credit card primary account number in the response body.</td>
</tr>
<tr>
<td>920100</td>
<td>Invalid HTTP Request Line</td>
<td>Invalid HTTP Request Line.</td>
</tr>
<tr>
<td>920120</td>
<td>File Name Validation</td>
<td>Detects multipart/form-data file name evasion attempts.</td>
</tr>
<tr>
<td>920160</td>
<td>Content-Length Header Validation</td>
<td>Detects if content-length HTTP header is not numeric.</td>
</tr>
<tr>
<td>920170</td>
<td>GET/HEAD Requests Validation</td>
<td>Detects if GET/HEAD requests contain request body by checking for content-length header, since it is not a common practice.</td>
</tr>
<tr>
<td>920171</td>
<td>GET/HEAD Requests Validation</td>
<td>Detects if GET/HEAD requests contain request body by checking for Transfer-Encoding header since it is not a common practice.</td>
</tr>
<tr>
<td>920180</td>
<td>Content-Length Header Validation</td>
<td>Detects if content-length and Transfer-Encoding headers are provided with every POST request.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920190</td>
<td>Range Header Validation</td>
<td>This rule inspects the Range request header to see if it starts with 0.</td>
</tr>
<tr>
<td>920200, 920201</td>
<td>Range Header Validation</td>
<td>Detects range header inconsistencies and invalid formatting.</td>
</tr>
<tr>
<td>920220, 920240</td>
<td>Check URL encodings</td>
<td>There are two different chained rules. We need to separate them as we are inspecting two different variables - REQUEST_URI and REQUEST_BODY. For REQUEST_BODY, we only want to run the @validateUrlEncoding operator if the content-type is application/x-www-form-urlencoded.</td>
</tr>
<tr>
<td>920230</td>
<td>Detect multiple url encoding</td>
<td>Detection of multiple url encodings.</td>
</tr>
<tr>
<td>920260</td>
<td>Disallow use of full-width unicode as decoding evasions may be possible.</td>
<td>This rule looks for full-width encoding by looking for %u followed by 2 'f' characters and then 2 hex characters. It is a vulnerability that affected IIS circa 2007.</td>
</tr>
<tr>
<td>920270</td>
<td>Restrict type of characters sent</td>
<td>This rule uses the @validateByteRange operator to restrict the request payloads.</td>
</tr>
<tr>
<td>920280</td>
<td>Missing/Empty Host Header</td>
<td>Missing/Empty Host Header.</td>
</tr>
<tr>
<td>920300</td>
<td>Missing Accept Header</td>
<td>Detection of missing accept header.</td>
</tr>
<tr>
<td>920310, 920311</td>
<td>Empty Accept Header</td>
<td>Checks if an Accept header exists, but has an empty value. Also detects an empty Accept header if there is no user agent.</td>
</tr>
<tr>
<td>920320</td>
<td>Missing User-Agent header</td>
<td>Detection of missing user-agent header.</td>
</tr>
<tr>
<td>920330</td>
<td>Empty User-Agent Header</td>
<td>Detects empty request user-agent header.</td>
</tr>
<tr>
<td>920350</td>
<td>Invalid HTTP Request Line</td>
<td>Invalid HTTP Request Line.</td>
</tr>
<tr>
<td>Rule ID/Key</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>920360</td>
<td>Limit length of argument names</td>
<td>Detects HTTP requests argument name length exceeding the configurable &quot;Max length of argument name&quot; value.</td>
</tr>
<tr>
<td>920370</td>
<td>Limit argument value length</td>
<td>Detects HTTP requests argument values exceeding the configurable &quot;Max argument value length&quot; parameter.</td>
</tr>
<tr>
<td>920380</td>
<td>Number of Arguments Limits</td>
<td>Detects HTTP requests with number of arguments exceeding the configurable &quot;Max amount of arguments&quot; value.</td>
</tr>
<tr>
<td>920390</td>
<td>Limit arguments total length</td>
<td>Detects HTTP requests argument length exceeding the configurable &quot;Max argument length&quot; parameter.</td>
</tr>
<tr>
<td>920400</td>
<td>Limit file size</td>
<td>Limits the size of a file by checking Content-Length Header for a variable max_file_size.</td>
</tr>
<tr>
<td>920410</td>
<td>Limit combined file size</td>
<td>Limits the size of combined files by checking Content-Length Header for a variable combined_file_sizes.</td>
</tr>
<tr>
<td>920420</td>
<td>Check content-type header against allow list</td>
<td>Restrict Content Types by checking the variable allowed_request_content_type.</td>
</tr>
<tr>
<td>920430</td>
<td>Request protocol version restriction</td>
<td>Restrict protocol versions by using the variable allowed_http_versions.</td>
</tr>
<tr>
<td>920440</td>
<td>Restriction by file extension</td>
<td>Restrict file extensions using the variable restricted_extensions.</td>
</tr>
<tr>
<td>920450</td>
<td>Restricted HTTP headers</td>
<td>The use of certain headers is restricted. They are listed in the variable restricted_headers.</td>
</tr>
<tr>
<td>920470</td>
<td>Restrict Content Type</td>
<td>Restrict Content Types by checking the content-type header.</td>

<tr>
<td>950009, 950003, 950000</td>
<td>Session fixation</td>
<td>Session Fixation is an attack technique that forces a user's session ID to an explicit value. Depending on the functionality of the target web site, a number of techniques can be utilized to &quot;fix&quot; the session ID value. These techniques range from Cross-site Scripting exploits to peppering the web site with previously made HTTP requests. After a user's session ID has been fixed, the attacker will wait for that user to login. Once the user does so, the attacker uses the predefined session ID value to assume the same online identity.</td>
</tr>
<tr>
<td>950010</td>
<td>LDAP Injection</td>
<td>Detects common LDAP data constructions injections.</td>

### Custom Protection Rules

The WAF service allows you to define and apply custom protection rules from open source firewall modules to your WAF configurations, such as ModSecurity modules. This topic describes how to format, create, and implement custom protection rules in your WAF policies using the Console and WAAS API. For a list of protection rules already available in the service, see Supported Protection Rules on page 5199.

### Custom Protection Rule Syntax

All custom protection rules are expressed in ModSecurity Rule Language. For more information about ModSecurity syntax, see Making Rules: The Basic Syntax.

Additionally, each rule must include two placeholder variables that are updated by the WAF service upon publication of the rule.

**id: \{id_1\}** - This field is updated with a unique rule ID generated by the WAF service which identifies a `SecRule`. More than one `SecRule` can be defined in the template field of a `CreateCustomProtectionRule` call. The value of the first `SecRule` must be `id: \{id_1\}` and the `id` field of each subsequent `SecRule` should increase by one, as shown in the example.

**ctl:ruleEngine=\{mode\}** - The action to be taken when the criteria of the `SecRule` are met, either `OFF`, `DETECT` or `BLOCK`. This field is updated with the corresponding value of the `action` field of the `CustomProtectionRuleSetting` object when using the `UpdateWafConfig` operation.

**Example of a custom protection rule format:**

```
SecRule REQUEST_COOKIES "regex matching SQL injection - part 1/2" \
```
Web Application Firewall

"phase:2,
msg:'Detects chained SQL injection attempts 1/2.',
id: {{id_1}},
ctl:ruleEngine={{mode}},
deny"
SecRule REQUEST_COOKIES "regex matching SQL injection - part 2/2"
"phase:2,
msg:'Detects chained SQL injection attempts 2/2.',
id: {{id_2}},
ctl:ruleEngine={{mode}},
deny"

Actions

The WAF service can take an action on an HTTP request when the criteria of a custom protection rule are met.

- **DETECT** - Logs the request when the criteria of the custom protection are met.
- **BLOCK** - Blocks the request when the criteria of the custom protection rule are met.
- **OFF** - The custom protection rule is inactive and will take no action.

Using the Console

To create a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click **Create WAF Custom Protection Rule**.
4. In the Create a Custom Protection Rule dialog box, enter the following:
   - **Name**: A unique name for the protection rule. Avoid entering confidential information.
   - **Description**: Optional. A description of the custom protection rule.
   - **Template**: Enter the protection rule criteria in ModSecurity Rule Language. Each rule must include two placeholder variables: id: {{id_1}} and ctl:ruleEngine={{mode}}. For more information about ModSecurity syntax, see **Making Rules: The Basic Syntax**.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

To edit a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click the name of the custom protection rule you want to edit.
4. Click **Edit**.
5. Make the necessary changes and then click **Save Changes**.

To manage tags for a custom protection rule

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Click the name of the protection rule you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

To move a custom protection rule to another compartment

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Find the protection rule in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To delete a custom protection rule**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Custom Protection Rules**.
3. Select the check box for the protection rule you want to delete.
4. Click **Delete**.
5. In the confirmation dialog box, click **Delete**.

**To add a custom protection rule to a WAF policy**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Custom Rules** tab.
5. Click **Add** from the Actions drop down menu.
6. In the Add Custom Rule dialog box, select a custom protection rule from the drop down menu. If the custom protection rule exists in another compartment, you can change the compartment where the rule exists.
7. Select one of the following actions to apply to the rule:
   - **Detect**: Matching requests generate an alert and the request is proxied.
   - **Block**: Matching requests are blocked.
8. Click **Add**.

**To apply a new action to a custom protection rule in a WAF policy**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy where you want to edit a custom protection rule.
3. Click **Protection Rules** and then click the Custom Rules tab.
4. Select the check box for the custom rule you want to change the action for.
5. Select the action from the **Actions** drop down menu.

**To delete a custom protection rule from a WAF policy**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy where you want to remove a custom protection rule. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Custom Rules** tab.
5. Select the check box for the custom rule you want to delete.
6. Select delete from the **Actions** drop down menu.

**Using the API**

Custom protection rules can be created and added to a compartment using the **CreateProtectionRule** call in the WAAS API. Using ModSecurity Rule Language formatting, populate the **template** field with the criteria of the rule.

**Example:**

```json
{
    "compartmentId": "ocid1.compartment.region1..<unique_ID>",
    "description": "The description text for the rule being created",
    "displayName": "Custom Protection Rule Name",
    "template": "SecRule REQUEST_URI / "phase:2, t: none, capture, msg:'Custom (XSS) Attack. Matched Data: %{TX.0} found within %{MATCHED_VAR_NAME}: %{MATCHED_VAR}\'', id:{{id_1}}, ctl:ruleEngine={{mode}}, tag:'Custom', severity:'2'"
}
```
Adding Custom Protection Rules to a WAF Configuration

Custom protection rules can be added to a WAF configuration using the `UpdateWafConfig` call in the WAAS API. Add the OCID and the desired action to take to the `CustomProtectionRuleSetting` object of the `UpdateWafConfig` schema.

Example:

```json
[
  {
    "action": "BLOCK",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaalxd4jrws4rbbnddz1notu3giuzo53kopbj747mbvar
  },
  {
    "action": "DETECT",
    "id": "ocid1.waascustomprotectionrule.oc1..aaaaaaaamx5r72ntmmhgwseaspzpdqcwsgprpvuwa7xoshnyo"n
  }
]
```

To view a list of available custom protection rules in a compartment and their corresponding OCIDs, use the `ListCustomProtectionRules` call in the WAAS API.

Access Control

See these topics for more information about access control:

- Access Rules on page 5267
- IP Address Lists on page 5270
- IP Address Whitelist on page 5272

Access Rules

As a WAF administrator you can define explicit actions for requests that meet various conditions. Conditions use various operations and regular expressions. A rule action can be set to log and allow, detect, block, redirect, bypass, or show a CAPTCHA for all matched requests.

The available conditions for an access rule are shown in the following table:

<table>
<thead>
<tr>
<th>Criteria Type</th>
<th>Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Users shall be able to define one or more criteria based on:</td>
</tr>
<tr>
<td></td>
<td>• URL is</td>
</tr>
<tr>
<td></td>
<td>• URL is not</td>
</tr>
<tr>
<td></td>
<td>• URL starts with</td>
</tr>
<tr>
<td></td>
<td>• URL does not start with</td>
</tr>
<tr>
<td></td>
<td>• URL part ends with</td>
</tr>
<tr>
<td></td>
<td>• URL part does not end with</td>
</tr>
<tr>
<td></td>
<td>• URL part contains</td>
</tr>
<tr>
<td></td>
<td>• URL part does not contain</td>
</tr>
<tr>
<td></td>
<td>• URL regex</td>
</tr>
<tr>
<td></td>
<td>• URL does not match regex</td>
</tr>
</tbody>
</table>

The URL regex matching uses Perl-compatible regular expressions.
## Web Application Firewall

<table>
<thead>
<tr>
<th>Criteria Type</th>
<th>Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IP Address</strong></td>
<td>Users shall be able to define one or more criteria based on:</td>
</tr>
<tr>
<td></td>
<td>- IP Address is</td>
</tr>
<tr>
<td></td>
<td>- IP Address is not</td>
</tr>
<tr>
<td></td>
<td>- IP Address in Address List</td>
</tr>
<tr>
<td></td>
<td>- IP Address not in Address List</td>
</tr>
<tr>
<td></td>
<td>These values can be a valid IPv4 address, subset, or CIDR notation for a range. IPv6 is not yet supported. See IP Address Lists on page 5270 for information on how to create a list of IP addresses that can be used in the access rule.</td>
</tr>
<tr>
<td><strong>Country/Region</strong></td>
<td>Users shall be able to define one or more criteria based on:</td>
</tr>
<tr>
<td></td>
<td>- Country/Region is</td>
</tr>
<tr>
<td></td>
<td>- Country/Region is not</td>
</tr>
<tr>
<td></td>
<td>For the API, use a two letter country code.</td>
</tr>
<tr>
<td><strong>User Agent</strong></td>
<td>User Agent is a value that identifies the browser client.</td>
</tr>
<tr>
<td></td>
<td>- User Agent is</td>
</tr>
<tr>
<td></td>
<td>- User Agent is not</td>
</tr>
<tr>
<td><strong>HTTP Header</strong></td>
<td>HTTP Request headers can be evaluated as criteria:</td>
</tr>
<tr>
<td></td>
<td>- HTTP Header contains</td>
</tr>
<tr>
<td></td>
<td>The HTTP Header contains value should be entered with colon-delimited &lt;name&gt;:&lt;value&gt;.</td>
</tr>
<tr>
<td><strong>HTTP Method</strong></td>
<td>HTTP Methods can be evaluated as criteria:</td>
</tr>
<tr>
<td></td>
<td>- HTTP method is</td>
</tr>
<tr>
<td></td>
<td>- HTTP method is not</td>
</tr>
<tr>
<td></td>
<td>Available methods include GET, POST, PUT, DELETE, HEAD, CONNECT, OPTIONS, TRACE, and PATCH.</td>
</tr>
</tbody>
</table>

### Using the Console

**Note:**

The WAF uses a first-match algorithm so that once an Access Rule criteria matches, it will stop evaluating future rules. The order of rules matters. Use the API to reorder rules.

**To add an access rule**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click **Access Control**.
4. Click **Add Access Rule**.
5. In the Add Access Rule dialog box, enter the following:
   • **Name:** A unique name for the access rule. Avoid entering confidential information.
   • **Action:** Determines the response to a request when the rule is matched. Select one of the following options:
     • **Log and Allow:** A log will be created for all matched requests and no further action will be taken.
     • **Detect Only:** A detection alert will be created for all matched requests and no further action will be taken.
     • **Block:** All matched requests will be blocked and a browser page for the selected response code will be returned.
       • **Block Action:** Select the action that will be taken when a matching request is blocked.
       • **Block Response Code:** Select a response code that will be returned when the request has been blocked. The response code provides information indicating why the request was blocked. The default response code is 403 "Forbidden".
   • **Redirect:**
     • **Redirect Status Code:** The status code returned in response to redirect requests.
     • **Redirect URL:** The URL address to redirect the request to.
   • **Bypass:** Select the challenge(s) to bypass. If this section is not specified, all challenges are bypassed.
   • **Show CAPTCHA:** Select this option to show a CAPTCHA for all matched requests and take no further action. Enter the following:
     • **CAPTCHA Title:** Enter the text for the CAPTCHA page title.
     • **CAPTCHA Header:** Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
     • **CAPTCHA Footer Text:** Enter the text that will be shown after the CAPTCHA input box and before the submit button.
     • **CAPTCHA submit button:** Enter the text for the Submit button (for example, "Yes, I am human.").
   • **Conditions:** Select the condition that must be met before the rule is matched and specify the details of the condition. Additional conditions can be added in this section.
   • **Header Manipulation(s):**
     • **Action:** Select the action to apply to the request.
     • **Header Name:** Enter the HTTP header name of the request.
     • **Header Value:** Enter the HTTP header value of the request.

6. Click **Add Access Rule**. The access rule is added to the access rule list.

To edit an access rule
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click **Access Control**.
4. Select the check box for the access rule you want to update, and then click **Edit**.
5. In the Edit Access Rule dialog box, make the necessary updates and then click **Save**.

To delete an access rule
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy you want to view access rules for. The WAF policy overview appears.
3. Click **Access Control**.
4. Select the check box for the access rule you want to delete and then click **Delete**.

To publish changes
Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.
1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

**Access Rules**

Use the following operations to get an array of all access rules in the policy:

- **UpdateAccessRules**
- **ListAccessRules**

**Example**

To create an access rule:

```
PUT /waasPolicies/{waasPolicyId}/wafConfig/accessRules
{
 "name": "DetectRequestsToHealthCheck",
 "criteria": [
  {
   "condition": "URL_IS",
   "value": "/health/check"
  },
  "action": "DETECT"
 ]
}
```

**IP Address Lists**

WAF IP Address Lists allow you to define a list of IP addresses to use in WAF policy configurations. An IP Address List can be used in multiple WAF policies. The IP addresses in the list can be a valid IPv4 address, a subset, or CIDR notations. You can use the IP address list to define the conditions for an access rule. Access rules allow you to specify explicit actions for requests that meet various conditions.

**Using the Console**

**To add an IP address list**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **IP Address Lists**.
3. Click **Create WAF IP Address List**.
4. In the Create WAF IP Address List dialog box, enter the following:

- **Name**: A user-friendly name for the IP address list. Avoid entering confidential information.
- **IP Addresses**: Enter IP addresses or CIDR notations.
- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click Create.

**To edit an IP address list**

2. Click IP Address Lists.
3. Click the name of the IP address list you want to update.
4. Click Edit.
5. In the Edit WAF IP Address List dialog box, update the Name or IP Addresses. Avoid entering confidential information.

6. Click Save Changes.

**To delete an IP address list**

2. Click IP Address Lists.
3. Select the check box for the IP address list you want to delete.
4. Click Delete.
5. In the confirmation dialog box, click Delete.

**To move an IP address list to another compartment**

2. In the List Scope section, select a compartment.
3. Click IP Address Lists.
4. Find the IP address list in the list, click the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

**To manage tags for an IP address list**

2. Click IP Address Lists.
3. Click the name of the IP address list you want to manage tags for.
4. Click the Tags tab to view or edit existing tags. Or click Add tag(s) to add new ones.

For more information, see Resource Tags on page 239.

**To publish changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click Publish All.
4. In the Publish Changes dialog box, click Publish All.

**To discard changes**

Updates to your WAF policy appear in the list to be published in Unpublished Changes.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click Discard.
5. In the Discard Change dialog box, click Discard.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations to create and manage address lists that can be applied to access rules:

- CreateAddressList
- ListAddressLists
- GetAddressLists
- UpdateAddressList
- DeleteAddressLists

Example

To create an address list:

```json
POST /addressLists
{
  "addresses": [
    "198.51.100.0",
    "198.51.255.45",
    "198.51.145.55"
  ],
  "compartmentId": "ocid1.compartment.region1...",
  "displayName": "example IP addresses"
}
```

IP Address Whitelist

You can use the IP Address Whitelist tab in Access Control to manage whitelists containing trusted IP addresses that bypass all rules and challenges. See Access Control on page 5267 for more information.

Using the Console

To add an IP address whitelist in a WAF policy

2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click Access Control.
4. Select the IP Whitelist tab.
5. Click Add IP Address Whitelist.
6. In the Add IP Address Whitelist dialog box, enter the following:
   - Whitelist Name: A name for the IP addresses used in the list.
   - IP Addresses: Select an IP address or enter an IP address and select it to add it. This field supports CIDR notation.
7. Click Add IP Address Whitelist.

The IP Address Whitelist is added to the list of changes to be published.

To edit an IP address whitelist in a WAF policy

2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **IP Whitelist** tab.
5. Select the check box for the IP Address Whitelist name you want to edit.
6. Click **Edit**.
7. In the Edit IP Address Whitelist dialog box, make the needed changes.
8. Click **Save**.

The IP Address Whitelist change is added to the list of changes to be published.

To delete an IP address whitelist in a policy

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to view alerts for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **IP Whitelist** tab.
5. Select the check box for the IP Address Whitelist name you want to delete.
6. Click **Delete**.

The deleted IP Address Whitelist is added to the list of changes to be published.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

- UpdateWhitelists
- ListWhitelists

Caching Rules

Caching rules allow you to selectively cache requested content on Oracle Cloud Infrastructure's edge servers, such as web pages or certain file types.

**Using the Console**

**To create a caching rule**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy you want to add a caching rule. The WAF Policy overview appears.
3. Click **Caching Rules**.
4. Click **Create Caching Rule**.
5. In the Create Caching Rule dialog box, enter the following:
   - **Name**: A unique name for the access rule. Avoid entering confidential information.
   - **Caching Rule Action**: Select one of the following options:
     - **Cache**: Cache the requested content when criteria of the rule is met.
     - **Caching Duration**: The duration to cache content for the caching rule.
     - **Time Unit**: The unit of time for the caching duration.
     - **Enable Client Caching**: Select this check box to specify the duration to cache content in the user’s browser.
     - **Bypass Cache**: Allow requests to bypass the cache and be directed to the origin when the criteria of the rule is met.
   - **Conditions**: Select the condition and URL address that must match for the action to be taken. At least one condition must match for the set action to be taken.
6. Click **Create**. The caching rule is added to the Caching Rules list.

**To edit a caching rule**
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy you want to edit the Caching Rules for. The WAF policy overview appears.
3. Click **Caching Rules**.
4. Select the check box for the caching rule you want to update.
5. Select **Edit** from the Actions drop down menu.
6. In the Edit Caching Rule dialog box, make the necessary updates.
7. Click **Save Changes**.

**To delete a caching rule**
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF policy where you want to delete a caching rule. The WAF policy overview appears.
3. Click **Caching Rules**.
4. Select the check box for the caching rule you want to delete.
5. Select **Delete** from the Actions drop down menu.
6. In the confirmation dialog box, click **Delete**.

**To purge the cache**
1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy where you want to purge the cache. The WAF Policy overview appears.
3. Click **Caching Rules**.
4. Select **Purge Cache** from the Actions dropdown menu.
5. In the Purge Cache dialog box, select the condition and URL address to purge and click **Purge**.

**Using the API**
Use the following API operations to create and manage caching rules that can be applied to your WAF configurations:
- **ListCachingRules**
- **UpdateCachingRules**
- **PurgeCache**

**Available Cache Rules Criteria**
The criteria of the caching rules determine if the requested content should be cached.
• **URL_IS** - Matches if the concatenation of requested URL path and query is identical to the contents of the value field. For example, if this rule is set to cache the content of www.example.com/products, only HTTP requests for www.example.com/products will cache.

• **URL_STARTS_WITH** - Matches if the concatenation of requested URL path and query starts with the contents of the value field. For example, if this rule is set to cache content from www.example.com/products, all HTTP requests requesting URLs starting with www.example.com/products will be cached and subsequent requests will receive content from the cache, including requests for www.example.com/products/new-product and www.example.com/products/old-product.

• **URL_PART_ENDS_WITH** - Matches if the concatenation of requested URL path and query ends with the contents of the value field. For example, if the rule is set to cache content from URLs that end with /product.jpg, HTTP requests for the URLs www.example.com/products/new-product/product-banner.jpg and www.example.com/products/old-product/product-banner.jpg will be cached and subsequent requests will receive content from the cache.

• **URL_PART_CONTAINS** - Matches if the concatenation of requested URL path and query contains the contents of the value field. If the rule is set to cache content from URLs that contain /product-banner, HTTP requests for the URLs www.example.com/products/new-product/product-banner/blue.jpg and www.example.com/products/new-product/product-banner/red.jpg will be cached and subsequent requests will receive content from the cache.

### Available Cache Rule Actions

A caching rule can be set to take one of two available actions when receiving a request:

- **CACHE** - Requests matching the criteria of the rule will be cached and subsequent requests will receive content from the cache.
- **BYPASS_CACHE** - Requests matching the criteria of the rule will bypass the cache and be directed to the origin.

### Cache Duration

Content can be cached for a specified period of time on Oracle Cloud Infrastructure's edge servers or cached locally by the client. The duration is set in the cachingDuration and clientCachingDuration fields, in ISO 8601 extended format.

### Example of a Caching Rule

```json
[
  {
    "action": "CACHE",
    "cachingDuration": "PT20M",
    "clientCachingDuration": "PT20M",
    "criteria": [
      {
        "condition": "URL_IS",
        "value": "/path/to-cache"
      }
    ],
    "isClientCachingEnabled": true,
    "name": "Caching Rule 1"
  },
  {
    "action": "BYPASS_CACHE",
    "criteria": [
      {
        "condition": "URL_PART_ENDS_WITH",
        "value": "urp-part-not-to-cache"
      }
    ],
    "isClientCachingEnabled": false,
    "name": "Do not cache"
  }
]
```
Best Practices

The order the caching rules is specified in are important. The rules are processed in the order they are specified in and the first matching rule will be used when processing a request. It is best to add rules that bypass cache to the top of the order and caching rules below any bypass rules.

Purge Caches

Caches can be purged using the PurgeCache operation. Caches can either be selectively purged by specifying the URL path of a resource or all caches can be purged for the WAF by not specifying any resources to pass to the API.

Examples

Purge the cache for specified resources:

```
{
  "resources": [
    "/path/to-purge",
    "/multiple-paths"
  ]
}
```

Threat Intelligence

WAF has several sources of known IP address threats that are updated daily. The IP address threats are displayed in the following table:

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABUSE</td>
<td>ch</td>
</tr>
<tr>
<td>Bambenek Consulting</td>
<td>Active and non-sinkholed Command &amp; Control (C&amp;C) IP addresses.</td>
</tr>
<tr>
<td>BlockList.de</td>
<td>Includes IP addresses for hosting phishing sites and other kinds of fraud activities such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>BruteForceBlocker Project</td>
<td>The feed of known IP addresses from blocked SSH brute force attacks.</td>
</tr>
<tr>
<td>Proofpoint ET Labs</td>
<td>IP addresses involved in suspicious and malicious activity.</td>
</tr>
<tr>
<td>Feodo IP Blocklist</td>
<td>IP addresses used as C&amp;C communication channel by the Feodo Trojan.</td>
</tr>
<tr>
<td>Palevo</td>
<td>IP addresses which are being used as botnet C&amp;C for the Palevo crimeware.</td>
</tr>
<tr>
<td>Source</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TOR Nodes</td>
<td>List of IP addresses for known Tor nodes. The Tor network is a group of volunteer-operated servers that allows people to improve their privacy and security on the internet. Tor's users employ this network by connecting through a series of virtual tunnels rather than making a direct connection, thus allowing both organizations and individuals to share information over public networks without compromising their privacy.</td>
</tr>
<tr>
<td>Webroot BotNets</td>
<td>Botnet C&amp;C channels and infected zombie machines controlled by Botmaster.</td>
</tr>
<tr>
<td>Webroot Denial of Service</td>
<td>Includes DOS, DDoS, anomalous sync flood, and anomalous traffic detection.</td>
</tr>
<tr>
<td>Webroot Mobile Threats</td>
<td>IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research tea.</td>
</tr>
<tr>
<td>Webroot Phishing</td>
<td>IP addresses hosting phishing sites and other kinds of illicit activities such as ad-click or gaming fraud.</td>
</tr>
<tr>
<td>Webroot Proxy</td>
<td>IP addresses providing proxy and def services.</td>
</tr>
<tr>
<td>Webroot Reputation</td>
<td>IP addresses currently known to be infected with malware. This category also includes IP addresses with an average low Webroot Reputation Index score.</td>
</tr>
<tr>
<td>Webroot Scanners</td>
<td>Includes all reconnaissance such as probes, host scan, domain scan and password brute force attacks.</td>
</tr>
<tr>
<td>Webroot Spam Sources</td>
<td>Includes tunneling spam messages through proxy, anomalous SMTP activities, and forum spam activities.</td>
</tr>
<tr>
<td>Webroot Tor Proxy</td>
<td>Includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator's intended destination.</td>
</tr>
<tr>
<td>Webroot Web Attacks</td>
<td>Includes known IP addresses involved in cross-site scripting, iFrame injection, SQL injection, cross-domain injection, or domain password brute force attacks.</td>
</tr>
<tr>
<td>Webroot Windows Exploits</td>
<td>Includes active IP addresses offering or distributing malware, shell code, rootkits, worms, or viruses.</td>
</tr>
<tr>
<td>ZeuS</td>
<td>IP blocklist including known C&amp;C servers/hosts.</td>
</tr>
</tbody>
</table>

**Using the CLI**

You can use the CLI to enable threat intelligence sources to block.

Open a command prompt and run the following command to list the keys for all of the threat intelligence:

```bash
ci waas threat-feed list --waas-policy-id <policy_ocid>
```

Then parse the keys to block and add them to the JSON:

```bash
ci waas threat-feed update --threat-feeds '[]' --waas-policy-id <policy_ocid>
```
Using the API

Enabling Threat Intelligence can only be performed by using the API at this time.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To return a set of keys for the threat intelligence:

- **ListThreatFeeds**

  ```
  Note:
  Do not use the keys in the example below, as keys are unique across each policy.
  
  {  
    "8d3f7f1b-673f-4e3a-ba49-08226f385df3": "OFF",  
    "0ff7b308-6afe-4b83-91e0-e3ca04afed6e": "OFF",  
    "ea5d7c67-1326-43c9-ac31-1df034b9c063": "OFF",  
    "87b420ca-5fbb-4ad4-aeba-1b02a9e60b30": "OFF",  
    "2168fc70-2d05-466a-9db5-c13c0e32177d": "OFF",  
    "7d080a4a-58ce-4370-a02c-f600b3a84e7b": "OFF",  
    "a36c7c50-e99e-4b84-9140-5653fc68ce8d": "OFF",  
    "5de7bbc1-313f-4995-9810-f6f77cf3d30c9": "OFF",  
    "fd2152cc-14f5-4471-a58b-d94cc8a61444": "OFF",  
    "cfac3d3d-65d9-4368-93e0-62c906e7a748": "OFF",  
    "6eb86368-01ea-4e94-ac1b-49fb0e551443": "OFF",  
    "aabb45d9-0d75-481d-9568-58ecad217ele": "OFF",  
    "3805ecc2-1d6d-428b-a03e-2a0fe77fd46f": "OFF",  
    "c3452861-4910-4f3a-9872-22cf92d424eb": "OFF",  
    "4cf31de8-11af-460e-a46a-ec91946a6688": "OFF",  
    "eff34d63-6235-4081-976d-acd39248bd3": "OFF",  
    "1d1c94d9-0338-45eb-acd4-fb422e281f4c": "OFF",  
    "687b5ff4-b1b6-4d12-8db3-3ea90b4536a1": "OFF",  
    "65cf274d-991b-4368-93e0-62c906e7a748": "OFF"  
  }
  ```

To set all threats to DETECT:

- **UpdateThreatFeeds**

  ```
  With body:
  
  [  
    {"action":"DETECT","key":"8d3f7f1b-673f-4e3a-ba49-08226f385df3"},  
    {"action":"DETECT","key":"0ff7b308-6afe-4b83-91e0-e3ca04afed6e"},  
    {"action":"DETECT","key":"ea5d7c67-1326-43c9-ac31-1df034b9c063"},  
    {"action":"DETECT","key":"87b420ca-5fbb-4ad4-aeba-1b02a9e60b30"},  
    {"action":"DETECT","key":"2168fc70-2d05-466a-9db5-c13c0e32177d"},  
    {"action":"DETECT","key":"7d080a4a-58ce-4370-a02c-f600b3a84e7b"},  
    {"action":"DETECT","key":"a36c7c50-e99e-4b84-9140-5653fc68ce8d"},  
    {"action":"DETECT","key":"5de7bbc1-313f-4995-9810-f6f77cf3d30c9"},  
    {"action":"DETECT","key":"fd2152cc-14f5-4471-a58b-d94cc8a61444"},  
    {"action":"DETECT","key":"cfac3d3d-65d9-4368-93e0-62c906e7a748"},  
    {"action":"DETECT","key":"aabb45d9-0d75-481d-9568-58ecad217ele"},
    ]
  ```
Web Application Firewall

This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

**Certificates**

To use SSL with your WAF policy, you must add a certificate bundle. The certificate bundle you upload includes the public certificate and the corresponding private key. Self-signed certificates can be used for the internal communication within Oracle Cloud Infrastructure.

**Working with SSL Certificates**

Oracle Cloud Infrastructure accepts third-party and self-signed certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

**Obtaining Third-Party SSL Certificates**

You can purchase an SSL certificate from a trusted Certificate Authority such as Symantec, Thawte, RapidSSL, or GeoTrust. The certificate issuer will provide an SSL certificate that includes a certificate, intermediate certificate, and private key. Use this information, including the intermediate certificate, when adding an SSL certificate to Oracle Cloud Infrastructure.

**Converting to PEM format**

If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format.

**Uploading Certificate Chains**

If you have multiple certificates that form a single certification chain, you must include all relevant certificates in one file before you upload them to the system. The following example of a certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```
Submitting Private Keys

If your private key submission returns an error, the most common reasons are your private key is malformed or the system does not recognize the encryption method used for your key.

Private key consistency

If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

Decrypting a private key

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

Using the Console

To create a WAF certificate

2. Click Certificates.
3. Click Create WAF Certificate.
4. In the Create WAF Certificate dialog box, enter the following:
   - **Name**: A unique name for the certificate. Avoid entering confidential information.
   - **SSL Certificate**: Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:
     
     ```
     -----BEGIN CERTIFICATE-----
     <Base64_encoded_certificate>
     -----END CERTIFICATE-----
     -----BEGIN CERTIFICATE-----
     <Intermediate_Base64_encoded_certificate>
     -----END CERTIFICATE-----
     ```
   - **Private Key**: Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:
     
     ```
     -----BEGIN PRIVATE KEY-----
     <Base64encoded_private_key>
     -----END PRIVATE KEY-----
     ```
   - **Self Signed Certificate**: Enable this field when using a self-signed certificate to show an SSL warning in the browser.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click Create.

To delete a WAF certificate

2. Click Certificates.
3. Select the check box for the certificate you want to delete.
4. Click **Delete**.
5. In the confirmation dialog box, click **Delete**.

**To edit the name of a WAF certificate**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Certificates**.
3. Click the name of the certificate you want to edit.
4. Click **Edit**.
5. In the Edit WAF Certificate dialog box, update the **Name** field. Avoid entering confidential information.
6. Click **Save Changes**.

**To manage tags for a WAF certificate**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click **Certificates**.
3. Click the name of the WAF certificate you want to manage tags for.
4. Click the **Tags** tab to view or edit existing tags. Or click **Add tag(s)** to add new ones.

For more information, see **Resource Tags** on page 239.

**To move a WAF certificate to a different compartment**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. In the **List Scope** section, select a compartment.
3. Click **Certificates**.
4. Find the WAF certificate in the list, click the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

**To add a certificate to a WAF policy**

1. Open the navigation menu and click **Identity & Security**. Under **Web Application Firewall**, click **Policies**.
2. Click the name of the WAF Policy where you want to view certificate settings. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **General Settings**.
5. Click **Edit**.
6. In the **Edit Settings** dialog box, enter the following:
   - **Enable HTTPS Support**: Click this check box to enable all communications between the browser and web app to be encrypted.
   - **Certificate Source**: Choose one of the following methods:
     - **Choose Certificate**: Select an existing certificate from the drop down menu. Click **Change Compartment** to select a certificate from another compartment.
     - **Upload or Paste Certificate and Private Key**
       - Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Intermediate_Base64_encoded_certificate>
```

Oracle Cloud Infrastructure User Guide 5281
---BEGIN CERTIFICATE-----
Private Key: Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

---BEGIN PRIVATE KEY-----
<Base64_encoded_private_key>
---END PRIVATE KEY-----

• Self Signed Certificate: Enable this field when using a self-signed certificate to show an SSL warning in the browser.
• HTTP to HTTPS Redirect: When enabled, all HTTP traffic is automatically redirected to HTTPS.
• TLS Protocols Support: Select a TLS protocol from the drop down list.

Caution:
TLS versions 1 and 1.1 have been deprecated and cannot be used in policy configurations. If you use these versions, a validation error might occur. Use versions 1.2 or 1.3 instead.

• Enable SNI: Server Name Indication (SNI) is an extension of the TLS protocol, which allows multiple secure hostnames to be served from a single IP address.
• Advanced Options
  • Enable Response Buffering: Enable or disable buffering of the response from the origin.
  • Cache Control Respected: Enable or disable automatic content caching based on the response cache-control header.
  • Behind CDN: Enable this to allow the collection of IP addresses from the client request if WAF is connected to a CDN.

7. Click Save Changes.

To edit a certificate in a WAF policy
2. Click the name of the WAF Policy where you want to view certificate settings. The WAF Policy overview appears.
3. Click Settings.
4. Click General Settings.
5. Click Edit.
6. In the Edit Settings dialog box, make the necessary updates to the certificate.
7. Click Save Changes.

Using the API
For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

• CreateCertificate
• GetCertificate
• DeleteCertificate

Logs
Logs displays log activity and the details of each logged event within a specified time frame. Logs enable you to understand what rules and countermeasures are triggered by requests and are used as a basis to move request handling into block mode. Logs can come from Access Control, Protection Rules, or Bot events.
Note:

If you have concerns over General Data Protection Regulation (GDPR) requirements, Logs can be disabled for the WAF service. You can use My Oracle Support to file a service request to disable Logs.

Using the Console

To view Logs

2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click Logs. Logs for the WAF policy appear.
4. To help find a log, you can use the following filter options:
   • To view alerting activity data for a specific time range, enter a Start Date, Start Time, End Date, or End Time.
   • To view logs for a URL, enter a Request URL.
   • To view logs for a client IP address, select an address from the Client IP Address drop-down menu.
   • To view logs for a country, select a country from the Country Name drop-down list.
   • To find a type of action, select an Action check box.
   • To find a type of log, select a Log Type check box from the following options:
     • Access Rules
     • CAPTCHA Challenge
     • JavaScript Challenge
     • Protection Rules
     • Human Interaction Challenge
     • Device Fingerprinting Challenge
     • Threat Intelligence Feeds
     • Address Rate Limiting
     • Access
5. Click the plus sign next to the Alert Type you want to view.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the ListWafLogs API operation to display log activity. You can use filters to help find a log.

Example

You can filter logs by the following logType:

• ACCESS_RULES
• CAPTCHA_CHALLENGE
• JAVASCRIPT_CHALLENGE
• PROTECTION_RULES
• HUMAN_INTERACTION_CHALLENGE
• DEVICE_FINGERPRINT_CHALLENGE
• THREAT_INTELLIGENCE_FEEDS
• ADDRESS_RATE_LIMITING
• ACCESS
Web Application Firewall

Logs can be filtered by logType by making the following request:

```
GET /20181116/waasPolicies/<unique_ID>/wafLogs?
logType=<logType>&timeObservedGreaterThanOrEqualTo=<timestamp>&timeObservedLessThan=<timestamp>&compartmentId=<unique_ID>
```

For example:

```
GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?
logType=PROTECTION_RULES&timeObservedGreaterThanOrEqualTo=2019-10-24T13:00:00+00:00&timeObservedLessThan=2019-10-24T13:47:00+00:00&compartmentId=ocid1.compartment.oc1..,
```

The following response output for the filtered logs is returned:

```

WAF Metrics

You can monitor the health, capacity, and performance of your WAF policies by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_waf (the WAF service).

Overview of the WAF Service Metrics

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based global security service that protects applications from malicious and unwanted internet traffic. The WAF service metrics help you measure various levels of traffic encountering your WAF policies, including non-malicious traffic. For more information, see Overview of the Web Application Firewall Service.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

- Permissions are required to allow monitoring, alarm, and notification (ONS) definition for users in a group for all compartments. The following policies must be configured in the root compartment:

```
Allow group <WAFMonitors> to read metrics in compartment <CompartmentName>

Allow group <WAFMonitors> to manage alarms in compartment <CompartmentName>

Allow group <WAFMonitors> to manage ons-family in compartment <CompartmentName>
```

Available Metrics: oci_waf

The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have the policy properly set up with web
traffic passing through it to make the `oci_waf` metric space available in the Metrics Explorer feature. Policies with no web traffic emit no metric data.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumberOfRequests</td>
<td>Requests count</td>
<td></td>
<td>The total number of requests serviced by the WAF.</td>
<td><code>resourceID</code>, <code>primaryDomain</code>, <code>module</code>, <code>action</code>, <code>countryCode</code>, <code>responseCode</code>, <code>responseCodeGroup</code></td>
</tr>
<tr>
<td>Traffic</td>
<td>Traffic bytes</td>
<td>byte</td>
<td>Data egress from the WAF (compressed by default) measured in one minute intervals.</td>
<td><code>resourceID</code>, <code>primaryDomain</code>, <code>module</code>, <code>responseCode</code>, <code>responseCodeGroup</code></td>
</tr>
<tr>
<td>Bandwidth</td>
<td>Bandwidth bytes per second (B/s)</td>
<td>B/s</td>
<td>Bandwidth rate calculated by dividing total data egress in a minute by 60.</td>
<td><code>resourceID</code>, <code>primaryDomain</code>, <code>module</code></td>
</tr>
<tr>
<td>NumberOfRequestsDetected</td>
<td>Requests count</td>
<td></td>
<td>The number of requests that triggered a detect (alert) for a WAF policy.</td>
<td><code>resourceID</code>, <code>primaryDomain</code>, <code>module</code></td>
</tr>
</tbody>
</table>

**Available Dimensions**

The following dimensions are available for WAF metrics:
<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
<th>Sample Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td>Two-letter country code where the request originated.</td>
<td>• US</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• BZ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CN</td>
</tr>
<tr>
<td><strong>Country</strong></td>
<td>The rule type that was triggered by the request.</td>
<td>• access_rules</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• captcha</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• threat (threat intelligence)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• modsecurity (protection</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rule)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• origin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• fp_challenge (device</td>
</tr>
<tr>
<td></td>
<td></td>
<td>fingerprint)</td>
</tr>
<tr>
<td><strong>PrimaryDomain</strong></td>
<td>Web domain of the WAF policy.</td>
<td><a href="http://www.mydomain.com">www.mydomain.com</a></td>
</tr>
<tr>
<td><strong>ResponseCode</strong></td>
<td>HTTP response.</td>
<td>• 200</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 403</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 404</td>
</tr>
<tr>
<td><strong>ResponseCodeGroup</strong></td>
<td>HTTP response status code series.</td>
<td>• 2XX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 4XX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 5XX</td>
</tr>
<tr>
<td><strong>ResourceId</strong></td>
<td>The OCID of the WAF policy.</td>
<td>ocid1.waaspolicy</td>
</tr>
</tbody>
</table>

Multiple dimensions can be combined and aggregated to form ad-hoc subset reports of telemetry.

**Using the Console**

WAF service metrics are currently only available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

Any metric/dimension combination can be used as criteria for alarms. Alarms can leverage Oracle Notification Service for alerting through communication mechanisms like email and pagerduty.

**To view WAF metric charts**

   For Metric Namespace, select oci_waf.

2. Select a metric to view from the Metric Name field.

3. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId is specified in the metric definition for NumberOfRequests.

4. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.

5. Click Update Chart.

   The chart will be updated with the metrics that have been requested. You can hover over the line graphs to see a breakdown of the dimensions for data displayed.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.
Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Layer 7 DDoS Mitigation

Distributed Denial of Service (DDoS) Overview

A DDoS attack is an often intentional attack that consumes an entity’s resources, usually using a large number of distributed sources. DDoS can be categorized into either Layer 7 or Layer 3/4 (L3/4), as defined by the Open Systems Interconnection (OSI) model. L3/4 DDoS attacks are DDoS attacks that occur at lower levels of the OSI stack than layer 7. Examples of such attacks include UDP, CharGen, and NTP Floods. L3/4 DDoS mitigation is inherently provided by Oracle Cloud Infrastructure.

A layer 7 DDoS attack is a DDoS attack that sends HTTP/S traffic to consume resources and hamper a website’s ability to delivery content or to harm the owner of the site. The Web Application Firewall (WAF) service can protect layer 7 HTTP-based resources from layer 7 DDoS and other web application attack vectors.

Layer 7 DDoS Mitigation Services

Oracle provides a Layer 7 DDoS Mitigation service to help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists are trained members of our Cloud Customer Support team who help mitigate layer 7 DDoS attacks. DDoS Mitigation Specialists help onboard you to WAF if you are not already using it. They must be granted access to your account to make changes to the WAF policy on your behalf. A DDoS attack report is generated after mitigation is complete. The report describes the type and parameters of the attack and what actions were taken to mitigate the attack. At the conclusion of the DDoS mitigation effort of a layer 7 DDoS attack, you may seek to receive credits for services that incurred additional Cloud Service fees. Details of this claim is available in the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Requesting Help

It is your responsibility to report an attack through My Oracle Support. You can use monitoring and alarm definitions based on telemetry to receive notifications of thresholds exceeded. For more information about setting up alarms, see Managing Alarms on page 3523. All changes will be audited in the Audit service.

To request help, go to My Oracle Support and select the WAF product and then DDoS. You will be invited to a web conference where you will interact with a DDoS Mitigation Specialist to review the issue. At this time, you can also participate in the WAF on-boarding and tuning process.

Required IAM Service Policy

In order for the Mitigation Specialist to manage rules to block the attack, you must provision an IAM user account with permissions.

To create an account with the correct permissions:

1. Create a user with the email address of the Mitigation Specialist. See Managing Users on page 3110.
2. Create a group named "SOCMember". See Managing Groups on page 3115.
3. Assign the user to the new group.
4. Grant group access to WAF, audit, and metrics in the compartment where the WAF policy resides.

Policy example:

- To allow the SOCMember group to manage WAF:

  Allow group SOCMember to manage waas-family in compartment <CompartmentName>
To allow the SOCMember group to read audit events:

```
Allow group SOCMember to read audit-events in compartment <CompartmentName>
```

To allow the SOCMember group to read metrics:

```
Allow group SOCMember to read metrics in compartment <CompartmentName>
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service on page 3049.

The following scripts in the SDK for Python on page 5373 enable you to provision an IAM user account with the correct permissions.

- **add_soc_user.py**
- **add_soc_group_policy.py**

**Python script example:**

```
python add_soc_user.py -c ~/.oci/config -u 'ddos.mitigation.specialist@oracle.com' -g DDoSMitigationGroup -f ~/.oci/ddos_public_key.pem
```

Where:
- `-c` is the tenancy configuration file
- `-u` is the username to be created
- `-g` is the group name to be created
- `-f` is the path to the public certificate to be attached to the user in PEM format

Debug options:
- `-h` shows help
- `-d` turns on debug mode

```
python add_soc_group_policy.py -c ~/.oci/config -g DDoSMitigationGroup -o ocid1.compartment.oc1..<unique_ID>
```

Where:
- `-c` is the tenancy configuration file
- `-g` is the existing group name to be used in IAM policy
- `-o` is the compartment of the WAF policy and where the IAM policy will be created

**DDoS Attack Report**

A DDoS attack report will be sent to you within a few days of the attack. The report contains metrics on the resources consumed by the attack and include all WAF policy changes made during the mitigation effort. This report is used by Oracle Cloud Infrastructure to review what possible service credits are available.

**Price Insurance Program**

You may be eligible for credits due to excessive consumption due to a DDoS attack. Refer to the Oracle PaaS and IaaS Public Cloud Services Pillar documentation for details. Contact your customer success manager for details on how to apply for credits.

**Monitoring**

For future monitoring, you can create an alarm definition in the Monitoring service that will alert you of high activity levels of HTTP traffic that could indicate another layer 7 DDoS attack. For more information, see Managing Alarms.
Web Application Firewall

on page 3523. Oracle Cloud Infrastructure automatically scrubs layer 3 and 4 attacks. If you suspect malicious activity that is not being properly remediated, go to My Oracle Support to open a service request to report your concerns.

HTTP WAF Headers

HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with X-, are common. The WAF service adds or modifies the following headers when it passes the requests to your servers or the response to the end users.

X-Client-IP

Contains the remote user IP address. If the webapp is using a CDN and has the feature "behind cdn" enabled, this IP is taken from one of the configured headers. While forwarding the request to the origin, WAF adds X-Client-IP.

X-Country-Code

Contains the geo location country code where the user's IP belongs to. While forwarding the request to the origin, WAF adds X-Country-Code.

Zen-Host: ZENEDGE

Identifies that the request was analyzed by a WAF node. While forwarding the request to the origin, WAF adds Zen-Host: ZENEDGE.

Request-Id

Identifies the request in the logs. While forwarding the request to the origin, WAF adds Request-Id.

Connection

If there is not a defined Connection value previously established (for example, "Upgrade" or "WebSocket"), WAF clears the Connection header by default. This header can be modified based on the available connection pool to "close" or "keep-alive". While forwarding the request to the origin, WAF modifies, adds, or removes Connection.

Accept-Encoding

In this header, WAF clears Accept-Encoding with an empty string. This means the header is not passed to the origin side as it comes from the user side. This header can be removed, based on WAF settings on response body inspection and caching. While forwarding the request to the origin, WAF modifies or adds or removes Accept-Encoding.

X-Cdn: Served-By-Zenedge

Our platform injects this header to say that we are handling the connection. While forwarding the response to the client, WAF adds X-Cdn: Served-By-Zenedge.

X-Zen-Fury

This header identifies the WAF node which processed the request via an encrypted token. While forwarding the response to the client, WAF adds X-Zen-Fury.

X-Cache-Status

WAF can act as a cache server. Based on the configuration, WAF can respect Cache-Control headers or cache based on the caching configuration rules. The status of the cache is reported via the X-Cache-Status response header. The value of the header can be one of the standard values: MISS, BYPASS, EXPIRED, STALE, UPDATING, REVALIDATED, or HIT. In addition, for never cache rules, a non-standard NOTCACHED value will be set.
**Cache-Control**

This header can be modified based on various user caching and Bot Management configurations. While forwarding the response to the client, WAF modifies or adds Cache-Control.

**Frequently Asked Questions**

Questions often asked about WAF.

**General**

General questions about WAF.

**What is the order in which rules and handlers are processed inside OCI WAF?**

1. IP Whitelists/Blacklists/Good Bot Whitelists
2. Threat Intelligence
3. Access Rules
4. Rate Limiting (available in the API)
5. JavaScript Challenge
6. Device Fingerprint Challenge
7. Human Interaction Challenge
8. CAPTCHA Challenge
9. Protection Rules
10. Caching Rules

**What ports are available to use with WAF?**

WAF supports ports 80 (for HTTP) and 443 (for HTTPS), however, after requests reach WAF on ports 80/443, we are able to send the requests to your origin server on any port necessary. The following is an example:

End User # Port 80/443 # WAF # Port 443/8000/555/### # Origin Server

**Can WAF be used to restrict specific IP addresses and CIDR ranges from within Oracle (instead of non-Oracle external IPs) from reaching the load balancer?**

Yes, the WAF Access Rules feature can be used to restrict specific IP addresses and CIDR ranges. If you have many prefixes, you can use address lists.

**Does WAF support other compression methods besides Gzip compression?**

No, all other compression methods that come to the infrastructure are forwarded unaltered to the origin.

**How long it takes for changes to propagate?**

- Changes usually take 10–30 minutes to propagate, depending on the change. It takes that long to propagate because we have hundreds of nodes where your new configurations are pushed to.
- The following is a list of feature changes which propagate within 10–15 minutes:
  - Bots policies
  - Human Interaction Challenge (HIC)
  - Device Fingerprint Challenge
  - Javascript Challenge
  - CAPTCHA Challenge
  - Good Bot Whitelist
  - Access Rules
  - Thread Intelligence
  - IP Lists
  - IP Whitelist

**Is IPv6 supported?**
No, IPv6 is not supported currently.

**Does WAF inspect the response body?**
Yes, WAF inspects, but doesn't alter the response body.

**Can you use WAF for traffic like SSH, FTP, or SMTP?**
No, WAF only allows HTTP traffic on ports 80 and 443. All other traffic and all other ports are blocked.

**What is the caching limit?**
The caching limit is 1 GB per policy.

**Is there a limit for "Additional Domains" that can be added to a WAF policy?**
No, limits do not exist on the number of domains that can be added.

Questions about file size upload limitations.

**Is there a maximum upload file size limitation for WAF?**
Yes, the limit is 1 GB.

**Does the limit effect certain file types (images, videos, binaries, and so on)?**
No, it doesn't depend on the type of upload.

**Does the Content-Type header effect the limit?**
No, only different protection rules are applied based on the Content-Type header.

**Does the limit affect only chunked uploads or stream uploads?**
Usually, uploads using chunked or streams do not affect the limit. In buffering mode, the limit is 1 GB for uploads and downloads. However, there are some other modes including streaming the response body, which disregards the 1-GB limit.

**Are the upload processes interrupted because of the node reloads? What is the root cause for upload errors with large files?**
No, reloads do not cause connection interruptions. However, after the reload, the next step is "cleanup," which is only run if the request or response cycle takes too long. It terminates the connection. Connection terminations rarely happen, but users with large uploads and slow connections are sometimes affected.

**What information do I need to know about using WAF with content streaming services?**
Since our protection rules require buffering of the full HTML content before analysis, streaming services might be affected. Streaming services might be effected because the entire content needs to be buffered within our protection rules core engine which might lead to slow responses or events not displaying the streaming content.

**Access Rules**
Questions about Access Rules.

**Is there a sequence of processing for "Access Rules" versus "IP Whitelist" tabs?**
Yes, IP whitelist is triggered first. If the IP address is not in the IP address allowlist, it then goes to access rules.

**Can I use wildcards for access rules specified in the “HTTP header contains” field?**
No, wildcards for this field are not currently supported.

**Which HTTP redirect response codes does WAF support?**
- 301 - Moved permanently: Use this response code if your website was permanently moved to the redirection URL and you want search engines to index it.
- 302 - Temporary redirect: Use this response code if a certain URL has been changed to a different address for a short amount of time.
Web Application Firewall

Is it possible to include CAPTCHA as an inline component in the website instead of an entry point?
Currently, you can only have CAPTCHA as a full page. It is not possible to include it as an inline component.

Can I reorder access rules?
No, access rule reordering is not currently supported. We advise taking this into consideration when creating an access rule with the BLOCK action.

Is the URL-based match in Access Rules the absolute URL (www.example.com/example.php) or relative URL (/example.php)?
The URL-based matching is for a location on the same domain. For example, “/login.php”. To target a full absolute URL, you can use a combination of header matching (Host:www.example.com) and URL “/login.php”.

For a URL-based match, is the scheme (http:// or https://) relevant, or is the FQDN enough?
The URL-based matching is for a location on the same domain. For example, “/login.php”. To target a full absolute URL, you can use a combination of header matching (Host:www.example.com) and URL “/login.php”.

How do you block everything except specific IP addresses?
The easiest way to allow only specific IPs is to create a single access rule to BLOCK if “IP Address not in Address list”. This rule blocks all traffic other than the IP addresses you have in your IP address lists. If you have other security features enabled, they will still be active, even for your IP addresses in the address list. To bypass all security measures, you need to add your IP addresses to the IP address whitelist.

Protection Rules
Questions about protection rules.

Do new WAF rule definitions get added or updated?
WAF policies are kept up to date with CRS and CVEs releasing new and updated definitions on a quarterly basis. Rule definitions in use will never be updated since they could cause unexpected behavior. New definitions are always pushed in an off state.

How can I exclude multiple cookies that end with the same string from inspection by WAF Protection Rules?
For this example, we received alerts from WAF Protection from values under multiple cookies:

123_SessionID=bad_value1; 456_SessionID=bad_value2; 789_SessionID=bad_value3; ...

Instead of adding each cookie manually, you can group them all in a "Regex" format:

2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click Protection Rules.
4. Click the Rules tab.
5. Find the protection rule you want to apply the exclusion to.
6. Click the Actions icon (three dots) and select Exclusions.
7. In the Exclusions dialog box, enter the following criteria:
   • Exclusion: Select request cookie values.
   • Value: Enter /_SessionID$/ This value matches all cookies that end with _SessionID triggering WAF rules with "bad_values."
8. Click Save Changes.

Is there any limit on the number of rules that can be enabled for a WAF policy?
Yes, you can only enable a maximum of 100 rules per WAF policy.

Why is my application slow when I have enabled all protection rules?
Each WAF rule adds CPU cycles to each transaction. The more rules you enable, regardless of the action (DETECT or BLOCK), slows transaction, especially with large payload transactions. We recommend that you only enable
the recommended WAF protection rules in DETECT mode and open a service request with My Oracle Support requesting OCI WAF tuning help before changing the rules to BLOCK. An expert will guide you through the process.

**Which protection rules require me to enable response body inspection?**

The following protection rule IDs require you to enable response body inspection:

90002  
90005  
90014  
90015  
90016  
90017  
90018  
90019

IP Address List
Questions about IP address lists.

Does IP Whitelist bypass every security measure?
Yes, IP Whitelist bypasses everything, including caching rules.

While adding an IP address to the WAF IP Address List, I received the following error: "Authorization failed or requested resource not found". Why am I receiving this error?
This error can occur when you do not have the correct policies set up to create an address list. To create an address list, manage permissions are required for waas-address-list. If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service on page 3049.

Logs
Questions about logs.

What is the log retention policy in WAF?
The log retention policy is seven days, however, you can request to set up an S3 bucket and have more logs delivered to it. The logs in your bucket can be kept as long as you want.

Do you support log delivery to ELK?
Log delivery is only supported to OCI and S3 buckets. Raw logs are sent to the buckets. From the buckets, you can implement them into elastic search.

What type of OCI Object Storage bucket can I deliver logs to?
Only "Standard" OCI buckets are supported. The "Archive" storage tier is not supported.

Certificates
Questions about certificates.

Are there any limitations when adding SSL certificates?

- Yes, each line except the last must contain exactly 64 printable characters. The final line must contain 64 or fewer printable characters. The text editor you use could save it differently and might have a different number of characters per line.
- To check how many characters there are per line, run following command: awk '{ print length }' filename.pem

Can I add an SSL certificate for another domain?
No, only one certificate per WAF policy is supported for the main domain. If you want to apply an SSL certificate for an extra domain, you need to create a separate WAF policy for it.

What SSL cipher suites are supported?
The following SSL cipher suites are supported:

ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES256-GCM8
ECDHE-ECDSA-AES256-CCM
ECDHE-ECDSA-AES128-GCM8
ECDHE-ECDSA-AES128-CCM
DHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-CCM8
DHE-RSA-AES256-CCM
DHE-RSA-AES128-GCM-SHA256
Troubleshooting and debugging

Questions about troubleshooting and debugging WAF.

What is the maximum upstream time to live (TTL) on the OCI WAF side? How can it be increased?

The maximum upstream timeout for WAF can be increased up to 1,200 seconds (20 minutes). By default, the timeout is set to 300 seconds. If you need to increase it, you need to create a service request in My Oracle Support with the following information:

- Tenancy ID
- Policy ID
- Webapp domain
- Upstream timeout time
- The reason why you need us to increase it

**Note:**

WAF has an internal 100-second timeout value (which is not changeable) that drops the connection if the origin doesn't send any keep-alive, stating that origin is still working on a response, "please wait." If the origin is sending keep-alives, you won't reach this type of timeout, since it always resets with keep-alive.

What do I do if my domain works by using an A record instead of the CNAME?

It is recommended that your APEX domains point to the IP address based on your server location:

- US: 147.154.3.128
- EU: 147.154.225.212
- APAC: 192.29.50.64
- AUS: 192.29.152.173

What value must I configure for the origin keep-alive timeout?

WAF requires that your origin's (load balancer or web server) keep-alive timeouts are maintained for 301 seconds or more, as our upstream timeout value is 300 seconds. During this time, the connections are safely maintained while TCP is optimized. The network multiplexing methodology our nodes use to maintain connectivity with your origin ensure that the connections are safely maintained while TCP is optimized. For more information, see Getting Started with WAF on page 5163.

Is Palo Alto firewall supported?

- OCI requires Palo Alto firewall to enable Jumbo frames as part of our PMTUd format and our MTU of 9000.
- Refer to Hanging Connection on page 4221 for troubleshooting information.
- Refer to Throughput troubleshooting with Palo Alto and OCI for Palo Alto's troubleshooting information.

Why is my API application responding with a 5XX HTTP status code?

Multiple factors can lead to a 5xx HTTP status code. Review the following information:

- The origin keep alive timeout must be 301 seconds.
• Session persistency must be cookie-based.
• IP affinity is a best practice as our nodes work in a round robin scenario and every 10 minutes the node IP potentially changes within the same transaction.
• If you have multiple WAF rules enabled and the transaction includes a large payload, it causes the transaction to timeout on the origin. The request is still in the WAF buffer and has been parsed before responding to the origin.
• One or more nodes are not fully whitelisted on the ingress rules from the origin side.
• One specific node is failing. In this case, immediately escalate the issue to our support team.

**Why is my website timing out?**

• Refer to [Why is my API application responding with a 5XX HTTP status code?](#) for a list of checkpoints.
• The timeout can also be related to the Whitelist (Security Lists or NSG). Review the following information:
  • Did you add the security lists to allow the OCI WAF nodes?
  • Are the rules stateless?
  • If the rules are stateless, did you add the respective egress rules?

**Command Line Interface (CLI)**

Questions about the CLI.

**Where can I find information on setting up the CLI?**

Refer to the following documentation for CLI-related topics:

• [Getting started with the CLI](#)
• [Command Line Reference for Web Application Acceleration and Security Services](#)
• [Web Application Acceleration and Security (WAAS) API](#)
• [OCI Cloud Shell Reference](#)

**Can I create or restore WAF policy backups?**

Yes, you can create or restore WAF policy backups with the OCI CLI. Extract the full JSON file of the web application and then re-create it in parts. We recommend that you re-create the main settings first and then the security challenges and features of the web application.

**How do I enable WebSocket for a specific URL through the CLI?**

To enable WebSocket for a specific URL, perform the following command:

```bash
oci waas policy-config update --waas-policy-id ocid1.waaspolicy.oc1..[WAAS POLICY OCID] --websocket-path-prefixes "[/url/url/websocket"]"
```

**Note:**

WebSocket support prevents WAF processing in the specified paths, which means that if a WAF rule is enabled it doesn't analyze the requests going to the URL excluded in the configuration. However, other countermeasures such as Human Interaction Challenge and JavaScript Challenge can be enabled to provide an extra layer of security for WebSocket URL.

I generated a JSON sample file (--generate-full-command-json-input|--generate-param-json-input) as input for my WAAS CLI commands through the PowerShell console, however, they are failing to load. Why am I getting a "Parameter 'from-json' must be in JSON format" error?
Ensure that the generated JSON file is saved with UTF-8 encoding. Older PowerShell versions might save JSON files with a different encoding.

**Does the "key" in Threat Intelligence Feed remain the same for all WAF policies?**

No, the "key" generated is different for each WAF policy.
Chapter 51

Developer Tools

This chapter includes general information about using the Oracle Cloud Infrastructure REST API and developer tools.

Developer Resources

This section provides reference documentation and tutorials for building applications that leverage Oracle Cloud Infrastructure.

- Developer Guide on page 5302
- Developer Tutorials
- API Reference

Developer Guide

Welcome to the Oracle Cloud Infrastructure Developer Guide.

This guide is intended to be a one-stop source for anyone interested in developing applications that leverage Oracle Cloud Infrastructure resources.

What's In This Guide

Here's an overview of what's in this guide:

- Introduction and overview (you are here)
- Quick-start walkthroughs that let you try out some of the SDKs using Cloud Shell
- How to setup SSH keys and configure the SDKs
- Working with Cloud Shell
- Working with the Command Line Interface (CLI)
- SDK references
- DevOps Tools and Plug-ins
- Other Tools
- Appendix and API Reference

Overview

Oracle Cloud Infrastructure provides kits, tools, and plug-ins to facilitate the development of apps and simplify the management of infrastructure.

- Cloud Shell Cloud Shell is a free-to-use browser-based terminal accessible from the Oracle Cloud Console that provides access to a Linux shell with pre-authenticated Oracle Cloud Infrastructure CLI and other useful developer tools. You can use the shell to interact with OCI resources, follow labs and tutorials, and quickly run OCI CLI commands.
- Command Line Interface (CLI) on page 5316 The CLI is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend the Console's functionality.
• **Software Development Kits and Command Line Interface** on page 5351 Oracle Cloud Infrastructure provides Software Development Kits (SDKs) to enable the development of apps and custom solutions.

• **Other Tools** on page 5504 These tools can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery. Tools include Terraform Provider used with Resource Manager.

• **API Reference and Appendices** on page 5528 This general reference shows how to configure the SDKs and other developer tools to integrate with Oracle Cloud Infrastructure services.

• **REST APIs** on page 5528 This complete reference provides details on the Oracle Cloud Infrastructure REST APIs, including descriptions, syntax, endpoints, errors, and signatures.

**Other Resources**

You can also stay up-to-date on the latest news on Oracle Cloud Infrastructure developer tools with these other resources and communities.

• **Oracle GraalVM Enterprise** is a JDK distribution designed to accelerate the execution of applications written in Java and other JVM languages while also providing a high-performance runtime for JavaScript, Ruby, Python, and a number of other popular languages. For more information, see Getting Started with GraalVM Enterprise on OCI.

**Setup and Prerequisites**

This section covers how to set up the required SSH keys to work with the OCI SDKs and developer toolkits as well as how to configure your SDKs.

What's included:

• **Required Keys and OCIDs** on page 5303

• **SDK and CLI Configuration File** on page 5308

**Required Keys and OCIDs**

Whether you're using an Oracle client (see Software Development Kits and Command Line Interface on page 5351) or a client you built yourself, you need to do the following:

1. Create a user in IAM for the person or system who will be calling the API, and put that user in at least one IAM group with any desired permissions. See "Adding Users" in the Oracle Cloud Infrastructure Getting Started Guide. You can skip this if the user exists already.

2. Get these items:
   • RSA key pair in PEM format (minimum 2048 bits). See How to Generate an API Signing Key on page 5304.
   • Fingerprint of the public key. See How to Get the Key's Fingerprint on page 5307.
   • Tenancy's OCID and user's OCID. See Where to Get the Tenancy's OCID and User's OCID on page 5308.

3. Upload the public key from the key pair in the Console. See How to Upload the Public Key on page 5308.

4. If you're using one of the Oracle SDKs or tools, supply the required credentials listed above in either a configuration file or a config object in the code. See SDK and CLI Configuration File on page 5308. If you're instead building your own client, see Request Signatures on page 5546.

**Important:**

This key pair is not the SSH key that you use to access compute instances. See Security Credentials on page 207.
Both the private key and public key must be in PEM format (not SSH-RSA format). The public key in PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQE...
...
-----END PUBLIC KEY-----
```

### How to Generate an API Signing Key

**Note:**

You can use the Console or command line tools available for Linux, Mac OS or Windows to generate an API signing key.

### Generating an API Signing Key (Console)

You can use the Console to generate the private/public key pair for you. If you already have a key pair, you can choose to upload the public key. When you use the Console to add the key pair, the Console also generates a configuration file preview snippet for you.

The following procedures work for a regular user or an administrator. Administrators can manage API keys for either another user or themselves.

**About the Config File Snippet**

When you use the Console to add the API signing key pair, a configuration file preview snippet is generated with the following information:

- **user** - the OCID of the user for whom the key pair is being added.
- **fingerprint** - the fingerprint of the key that was just added.
- **tenancy** - your tenancy's OCID.
- **region** - the currently selected region in the Console.
- **key_file** - the path to your downloaded private key file. You must update this value to the path on your file system where you saved the private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

You can copy this snippet into your config file, to help you get started. If you don't already have a config file, see [SDK and CLI Configuration File](#) on page 5308 for details on how to create one. You can also retrieve the config file snippet later for an API signing key whenever you need it. See: To get the config file snippet for an API signing key.

**To generate an API signing key pair**

**Prerequisite:** Before you generate a key pair, create the `.oci` directory in your home directory to store the credentials. See [SDK and CLI Configuration File](#) on page 5308 for more details.

1. View the user's details:
   - If you're adding an API key for yourself:
     
     Open the [Profile menu](#) and click [User Settings](#).
   - If you're an administrator adding an API key for another user: Open the navigation menu and click [Identity & Security](#). Under [Identity](#), click [Users](#). Locate the user in the list, and then click the user's name to view the details.

2. Click [Add API Key](#).
3. In the dialog, select [Generate API Key Pair](#).
4. Click **Download Private Key** and save the key to your `.oci` directory. In most cases, you do not need to download the public key.

   **Note:** If your browser downloads the private key to a different directory, be sure to move it to your `.oci` directory.

5. Click **Add**.

   The key is added and the **Configuration File Preview** is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config_file`. (If you have not yet created this file, see **SDK and CLI Configuration File** on page 5308 for details on how to create one.)

   After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:

   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

6. Update the permissions on your downloaded private key file so that only you can view it:

   a. Go to the `.oci` directory where you placed the private key file.
   b. Use the command `chmod go-rwx ~/.oci/<oci_api_keyfile>.pem` to set the permissions on the file.

**To upload or paste an API key**

**Prerequisite:** You have generated a public **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCQ8AMIIICgKCAQEHoTFgF...
....
-----END PUBLIC KEY-----
```

1. View the user's details:

   - If you're adding an API key for **yourself**:

     Open the **Profile menu** and click **User Settings**.

     - If you're an administrator adding an API key for **another user**: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select **Choose Public Key File** to upload your file, or **Paste Public Key**, if you prefer to paste it into a text box

4. Click **Add**.

   The key is added and the **Configuration File Preview** is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config_file`. (If you have not yet created this file, see **SDK and CLI Configuration File** on page 5308 for details on how to create one.)

   After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:

   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.
To get the config file snippet for an API signing key

The following procedure works for a regular user or an administrator.

1. View the user's details:
   - If you're getting an API key config file snippet for yourself:
     Open the Profile menu (_profile_image_ ) and click User Settings.
   - If you're an administrator getting an API key config file snippet for another user:
     Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click API Keys. The list of API key fingerprints is displayed.

3. Click the the Actions icon (three dots) for the fingerprint, and select View configuration file.

   The Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 5308 for details on how to create one.) After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:
   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

Generating an API Signing Key (Linux and Mac OS X)

Use the following OpenSSL commands to generate the key pair in the required PEM format.

1. If you haven't already, create an oci directory to store the credentials:
   ```
mkdir ~/.oci
   ```

2. Generate the private key with one of the following commands.
   - To generate the key, encrypted with a passphrase you provide when prompted:
     ```
     Note:
     We recommend that you use a passphrase for your key.
     
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```
   - To generate the key with no passphrase:
     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Change the file permission to ensure that only you can read the private key file:
   ```
   chmod go-rwx ~/.oci/oci_api_key.pem
   ```

4. Generate the public key from your new private key:
   ```
   openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
   ```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:
   ```
   cat ~/.oci/oci_api_key_public.pem | pbcopy
   ```
Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

Generating an API Signing Key (Windows)

If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

Note:
Be sure to include the openssl binary in your Windows path. On default installations, the openssl.exe file can be found in C:\Program Files \Git\mingw64\bin.

Use the following OpenSSL commands to generate the key pair in the required PEM format.

1. If you haven't already, create a .oci directory to store the credentials. For example:
   ```
   mkdir %HOMEDRIVE%%HOMEPATH%\.oci
   ```

2. Generate the private key with one of the following commands:
   - To generate the key that is encrypted with a passphrase you provide when prompted:
     ```
     openssl genrsa -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem -aes128 -passout stdin 2048
     ```
     
   - To generate the key with no passphrase:
     ```
     openssl genrsa -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem 2048
     ```

3. Generate the public key from your new private key:
   ```
   openssl rsa -pubout -in %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key.pem -out %HOMEDRIVE%%HOMEPATH%\.oci\oci_api_key_public.pem
   ```

4. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later). For example:
   ```
   type \.oci\oci_api_key_public.pem
   ```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

How to Get the Key's Fingerprint

You can get the key's fingerprint with the following OpenSSL command.

For Linux and Mac OS X:

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

For Windows:

Note:
If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.

```
openssl rsa -pubout -outform DER -in \.oci\oci_api_key.pem | openssl md5 -c
```
When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef

Where to Get the Tenancy's OCID and User's OCID

Both OCIDs are in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator. If you're not familiar with OCIDs, see Resource Identifiers.

Tenancy's OCID

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

User's OCID

Get the user's OCID in the Console on the page showing the user's details. To get to that page:

• If you're signed in as the user:
  Open the Profile menu and click User Settings.
  • If you're an administrator doing this for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Select the user from the list.
  • The user OCID is shown under User Information. Click Copy to copy it to your clipboard.

How to Upload the Public Key

You can upload the PEM public key in the Console, which can be accessed by signing in here: https://cloud.oracle.com. If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
   • If you're signed in as the user:
     Open the Profile menu and click User Settings.
   • If you're an administrator doing this for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Select the user from the list.
3. Click Add Public Key.
4. Paste the contents of the PEM public key in the dialog box and click Add.

Notice that after you've uploaded your first public key, you can also use the UploadApiKey API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

SDK and CLI Configuration File

Oracle Cloud Infrastructure SDKs and CLI require basic configuration information, like user credentials and tenancy OCID. You can provide this information by:

• Using a configuration file
• Declaring a configuration at runtime

Note:

You can use the Console to help generate a configuration file. For more information, see Generating an API Signing Key (Console) on page 5304.
The SDKs fully support both options. Refer to the documentation for each SDK for information about the config object and any exceptions when using a configuration file:

- Oracle Cloud Infrastructure SDK for Java Configuration
- Oracle Cloud Infrastructure SDK for Python Configuration
- Oracle Cloud Infrastructure SDK for Ruby Configuration
- Oracle Cloud Infrastructure SDK for Go Configuration
- Oracle Cloud Infrastructure SDK for TypeScript and JavaScript Configuration
- Oracle Cloud Infrastructure SDK for .NET Configuration

The CLI requires a configuration file, but also allows you to set environment variables to provide certain information. See CLI Environment Variables for more information.

**File Name and Location**

The default configuration file name and location is `~/.oci/config`.

**Note:**

On Windows, you can use PowerShell to create the folder with the following command: `mkdir %HOMEDRIVE%%HOMEPATH%\.oci`. File Explorer does not support creating folder names that start with a period.

**File Entries**

The following table lists the basic entries that are required for the configuration file, as well as where to get the required information.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the user calling the API. To get the value, see Required Keys and OCIDs. Example: <code>ocid1.user.oc1..&lt;unique_ID&gt;</code> (shortened for brevity)</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the public key that was added to this user.</td>
</tr>
<tr>
<td>key_file</td>
<td>Full path and filename of the private key. <strong>Important:</strong> The key pair must be in PEM format. For instructions, see Required Keys and OCIDs. Example (Linux/Mac OS): <code>~/.oci/oci_api_key.pem</code> Example (Windows): <code>%HOMEDRIVE%\%HOME%\.oci\oci_api_key.pem</code></td>
</tr>
<tr>
<td>pass_phrase</td>
<td>Passphrase used for the key, if it is encrypted. <strong>Caution:</strong> This entry is deprecated, and is included for backward compatibility only. Avoid saving confidential information in the configuration file. For additional security, pass the passphrase to the SDK/CLI at runtime.</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 5309
<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenancy</td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 5303. Example: ocid1.tenancy.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 208. Example: us-ashburn-1</td>
</tr>
</tbody>
</table>

**Custom Values**

Some Oracle Cloud Infrastructure SDKs support defining custom values in the configuration file. Refer to the documentation for each SDK for more information.

**Profiles and Inheritance**

You can create multiple profiles with different values for these entries, then you can specify which profile to load.

Some Oracle Cloud Infrastructure SDKs require a DEFAULT profile and support profile inheritance. This means that any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile. Refer to the documentation for each SDK for more information.

**Example Configuration**

The following example (for Linux and Mac OS) shows key values in a configuration file and how to set profiles for a SDK that supports profile inheritance.

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=./.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=keys/admin_key.pem
pass_phrase=<your_passphrase>
```

This example is for Windows:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=%HOMEDRIVE%%HOMEPATH%/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..<unique_ID>
fingerprint=<your_fingerprint>
key_file=keys/admin_key.pem
pass_phrase=<your_passphrase>
```

**SDK Quick Starts with Cloud Shell**

This section includes quick and easy no-setup walk-throughs that demonstrate how to use OCI developer tools and SDKs using Cloud Shell.
Developer Tools

• SDK for Python Cloud Shell Quick Start on page 5311
• SDK for Java Cloud Shell Quick Start on page 5311
• SDK for .NET Cloud Shell Quick Start on page 5312
• SDK for Go Cloud Shell Quick Start on page 5313
• SDK for TypeScript and JavaScript Cloud Shell Quick Start on page 5314
• SDK for Ruby Cloud Shell Quick Start on page 5316
• OCI Modules for PowerShell Cloud Shell Quick Start on page 5316

SDK for Python Cloud Shell Quick Start

This section discusses how to quickly get started with the Oracle Cloud Infrastructure SDK for Python using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Run Python:

   ```
   user@cloudshell:oci (us-phoenix-1)$ python3
   Python 3.6.8 (default, Oct 1 2020, 20:32:44)
   [GCC 4.8.5 20150623 (Red Hat 4.8.5-44.0.3)] on linux
   Type "help", "copyright", "credits" or "license" for more information.
   >>>
   ```

4. Run the following code sample to see your current Object Storage namespace:

   ```
   import oci
   object_storage_client =
   oci.object_storage.ObjectStorageClient(oci.config.from_file())
   result = object_storage_client.get_namespace()
   print("Current object storage namespace: {}".format(result.data))
   ```

   This will return output similar to the following:

   ```
   Current object storage namespace: mynamespace
   ```

SDK for Java Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Java using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a working directory and move to it:

   ```
   mkdir java_demo
   cd java_demo
   ```

4. Copy a pre-installed example (also available from github) from the OCI Java SDK examples/ folder to your working directory:

   ```
   cp $OCI_JAVA_SDK_LOCATION/examples/ListDBVersionExample.java .
   ```

5. Compile the example:

   ```
   javac -cp .:$OCI_JAVA_SDK_FULL_JAR_LOCATION:$OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample.java
   ```
6. Run the example:

```
java -cp .:OCI_JAVA_SDK_FULL_JAR_LOCATION:OCI_JAVA_SDK_LOCATION/third-party/lib/* ListDBVersionExample $OCI_TENANCY $OCI_TENANCY BM.HighIO1.36
```

This will return output similar to the following:

```
SLF4J: Failed to load class "org.slf4j.impl.StaticLoggerBinder".
SLF4J: Defaulting to no-operation (NOP) logger implementation
SLF4J: See http://www.slf4j.org/codes.html#StaticLoggerBinder for further details.
DB Versions Fetched for Shape ocid1.tenancy.oc1..aaaaaaayexample and compartment ocid: BM.HighIO1.36
[DbVersionSummary(version=11.2.0.4, isLatestForMajorVersion=true, supportsPdb=false, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
 DbVersionSummary(version=12.1.0.2, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
 DbVersionSummary(version=12.2.0.1, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
 DbVersionSummary(version=18.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
 DbVersionSummary(version=19.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=true, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb]),
 DbVersionSummary(version=21.0.0.0, isLatestForMajorVersion=true, supportsPdb=true, isPreviewDbVersion=false, isUpgradeSupported=false, __explicitlySet__=[isPreviewDbVersion, isUpgradeSupported, isLatestForMajorVersion, version, supportsPdb])]
```

### SDK for .NET Cloud Shell Quick Start

This topic explains how to quickly get started with the Oracle Cloud Infrastructure SDK for .NET using Cloud Shell.

1. **Login to the Console.**
2. **Click the Cloud Shell icon in the Console header.** Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. **Create a working directory and move to it:**

```
mkdir DotnetDemo && cd DotnetDemo
```
4. **Create a new .NET console application project:**

```
dotnet new console
```
5. Add the `OCI.DotNetSDK.Objectstorage` package to your project.

```bash
dotnet add package OCI.DotNetSDK.Objectstorage --source /usr/lib/dotnet/NuPkg/
```

 Optionally, you can include the `--source` parameter, which will fall back to retrieving the package from the pre-installed location (`/usr/lib/dotnet/NuPkg/`) if it cannot be downloaded from nuget.org.

**Note:**
To bypass nuget.org and force usage of the pre-installed .NET SDK, you can use the `nuget.config` provided in step 2a of the instructions here.

6. Add the following code to the `Program.cs` file:

```csharp
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Oci.ObjectstorageService;
using Oci.ObjectstorageService.Requests;
using Oci.ObjectstorageService.Responses;
using Oci.Common.Auth;

namespace DotnetDemo
{
    public class Program
    {
        static void Main(string[] args)
        {
            var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
            var compartmentId = Environment.GetEnvironmentVariable("OCI_TENANCY");
            var objectStorageClient = new ObjectStorageClient(provider);

            Task<GetNamespaceResponse> getNamespaceResponse =
                objectStorageClient.GetNamespace(new GetNamespaceRequest());
            Console.WriteLine(getNamespaceResponse.Result.Value);
        }
    }
}
```

7. Run the example:

```bash
dotnet run
```

**SDK for Go Cloud Shell Quick Start**

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Go using Cloud Shell. The OCI Go SDK is pre-installed in the Cloud Shell environment and included in your `$GOPATH`.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named `main.go` with the following code, which will list the availability domains in your tenancy:

```go
package main

import (
    "context"
    "fmt"
)
func main() {
    c, err :=
        identity.NewIdentityClientWithConfigurationProvider(common.DefaultConfigProvider())
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    // The OCID of the tenancy containing the compartment.
    tenancyID, err := common.DefaultConfigProvider().TenancyOCID()
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    request := identity.ListAvailabilityDomainsRequest{
        CompartmentId: &tenancyID,
    }

    r, err := c.ListAvailabilityDomains(context.Background(), request)
    if err != nil {
        fmt.Println("Error:", err)
        return
    }

    fmt.Printf("List of available domains: %v", r.Items)
}

4. Run the example:

go run main.go

SDK for TypeScript and JavaScript Cloud Shell Quick Start

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript using Cloud Shell. The OCI SDK for TypeScript and JavaScript SDK is pre-installed globally through npm.

JavaScript Example

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named region_subscriptions_example.js with the following example code, which lists the subscribed regions for your current tenancy:

```javascript
const identity = require("oci-sdk/node_modules/oci-identity");
const common = require("oci-sdk/node_modules/oci-common");
const provider = new common.ConfigFileAuthenticationDetailsProvider();
const compartmentId = provider.getTenantId() || ";

let identityClient;

async function getSubscriptionRegions(tenancyId) {
    const regions = await identityClient.listRegionSubscriptions({
        tenancyId: tenancyId
    });
```
return regions.items.map(region => {
    return region.regionName;
});
}

(async () => {
    identityClient = await new identity.IdentityClient({
        authenticationDetailsProvider: provider
    });
    
    const regions = await getSubscriptionRegions(compartmentId);
    console.log("Currently subscribed to the following region(s): ", regions);
})();

4. Run the example:

   node region_subscriptions_example.js

TypeScript Example

This TypeScript example will list the subscribed regions for the current tenancy.

1. Create an empty project named ts_demo and link the global installation of oci-sdk library using the following commands:

   # create a new project folder and move into it
   mkdir ts_demo
   cd ts_demo

   # initialize a new javascript/typescript project
   npm init --y

   # link the global installation of oci-sdk to the current project
   npm link oci-sdk
   npm link @types/node

2. Create a file named region_subscriptions_example.ts inside your ts_demo project with the following code:

   import * as identity from "oci-sdk/node_modules/oci-identity";
   import common = require("oci-sdk/node_modules/oci-common");
   const provider: common.ConfigFileAuthenticationDetailsProvider = new
   common.ConfigFileAuthenticationDetailsProvider();
   const compartmentId = provider.getTenantId();
   let identityClient: identity.IdentityClient;

   export async function getSubscriptionRegions(tenancyId: string) {
       const listRegionSubscriptionsRequest:
       identity.requests.ListRegionSubscriptionsRequest = {
           tenancyId: tenancyId
       };

       const regions = await
       identityClient.listRegionSubscriptions(listRegionSubscriptionsRequest);
       return regions.items.map(region => {
           return region.regionName;
       });
   }
   
   (async () => {
   

identityClient = await new identity.IdentityClient({ authenticationDetailsProvider: provider });
const regions = await getSubscriptionRegions(compartmentId);
console.log("Currently subscribed to the following region(s): ", regions)
})

3. Compile the example:

```
# use the TypeScript compiler to compile the example
tsc region_subscriptions_example.ts
```

4. Run the example:

```
# run the example using node
node region_subscriptions_example.js
```

**SDK for Ruby Cloud Shell Quick Start**

This quick start shows you how to quickly get started running sample code with the Oracle Cloud Infrastructure SDK for Ruby using Cloud Shell. The OCI SDK for Ruby is installed in the cloud shell environment and automatically added to your GEM_PATH.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. Create a file named list_users_example.rb with the following code, which lists the users in your tenancy:

```
require 'oci'
api = OCI::Identity::IdentityClient.new()
response = api.list_users(OCI.config.tenancy)
response.data.each { |user| puts user.name }
```

4. Run the example:

```
ruby list_users_example.rb
```

**OCI Modules for PowerShell Cloud Shell Quick Start**

This topic discusses how to quickly get started with the Oracle Cloud Infrastructure Modules for PowerShell using Cloud Shell.

1. Login to the Console.
2. Click the Cloud Shell icon in the Console header. Note that Cloud Shell will execute commands against the region selected in the Console's Region selection menu when Cloud Shell was started.
3. From the Cloud Shell session's command prompt, start the PowerShell environment:

```
user@cloudshell:oci (us-phoenix-1)$ pwsh
```

4. Run the following command to get the current object storage namespace:

```
Get-OCIObjectstorageNamespace
```

**Command Line Interface (CLI)**

The CLI is a small-footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend Console functionality.
Tip:

**Cloud Shell:** The CLI is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the CLI from within Cloud Shell, see [Getting Started with Cloud Shell](#).

**Oracle Linux Cloud Developer image:** The CLI is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see [Oracle Linux Cloud Developer](#).

This CLI and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

The CLI is built on the Oracle Cloud Infrastructure SDK for Python and runs on Mac, Windows, or Linux. The Python code makes calls to Oracle Cloud Infrastructure APIs to provide the functionality implemented for the various services. These are REST APIs that use HTTPS requests and responses. For more information, see [About the API](#).

**Installation:** See [Quickstart](#) on page 5320.

**Reference:** For help with a specific command, you can enter `help <command>` on the command line or view the [Command Line Reference](#). This reference is derived from the APIs and help text in the Python source code.

**Requirements**

To install and use the CLI, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This account user can be you, another person, or a system that calls the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](#). For a list of other typical Oracle Cloud Infrastructure policies, see [Common Policies](#).
- A keypair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. See [Configuring the CLI](#).

**Note:**

To use the CLI without a keypair, you can use token-based authentication. For more information, see [Token-based Authentication for the CLI](#) on page 5325.

- A supported version of Python on a supported operating system.
- If you require FIPS-compliance, see [Using FIPS-validated Libraries](#) on page 5332.

**Supported Python Versions and Operating Systems**

The CLI supports Python versions 3.6 and later running on MacOS, Windows, or supported Linux and UNIX-like operating systems:

- Oracle Linux 6.10, Oracle Linux 7.7 and 7.8, and Oracle Linux 8.0
- Oracle Autonomous Linux 7.8
- Oracle Linux Cloud Developer 8.x
- CentOS 7.0 and CentOS 8.x
- Ubuntu 16.04, Ubuntu 18.04, and Ubuntu 20.04

**Note:**

You need to upgrade to Python version 3.6 or later to continue receiving support from Oracle. OCI support for Python version 2.x is being deprecated. Versions of the OCI CLI released after August 1st, 2021, (version 3.x.x and later), will not work with Python version 2.7. Versions of the OCI CLI released before August 1st 2021, (version 2.x.x), will continue
to work with Python versions 2.7 by setting the environment variable OCI_CLI_ALLOW_PYTHON2 to True.

Newer versions of Python may not be immediately supported. The CLI might work on unlisted operating systems, but we do not test them for compatibility.

If you use the CLI installer and do not have Python on your machine, the installer offers to automatically install Python for you. If you already have Python installed on your machine, you can use the python --version command to find out which version is installed.

**Services Supported**

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data
- Blockchain Platform
- Budgets
- Cloud Guard
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content Management
- Core Services (Networking, Compute, Block Volume)
- Database Migration
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- DevOps
- Digital Assistant
- DNS
- Email Delivery
- Events
- Functions
- File Storage
- Generic Artifacts
- Golden Gate
- Health Checks
- IAM
- Integration
- Java Management
- Key Management (for the Vault service)
Developer Tools

- Limits
- Load Balancing
- Logging
- Logging Analytics
- Logging Search
- Logging Ingestion
- Management Agent Cloud
- Management Dashboard
- Marketplace
- Monitoring
- MySQL Database
- Network Load Balancing
- Networking Topology
- NoSQL Database Cloud
- Notifications
- Object Storage
- OCI Registry
- Organizations
- Operations Insights
- Operator Access Control
- Optimizer
- OS Management
- Quotas
- Resource Manager
- Search
- Secret Management (for the Vault service)
- Secret Retrieval (for the Vault service)
- Service Catalog
- Service Connector Hub
- Streaming
- Support Management
- Usage
- VMWare Solution
- Web Application Acceleration and Security
- Work Requests (Compute, Database)

Quickstart

Using the installer script and the setup command is the fastest way to get up and running with the CLI.

Installing the CLI

The installer script automatically installs the CLI and its dependencies, Python and virtualenv. Before running the installer, be sure you meet the Requirements on page 5317.

Note:

Oracle Autonomous Linux 7, Oracle Linux Cloud Developer 8, and Cloud Shell have the CLI pre-installed.

Linux and Unix

1. Open a terminal.
2. To run the installer script, run the following command.

```
```

Note:

To run a 'silent' install that accepts all default values with no prompts, use the `--accept-all-defaults` parameter.

Oracle Linux 8

If you're using Oracle Linux 8, you can use dnf to install the CLI.

Note:

We strongly recommend running `sudo dnf update` regularly to ensure your system is up-to-date by installing available updated RPMs.

To use dnf to install the CLI:

```
sudo dnf -y install oraclelinux-developer-release-el8
sudo dnf install python36-oci-cli
```

The CLI will be installed to the Python site packages:

- `/usr/lib/python3.6/site-packages/oci_cli`
- `/usr/lib/python3.6/site-packages/services`

Documentation and examples will be installed in the `/usr/share/doc/python36-oci-cli-<version>/` directory.

To uninstall the CLI:

```
sudo dnf remove python36-oci-cli
```

Oracle Linux 7

If you're using Oracle Linux 7, you can use yum to install the CLI.

To use yum to install the CLI:

```
sudo yum install python36-oci-cli
```
The CLI will be installed to the Python site packages:

- /usr/lib/python3.6/site-packages/oci_cli
- /usr/lib/python3.6/site-packages/services

Documentation and examples will be installed in the /usr/share/doc/python36-oci-cli-<version>/ directory.

To uninstall the CLI:
```
sudo yum remove python36-oci-cli
```

**Mac OS X**

You can use Homebrew to install, upgrade, and uninstall the CLI on Mac OS.

To install the CLI on Mac OS X with Homebrew:
```
brew update && brew install oci-cli
```

To upgrade your CLI install on Mac OS X using Homebrew:
```
brew update && brew upgrade oci-cli
```

To uninstall the CLI on Mac OS X using Homebrew:
```
brew uninstall oci-cli
```

**Windows**

1. Open the PowerShell console using the **Run as Administrator** option.
2. The installer enables auto-complete by installing and running a script. To allow this script to run, you must enable the RemoteSigned execution policy.
   
   To configure the remote execution policy for PowerShell, run the following command.
   
   ```
   Set-ExecutionPolicy RemoteSigned
   ```

3. Download the installer script:
   
   ```
   ```

4. Run the installer script with or without prompts:
   
   a. To run the installer script with prompts, run the following command:
      
      ```
      ```
      
      ...and respond to the **Installation Script Prompts** on page 5321.

   b. To run the installer script without prompting the user, accepting the default settings, run the following command:
      
      ```
      install.ps1 -AcceptAllDefaults
      ```

**Installation Script Prompts**

The installation script prompts you for the following information.
If you do not have a compatible version of Python installed:

- Windows and Linux: You are prompted to provide a location for installing the binaries and executables. The script will install Python for you.
- MacOS: You are notified that your version of Python is incompatible. You must upgrade before you can proceed with the installation. The script will not install Python for you.
- When prompted to upgrade the CLI to the newest version, respond with `Y` to overwrite an existing installation.
- When prompted to update your PATH, respond with `Y` to be able to invoke the CLI without providing the full path to the executable. This will add oci.exe to your PATH.

**Setting up the Config File**

Before using the CLI, you must create a config file that contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup dialog or manually using a text editor.

**Use the Setup Dialog**

To have the CLI walk you through the first-time setup process, use the `oci setup config` command. The command prompts you for the information required for the config file and the API public/private keys. The setup dialog generates an API key pair and creates the config file.

For more information about how to find the required information, see:

- [Where to Get the Tenancy's OCID and User's OCID](#) on page 5308
- [Regions and Availability Domains](#) on page 208

**Manual Setup**

If you want to set up the API public/private keys yourself and write your own config file, see [SDK and Tool Configuration](#).

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the <code>oci setup keys</code> command to generate a key pair to include in the config file.</td>
</tr>
</tbody>
</table>

**Next Steps**

- For details on starting a session, see [Starting a CLI Session](#) on page 5333.
- [Getting Started with the Command Line Interface](#) provides an end-to-end walk-through of using the CLI to launch an instance.

**Manual and Offline Installations**

Instead of using the installer script as described in the [Quickstart](#) on page 5320, you can manually install the CLI and its dependencies. Before proceeding, be sure you meet the [Requirements](#) on page 5317.

You can also download the CLI installation files and perform an offline installation.

**Step 1: Installing Python**

Python installation instructions vary for each operating system that the CLI supports.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The CLI supports only the Python versions listed in the <a href="#">CLI Requirements</a>.</td>
</tr>
</tbody>
</table>

**Windows**

Install a supported version of Python from the [Python Windows downloads](#) page. During installation, choose to add Python to the PATH and/or environment variables (depending on the prompt).

**Oracle Linux**
Some versions of Oracle Linux come with incompatible versions of Python, and might require additional components to install the CLI. Before installing the CLI, run the following commands on a new Oracle Linux image.

**Tip:**
Oracle Autonomous Linux 7 and Oracle Linux Cloud Developer 8 come with the CLI pre-installed.

### Oracle Linux 7 and Oracle Linux 8

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
  ./configure --enable-optimizations
  sudo make altinstall
```

### Oracle Linux 6

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.6.3/Python-3.6.3.tgz
tar xvf Python-3.6.3.tgz
cd Python-3.6*/
  ./configure --enable-optimizations
  sudo make altinstall
```

### CentOS

Before you install the CLI, run the following commands on a new CentOS image.

### CentOS 7, CentOS 8

```
sudo yum -y update
sudo yum -y groupinstall "Development Tools"
sudo yum -y install gcc wget openssl-devel bzip2-devel libffi-devel
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar xvf Python-3.8.3.tgz
cd Python-3.8*/
  ./configure --enable-optimizations
  sudo make altinstall
```

### Ubuntu

Before you install the CLI, run the following commands on a new Ubuntu image.

### Ubuntu 16, Ubuntu 18, and Ubuntu 20

```
sudo apt update
sudo apt install build-essential zlib1g-dev libncurses5-dev libgdbm-dev
libnss3-dev libssl-dev libreadline-dev libffi-dev libsqlite3-dev wget
libbz2-dev
wget https://www.python.org/ftp/python/3.8.3/Python-3.8.3.tgz
tar -xf Python-3.8.3.tgz
cd Python-3.8.3
  ./configure --enable-optimizations
  sudo make altinstall
```
Mac OS X

Mac OS X comes with Python pre-installed.
To install the latest version of Python on Mac OS X, see the official Python documentation.

**Step 2: Creating and Configuring a Virtual Environment**

The [venv](https://docs.python.org/3/library/venv.html) Python module is a virtual environment builder that lets you create isolated Python environments. We recommend installing the CLI in a virtual environment.

**Installing and Activating your Virtual Environment**

After Python is installed, set up a virtual environment for your operating system using the following steps.

**Windows**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running the following command:
   ```sh
   python -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:
   ```sh
   oracle-cli/Scripts/activate
   ```

**Linux and Mac**

1. Navigate to the directory in which you would like to create the virtual environment.
2. Create the virtual environment by running one of the following commands, depending on the version of Python installed:
   ```sh
   python3.8 -m venv oracle-cli
   python3.6 -m venv oracle-cli
   ```
3. Activate the virtual environment by running the following command:
   ```sh
   source oracle-cli/bin/activate
   ```

**Step 3: Installing the Command Line Interface**

You can download the CLI from GitHub or install the package from Python Package Index (PyPI).

To install using the GitHub download:
- Download and unzip `oci-cli.zip`.
- Run the following command.
  ```sh
  pip install oci-cli-*-py2.py3-none-any.whl
  ```

To install using PyPI, run the following command:

```sh
pip install oci-cli
```

For information on how to start a CLI session, see [Starting a CLI Session](#) on page 5333.

**Installing Without a Virtual Environment**

We do not recommend installing the CLI in your system-wide Python and suggest that instead you install the CLI using the installer or virtual environment.
In cases where you are trying to install the CLI in your system-wide Python using the latest pip version, you might encounter conflicts with some distutils installed packages. Following is an example error message when this occurs:

```
sudo pip install oci-cli
...  
Cannot uninstall 'requests'. It is a distutils installed project and thus we cannot accurately determine which files belong to it which would lead to only a partial uninstall.
```

Another option is to install the CLI for the user using the following command, although this approach is not supported:

```
pip install --user oci-cli
```

**Offline Installation**

If you have Python 3 installed, you can perform an offline installation of the OCI CLI.

To perform an offline installation:

1. Go to the OCI CLI release page on GitHub and select the version of the CLI that you want to install.
2. Scroll down to the Assets section of the release page and click on the zip file to download it.
3. Copy the zip file to the target system.
4. Unzip the zip file.
5. Run the appropriate installer for the platform:
   a. On Unix and Linux, run `bash install.sh --offline-install`
   b. On Windows, run `install.ps1 -OfflineInstall`
6. Follow the installation prompts.

For troubleshooting offline installs, see Common Issues or create an issue on GitHub.

**Token-based Authentication for the CLI**

Token-based authentication for the CLI allows customers to authenticate their session interactively, then use the CLI for a single session without an API signing key. This enables customers using an identity provider that is not SCIM-supported to use a federated user account with the CLI and SDKs.

**Requirements**

The requirements are the same as those listed for the CLI in Requirements on page 5317, except that instead of a SSH keypair, you need a web browser for the authentication process.

**Starting a Token-based CLI Session**

To use token-based authentication for the CLI on a computer with a web browser:

1. In the CLI, run the following command. This will launch a web browser.
   ```
   oci session authenticate
   ```

2. In the browser, enter your user credentials. This authentication information is saved to the `.config` file.

**Validating a Token**

To verify that a token is valid, run the following command:

```
oci session validate --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

You should receive a message showing the expiration date for the session. If you receive an error, check your profile settings.
**Refreshing a Token**

The default token TTL is set to 1 hour before it expires and can be refreshed within the validity period up to 24 hours. To refresh the token, run the following command:

```bash
ci session refresh --profile <profile_name>
```

**Starting a Token-based CLI Session without a Browser**

To use token-based authentication for the CLI on a computer without a web browser, you must export a session from a web-enabled computer, then import it to the computer without a web browser.

**Exporting from Source Computer**

On the source computer with the browser:

1. In the CLI, run the following command:

   ```bash
ci session authenticate
   ```

2. Enter the user credentials you wish to use on the target computer.

3. To export a zip file, run the following command:

   ```bash
ci session export --profile <profile_name> --output-file <output_filename>
   ```

To verify the export, see [Validating a Token](#) on page 5325.

**Importing to Target Computer**

On the target computer without the browser, run the following command in the CLI:

```bash
ci session import --session-archive <path_to_exported_zip>
```

You can test the import by running the following:

```bash
ci iam region list --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

It should return a list of regions. Successful execution of this command verifies that the token authentication is working as expected.

**Running Scripts on a Computer without a Browser**

After importing the authentication to the target computer, you can run the CLI and SDKs by using the following settings.

**For CLI**

To run scripts on the CLI, append the following suffix:

```bash
--config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

**For SDKs**

To run SDKs on the target computer, you must read in the token file, then use it to initialize the SecurityTokenSigner.

After creating a token file as shown in [Starting a Token-based CLI Session](#) on page 5325, use the following process.
Note:
These code samples demonstrate how to accomplish this using the Oracle Cloud Infrastructure SDK for Python. For other SDKs, follow the same process, but adjust the syntax accordingly.

1. Read the token file from the `security_token_file` parameter of the `.config` file.

   ```python
   config = oci.config.from_file(profile_name='TokenDemo')
   token_file = config['security_token_file']
   token = None
   with open(token_file, 'r') as f:
       token = f.read()
   ```

2. Read the private key specified by the `.config` file.

   ```python
   private_key = oci.signer.load_private_key_from_file(config['key_file'])
   ```

3. Create the initial SDK client which targets the user-specified region.

   ```python
   signer = oci.auth.signers.SecurityTokenSigner(token, private_key)
   client = oci.identity.IdentityClient({'region': region}, signer=signer)
   ```

4. Make the identity request.

   ```python
   result = client.list_region_subscriptions(config['tenancy'])
   ```

Configuring the CLI

You can use these optional configurations to extend CLI functionality. The CLI supports using a file for CLI-specific configurations. You can:

- Specify a default profile.
- Set default values for command options so you don't have to type them into the command line.
- Define aliases for commands. For example, using "ls" as an alias for list.
- Define aliases for options. For example, using "--ad" as an alias for --availability-domain.
- Define named queries that are passed to the --query option instead of typing a JMESPath expression on the command line.

The CLI also supports the use of environment variables to specify defaults for some options. See CLI Environment Variables for more information.

**CLI Configuration File**

The default location and file name for the CLI-specific configuration file is `~/.oci/oci_cli_rc`, but you can use the OCI_CLI_RC_FILE environment variable to modify where the CLI looks for a configuration file and its default values upon startup.

You can also explicitly specify a CLI configuration file with the `--cli-rc-file` option or with the legacy `--defaults-file` option. For example:

```
# Uses the file from ~/.oci/oci_cli_rc
# or OCI_CLI_RC_FILE environment variable
oci os bucket list

# Uses a custom file
oci os bucket list --cli-rc-file path/to/my/cli/rc/file
```

To set up an oci_cli_rc file, run the following command.

```
oci setup oci-cli-rc --file path/to/target/file
```
This command creates the file you specify that includes examples of default command aliases, parameter aliases, and named queries.

**Note:**

If you are using Windows, you should use backslash as the directory separator in pathnames, instead of the forward slash.

**Specifying a Default Profile**

Specify a default profile in the `OCI_CLI_SETTINGS` section of the CLI configuration file. The next example shows how to specify a default profile named IAD. The CLI looks for a profile named IAD in your `~/.oci/config` file, or any other file that you specify using the `--config-file` option or the `OCI_CLI_CONFIG_FILE` environment variable.

```
[OCI_CLI_SETTINGS]
default_profile=IAD
```

You can also specify a default profile by using the `--profile` option or by setting the `OCI_CLI_PROFILE` environment variable.

If a default profile value has been specified in multiple locations, the order of precedence is:

1. The value specified in the `--profile` option.
2. The value specified in the `OCI_CLI_PROFILE` environment variable.
3. The value specified in the `default_profile` field in the `OCI_CLI_SETTINGS` section of the CLI configuration file.

**Specifying Default Values**

The CLI supports using default values so that you don't have to keep typing every value into the command line. For example, instead of typing in a `--compartment-id` on each launch instance command or having to keep specifying the `--namespace` when using Object Storage commands. You can specify this information in a default values file.

Default values can be applied at different levels, from general to specific:

- Globally, across all the CLI commands.
- To a particular service, such as Compute or Object Storage.
- To a specific group, such as commands related to exporting images.
- To a specific command.

Default values are treated hierarchically, with specific values having a higher order of precedence than general values. For example, if there is a globally defined value for `compartment-id` and a specific `compartment-id` defined for the `compute instance launch` command, the CLI uses the value for the `compute instance launch` instead of the global default.

**Command Value Priority**

If a value is provided on the command line also exists in `--cli-rc-file`, the value from the command line has priority. For a command with options that take multiple values, the values are taken entirely from the command line or from `--cli-rc-file`. The 2 sources aren't merged.

**Defaults Value File Syntax**

The `--cli-rc-file` file can be divided into different sections with one or more keys per section.
Sections

In the next example, the file has two sections, with a key in each section. To specify which section to use, you use the --profile option in the CLI.

```
[DEFAULT]
compartment-id = ocid1.compartment.oc1..<unique_ID_1>

[ANOTHER_SECTION]
compartment-id = ocid1.compartment.oc1..<unique_ID_2>
```

Keys

Keys are named after command line options, but do not use a leading double hyphen (--). For example, the key for --image-id is image-id. You can specify keys for single values, multiple values, and flags.

- Keys for Single Values. The next example shows how to specify key values at different levels, and with different scope.

```
[DEFAULT]
# Defines a global default for bucket-name
bucket-name = my-global-default-bucket-name

# Defines a default for bucket-name, which applies to all 'compute' commands
compute.bucket-name = bucket-name-for-image-import-export

# Defines a default for bucket-name, which applies to all 'os object' commands (e.g., os object get)
os.object.bucket-name = bucket-name-for-object-commands

# Defines a default for bucket-name, for the 'os object multipart list' command
os.object.multipart.list.bucket-name = bucket-name-for-multipart-list
```

- Keys for Multiple Values. Some options, such as --include and --exclude on the oci os object bulk-upload command can be specified more than once. For example:

```
oci os object bulk-upload -ns my-namespace -bn my-bucket --src-dir my-directory --include *.txt --include *.png
```

The next example shows how you would enter the --include values in the --cli-rc-file file

```
[DEFAULT]
os.object.bulk-upload.include =
  *.txt
  *.png
```

In the previous example, one value is given for each line and each line must be indented underneath its key. You can use tabs or spaces and the amount of indentation doesn't matter. You can also put a value on the same line as the key, add more values on the following lines, and use a path statement for a value. For example:

```
[DEFAULT]
os.object.bulk-upload.include = *.pdf
  *.txt
  *.png
  my-subfolder/*.tiff
```
• Keys for Flags. Some command options are flags, like `--force`, which uses a Boolean value. To set a flag for the `--force` option, use the following command.

```
os.object.delete.force=true
```

**Specifying Command Aliases**

Specify named queries in the `OCI_CLI_COMMAND_ALIASES` section of the CLI configuration file. There are two types of aliases, global aliases and command sequence aliases. The following example shows each type of alias.

```
[OCI_CLI_COMMAND_ALIASES]
# This is a global alias that lets you use "ls" instead of "list" for any
# list command in the CLI.
#
ls = list
#
# Command examples:
# oci os object ls or oci os compute ls
#
# This is a command sequence alias that lets you use "oci os object rm"
# instead of "oci os
# object delete".
# <alias> = <dot-separated sequence of groups and sub-groups>.<command or
# group to alias>
#
rm = os.object.delete
#
# Command example:
# <alias> = rm, <sequence of groups and sub-groups> = os object, <command or
# group to alias> = delete
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `-ls` as an alias for `--list`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.ls.compartment-id=ocid1.compartment.oc1..<unique_ID>
```

**Specifying Option Aliases**

Specify option aliases in the `OCI_CLI_PARAM_ALIASES` section of the CLI configuration file. Option aliases are applied globally. The following example shows some aliases for command options.

```
[OCI_CLI_PARAM_ALIASES]
# Option aliases either start with a double hyphen (--), or are a single
# hyphen (-) followed by a single letter. For example: --example-alias, -e
#
--ad = --availability-domain
--dn = --display-name
--egress-rules = --egress-security-rules
--ingress-rules = --ingress-security-rules
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `--ad` as an alias for `--availability-domain`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.list.ad=xyx:PHX-AD-1
```
### Specifying Named Queries

If you use the `--query` parameter to filter or manipulate output, you can define named queries instead of using a JMESPath expression on the command line.

Specify named queries in the `OCI_CLI_CANNED_QUERIES` section of the CLI configuration file.

#### Examples of Named Queries

```json
[OCI_CLI_CANNED_QUERIES]
# For list results, this gets the ID and display-name of each item in the list.
# Note that when the names of attributes have dashes in them they need to be surrounded
# with double quotes. This query knows to look for a list because of the `[*]` syntax
get_id_and_display_name_from_list=data[*].{id: id, "display-name": "display-name"

get_id_and_display_name_from_single_result=data.{id: id, "display-name": "display-name"

# Retrieves a comma separated string, for example:
# ocid1.instance.oc1.phx.xyz....,cli_test_instance_675195,RUNNING
#
get_id_display_name_and.lifecycle_state_from_single_result_as_csv=data.[id, "display-name", "lifecycle-state"] | join(``, ``, @)

# Retrieves comma separated strings from a list of results
#
get_id_display_name_and.lifecycle_state_from_list_as_csv=data[*].[join(``, ``, [id, "display-name", "lifecycle-state"])]

# Filters where the display name contains some text
#
filter_by_display_name_contains_text=data[?contains("display-name", `your_text_here`)]

# Filters where the display name contains some text and pull out certain attributes(id and time-created)
#
filter_by_display_name_contains_text_and_get_attributes=data[?contains("display-name", `your_text_here`)].{id: id, timeCreated: "time-created"}

# Get the top 5 results from a list operation
#
get_top_5_results=data[:5]

# Get the last 2 results from a list operation
#
get_last_2_results=data[-2:]
```

You can reference any of these queries using this syntax: `query://<query name>`.

For example, to get id and display name from a list, run the following command.

```bash
oci compute instance list -c $C --query query://get_id_and_display_name_from_list
```

### Enabling Auto-complete

If you used the CLI installer, you don't have to configure auto-complete because it's enabled automatically.
To enable auto-complete (tab completion) for a manual CLI installation, run the following command.

```
oci setup autocomplete
```

To enable auto-complete on a session by session basis, run the following command.

```
eval "$_OCI_COMPLETE=source oci"
```

**Note:**

**Support for Auto-complete on Windows**

Auto-complete on Windows is only supported if you're using PowerShell. A script runs to enable this feature. However, you must change the PowerShell execution policy to RemoteSigned. To configure this policy, run the following command at the PowerShell command line.

```
Set-ExecutionPolicy RemoteSigned
```

---

**Specifying a Proxy Server**

If your environment requires you to use a proxy server for outgoing HTTP requests, you can specify that in the configuration file.

To configure a proxy server, add a `proxy` entry to the configuration file. For example:

```
proxy=http://<add your proxy URL here>/
```

**Using FIPS-validated Libraries**

The CLI can be configured to use FIPS-validated libraries on Linux. The CLI is built on the Oracle Cloud Infrastructure SDK for Python and leverages operating system level cryptographic libraries.

**Configuring the Environment**

1. Verify the installed version of OpenSSL is FIPS-compliant. Run the following command:

   ```
   openssl version
   ```

   If "fips" is not part of the version name, you should upgrade OpenSSL to a FIPS-compliant version. You can download the latest versions of OpenSSL at: [https://www.openssl.org/source/](https://www.openssl.org/source/)

2. Determine the location of the FIPS-compliant version of libcrypto:

   ```
   ls -l /usr/lib64/libcrypto*
   ```

3. Set the environment variable `OCI_CLI_FIPS_LIBCRYPTO_FILE` to the location of libcrypto:

   ```
   export OCI_CLI_FIPS_LIBCRYPTO_FILE=/path/to/libcrypto.x.x.x
   ```

   If you do not want to run this command at the start of every session, you can add it to your `.bashrc` or `.bash_profile` file.

   You can confirm that the environment variable is set properly with this command:

   ```
   set | grep OCI_CLI_FIPS_LIBCRYPTO_FILE
   ```

   You can now proceed to the standard installation process outlined in Quickstart on page 5320.
Verifying the Configuration

To verify that the CLI is using the library that you specified during Configuring the CLI on page 5327, execute the following commands in Python. Be sure to do so in the same environment that the CLI uses.

```python
import ssl
ssl.FIPS_mode()
```

This should return 1, indicating that SSL is using the library specified by the OCI_CLI_FIPS_LIBCRYPTO_FILE environment variable.

Using the CLI

This topic describes how to use the CLI to access Oracle Cloud Infrastructure and carry out service-related tasks. This topic assumes that you have configured the CLI and are ready to start using it.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.</td>
</tr>
</tbody>
</table>

Starting a CLI Session

MacOS, Linux, and Unix

To start a CLI session, run the following commands.

1. Open a terminal.
2. Change the working directory.
   ```
   cd myvirtualspaces/virtualenvs/cli-testing/bin
   ```
3. Run the activate batch file.
   ```
   source activate
   ```

To stop using the CLI, run the following command in a terminal.

```
deactivate
```
Command Line Syntax
Most commands must specify a service, followed by a resource type and then an action. The basic command line syntax is:

```bash
oci <service> <type> <action> <options>
```

For example, this syntax is applied as follows:
- `compute` is the `<service>`
- `instance` is the resource `<type>`
- `launch` is the `<action>`, and
- the rest of the command string consists of `<options>`.

The following command to launch an instance shows a typical command line construct.

```bash
oci compute instance launch --availability-domain "EMIr:PHX-AD-1" -c ocid1.compartment.oc1..aaaaaaaal3gzijdliegeyg35nz5xxi126astxxhgo12pgeyqdrggnx7jnhwa --shape "VM.Standard1.1" --display-name "Instance 1 for sandbox" --image-id ocid1.image.oc1.phx.aaaaaaaaqutj4qxjihp14mboabsa27mrpusygv6gurp47kat5z7vljmq3puq --subnet-id ocid1.subnet.oc1.phx.aaaaaaaaaypsr25bzjmjyn6xwgkcrgxd3dbhiha61odzus3gafscirbhj5bpa
```

In the previous example, you can provide a friendly name for the instance using the `--display-name` option. Avoid entering confidential information.

Basic Examples
This section provides examples of basic operations using the CLI.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using Environment Variables for OCIDs</td>
</tr>
<tr>
<td>Several of the CLI examples use environment variables for OCIDs, such as:</td>
</tr>
<tr>
<td>- <code>$T</code> for a tenancy OCID</td>
</tr>
<tr>
<td>- <code>$C</code> for a compartment OCID</td>
</tr>
<tr>
<td>For example:</td>
</tr>
<tr>
<td>T=ocid1 tenancy.oc1..aaaaaaaaba3pv6wm2ytdrwx32uzr4h25vkcr4jqaе5f15p2b2qst566ts3kmhknjx6f48c10m5m385612k5</td>
</tr>
</tbody>
</table>

To get a namespace, run the following command.

```bash
oci os ns get
```

To list compartments, run the following command.

```bash
oci iam compartment list -c $T
```

To get a list of buckets, run the following command.

```bash
oci os bucket list -ns mynamespace --compartment-id $C
```

To list users and limit the output, run the following command.

```bash
oci iam user list --compartment-id $T --limit 5
```
To add a user to a group, run the following command.

```bash
oci iam group add-user --user-id ocid1.user.oc1..aaabcaaxkkkt7gjvhvqqq7y4uc5sprzli377q --group-id ocid1.group.oc1..aaabcaaa66plootq6uuwwxfw21sdqtegb6l4pjsv5eeuenxraujj35b7b
```

**Getting Help with Commands**

You can get help for any command using `--help`, `-h`, or `?-`. For example:

```bash
oci --help
oci os bucket -h
oci os bucket create -?
```

**Viewing all the CLI Help**

You can view the command line help.

**Determining the Installed Version of the CLI**

To get the installed version of the CLI, run the following command.

```bash
oci --version
```

**Using a Proxy Server**

The CLI uses HTTP requests to make calls to Oracle Cloud Infrastructure services. If you need to use a proxy server for outgoing HTTP requests in your environment, you can use one of the following methods:

**Use the `--proxy` parameter on the command line**

You can specify a proxy server on the command line by including the `--proxy` parameter when calling a CLI command.

For example:

```bash
oci os ns get --proxy https://<add your proxy URL here>/
```

**Add a proxy entry to the CLI configuration file**

For details, see Specifying a Proxy Server on page 5332.

**Use environment variables**

Set the `HTTP_PROXY` and `HTTPS_PROXY` environment variables to point to your proxy server.

For example, on Linux:

```
https_proxy=https://<add your proxy URL here>/
http_proxy=http://<add your proxy URL here>/
```

On Windows, using PowerShell:

```
$Env:http_proxy = "http://<add your proxy URL here>/"
```

**Using Dates and Times in CLI Commands**

The CLI supports the following accepted date formats.
• UTC with milliseconds
  Format: YYYY-MM-DDTHH:mm:ss.sssTZD, Example: 2017-09-15T20:30:00.123Z
• UTC without milliseconds
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T20:30:00Z
• UTC with minute precision
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T20:30Z
• Timezone with milliseconds
  Format: YYYY-MM-DDTHH:mm:ss.sssTZD, Example: 2017-09-15T12:30:00.456-08:00
• Timezone without milliseconds
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T12:30:00-08:00
• Timezone with offset with minute precision
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T12:35-08:00
• Date Only (This date will be taken as midnight UTC of that day)
  Format: YYYY-MM-DD, Example: 2017-09-15
• Epoch seconds
  Example: 1412195400

Note:
In our datetime formats, the T can be replaced with a space.
For example, both "2017-09-15 20:30:00.123Z" and
2017-09-15T20:30:00.123Z are acceptable. (Note that if you do not
include the T, you must wrap the value in quotes.) We also support time
zones with and without the colon. Both +10:00 and +1000 are acceptable.

Managing CLI Input and Output
The CLI provides several options for managing command input and output.

Passing Complex Input
Complex input, such as arrays and objects with more than one value, are passed in JSON format and can be provided
as a string at the command line, as a file, or as a command line string and as a file.

MacOS, Linux, or Unix
The following command shows how to pass two values for the --metadata object.

```
oci os bucket create -ns mynamespace --name mybucket --metadata '{"key1":"value1","key2":"value2"}' --compartment-id ocid1.compartment.oc1..aaaaaaarhifmvrqyt3ukc5f1drwpp2jojdcypxfga
```

Windows
On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes.
Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.
The following command shows how to pass two values for the --metadata object on Windows.

```bash
oci os bucket create -ns mynamespace --name mybucket --metadata "{"key1":"value1","key2":"value2"}" --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvruqyte5q66rck6copzqck3ukc5f1drwpp2jojdcypxfga
```

**Note:**

JSON Errors

The error message "Parameter `<PARAMETER NAME>` must be in JSON format." indicates that the value you passed for the parameter with name `<PARAMETER NAME>` was not valid JSON. This error is typically a result of the JSON string not being escaped correctly.

For more information about using JSON strings, see [Advanced JSON Options](#).

**Format Output as a Table**

By default, all responses to a command are returned in JSON format. For example, a response like the following is returned when you issue the command to get a list of regions.

```json
{
  "data": [
    {
      "key": "FRA",
      "name": "eu-frankfurt-1"
    },
    {
      "key": "IAD",
      "name": "us-ashburn-1"
    },
    {
      "key": "ICN",
      "name": "ap-seoul-1"
    },
    {
      "key": "PHX",
      "name": "us-phoenix-1"
    },
    {
      "key": "LHR",
      "name": "uk-london-1"
    },
    {
      "key": "NRT",
      "name": "ap-tokyo-1"
    },
    {
      "key": "YYZ",
      "name": "ca-toronto-1"
    }
  ]
}
```

In some cases, readability can become an issue, which is easily resolved by formatting a response as a table. To get a response to a command formatted as a table, run the following command.

```bash
oci iam region list --output table
```
The following sample list of regions is returned as a two column table.

```
+-----+----------------+
| key | name           |
+-----+----------------+
| FRA | eu-frankfurt-1 |
| IAD | us-ashburn-1   |
| ICN | ap-seoul-1     |
| PHX | us-phoenix-1   |
| NRT | ap-tokyo-1     |
| LHR | uk-london-1    |
| YYZ | ca-toronto-1   |
+-----+----------------+
```

**Filter Output**

You can filter output using the JMESPath query option for JSON. Filtering is very useful when dealing with large amounts of output. For example, run the following command with the output table option to get a list of images.

```
oci compute image list -c
oci id1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7rrob2u2zbesh3wlafsgthhqtea
--output table
```

The image information is returned in table format, but too much data is returned, which overflows the width of the terminal. In addition, you might not need all the information that's returned.
You can limit the amount of data returned by combining the `--query` option with `--output table` to get the information you want from a command.

To get filtered image information returned in a table format, run the following command.

```
oci compute image list -c ocid1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7trob2u2zbesh3wlafsgthhqtea --output table --query "data [".".ImageName:"display-name"", OCID:id]"
```

The previous command returns the following image information, formatted as a two column table.

```
+---------------------------------------------------------+----------------------------------------------------------------------------------+
| ImageName                                               | OCID                                                                             |
+---------------------------------------------------------+----------------------------------------------------------------------------------+
| Windows-Server-2012-R2-Standard-Edition-VM-2017.04.03-0 | ocid1.image.oc1.phx.aaaaaaaa53cliasgvgqmutflwqkafbro2y4ywjebc15szc4eus5byy2e2b7ua |
| Oracle-Linux-7.4-2017.09.29-0                           | ocid1.image.oc1.phx.aaaaaaaaa3g2xplbrdknqctzv2tvxcofjc55vdcmpxd1bohmtt7encpana |
| Oracle-Linux-7.4-2017.08.25-1                           | ocid1.image.oc1.phx.aaaaaaaaajan2cd2g65tphpaieqiz4lbs422rde73okcu7dt2uya6p5szywsa |
| Oracle-Linux-7.4-2017.08.25-0                           | ocid1.image.oc1.phx.aaaaaaaaabif12bmaygtyu4riw3vcuowl5cqwdezqwndqnoeyobcfnc2pgyc6a |
| Oracle-Linux-7.3-2017.07.17-1                           | ocid1.image.oc1.phx.aaaaaaaa7jvf572d4ehcgh3ijavh5rt52voel33ispumnygi3kl7mph55ha |
| Oracle-Linux-7.3-2017.07.17-0                           | ocid1.image.oc1.phx.aaaaaaaaa5yu6pw3riqhtuxzov7fndgi4tsteganmao54nq3pyuxu3hxcuzmoa |
| Oracle-Linux-6.9-2017.09.29-0                           | ocid1.image.oc1.phx.aaaaaaaa2d243dmn6mj53zieyp5bdvtq7xfmr5kg5xlulrdijzdavaeljo6a |
```
For more information about the JMESPath query language for JSON, see JMESPath.

Advanced JSON Options

You can get the correct JSON format for command options and commands.

- For a command option, use `--generate-param-json-input` and specify the command option that you want to get the JSON for. To generate the JSON for creating or updating a security rule, run the following command.

  ```
  oci network security-list create --generate-param-json-input ingress-security-rules
  ```

- For an entire command, use `--generate-full-command-json-input`. To generate the JSON for launching an instance, run the following command.

  ```
  oci compute instance launch --generate-full-command-json-input
  ```

Order of Precedence for JSON Input

The CLI supports combining arguments on the command line with file input. However, if the same values are provided in a file and on the command line, the command line takes precedence.

Using a JSON File for Complex Input

You can pass complex input from a file by referencing it from the command line. For Windows users, this removes the requirement of having to escape JSON text. You provide a path to the file using the `file://` prefix.

Path Types

Using `testfile.json` as an example, the following types of paths are supported.

- Relative paths from the same directory, for example: `file://testfile.json` and `file://relative/path/to/testfile.json`
- Absolute paths on Linux, MacOS or Unix, for example: `file:///absolute/path/to/testfile.json`
- Full file paths on Windows, for example: `file://C:\path\to\testfile.json`

**Note:**

File Path Expansions

File path expansions, such as "~/", ".", and ".", are supported. On Windows, the "~/" expression expands to your user directory, which is stored in the
Developer Tools

%USERPROFILE% environment variable. Using environment variables in paths is also supported.

File Locations

The following file locations are supported.

- Your home directory.
  
  `oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqyte5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file://~/testfile.json`

- The current directory.
  
  `oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqyte5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file://testfile.json`

- The /tmp directory (Linux, Unix, or MacOS).
  
  `oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqyte5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file:///tmp/testfile.json`

- The C:\temp directory (Windows).
  
  `oci os bucket create -ns mynamespace --name mybucket --compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqyte5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata file://C:\temp\testfile.json`

Examples of Using a JSON File as Input

The examples in this section use JSON that's generated for a command option and an entire command. The JSON is saved in a file, edited, and then used as command line input.

Use File Input for a Command Option

This end-to-end example shows how to generate the JSON for a security list id option used to create a subnet. The JSON is saved in a file, edited, and then used as command line input.

Response from the Command

```
[
  {
    "icmpOptions": {
      "code": 0,
      "type": 0
    },
    "isStateless": true,
    "protocol": "string",
    "source": "string",
    "tcpOptions": {
      "destinationPortRange": {
        "max": 0,
        "min": 0
      },
      "sourcePortRange": {
        "max": 0,
        "min": 0
      }
    }
  }
]```
Response from the Command

{
  "assignPublicIp": true,
  "availabilityDomain": "string",
  "compartmentId": "string",
  "displayName": "string",
  "extendedMetadata": {
    "string1": {
      "string1": "string",
      "string2": "string"
    },
    "string2": {
      "string1": "string",
      "string2": "string"
    }
  },
  "hostnameLabel": "string",
  "imageId": "string",
  "metadata": {
}
Introduction

Use a JSON File as Input for a Security List Option

1. To generate the JSON for the `security-list-ids` option, run the following command.

   ```bash
   oci network subnet create --generate-param-json-input security-list-ids
   ```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   [
     "string",
     "string"
   ]
   ```

3. Edit the file and replace the "string" values with values, as shown in the following example.

   ```json
   [
     "ocid1.securitylist.oc1.phx.aaaaaaaaw7c62ybv4676muq5tdrwup3v2maiquhbkbh4sf75tjcf5dm6",
     "ocid1.securitylist.oc1.phx.aaaaaaaa7snx4jh5drwo2h33rwcqev6elir55hnhi2yfndjfon5rcw"
   ]
   ```

4. Save the file as "security-list.json".

5. To create the subnet using "security-list.json" as input, run the following command.

   ```bash
   oci network subnet create --vcn-id
   ocid1.vcn.oc1.phx.aaaaaaaa6wmuahgxejky7ukyruqdrw1mrumt16vyisxxaxavagiqw2eeet2sa
   --compartment-id ocid1.compartment.oc1..aaaaaaaa3zijsndicdxxhlgog12rggdrwyg35nz5x1l26astpgeyq7jnhwa
   --availability-domain "EMIr:PHX-AD-1" --display-name TESTSUB --dns-label "testinstances" --cidr-block "10.0.0.0/16" --security-list-ids file://security-list.json
   ```

Use File Input for an Entire Command

This end-to-end example shows how to generate the JSON to create a virtual cloud network (VCN). The JSON is saved in a file, edited, and then used as command line input.

Use a JSON File as Input to Create a VCN

1. To generate the JSON needed to create a VCN, run the following command.

   ```bash
   oci network vcn create --generate-full-command-json-input
   ```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

   ```json
   {
     "cidrBlock": "string",
     "compartmentId": "string",
     "displayName": "string",
     "dnsLabel": "string"
   }
   ```

Oracle Cloud Infrastructure User Guide 5343
3. Edit the file and replace the "string" values with values, as shown in the following example.

```json
{
    "cidrBlock": "10.0.0.0/16",
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaal3gzijdliedxxhqol2rggndrwyg35nz5zxil26astpgeyq7jnhwa",
    "displayName": "TestVCN",
    "dnsLabel": "testdns"
}
```

4. Save the file and name it "create-vcn.json"

5. To create the VCN using "create-vcn.json" as input, run the following command.

```bash
oci network vcn create --from-json file://create-vcn.json
```

### Advanced Examples

The following examples show how you can use the CLI to complete complex tasks in Oracle Cloud Infrastructure.

#### Working with Object Storage

You can use the CLI for several object operations with the Object Storage service.

#### Uploading and Downloading Files

Objects can be uploaded from a file or from the command line (STDIN), and can be downloaded to a file or to the command line (STDOUT).

Upload an object:

```bash
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt --metadata '{"key1":"value1","key2":"value2"}'
```

Upload object contents from the command line (STDIN):

```bash
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file <--'object content'
```

Download an object:

```bash
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt
```

Print object contents to the command line (STDOUT):

```bash
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file -
```

#### Bulk Operations in Object Storage

The CLI supports the following bulk operations in Object Storage:

- Uploading files in a directory and all its subdirectories to a bucket

```bash
# Upload all the files in a directory.
oci os object bulk-upload -ns mynamespace -bn mybucket --src-dir path/to/upload/directory
```
• Downloading all objects, or all the objects that match a specified prefix, in a bucket

```bash
# Download all the objects.
oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory

# Download all the objects that match the specified prefix.
oci os object bulk-download -ns mynamespace -bn mybucket --download-dir path/to/download/directory --prefix myprefix
```

• Deleting all objects, or all the objects that match a specified prefix, in a bucket

```bash
# Delete all the objects.
oci os object bulk-delete -ns mynamespace -bn mybucket

# Delete objects that match the specified prefix.
oci os object bulk-delete -ns mynamespace -bn mybucket --prefix myprefix
```

Bulk operations support several options that let you:

• Overwrite or skip files/objects using `--overwrite` or `--no-overwrite`. *(Note: If you pass neither of these options you are prompted for confirmation every time there is something to overwrite.)*

• Limit delete, upload, or download operations using `--prefix` and/or `--delimiter`.

• Preview a bulk deletion with `--dry-run`.

To get more information about the commands for bulk operations, run the following help commands:

```bash
# bulk-upload
oci os object bulk-upload -h

# bulk-download
oci os object bulk-download -h

# bulk-delete
oci os object bulk-delete -h
```

**Multipart Operations in Object Storage**

Multipart operations for Object Storage include object uploads and downloads.

**Multipart Uploads**

Large files can be uploaded to Object Storage in multiple parts to speed up the upload. By default, files larger than 128 MiB are uploaded using multipart operations. You can override this default by using the `--no-multipart` option.

You can configure the following options for the `oci os object put` command:

• `--no-multipart` overrides an automatic multipart upload if the object is larger than 128 MiB. The object is uploaded as a single part, regardless of size.

• `--part-size` in MiB, to use in a multipart operation. The default part size is 128 MiB and a part size that you specify must be greater than 10 MiB. If the object is larger than the `--part-size`, it is uploaded in multiple parts.

• `--parallel-upload-count`, to specify the number of parallel operations to perform. You can use this value to balance resources and upload times. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The `--resume-put` command allows you to resume a large file upload in cases where the upload was interrupted.
Multipart Uploads from STDIN

Objects uploaded from STDIN are uploaded in multiple parts. If the object content is smaller than 10 MiB, the upload is only 1 part, and the MultipartUpload API is used for the upload. Specifying `--no-multipart` when uploading from STDIN will result in an error.

The following example shows the command for a multipart upload if the object is larger than 200 MiB.

```
oci os object put -ns my-namespace -bn my-bucket --file path/to/large/file --part-size 200
```

For more information about multipart uploads, see Using Multipart Uploads on page 4382.

Multipart Downloads

Large files can be downloaded from Object Storage in multiple parts to speed up the download.

You can configure the following options for the `oci os object get` command:

- `--multipart-download-threshold` lets you specify the size, in MiB at which an object should be downloaded in multiple parts. This size must be at least 128 MiB.
- `--part-size`, in MiB, to use for a download part. This gives you the flexibility to use more (smaller size) or fewer (larger size) parts as appropriate for your requirements. For example, compute power and network bandwidth. The default minimum part size is 120 MiB.
- `--parallel-download-count` lets you specify how many parts are downloaded at the same time. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The following example shows the command to download any object with a size greater than 500 MiB. The object is downloaded in 128 MiB parts.

```
oci os object get -ns my-namespace -bn my-bucket --name my-large-object --multipart-download-threshold 500 --part-size 128
```

Upgrading the CLI

If you installed the CLI manually, use one of the following commands to upgrade the CLI.

- To upgrade a standard installation, run the following command.
  ```
  pip install oci-cli --upgrade
  ```
- To upgrade a standard virtualenv installation, run the following command.
  ```
  cli-testing/bin/pip install oci-cli --upgrade
  ```

If you installed the CLI using the install script, use the following process to upgrade the CLI:

- Run the install script and specify the same install directory.
- When prompted, reply Y to remove the existing directory.

**Upgrading the CLI on Mac OS X with Homebrew**

Homebrew offers a convenient way to manage your CLI install on Mac OS.

To upgrade your CLI install using Homebrew:

```
brew update && brew upgrade oci-cli
```
Uninstalling the CLI

For Manual Installations
If you manually installed the CLI using pip, run the following command:

```
$ pip uninstall oci-cli
```

If you manually installed the CLI in a virtual environment, run the following command:

```
$ <path/to/virtualenv>/bin/pip uninstall oci-cli
```

For Script Installations
If you used the install script and the default installation location, you should delete the following directories.

On Windows:

- %USERPROFILE%/lib/oracle-cli
- %USERPROFILE%/bin/oci
- %USERPROFILE%/bin/oci-cli-scripts

On Mac:

- $HOME/lib/oracle-cli
- $HOME/bin/oci
- $HOME/bin/oci-cli-scripts

If you used the install script, but installed to a custom location, you should delete the directories at that location.

Uninstalling Python

The script also installs Python as a dependency if it was not already installed. In Windows 10, you can uninstall Python in Control Panel or at the command line.

Using Control Panel

To uninstall Python in Control Panel, select Programs and Features. Right-click Python and select Uninstall.

For more information, see Repair or remove programs in Windows 10.

Using the Command Line

To uninstall Python at the command line, run the following command:

```
$ msiexec /x python<version>.msi
```

If you do not have the MSI file, you can also use the package or product code. For more information, see Using the Windows Installer.

Uninstalling the CLI on Mac OS X with Homebrew

To unsinstall the CLI from Mac OS X using Homebrew:

```
$ brew uninstall oci-cli
```

Troubleshooting the CLI

This topic describes how to resolve issues that you might encounter when installing Python or the CLI, or when using the CLI.
**Service Errors**

Any operation resulting in a service error causes an error of type "ServiceError" to be returned by the CLI. For information about common service errors that Oracle Cloud Infrastructure returns, see API Errors.

**Oracle Linux Permissions Issues**

On Oracle Linux 7.3, if you encounter permission issues when running `pip install`, you might need to use `sudo`.

**oci Command Not Found**

If the `oci` command isn't found, this can be caused by one of the following reasons:

- `pip` installed the package to a different virtual environment than your active one.
- You switched to a different active virtual environment after you installed the CLI.

To determine where the CLI is installed, run the `which pip` and `which oci` commands.

**Wheel File Won't Install**

If the wheel file won't install, verify that pip is up to date. To update pip, run the `pip install -U pip` command. Try to install the wheel again.

**Windows Issues**

If the `oci` command isn't found, make sure that the `oci.exe` location is in your path (for example, the `Scripts` directory in your Python installation).

**No Matching Distribution Found**

Error: No matching distribution found for oci-cli==3.x.x

This error occurs if you are attempting to install the CLI in a Python 2 environment. Support for Python 2 was deprecated as of August 1, 2021.

To resolve this issue, update your Python to version 3.6.5 or later. If you require Python 2, any CLI version starting with 2.x.x will still support Python 2.

**Contact Information**

If you want to contribute ideas, report a bug, get notified about updates, have questions, or want to give feedback, use one of the following links.

**Contributions**

Got a fix for a bug, or a new feature you'd like to contribute? The CLI is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the CLI is released, subscribe to the Atom feed.

**Questions or Feedback**

Ways to get in touch:

- **GitHub**: To file bugs and feature requests only.
- **Stack Overflow**: Use the `oracle-cloud-infrastructure` and `oci-cli` tags in your post.
- **Developer Tools section** of the Oracle Cloud forums
- **My Oracle Support**

**CLI Environment Variables**

The Oracle Cloud Infrastructure CLI supports the use of environment variables to specify default values for some options.
Environment Variables

The following table lists the available environment variables and their corresponding CLI options or `~/.oci/config` entries.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>CLI option</th>
<th>OCI config entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCI_CLI_PROFILE</td>
<td>--profile</td>
<td>Specified by [DEFAULT]</td>
<td>The profile in the OCI config file to load. This profile will also be used to locate any default parameter values which have been specified in the OCI CLI-specific configuration file.</td>
</tr>
<tr>
<td>OCI_CLI_USER</td>
<td>n/a</td>

<td>The OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 5303. Example: <code>ocid1.tenancy.oc1..&lt;unique_ID&gt;</code></td>
</tr>
<tr>
<td>OCI_CLI_ENDPOINT</td>
<td>--endpoint</td>
<td></td>
<td>This value can be set in the OCI CLI-specific configuration file. See Configuring the CLI on page 5327.</td>
</tr>
<tr>
<td>OCI_CLI_CONFIG_FILE</td>
<td>config-file</td>
<td>n/a</td>
<td>The path to the OCI config file.</td>
</tr>
<tr>
<td>OCI_CLI_RC_FILE</td>
<td>--cli-rc-file</td>
<td>n/a</td>
<td>The path to the OCI CLI-specific configuration file, containing parameter default values and other configuration information such as command aliases and predefined queries. See Configuring the CLI on page 5327 for more information.</td>
</tr>
<tr>
<td>OCI_CLI_CERT_BUNDLE</td>
<td>cert-bundle</td>
<td>n/a</td>
<td>The full path to a CA certificate bundle to be used for SSL verification.</td>
</tr>
<tr>
<td>OCI_CLI_AUTH</td>
<td>--auth</td>
<td>n/a</td>
<td>The type of auth to use for the API request. By default the API key in your config file will be used. Accepted values are: <code>api_key</code>, <code>instance_oob_user</code>, <code>instance_principal</code>, <code>resource_principal</code>, <code>security_token</code></td>
</tr>
</tbody>
</table>

**Note:**
- The `--region` parameter is the recommended way of targeting different regions.
<table>

</tbody>
</table>

Order of precedence

The CLI respects and applies configurations specified by option, environment variable, or OCI config file entry in the following order of precedence:

1. The value specified in the command option.
2. The value specified in the environment variable.
3. The value specified in the OCI config file.

Software Development Kits and Command Line Interface

Oracle Cloud Infrastructure provides a number of Software Development Kits (SDKs) and a Command Line Interface (CLI) to facilitate development of custom solutions.

- Software Development Kits (SDKs) Build and deploy apps that integrate with Oracle Cloud Infrastructure services. Each SDK provides the tools you need to develop an app, including code samples and documentation to create, test, and troubleshoot. In addition, if you want to contribute to the development of the SDKs, they are all open source and available on GitHub.
  - SDK for Java
  - SDK for Python
  - SDK for TypeScript and JavaScript
  - SDK for .NET
  - SDK for Go
  - SDK for Ruby
- Command Line Interface (CLI) on page 5316 The CLI provides the same core capabilities as the Oracle Cloud Infrastructure Console and provides additional commands that can extend the Console's functionality. The CLI is convenient for developers or anyone who prefers the command line to a GUI.
- PL/SQL SDK The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write code to manage Oracle Cloud Infrastructure resources. The latest version of the PL/SQL SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

SDK for Java

The Oracle Cloud Infrastructure SDK for Java enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: GitHub or Maven.
Tip:

**Cloud Shell:** The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see [SDK for Java Cloud Shell Quick Start](#) on page 5311.

**Oracle Linux Cloud Developer image:** The SDK for Java is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see [Oracle Linux Cloud Developer](#).

**Requirements**

To use the SDK for Java, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](#) on page 81. For a list of typical policies you may want to use, see [Common Policies](#) on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see [Configuring the SDK](#) on page 5355.
- Java 8 or Java 11 (see [Java Support Notes](#)).
- A TTL value of 60. For more information, see [Configuring the SDK](#) on page 5355.

**Java Support Notes**

Java 11 Support

- The OCI SDK for Java has been tested with Java version 11.
- Java 8 is required to build the OCI SDK for Java from source, but once it's built you can use the OCI SDK for Java with Java version 11.
- For OCI Java SDK versions before 1.27.0, you need to include the `javax.bind` and `sun.bind` dependencies, since Java 11 no longer includes Java EE and CORBA modules. For more information, see the [JDK 11 Release Notes](#).

**Services Supported**

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data
- Blockchain Platform
- Budgets
- Cloud Guard
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content Management
- Core Services (Networking, Compute, Block Volume)
- Data Catalog
- Data Flow
• Data Integration
• Data Science
• Data Safe
• Data Transfer
• Database
• Database Management
• Database Migration
• DevOps
• Digital Assistant
• DNS
• Email Delivery
• Events
• File Storage
• Functions
• Generic Artifacts
• GoldenGate
• Health Checks
• IAM
• Integration
• Java Management
• Key Management (for the Vault service)
• Limits
• Load Balancing
• Logging
• Logging Analytics
• Logging Search
• Logging Ingestion
• Management Agent Cloud
• Management Dashboard
• Marketplace
• Monitoring

• Operations Insights
• Operator Access Control
• Optimizer
• Organizations
• OS Management
• Quotas
• Resource Manager
• Roving Edge Infrastructure
• Search
• Secret Management (for the Vault service)
• Service Catalog
• Service Connector Hub
Getting Started

This topic describes how to install and configure the Oracle Cloud Infrastructure SDK for Java.

**Tip:**

The SDK for Java is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Java from within Cloud Shell, see [SDK for Java Cloud Shell Quick Start](#) on page 5311.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Java, along with other Oracle development tools.

Downloading the SDK from GitHub

You can download the SDK for Java as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples. For best compatibility and to avoid issues, use the version of the dependencies included in the archive. Some notable issues are:

- **Bouncy Castle:** The SDK bundles 1.60 (included in this distribution). If you need FIPS compliance, see [Using BC-FIPS Instead of Bouncy Castle](#) on page 5360.
- **Jersey Core and Client:** The SDK bundles 2.24.1, which is required to support large object uploads to Object Storage. Older versions will not support uploads greater than ~2.1 GB.
- **Jax-RS API:** The SDK bundles 2.0.1 of the spec. Older versions will cause issues.

**Note:**

The SDK for Java is bundled with Jersey (included in this distribution), but you can also use your own JAX-RS implementation. For details, see [Using Your Own JAX-RS Implementation](#) on page 5361.
Downloading the SDK from Maven or JCenter

Maven Central and JCenter.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Java.

For Oracle Linux 7:

```bash
sudo yum-config-manager --enable ol7_developer
sudo yum install java-oci-sdk
```

For Oracle Linux 8:

```bash
sudo yum-config-manager --enable ol8_developer
sudo yum install java-oci-sdk
```

The OCI jar file will be located in: `/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar`, and third-party libraries will be in `/usr/lib64/java-oci-sdk/third-party/lib`.

You can add the following entries to your classpath: `:/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-<version>.jar:/usr/lib64/java-oci-sdk/third-party/lib/*` For example:

```bash
javac -cp "/usr/lib64/java-oci-sdk/third-party/lib/*:/usr/lib64/java-oci-sdk/lib/oci-java-sdk-full-1.8.2.jar" MyFile.java
```

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

### Configuring Credentials

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File on page 5308.

Next you need to set up the client to use the credentials. The credentials are abstracted through an `AuthenticationDetailsProvider` interface. Clients can implement this however you choose. We have included a simple POJO/builder class to help with this task (`SimpleAuthenticationDetailsProvider`).

* You can load a config with or without a profile:

```java
ConfigFile config = ConfigFileReader.parse("~/oci/config");
ConfigFile configWithProfile = ConfigFileReader.parse("~/oci/config", "DEFAULT");
```

* The private key supplier can be created with the file path directly, or using the config file:

```java
Supplier<InputStream> privateKeySupplier = new SimplePrivateKeySupplier("~/oci/oci_api_key.pem");
Supplier<InputStream> privateKeySupplierFromConfigEntry = new SimplePrivateKeySupplier(config.get("key_file"));
```

* To create an auth provider using the builder:

```java
AuthenticationDetailsProvider provider = SimpleAuthenticationDetailsProvider.builder()
    .tenantId("myTenantId")
    .userId("myUserId")
    .fingerprint("myFingerprint")
    .privateKeySupplier(privateKeySupplier)
```
To create an auth provider using the builder with a config file:

```java
AuthenticationDetailsProvider provider
    = SimpleAuthenticationDetailsProvider.builder()
        .tenantId(config.get("tenancy"))
        .userId(config.get("user"))
        .fingerprint(config.get("fingerprint"))
        .privateKeySupplier(privateKeySupplier)
        .build();
```

Finally, if you use standard config file keys and the standard config file location, you can simplify this further by using `ConfigFileAuthenticationDetailsProvider`:

```java
AuthenticationDetailsProvider provider
    = new ConfigFileAuthenticationDetailsProvider("ADMIN_USER");
```

### Configuring Client-side Options

Create a client-side configuration through the `ClientConfiguration` class. If you do not provide your own configuration, the SDK for Java uses a default configuration. To provide your own configuration, use the following:

```java
ClientConfiguration clientConfig
    = ClientConfiguration.builder()
        .connectionTimeoutMillis(3000)
        .readTimeoutMillis(60000)
        .build();
```

After you have both a credential configuration and the optional client configuration, you can start creating service instances.

### Configuring Custom Options

In the config file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file like so (highlighted in red italics):

```ini
[DEFAULT]
user=ocid1.user.oc1..aaaaaaaat5nvwcn56aqzjcmdy5eqbb6qt2jvpkanghtgdaqedqw3rynjq
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaaba3pv6kcr4jqaef15p2bcmdyt2j6ix32uzr4h25vqstifsfdsq

custom_compartment_id=ocid1.compartment.oc1..aaaaaaayzfqelbduyox61ib3olcmdar3ugly4fmamq
```

Then you can retrieve the value like so:

```java
ConfigFile config
    = ConfigFileReader.parse("~/oci/config");
String compartmentId = config.get("custom_compartment_id");
```

Using the SDK for Java
To use the Oracle Cloud Infrastructure SDK for Java in your project, import the `oci-java-sdk-bom`, followed by your project dependencies. For example:

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.oracle.oci.sdk</groupId>
      <artifactId>oci-java-sdk-bom</artifactId>
      <!-- replace the version below with your required version -->
      <version>1.5.2</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-audit</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-core</artifactId>
  </dependency>
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-database</artifactId>
  </dependency>
  <!-- more dependencies if needed -->
</dependencies>
```

**Configuration**

This topic provides details on compatibility, advanced configurations, and add-ons for the Oracle Cloud Infrastructure SDK for Java.

**Security Manager Permissions**

If your application needs to run inside the Java Security Manager, you must grant additional permissions by updating a policy file, or by specifying an additional or a different policy file at runtime.

The SDK requires the following permissions:

- **Required by Jersey:**

  ```
  permission java.lang.RuntimePermission "getClassLoader";
  permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
  permission java.lang.RuntimePermission "accessDeclaredMembers";
  permission java.util.PropertyPermission "]", "read,write";
  permission java.lang.RuntimePermission "setFactory";
  ```

- **Required by the SDK to overwrite reserved headers:**

  ```
  permission java.util.PropertyPermission "sun.net.http.allowRestrictedHeaders", "write";
  ```

- **Required by the SDK to open socket connections:**

  ```
  permission java.net.SocketPermission "*", "connect";
  ```
To include another policy file, in addition to Java Runtime Environment's default policy file, launch the Java Virtual Machine with:

```
java -Djava.security.manager -Djava.security.policy=</path/to/other_policy>
```

To replace the default policy file, launch the Java Virtual Machine with:

```
java -Djava.security.manager -Djava.security.policy==</path/to/other_policy>
```

**Note:**

Use a single equals sign (=) when supplying an additional policy file. Use a double equals sign (==) only if you wish to replace the default policy file.

Java Virtual Machine TTL for DNS Name Lookups

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called *time-to-live* (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the `networkaddress.cache.ttl` property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, -1, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

  ```
  networkaddress.cache.ttl=60
  ```

- To set TTL only for your application, set the following in your application's initialization code:

  ```
  java.security.Security.setProperty("networkaddress.cache.ttl", "60");
  ```

Using the Jersey Default HttpURLConnectionProvider

Starting with version 2.0.0, the SDK for Java supports using the Jersey `ApacheConnectorProvider` instead of the Jersey default `HttpURLConnectionProvider` to allow the Apache HttpClient to make OCI service calls.

**To change to the Jersey default connector at the client level**

- For clients that buffer requests into memory:

  ```
  IdentityClient.builder().clientConfigurator(new JerseyDefaultConnectorConfigurator())
  ```

- For clients that do not buffer requests into memory:

  ```
  IdentityClient.builder().clientConfigurator(new JerseyDefaultConnectorConfigurator.NonBuffering())
  ```

**Note:**

Overriding the `clientConfigurator` property of the client will revert back to the Jersey defaults. For configuring `clientConfigurator` with the use of Apache Connector, use `additionalClientConfigurator` or `additionalClientConfigurators`.
To change to the Jersey default connector at the global level

You can exclude the Apache HttpClient dependencies or use an environment variable.

Excluding HttpClient Dependencies

If you are managing dependencies yourself:

- Remove the org.apache.httpcomponents.httpclient and org.glassfish.jersey.connectors.jersey-apache-connector JARs from the classpath

If you are using Maven to manage your dependencies:

- Add exclusions for the org.apache.httpcomponents.httpclient and org.glassfish.jersey.connectors.jersey-apache-connector dependencies:

```xml
<dependencies>
  ...
  <dependency>
    <groupId>com.oracle.oci.sdk</groupId>
    <artifactId>oci-java-sdk-common</artifactId>
    <version>...</version>
    <exclusions>
      <exclusion>
        <groupId>org.glassfish.jersey.connectors</groupId>
        <artifactId>jersey-apache-connector</artifactId>
      </exclusion>
      <exclusion>
        <groupId>org.apache.httpcomponents</groupId>
        <artifactId>httpclient</artifactId>
      </exclusion>
    </exclusions>
  </dependency>
  ...
</dependencies>
```

Switching back via environment variable

The SDK for Java provides an environment variable to switch back to the old Jersey Default Connector at the global level. Set the value of the environment variable: OCI_JAVASDK_JERSEY_CLIENT_DEFAULT_CONNECTOR_ENABLED to true. By default, this value is set to false.

Switching off auto-close of streams

For API calls that return binary/stream response, the SDK will auto-close the stream once the stream has been completely read. This is because the SDK for Java supports the Apache Connector for sending requests and managing connections to the service. By default, the Apache Connector supports connection pooling. In the cases where the stream from the response is not closed, the connections don't get released from the connection pool.

To disable the auto-close behavior, call ResponseHelper.shouldAutoCloseResponseInputStream(false).

Choosing connection closing strategies with the Apache Connector to optimize performance

When using ApacheConnectionClosingStrategy.GracefulClosingStrategy, streams returned from a response are read until the end of the stream when closing the stream. This can introduce additional time when closing the stream with a partial read, depending on how large the remaining stream is. To avoid this delay, consider using ApacheConnectionClosingStrategy.ImmediateClosingStrategy for large files with partial...
reads. Note that `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` takes longer when using partial read for smaller stream size (streams smaller than 1MB).

**Note:**

If these Apache Connection closing strategies do not give you optimal results for your use cases, you can switch back to Jersey Default `HttpUrlConnectorProvider` using the method stated above.

For more information, see: https://github.com/oracle/oci-java-sdk/blob/master/ApacheConnector-README.md.

**Using BC-FIPS Instead of Bouncy Castle**

If you need FIPS compliance, you must download and use a FIPS-certified version. The SDK supports bc-fips 1.0.2 and bcpkix-fips 1.0.3. You can download them at: https://www.bouncycastle.org/fips-java/

For help installing and configuring Bouncy Castle FIPS, see "BC FIPS Documentation" in the User Guides and Security Policy of the Bouncy Castle Documentation.

**Self-Managed Dependencies**

If you are managing dependencies yourself:

1. Remove the non-FIPS Bouncy Castle jar files from the class path:
   a. `bcprov-jdk15on-1.60.jar`
   b. `bcpkix-jdk15on-1.60.jar`

2. Add the FIPS Bouncy Castle jar files to the class path instead:
   a. `bc-fips-1.0.2.jar`
   b. `bcpkix-fips-1.0.3.jar`

**Maven-Managed Dependencies**

If you are using Maven to manage your dependencies:

1. Add the correct versions of `bc-fips` and `bcpkix-fips` to your dependencies:

   ```xml
   <dependencies>
   . . .
   <dependency>
     <groupId>bc-fips</groupId>
     <artifactId>bc-fips</artifactId>
     <version>1.0.2</version>
   </dependency>
   <dependency>
     <groupId>bcpkix-fips</groupId>
     <artifactId>bcpkix-fips</artifactId>
     <version>1.0.3</version>
   </dependency>
   . . .
   </dependencies>
   ```

2. Since you are depending on an `oci-java-sdk-*` package, you need to remove the non-FIPS Bouncy Castle dependencies:

   ```xml
   <dependencies>
   . . .
   <dependency>
     <groupId>com.oracle.oci.sdk</groupId>
     <artifactId>oci-java-sdk-common</artifactId>
     <version> . . . </version>
     <exclusions>
       <exclusion>
         <groupId>org.bouncycastle</groupId>
         <artifactId>bcprov-jdk15on</artifactId>
       </exclusion>
     </exclusions>
   </dependency>
   . . .
   </dependencies>
   ```
Using Your Own JAX-RS Implementation

The SDK for Java is bundled with Jersey, but you can also use your own JAX-RS implementation.

**RESTEasy Client Configurator Add-On**

The `oci-java-sdk-addons-resteasy-client-configurator` is provided to demonstrate how to configure an alternate JAX-RS implementation. The add-on can be found in the `bmc-addons` directory of the SDK.

For details on installation and configuration, see the Readme for the add-on.

For code samples that demonstrate how to configure the client, see:

- ResteasyClientExample.java
- ResteasyClientWithObjectStorageExample.java
- InstancePrincipalsAuthenticationDetailsProviderWithResteasyClientExample.java

Using SLF4J for Logging

Logging in the SDK is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following is an example that enables basic logging to standard out. More advanced logging options can be configured by using the log4j binding.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath (e.g., add it to the `/third-party/lib` directory of the SDK download)
3. Add the following VM arg to enable debug level logging (by default, info level is used): `-Dorg.slf4j.simpleLogger.defaultLogLevel=debug`

**Concepts**

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for Java.

Synchronous Calls

To make synchronous calls, create an instance of the synchronous client. The general pattern for synchronous clients is that for a service named Example, there will be an interface named ExampleService, and the synchronous client implementation will be called ExampleServiceClient. Here's an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorage clientWithDefaultClientConfig = new
    ObjectStorageClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorage clientWithExplicitClientConfig = new
    ObjectStorageClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```
Synchronous calls will block until the response is available. All SDK APIs return a response object (regardless of whether or not the API sends any content back). The response object typically contains at least a request ID that you can use when contacting Oracle support for help on a particular request.

```java
ObjectStorage client = ...;
GetBucketResponse response = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace")
        .bucketName("myBucket").build());
String requestId = response.getOpcRequestId();
Bucket bucket = response.getBucket();
System.out.println(requestId);
System.out.println(bucket.getName());
```

Asynchronous Calls

To make asynchronous calls, create an instance of the asynchronous client. The general pattern for asynchronous clients is that for a service named Example, there will be an interface named ExampleServiceAsync, and the asynchronous client implementation will be called ExampleServiceAsyncClient. Here's an example of creating an Object Storage client:

```java
AuthenticationDetailsProvider provider = ...;
ObjectStorageAsync clientWithDefaultClientConfig = new
    ObjectStorageAsyncClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);
ClientConfiguration clientConfig = ...;
ObjectStorageAsync clientWithExplicitClientConfig = new
    ObjectStorageAsyncClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Asynchronous calls return immediately. You need to provide an AsyncHandler that will be invoked after the call completes either successfully or unsuccessfully:

```java
AsyncHandler<GetBucketRequest, GetBucketResponse> handler = new
    AsyncHandler<GetBucketRequest, GetBucketResponse>() {
        @Override
        public void onSuccess(GetBucketRequest request, GetBucketResponse
            response) {
            String requestId = response.getOpcRequestId();
            Bucket bucket = response.getBucket();
            System.out.println(requestId);
            System.out.println(bucket.getName());
        }
        @Override
        public void onError(GetBucketRequest request, Throwable error) {
            error.printStackTrace();
        }
    }
Future<GetBucketResponse> future = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace")
        .bucketName("myBucket").build(),
    handler);
```

Polling with Waiters

The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the
desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write into an easy-to-use single method call.

Waiters are obtained through the service client (client.getWaiters()). Both a Get<Resource>Request and the desired lifecycle state are passed in to the waiters.for<Resource> method. For example:

```java
public static Instance waitForInstanceProvisioningToComplete(ComputeClient computeClient, String instanceId) throws Exception {
    ComputeWaiters waiters = computeClient.getWaiters();
    GetInstanceResponse response = waiters.forInstance(
            GetInstanceRequest.builder().instanceId(instanceId).build(),
            Instance.LifecycleState.Running)
            .execute();
    return response.getInstance();
}
```

Each waiters.for<Resource> method has two versions:

- One version uses the default polling values. For example:

  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState)
  ```

- The other version gives you full control over how long to wait and how much time between polling attempts. For example:

  ```java
  waiters.forInstance(GetInstanceRequest, LifecycleState,
                      TerminationStrategy, DelayStrategy)
  ```

**Threading Model**

A client becomes thread-safe when it is initialized. After setting its endpoint, you can safely use a client in multiple threads and concurrently call methods on it.

You can reuse a client on multiple requests, both across concurrent threads or within a single thread. Unless the environment's resources are constrained, you should only close the client immediately before it goes out of scope.

**Note:**

This guarantee applies only to the default JAX-RS implementation, Jersey. When using an alternate implementation, you must manage thread safety yourself. For more information, see Configuring the SDK on page 5355

**Uploading Large Objects**

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for Java supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the UploadManager, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The UploadObject example shows how to use the UploadManager to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

**Retries**

You can configure the SDK for Java to retry SDK operations that fail. The SDK allows you to specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.
**Delay Strategy**

The `delayStrategy` parameter determines how long to wait between each retry call. There are two options for this parameter:

- **FixedTimeDelayStrategy (milliseconds)** - Each retry is delayed by a specified number of milliseconds.
- **ExponentialBackoffDelayStrategy (milliseconds)** - The delay time for subsequent retry calls increases by an exponential factor of 2 until it reaches the defined maximum delay (in milliseconds), with a base value of one millisecond.

The default delay strategy is set to `ExponentialBackoffDelayStrategy` with 30 seconds (30000 milliseconds) of delay.

**Retry Condition**

The `retryCondition` defines a function with an error argument that returns a boolean indicating whether to retry or not. The operation will be retried if this function returns `true`.

**Termination Strategy**

The `terminationStrategy` parameter defines when to terminate the retry attempts. This parameter supports the following options:

- **MaxTimeTerminationStrategy (milliseconds)** - Defines total duration in milliseconds for which the retry attempts.
- **MaxAttemptsTerminationStrategy (attempts)** - Defines the total number of retry attempts.

**Retry Examples**

**Java**

This example shows how to configure and use retries with the SDK for Java:

```java
/**

import com.oracle.bmc.waiter.MaxAttemptsTerminationStrategy;

/**
 * This example demonstrates how to use the SDK retries.
 * a) the SDK level (using @link Retriers#setDefaultRetryConfiguration(RetryConfiguration))
 */
```
public class RetryExample {
    public static void main(String[] args) throws Exception {
        String configurationFilePath = System.getProperty("user.home") + "/.oci/config";
        String profile = "DEFAULT";

        // Configuring the AuthenticationDetailsProvider. It's assuming
        // there is a default OCI config file
        // "~/.oci/config", and a profile in that config with the name
        // "DEFAULT". Make changes to the following
        // line if needed and use
        ConfigFileReader.parse(configurationFilePath, profile);
        final ConfigFileReader.ConfigFile configFile = ConfigFileReader.parseDefault();
        final AuthenticationDetailsProvider provider = new ConfigFileAuthenticationDetailsProvider(configFile);

        // Set the default retry strategy for all operations to set retry
        // attempts to 3
        Retriers.setDefaultRetryConfiguration(
            RetryConfiguration.builder()
                .terminationStrategy(new MaxAttemptsTerminationStrategy(3))
                .build());

        // Override the default retry strategy for the identity client and
        // update retry attempts to 4
        final Identity identityClient = new IdentityClient(
            provider,
            ClientConfiguration.builder()
                .retryConfiguration(
                    RetryConfiguration.builder()
                        .terminationStrategy(new MaxAttemptsTerminationStrategy(4))
                        .build())
                .build());

        // Override the client's retry strategy for the list regions request
        // and wait for 5ms between retrying
        final ListRegionsRequest listRegionsRequest = ListRegionsRequest.builder()
            .retryConfiguration(
                RetryConfiguration.builder()
                    .terminationStrategy(new MaxAttemptsTerminationStrategy(2))
                    .delayStrategy(new FixedTimeDelayStrategy(5L))
                    .build())
            .build();

        final ListRegionsResponse listRegionsResponse = identityClient.listRegions(listRegionsRequest);
        System.out.println(listRegionsResponse.getItems());
    }
}
Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for Java exposes the DefaultRequestSigner class that you can use to create a RequestSigner instance for non-standard requests.

The Raw Request example on GitHub shows how to:

- create an authentication provider and request signer
- integrate with an HTTP client (Jersey in this example) to authenticate requests

Setting the Endpoints

Service endpoints can be set in three ways.

- Call setEndpoint() on the service instance. This lets you specify a full host name (for example, https://www.example.com).
- Call setRegion() on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for Java returns an error.
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 5308.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

Forward Compatibility and enums

If you have conditional logic based on an enum, be sure that your code handles the UnknownEnumValue case to ensure forward compatibility. Some response fields are of type enum, but in the future, individual services may return values not covered by existing enums for that field. To address this possibility, every response field of type enum has an additional value named UnknownEnumValue. If a service returns a value that is not recognized by your version of the SDK, then the response field will be set to this value.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains on page 208.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for xyz.abc.123.oraclecloud.com is oraclecloud.com.

You must first call Region.register to register the new region, and then you can set the region by either using the configuration file or by calling the setRegion method.

**Note:**

Once a region is registered, the federation endpoint is no longer required while using instance principals. For an example, see https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java.

oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the Region enum for your SDK version.

**Note:**

For the following code samples, be sure to supply the appropriate endpoints for your region.
If you are using version 1.2.34 or later of the SDK for Java, you can pass the new region name as a string using one of the following methods:

- To set the region on a previously created client:
  ```java
  client.setRegion("ca-toronto-1");
  ```

- To set a region when building a new client:
  ```java
  Identity identityClient = IdentityClient.builder()
      .region("ca-toronto-1")
      .build(provider);
  ```

- You can also pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 5308.

**Other Realms**

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To specify the endpoint:

```java
AuthenticationDetailsProvider provider =
    new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);

IdentityClient client = IdentityClient.builder()
    .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
    .build(provider);
```

If you are authenticating via instance principals, you can set the endpoint and federationEndpoint via the following process:

```java
InstancePrincipalsAuthenticationDetailsProvider provider =
    InstancePrincipalsAuthenticationDetailsProvider.builder()
        .federationEndpoint("https://auth.ca-toronto-1.oraclecloud.com/v1/x509")
        .build();

IdentityClient identityClient = IdentityClient.builder()
    .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
    .build(provider);
```

**Paginated Responses**

Some APIs return paginated result sets, so you must check for additional items and if necessary, fetch the next page. You can do so manually or you can use an iterator.

**Manually Fetching Pages**

The Response objects contain a method to fetch the next page token. If the token is null, there are no more items. If it is not null, you can make an additional request, by setting the token on the Request object, to get the next page of responses.

**Note:**

Some APIs may return a token even if there are no additional results. Be sure to also check whether any items were returned and stop if there are none.
This example shows how to handle page tokens returned by the Object Storage API:

```java
ObjectStorage client = ...;
ListBucketsRequest.Builder builder =
    ListBucketsRequest.builder().namespaceName(namespace);
String nextPageToken = null;
do {
    builder.page(nextPageToken);
    ListBucketsResponse listResponse = client.listBuckets(builder.build());
    List<Bucket> buckets = listResponse.getItems();
    // handle buckets
    nextPageToken = listResponse.getOpcNextPage();
} while (nextPageToken != null);
```

### Using an Iterator

Instead of manually working with page tokens, you can use an iterator. Each service client exposes a `getPaginators()` method that returns a `Paginator` object. This object contains methods to return objects of type `Iterable`. We support two approaches to using `Iterable`:

- **Response Iterator**: You can iterate over the `Response` objects that are returned by the list operation. These are referred to as `ResponseIterators`, and their methods are suffixed with "ResponseIterator," for example, `listUsersResponseIterator`.

  ```java
  Iterable<ListUsersResponse> responseIterator =
      identityClient.getPaginators().listUsersResponseIterator(request);
  for (ListUsersResponse response : responseIterator) {
      for (User user : response.getItems()) {
          System.out.println(user);
      }
  }
  ```

- **Record Iterator**: You can iterate over the resources/records that are listed. These are referred to as `RecordIterator`, and their methods are suffixed with "RecordIterator," for example, `listUsersRecordIterator`.

  ```java
  Iterable<User> recordIterator =
      identityClient.getPaginators().listUsersRecordIterator(request)
  for (User user : recordIterator) {
      System.out.println(user);
  }
  ```

### Client-Side Encryption

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the `CreateKey` or `ImportKey` operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

### Java Prerequisites

The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171, and 6u16. For those versions and later the policy files are included but not enabled by default.

Current versions of the JDK do not require these policy files. They are provided here for use with older versions of the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.
Exceptions
When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or timeout. You can also get the request ID when handling a `BmcException` by using the `getOpcRequestId` method.

This example shows a try-catch block that handles a `BmcException` and prints the request ID.

```java
ObjectStorage client = ...;
try {
    GetBucketResponse response = client.getBucket(
        GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
    String requestId = response.getOpcRequestId();
    System.out.println(requestId);
} catch (BmcException e) {
    String requestId = e.getOpcRequestId();
    System.out.println(requestId);
    e.printStackTrace();
}
```

Exceptions in the SDK for Java are runtime exceptions (unchecked), so they do not show up in method signatures. All APIs can throw a `BmcException`.

**Examples**

**GitHub**

Examples of SDK usage can be found on GitHub, including:

- Example: Synchronous Object Storage
- Example: Asynchronous Object Storage
- Example: Create an instance
- Example: Get an instance's public IP address

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

**SDK Reference**

In addition to the examples found on GitHub, the SDK for Java API reference contains code examples that you can copy and modify to run in your own environment.

**Running Examples**

1. Download the SDK to a directory named `oci`. See GitHub for the download.
2. Unzip the SDK into the `oci` directory. For example: `tar -xf oci-java-sdk-dist.zip`
3. Create your configuration file in your home directory (`~/.oci/config`). See Configuring the SDK on page 5355.
4. Use `javac` to compile one of the previous example classes from the `examples` directory, ex:

   ```
   javac -cp lib/oci-java-sdk-full-<version>.jar:third-party/lib/* examples/ObjectStorageSyncExample.java
   ```

5. You should now have a class file in the `examples` directory. Run the example:

   ```
   java -cp examples:lib/oci-java-sdk-full-<version>.jar:third-party/lib/* ObjectStorageSyncExample
   ```
**Third-Party Dependencies and Shading**

The SDK requires a number of third-party dependencies, which are available in the `third-party/lib` directory. To use the SDK library `lib/oci-java-sdk-full-<version>.jar`, all of the third-party dependencies in `third-party/lib` have to be on the class path.

The SDK also includes a second version of the SDK library, `shaded/lib/oci-java-sdk-full-shaded-<version>.jar`, which contains most of the third-party dependencies already. Only a few more third-party libraries in `shaded/third-party/lib` have to be on the class path when you use this version of the SDK library.

These two versions of the SDK library are functionally the same, however the second version, `shaded/lib/oci-java-sdk-full-shaded-<version>.jar` can simplify dealing with different versions of third-party dependencies. This is because all the dependencies that are included in `shaded/lib/oci-java-sdk-full-shaded-<version>.jar` were shaded, which means they will not interfere with other versions of themselves you may want to include along with this SDK.

To use the shaded version of the SDK, replace the `javac` commands in steps 4 and 5 with the following:

- **Step 4:**
  ```
  ```

- **Step 5:**
  ```
  ```

**Troubleshooting**

This section contains troubleshooting information for the Oracle Cloud Infrastructure SDK for Java.

**Program hangs for an indefinite time**

If a request to the server hangs for an indefinite time, it could be because the connection was not released from the connection pool.

The SDK for Java now supports the Apache Connector for sending requests and managing connections to the service. The Apache Connector supports connection pooling. If a stream is not closed, the connections do not get released from the connection pool, which can result in an indefinite wait time.

The SDK automatically closes the stream to release the connection from the connection pool, but only when the stream is read completely.

To avoid program hangs, be sure to close all streams returned from the response to release the connections from the connection pool to avoid indefinite wait times. For example:

```java
GetObjectResponse getObjectResponse = client.getObject(getObjectRequest);
getObjectResponse.getInputStream().close(); // Close the stream OR use try-with-resources
try (final InputStream fileStream = getResponse.getInputStream()) {
} // try-with-resources automatically closes fileStream
```

You can also switch back to the Jersey default connector `HttpUrlConnector`. For more information, see Using the Jersey Default `HttpUrlConnectorProvider` on page 5358.

**Server drops Apache Client Library connection with no response**
In some cases, usually under heavy load, the server receives but does not process a request. This may cause
the server to drop the connection to the client without giving any response. The Apache HttpClient throws a
NoHttpResponseException when it encounters such a condition. In such cases, the underlying Apache
HttpClient will retry requests to the server and emit INFO level logs about retries to the server. If the retries fail and
the request fails to complete, you should switch back to the Jersey default connector HttpUrlConnector. For
more information, see Using the Jersey Default HttpUrlConnectorProvider on page 5358.

ObjectStorage client does not close connections when client is closed.

Too many file descriptors are opened up, and it takes too long to close existing ones. An exception may look like this:

```
Caused by: java.io.FileNotFoundException: classes/caspertest.pem (Too many open files)
  at java.io.FileInputStream.open0(Native Method)
  at java.io.FileInputStream.open(FileInputStream.java:195)
  at java.io.FileInputStream.<init>(FileInputStream.java:138)
```

Use one of the following workarounds to fix this issue.

- Make this call before creating a client: `System.setProperty("http.keepAlive", "false");`
- Use this command line argument when running Java: `-Dhttp.keepAlive=false`

Serialization errors when making requests or handling responses

An UnrecognizedPropertyException error when handling a response indicates that the version of the
Jackson library does not support a feature that was injected at runtime from another dependency in your application's
class path. This happens even if the FAIL_ON_UNKNOWN_PROPERTIES deserialization property is set to false
for the configured ObjectMapper.

**Solution:**

Determine which version of Jackson libraries are referenced in your application’s class path and, if necessary,
upgrade to version 2.9.5. For a complete list of Jackson libraries that the SDK for Java depends on, please refer to the
pom.xml file that is hosted on GitHub.

**Note:**

If you customize a client when instantiated in your
application, ensure that you reference the preconfigured
ObjectMapper from the RestClientFactory using the
RestClientFactory#getObjectMapper() method.

An alternative solution is to use the shaded version of the SDK for Java jar file, which includes a bundled version
of the Jackson libraries.

Encryption key size errors

By default, the SDK for Java can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception"
and "Illegal key size" errors when they use longer keys, such as AES256.

Use one of the following workarounds to fix this issue.

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://
  www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be
thrown by the SDK. For information about common service errors returned by OCI, see API Errors.
**SDK for Python**

The Oracle Cloud Infrastructure SDK for Python enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** The SDK for Python is available on GitHub or the Python Package Index (PyPi).

**Documentation:** Available on docs.cloud.oracle.com and readthedocs.io.

Installing with Resource Manager

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Python, along with other Oracle development tools.

Installing with yum

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Python.

The following example shows how to use yum to install the OCI SDK for Python 3.6:

```
sudo yum install python36-oci-sdk
```

This example shows how to use yum to install the OCI SDK for Python 2.7:

```
sudo yum install python-oci-sdk
```

Client-Side Encryption

Client Side Encryption allows you to encrypt data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.

To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service. This can be done using the CreateKey or ImportKey operations.

The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK (encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs so that they can be used for decryption.

Examples

The following code example shows how to encrypt a string:

```python
import oci

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
data_to_encrypt_bytes = b"This is a secret message"

crypto_result = crypto.encrypt(kms_master_key_provider,
data_to_encrypt_bytes)
ciphertext = crypto_result.get_data()
print("ciphertext: {}".format(ciphertext))

# decrypt string example
crypto_result = crypto.decrypt(ciphertext, kms_master_key_provider)
print("unencrypted text: {}".format(crypto_result.get_data()))
```
The following example shows how to encrypt a file stream:

```python
import oci
import shutil

# user supplied vars
vault_id = TEST_VAULT_OCID
master_key_id = TEST_MASTER_KEY_ID
file_to_encrypt = "/file/to/encrypt/message.txt"
output_encrypted_file = "/tmp/message.txt.encrypted"
output_decrypted_file = "/tmp/message.txt.decrypted"

# setup OCI KMS keys
config = oci.config.from_file()
kms_master_key = oci.encryption.KMSMasterKey(
    config=config, master_key_id=master_key_id, vault_id=vault_id
)

kms_master_key_provider = oci.encryption.KMSMasterKeyProvider(
    config=config,
    kms_master_keys=[kms_master_key]
)

# encrypt stream example
with open(output_encrypted_file, 'wb') as output_stream,
    open(file_to_encrypt, 'rb') as stream_to_encrypt:
    with crypto.create_encryption_stream(
        kms_master_key_provider,
        stream_to_encrypt
    ) as encryption_stream:
        shutil.copyfileobj(encryption_stream, output_stream)

# decrypt stream example
with open(output_decrypted_file, 'wb') as output_stream,
    open(output_encrypted_file, 'rb') as stream_to_decrypt:
    with crypto.create_decryption_stream(
        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)
```

<td>The SDK for TypeScript and JavaScript is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see <a href="#">Oracle Linux Cloud Developer</a>.</td>
</tr>
</tbody>
</table>

**Requirements**

To use the SDK for TypeScript and JavaScript, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see [Adding Users](#) on page 81. For a list of typical policies you may want to use, see [Common Policies](#) on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see [Getting Started](#) on page 5379.

**Services Supported**

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data
- Blockchain Platform
- Budgets
- Compute Instance Agent (Oracle Cloud Agent)
- Container Engine for Kubernetes
- Content Management
- Core Services (Networking, Compute, Block Volume)
- Cloud Guard
- Data Catalog
- Data Flow
- Data Integration
- Data Safe
- Data Science
- Data Transfer
- Database
- Database Management
- Database Migration

**Versions Supported**

The SDK for TypeScript and JavaScript currently supports NodeJS version 14.x and TypeScript version 4.x.

**NodeJS & Browser Support**

The SDK for TypeScript and JavaScript currently supports NodeJS but does not have browser support.

**Contact Us**

**Contributions**

Got a fix for a bug or a new feature you’d like to contribute? The SDK is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the SDK for TypeScript and JavaScript is released, subscribe to the Atom feed.

**Questions or Feedback**

- GitHub Issues: To file bugs and feature requests only
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-typescript-sdk tags in your post
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

**Getting Started**

This topic describes how to install and configure the SDK for TypeScript and JavaScript.

To use the Oracle Cloud Infrastructure SDK for TypeScript and JavaScript in your project, import any service from `@/oci-typescript-sdk/index.ts`. For example:

```typescript
// Container Engine
export import containerengine = require("oci-containerengine");

// Core
export import core = require("oci-core");

// Database
export import database = require("oci-database");
```

**Downloading the SDK from GitHub**

You can download the SDK for TypeScript and JavaScript as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

**Installing with yum**

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for TypeScript and JavaScript.

For Oracle Linux 8:

```bash
sudo yum module enable nodejs:14
sudo yum install oci-typescript-sdk
```

For Oracle Linux 7:

```bash
sudo yum install oracle-nodejs-release-el7
sudo yum install --enablerepo=ol7_developer_nodejs14 --enablerepo=ol7_developer oci-typescript-sdk
```
The oci-typescript-sdk yum package will only work for Node version 10.X.X. The oci-sdk package will be installed into the global node_modules folder. To use the oci-sdk package in a project, link the oci-sdk global package to your local project.

For example:

```
# Assuming you are in your project's top level directory
npm link oci-sdk
# You should now see oci-sdk package in your local project's node_modules folder
```

Because the oci-sdk package is globally installed, you must update the import statements for oci-sdk's sub-packages when running the oci-typescript-sdk examples on GitHub.

For example:

```
import * as identity from "oci-identity"; // Change needed
import * as oci from "oci-sdk"; // No change needed

import * as identity from "oci-sdk/node_modules/oci-identity"; // Changed
import * as oci from "oci-sdk"; // No change
```

Using the SDK for TypeScript and JavaScript with NPM

**NPM.**

**Configuring the SDK**

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see [SDK and CLI Configuration File](#) on page 5308.

The default configuration location is "/.oci/config" and "DEFAULT" profile is used. You can use `ConfigFileAuthenticationDetailsProvider` with or without specifying the configuration location and profile name:

```
// TypeScript
import common = require("oci-common");
// Using default configuration
const provider: common.ConfigFileAuthenticationDetailsProvider = new
common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const provider: common.ConfigFileAuthenticationDetailsProvider = new
common.ConfigFileAuthenticationDetailsProvider(
configurationFilePath,
configProfile
);

// JavaScript
const common = require("oci-common");
// Using default configurations
const provider = new common.ConfigFileAuthenticationDetailsProvider();
// Using personal configuration
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const provider = new common.ConfigFileAuthenticationDetailsProvider(
configurationFilePath,
```
Configuring Custom Options

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

```
[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>
```

Then you can retrieve the value:

```
// TypeScript
import common = require("oci-common");
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile =
    config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";

// JavaScript
import common = require("oci-common");
const configurationFilePath = "~/your_config_location";
const configProfile = "your_profile_name";
const config = common.ConfigFileReader.parseDefault(configurationFilePath);
const profile =
    config.accumulator.configurationsByProfile.get(configProfile);
customCompartmentId = profile.get("customCompartmentId") || "";
```

Concepts

This topic explains some of the key concepts for using the SDK for TypeScript and JavaScript.

Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for TypeScript and JavaScript exposes the DefaultRequestSigner class that you can use to create an instance and call signHttpRequest.

The [Raw Request example on GitHub](https://github.com/oracleoci/oci-sdk) shows how to create an instance of DefaultRequestSigner and call signHttpRequest.

Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for TypeScript and JavaScript supports a higher level upload class that uses the multipart upload APIs. [Managing Multipart Uploads](https://docs.oracle.com/en(us)/cloud-infrastructure/oci-sdk-js/index.html#GUID-664B2151-F4B1-4083-92E9-DDAB65101477) provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the UploadManager, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage. The [UploadObject example](https://github.com/oracleoci/oci-sdk) shows how to use the UploadManager to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

Retries
Starting with version 2.0.0, the SDK for TypeScript and JavaScript is configured by default to retry SDK operations that fail using the default retry policy.

**Note:**
Default retry attempts for operations with binary or stream bodies (for example putObject or uploadPart) are only made if the backupBinaryBody property for the default retry configuration is set to true, or if you do not provide the content-length in the request.

If you have already implemented retry logic that does not use the default retry policy feature, this may result in looping retries. To opt-out of the new default retries feature, set the environment variable OCI_SDK_DEFAULT_RETRY_ENABLED to false.

**Note:**
The default retry configuration and the list of errors that can be retried can be seen on Github.

To change the global default retry configuration programmatically:

```javascript
let retryConfiguration : common.RetryConfiguration = {
  terminationStrategy : new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

**Retry Behavior Precedence**
- Any retry configuration that you explicitly define at the request level will override the client level retry configuration or the global level default retry configuration and the environment variable override for that specific request.
- Any retry configuration explicitly defined at the client level will override the global default retry configuration and the environment variable level override for the particular client.
- Default retry configuration set at the global level programmatically will override the environment variable level override.

**Retry Strategies**
You can specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

**Delay Strategy**
The `delayStrategy` parameter determines how long to wait between each retry call. There are two options for this parameter:
- **FixedTimeDelayStrategy (seconds)** - Each retry is delayed by a specified number of seconds.
- **ExponentialBackoffStrategy (seconds)** - The delay time for subsequent retry calls increases by an exponential factor of 2 until it reaches the defined maximum delay (in seconds), with a base value of one second.

The default delay strategy is set to `ExponentialBackoffDelayStrategy` with 30 seconds of delay.

**Retry Condition**
The `retryCondition` defines a function with an error argument that returns a boolean indicating whether to retry or not. The operation will be retried if this function returns true.

**Note:**
For all requests with binary/stream bodies, retries are only attempted if RetryConfiguration.backupBinaryBody is set to true, or if the original stream body is able to be retried. By default, stream bodies will be not be backed up. Stream bodies will only be backed up if...
backupBinaryBody is set to true or if you don’t provide the content-length in the request.

**Termination Strategy**

The `terminationStrategy` parameter defines when to terminate the retry attempts. This parameter supports the following options:

- `MaxTimeTerminationStrategy (seconds)` - Defines total duration in seconds for which the retry attempts.
- `MaxAttemptsTerminationStrategy (attempts)` - Defines the total number of retry attempts.

**Retry Examples**

**TypeScript**

This example sets the retry configuration at the client level:

```typescript
identityClient.clientConfiguration = {
  retryConfiguration: {
    delayStrategy: new common.FixedTimeDelayStrategy(5),
    terminationStrategy: new common.MaxTimeTerminationStrategy(30),
    retryCondition: (error) => { return error.statusCode >= 500; }
  }
}
```

This example sets the retry configuration at the request level:

```typescript
const request = identity.requests.ListAvailabilityDomainsRequest = {
  compartmentId: tenancyId,
  retryConfiguration: {
    terminationStrategy: new common.MaxAttemptsTerminationStrategy(6),
  }
};
```

To change the default retry condition programmatically:

```typescript
let retryConfiguration = common.RetryConfiguration = {
  terminationStrategy: new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

**JavaScript**

This example sets the retry configuration at the client level:

```javascript
identityClient.clientConfiguration = {
  retryConfiguration: {
    delayStrategy: new common.FixedTimeDelayStrategy(5),
    terminationStrategy: new common.MaxTimeTerminationStrategy(30),
    retryCondition: (error) => { return error.statusCode >= 500; }
  }
}
```

This example sets the retry configuration at the request level:

```javascript
const request = {
  compartmentId: tenancyId,
  retryConfiguration: {
    terminationStrategy: new common.MaxAttemptsTerminationStrategy(6),
  }
};
```
To change the default retry condition programmatically:

```javascript
let retryConfiguration = {
    terminationStrategy : new common.MaxAttemptsTerminationStrategy(1)
};
common.GenericRetrier.defaultRetryConfiguration = retryConfiguration;
```

Circuit Breakers

Starting with version 2.0.0, the SDK for Typescript and Javascript provides default support for circuit breakers. Circuit breakers help prevent the client from overwhelming the service by blocking the requests from being sent to the service after a certain failure threshold is reached. For default circuit breakers, all errors that can be retried will be treated as failures for the circuit breakers.

**Note:**
The default circuit breaker configuration can be viewed on Github.

To opt out of the default circuit breaker feature, set the environment variable `OCI_SDK_DEFAULT_CIRCUITBREAKER_ENABLED` to `false`. You can also turn the default behavior off programmatically with:

```
common.CircuitBreaker.EnableGlobalCircuitBreaker = false
```

To change the default circuit breaker configuration at the global level:

```javascript
let customDefaultCircuitBreakerConfig = {
    timeout: 10000, // If our function takes longer than 10 seconds, trigger a failure
    errorThresholdPercentage: 80, // When 80% of requests fail, trip the circuit
    resetTimeout: 30000, // After 30 seconds, try again.
    rollingCountTimeout: 120000, // the duration of the statistical rolling window, in milliseconds
    rollingCountBuckets: 120, // the number of buckets the rolling statistical window is divided into
    volumeThreshold: 10, // minimum number of failures in the circuit
    errorFilter: defaultErrorFilterFunction // defines the failure filter for the circuit
};
common.CircuitBreaker.defaultConfiguration =
customDefaultCircuitBreakerConfig;
```

Circuit Breaker Behavior Precedence

Any circuit breaker configuration that you explicitly define at the client level will override the global default circuit breaker configuration and the environment level override for that client.

For additional information on circuit breakers and the default circuit breaker configuration, see this example on Github.

Setting Endpoints

Service endpoints can be set in three ways:

- Set `.endpoint = '<YOUR_ENDPOINT>'` on the service instance. This lets you specify a full host name (for example, https://www.example.com).
- Set `.region = '<YOUR_REGION_ID>'` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for TypeScript and JavaScript returns an error. You can refer to the list of regionIds in: ./oci-typescript-sdk/common/lib/region.ts
• Pass the region in the configuration file. For more information, see SDK and CLI Configuration File.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for xyz.abc.123.oraclecloud.com is oraclecloud.com.

You must first call Region.register to register the new region, and then you can set the region by either using the configuration file or by set .region = <Your_new_registered_region>.

oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the Region enum for your SDK version.

To set the region:

```javascript
identityClient = await new
identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.region = 'us-phoenix-1'
```

Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the endpoint:

```javascript
// Instantiate an identity client
identityClient = await new
identity.IdentityClient({ authenticationDetailsProvider: provider });
identityClient.endpoint = 'https://<your_endpoint>.com'
```

Paginated Responses

Sometimes it is better to lazy load a result. In order to retrieve more data from lazy load, you have to continue to make calls to the list operation, passing in the value of the most recent response's next token. The pagination module allows you:

• Eagerly load all possible results from a list call
• Lazily load results

For an example on how to use these functions, please check GitHub.

Exception Handling

When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or timeout. You can also get the request ID when handling an exception by looking at the opcRequestId property of the error object.

```javascript
try {
    const response = await identityClient.listAllUsersResponses(listUserReq);
} catch (err) {
    console.log('requestId: ', err.opcRequestId);
}
```
Logging

The SDK for Typescript and JavaScript enables you to integrate your own logger. Logging in the SDK is done through the Logger interface. This interface is a logging abstraction that allows the use of a user-supplied logging library, such as log4js, bunyan, or winston.

For more information, see the logging example on GitHub.

To enable logging:

```typescript
// TypeScript
// Download the logger that you want to use with the SDK (like bunyan)
import { LOG } from "oci-sdk";
var bunyan = require("bunyan");

// Set the logger here
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;
```

```javascript
// Javascript
import { LOG } from "oci-sdk";
var bunyan = require("bunyan");

// Set the logger here.
var bunLog = bunyan.createLogger({ name: "LoggingExample", level: "debug" });
LOG.logger = bunLog;
```

Examples

GitHub

Examples of SDK usage can be found on GitHub, including:

- Example: Create an instance
- Example: Invoke Oracle Function
- Example: Move Compartment

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

SDK Reference

In addition to the examples found on GitHub, the SDK for TypeScipt and JavaScript API reference contains code examples that you can copy and modify to run in your own environment.

Running Examples

**Note:**

If you're using Windows, you'll need to install Git Bash for Windows before running the following commands.

1. git clone the SDK for TypeScipt and JavaScript
git clone https://github.com/oracle/oci-typescript-sdk.git
2. Change to the directory where you installed the oci-typescript-sdk repository.
3. Run npm install
4. Run npm run build
5. If you do not have typescript globally installed, run:

```shell
npm install -g typescript@4.1.3.
```

**Note:**
We've tested and support TypeScript version 4.1.3 with the OCI SDK for TypeScript and JavaScript. We cannot guarantee full support for other versions of TypeScript.

6. You can optionally install ts-node globally to make it easier to run examples:

```shell
npm install -g ts-node
```

7. Create your configuration file in your home directory. See SDK and CLI Configuration File on page 5308 for more information.

8. Change directory into the TypeScript example folder to run TypeScript examples. For example:

```shell
cd ./oci-typescript-sdk/examples/typescript/
```

9. Run any of the examples.

   For example, if you're running ts-node:

   ```shell
ts-node "./identity.ts"
```

   If you're not running ts-node:

   ```shell
tsc ./identity.ts
   node ./identity.js
```

10. Some examples are available in JavaScript. They are located in the `oci-typescript-sdk/examples/javascript` folder. To run the JavaScript equivalent of the above example:

    ```shell
    node "./identity.js"
    ```

**SDK for .NET**

The Oracle Cloud Infrastructure SDK for .NET enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** GitHub or Nuget.

**Requirements**

To use the SDK for .NET, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see SDK and CLI Configuration File on page 5308.
- .NET Standard version 2.0 or higher

Questions or Feedback
• GitHub Issues: To file bugs and feature requests only
• Stack Overflow: Please use the oracle-cloud-infrastructure and oci-dotnet-sdk tags in your post
• The Developer Tools section of the Oracle Cloud forums
• My Oracle Support

Getting Started
This topic describes how to install and configure the SDK for .NET.

To use a specific Oracle Cloud Infrastructure service in your project, you can use the dotnet add package command from the root directory of your project workspace that contains the project file. The syntax for the add package command is:

```
dotnet add package <PACKAGE_ID> -v <DESIRED_VERSION>
```

If you do not specify a version number, the add package command will install the latest version.
This example installs the latest version of the Core Service package:

```
dotnet add package OCI.DotNetSDK.Core
```

This example installs version 1.0.0 of the Identity Service package:

```
dotnet add package OCI.DotNetSDK.Identity -v 1.0.0
```

**Note:**

To avoid dependency conflicts, you should use the same versions of all OCI.NET SDK Nuget packages within an application.

**Downloading the SDK from GitHub**

You can download the SDK for .NET as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples.

**Installing the SDK with Yum**

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for .NET.

1. To install the OCI SDK for .NET using yum:
   a. For Oracle Linux 7:
      ```
      sudo yum-config-manager --enable ol7_developer
      sudo yum install oci-dotnet-sdk
      ```
   b. For Oracle Linux 8:
      ```
      sudo yum-config-manager --enable ol8_developer
      sudo yum install oci-dotnet-sdk
      ```

   The OCI Dotnet SDK service packages and its dependencies are located in `/usr/lib/dotnet/NuPkgs/`

2. So the dotnet CLI can find the installed packages, you must do one of the following:
   a. Create a file named `nuget.config` in the root of your .NET application project and add the following content:
      ```xml
      <?xml version="1.0" encoding="utf-8"?>
      <configuration>
      <packageSources>
      <!--To inherit the global NuGet package sources remove the <clear/>
      line below -->
      <clear />
      <add key="local" value="/usr/lib/dotnet/NuPkgs" />
      </packageSources>
      </configuration>
      ...
      ...
      ```
   b. Use the `--source` option with the dotnet CLI commands, passing in the directory `/usr/lib/dotnet/NuPkgs/`. For example:
      ```
      dotnet build --source /usr/lib/dotnet/NuPkgs/
      dotnet restore --source /usr/lib/dotnet/NuPkgs/
      dotnet add package OCI.DotNetSDK.Common --source /usr/lib/dotnet/NuPkgs/
      ```

3. To get information about the installed package, run the following command:

```
rpm -qi oci-dotnet-sdk
```
4. Add the OCI Service packages to your project using the dotnet command line:

```bash
dotnet add package OCI.DotNetSDK.Common
dotnet add package OCI.DotNetSDK.Audit --version 4.3.0
```

5. You can now import namespaces into your project. For example:

```csharp
using Oci.AuditService;
using Oci.AuditService.Models;
using Oci.Common;
using Oci.Common.Auth;
```

Using the SDK for .NET with Nuget

**Nuget.**

Configuring the SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

**Configuring Credentials**

First, you need to set up your credentials and config file. For instructions, see [SDK and CLI Configuration File](#) on page 5308.

Next, you need to set up the client to use the credentials. The credentials are abstracted through an `IAuthenticationDetailsProvider` interface that the client needs to implement.

These examples shows implementations of `ConfigFileAuthenticationDetailsProvider` and `SimpleAuthenticationDetailsProvider`.

**Using a Standard Configuration**

If you use standard config file keys and the standard config file location, you can use `ConfigFileAuthenticationDetailsProvider`:

```csharp
using Oci.Common.Auth;

// uses DEFAULT profile in default file location: i.e ~/.oci/config
var provider = new ConfigFileAuthenticationDetailsProvider("DEFAULT");
// uses custom configuration
var provider = new ConfigFileAuthenticationDetailsProvider("custom_file_location", "CUSTOM_PROFILE");
```

**Using a Custom Configuration**

If you are using custom key names in the config file, you can use `SimpleAuthenticationDetailsProvider`.

To load a config with or without a profile:

```csharp
using Oci.Common;

var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);
var configWithProfile = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH, "DEFAULT");
```

Next, create an `Auth` provider using `SimpleAuthenticationDetailsProvider`:

```csharp
using Oci.Common;
using Oci.Common.Auth;
```
```csharp
var config = ConfigFileReader.Parse(ConfigFileReader.DEFAULT_FILE_PATH);

// The private key supplier can be created with the file path, or using the config file
var provider = new SimpleAuthenticationDetailsProvider{
    TenantId = config.GetValue("tenancy"),
    UserId = config.GetValue("user"),
    Fingerprint = config.GetValue("fingerprint"),
    Region = Region.FromRegionId(config.GetValue("region")),
    PrivateKeySupplier = new
        FilePrivateKeySupplier(config.GetValue("key_file"),
        config.GetValue("pass_phrase"))
};
```

### Configuring Client-Side Options

Create a client-side configuration through the `ClientConfiguration` class. If you do not provide your own configuration, the SDK for .NET uses a default configuration.

The following example shows how to provide your own configuration:

```csharp
var clientConfiguration = new ClientConfiguration{
    ClientUserAgent = "DotNet-SDK-Example",
    RetryConfiguration = new RetryConfiguration{
        // maximum number of attempts to retry the same request
        MaxAttempts = 5,
        // retries the request if the response status code is in the range [400-499] or [500-599]
        RetryableStatusCodeFamilies = new List<int> { 4, 5 }
    }
};
```

### Configuring Custom Options

In the configuration file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file:

```ini
[DEFAULT]
user=ocid1.user.oc1..<your_unique_id>
fingerprint=<your_fingerprint>
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..<your_unique_id>
customCompartmentId=ocid1.compartment.oc1..<your_unique_id>
```

Then you can retrieve the value:

```csharp
using Oci.Common;
var config = ConfigFileReader.parse(ConfigFileReader.DEFAULT_FILE_PATH);
String compartmentId = config.GetValue("customCompartmentId");
```

### Enabling Logging

The OCI SDK for .NET uses the `NLog` package for logging. `NLog` is automatically installed with the .NET SDK, so no additional installation is required.

To enable logging in your project:

1. Add an `NLog.config` file at the project's root directory. You can find an example `NLog.config` file here.
2. Add an ItemGroup section in the project file. For example:

```xml
<ItemGroup>
  <Content Include="PATH TO NLog.config File" />
  <CopyToOutputDirectory>PreserveNewest</CopyToOutputDirectory>
</Content>
</ItemGroup>
```

3. To log from an application, create a Logger and use the Info() method. For example:

```csharp
var logger = NLog.LogManager.GetCurrentClassLogger();
logger.Info("Hello World");
```

**Note:**

Only SDK logging will be captured if you don't create a logger from an application.

**Concepts**

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for .NET.

**Raw Requests**

Raw requests can be useful, and in some cases necessary. Typical use cases include using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, or making a request to a OCI API that is not currently supported in the SDK. The SDK for .NET exposes the OciHttpClientHandler class that you can use to create a client handler which signs the request.

This raw request example on GitHub shows how to use the OciHttpClientHandler.

**Setting the Endpoints**

Service endpoints can be set in several ways:

- Call `SetEndpoint(<YOUR_ENDPOINT>)` on the service client instance. This lets you specify a full host name (for example, `https://www.example.com`).
- Call `SetRegion(<YOUR_REGION_ID>)` on the service client instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the SDK for .NET returns an error.
- Call `SetRegion(<Region>)` on the service client instance. For example, `SetRegion(Region.US_PHOENIX_1)`.
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File on page 5308.

An example on setting endpoint can be found on GitHub.

Note that a service client instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service client instances.

**New Region Support**

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A region is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains on page 208.

A realm is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.Register()` to register the new region, and then you can set the region by either using the configuration file or by calling the `SetRegion` method.

An example on adding a new region can be found on GitHub.
oraclecloud.com Realm

For regions in the oraclecloud.com realm, you can pass new region names just as you would pass ones that are already defined in the `Region` enum for your SDK version.

To set the region:

```csharp
using Oci.IdentityService;

var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetRegion("US_NEWYORK_1");
```

Other Realms

For regions in realms other than oraclecloud.com, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To set the region:

```csharp
using Oci.IdentityService;

var identityClient = new IdentityClient(<IAuthenticationDetailsProvider>);
identityClient.SetEndpoint("https://<your_endpoint>.com");
```

Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for .NET supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the `UploadManager`, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The `UploadObject` example shows how to use the `UploadManager` to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

Retries

You can configure the SDK for .NET to retry SDK operations that fail. The SDK allows you to specify the strategy to use for how retries are handled, including the number of times to retry, the condition under which the SDK should retry an operation, and when to stop retrying an operation. You can set these parameters at the client level and at the individual request level.

**Delay Strategy**

You can define your own delay strategy with the `GetNextDelayInSeconds` property. The SDK for .NET provides two different Delay Strategies:

- `GetFixedDelayInSeconds (seconds)` - Each retry is delayed by a specified number of seconds.
- `GetExponentialDelayInSeconds` - The delay time for subsequent retry calls increases by an exponential factor of 2.

**Termination Strategy**

You can define a termination strategy with two properties:

- `TotalElapsedTimeInSecs (seconds)` - Defines total duration in seconds for which the retry attempts.
- `MaxAttempts (attempts)` - Defines the total number of retry attempts.

**Retryable Status Code Families**
You can specify a list of status codes to retry using the `RetryableStatusCodeFamilies` property. For example:

```csharp
// Retryable status code family - this will make the SDK retry for all 5xx status codes:
RetryableStatusCodeFamilies = new List<int>(new int[] { 5 });
```

### Retryable Errors

This property is a collection of integer and string tuples containing status and error codes returned by a service error for which the SDK can retry. For example:

```csharp
// Retry on the following HTTP status and error codes:
RetryableErrors = new Collection<Tuple<int, string>>(new Tuple<int, string>[] {
    new Tuple<int, string>(409, "IncorrectState"),
    new Tuple<int, string>(429, "TooManyRequests")
```

### Retry Examples

#### .NET

This example shows how to configure and use retries with the SDK for .NET:

```csharp
namespace Oci.Examples
{
    public class RetryExample
    {
        private static NLog.Logger logger =
            NLog.LogManager.GetCurrentClassLogger();
        const string OciConfigProfileName = "DEFAULT";
        public static async Task MainRetry()
        {
            string compartmentId =
                Environment.GetEnvironmentVariable("OCI_COMPARTMENT_ID");

            // Configuring the AuthenticationDetailsProvider. It's assumed
            // there is a default OCI config file
            // "/.oci/config", and a profile in that config with the name
            OciConfigProfileName. Make changes to the following
```
// line if needed and use
ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);
    var provider = new
ConfigFileAuthenticationDetailsProvider(OciConfigProfileName);
    // Create a client for the service to enable using its APIs
    var client = new IdentityClient(provider, new
ClientConfiguration());
    try
    {
        await ListOciRegions(client);
        await ListOciRegionSubscriptions(client, compartmentId);
    }
    catch (Exception e)
    {
        logger.Info($"Received exception due to {e.Message}");
    }
    finally
    {
        client.Dispose();
    }

    private static async Task ListOciRegions(IdentityClient client)
    {
        // Create a retry configuration to override defaults
        RetryConfiguration retryConfiguration = new RetryConfiguration
        {
            // Enable exponential backoff
            GetNextDelayInSeconds =
            DelayStrategy.GetExponentialDelayInSeconds,
            // Defines total duration in seconds for which the retry
            TotalElapsedTimeInSecs = 600,
            // Defines the total number of retry attempts.
            MaxAttempts = 4,
            // Retryable status code family - this will make the SDK
            retry for all 5xx status codes
            RetryableStatusCodeFamilies = new List<int>(new int[]
            { 5 })),
            // Retry on the following HTTP status and error codes
            RetryableErrors = new Collection<Tuple<int, string>>(new
            Tuple<int, string>[]
            {
                new Tuple<int, string>(409, "IncorrectState"),
                new Tuple<int, string>(429, "TooManyRequests")
            })
        };
        // List regions
        var listRegionsRequest = new ListRegionsRequest();
        ListRegionsResponse listRegionsResponse = await
        client.ListRegions(listRegionsRequest, retryConfiguration);
        logger.Info("List Regions");
        logger.Info("=================");
        foreach (Oci.IdentityService.Models.Region reg in
        listRegionsResponse.Items)
        {
            logger.Info($"{reg.Key} : {reg.Name}");
        }
    }
{ TenancyId = compartmentId }

RetryConfiguration retryConfiguration = new RetryConfiguration
{
    // Enable exponential backoff with Full Jitter.
    GetNextDelayInSeconds = GetJitterDelayInSeconds
};

ListRegionSubscriptionsResponse listRegionSubscriptionsResponse
= await client.ListRegionSubscriptions(listRegionSubscriptionsRequest,
retryConfiguration);

List<RegionSubscription> regionSubscriptions =
listRegionSubscriptionsResponse.Items;

logger.Info("List RegionSubscriptions");

foreach (RegionSubscription regionSubscription in
regionSubscriptions)
{
    logger.Info($"{regionSubscription.RegionName} : 
{regionSubscription.RegionKey}");
}

/// <summary>
/// Defining a custom retry strategy that mimics an exponential
/// backoff with full jitter to reduce
/// contention between competing calls
/// </summary>
private static double GetJitterDelayInSeconds(int retryAttempt)
{
    Random random = new Random();
    return random.NextDouble() * Math.Pow(2, retryAttempt);
}

Paginated Responses

For large result sets, most OCI calls supported paginated responses. Paginated responses require you to make multiple
calls to the list operation, passing in the value of the most recent response's next token. The pagination module allows
you to:

- Load all possible results from a list call in one call
- Lazily load results using token-based paginated responses

For an example on how to use these functions, please see GitHub.

Polling with Waiters

The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can
be invoked in both a blocking or a non-blocking (with asynchronous callback) manner, and will wait until either the
desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write
into an easy-to-use single method call.

Waiters are obtained through the service client (client.Waiters). Both a Get<Resource>Request and the
desired lifecycle state are passed in to the Waiters.For<Resource> method.

For example:

using Oci.CoreService;

public static Instance WaitForInstanceProvisioningToComplete(ComputeClient
computeClient, String instanceId)
GetInstanceRequest getInstanceRequest = new GetInstanceRequest
    { InstanceId = instanceId);
GetInstanceResponse getInstanceResponse =
    computeClient.Waiters.ForInstance(getInstanceRequest,
    Instance.LifecycleStateEnum.Running).Execute();
    return getInstanceResponse.Instance;
}

Each `waiters.for<Resource>` method has two versions:

One version uses the default polling values. For example:

```csharp
Waiters.ForInstance(getInstanceRequest, Instance.LifecycleStateEnum.Running)
```

The other version gives you full control over how long to wait and how much time between polling attempts. For example:

```csharp
using Oci.Common.Waiters;
WaiterConfiguration waiterConfiguration = new WaiterConfiguration
     {
         MaxAttempts = 5,
         GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds
     };
Waiters.ForInstance(getInstanceRequest, waiterConfiguration,
      Instance.LifecycleStateEnum.Running)
```

Some API requests return work request identifiers to track the progress of the request. Waiters can be used to wait until the work request has reached the desired state.

For example:

```csharp
using Oci.Common.Waiters;
using Oci.ContainerengineService;
using Oci.ContainerengineService.Responses;
using Oci.ContainerengineService.Requests;
CreateClusterResponse clusterResponse = await
    containerEngineClient.CreateCluster(createClusterRequest);
GetWorkRequestResponse workRequestResponse =
    WaitForWorkRequestFinished(containerEngineClient, workRequestId);
private static GetWorkRequestResponse
    WaitForWorkRequestFinished(ContainerEngineClient containerEngineClient,
      string workRequestId)
    {
        var waiterConfiguration = new WaiterConfiguration
            {
                MaxAttempts = 5,
                GetNextDelayInSeconds = DelayStrategy.GetExponentialDelayInSeconds
            };
        GetWorkRequestRequest getWorkRequestRequest = new GetWorkRequestRequest
            {
                WorkRequestId = workRequestId
            };
        return
            containerEngineClient.Waiters.ForWorkRequest(getWorkRequestRequest,
                waiterConfiguration, WorkRequestStatus.Succeeded).Execute();
    }
```

Further examples on waiters can be found on Github.

Exception Handling
Developer Tools

When handling an exception, you can get more information about the HTTP request that caused it, such as the status
code or service code. You can also get the request ID when handling an exception by looking at the opcRequestId
property of the error object.
For example:

try {
var response = await identityClient.ListAllUsersResponses(listUserReq);
} catch (OciException e) {
logger.Info($"requestId: {e.OpcRequestId}");
logger.Info($"StatusCode: {e.StatusCode}");
logger.Info($"ServiceCode: {e.ServiceCode}");
}
Authenticating with Instance Principals
Instance principals is an IAM service feature that enables instances to be authorized actors (or principals) that
can perform actions on service resources. Each compute instance has its own identity, and it authenticates using
the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated,
preventing the need for you to distribute credentials to your hosts and rotate them.
Note:
For more information on instance principals, see Calling Services from an
Instance on page 3106.
While using the .NET SDK on an OCI Instance, you can use
InstancePrincipalsAuthenticationDetailsProvider class as shown in the following example. You
will not need to provide your authentication details when you use this class.
using Oci.Common.Auth;
using Oci.IdentityService;
// Creates an Instance Principal provider that holds authentication details
of the OCI Instance
var instanceProvider = new
InstancePrincipalsAuthenticationDetailsProvider();
// Create a client for the service to enable using its APIs
var client = new IdentityClient(instanceProvider);
A full working example of using instance principals with the OCI .NET SDK can be found on GitHub.
Examples
GitHub
Examples of SDK usage can be found on GitHub, including:
•
•
•

Example: Create an instance
Example: Invoke Oracle Function
Example: Move Compartment

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the
downloadable .zip for the specific version, available on GitHub.
If you'd like to see another example not already covered, file a GitHub issue.
SDK Reference
In addition to the examples found on GitHub, the SDK for .NET API reference contains code examples that you can
copy and modify to run in your own environment.
Running Examples

Oracle Cloud Infrastructure User Guide

5399


1. Use git to clone the OCI SDK for .NET repository: `git clone https://github.com/oracle/oci-dotnet-sdk.git`

2. Create a configuration file in your home directory (`~/oci/config`). See SDK and CLI Configuration File on page 5308 for more information.

3. Change directory into the .NET Examples folder. For example: `cd ./oci-dotnet-sdk/Examples/`

4. All of the examples require the environment variable `OCI_COMPARTMENT_ID` populated with the tenant ID or compartment ID.

5. From the command line, run `dotnet run`. The Audit example runs by default.

6. To run any other example, make sure it has a `Main()` function.

### SDK for Go

The Oracle Cloud Infrastructure SDK for Go enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

**Download:** Download the SDK from GitHub.

**Documentation:** The reference documentation is available from Oracle here and at godoc.org.

**Tip:**

- **Cloud Shell:** The SDK for Go is pre-configured with your credentials and ready to use immediately from within Cloud Shell. For more information on using the SDK for Go from within Cloud Shell, see SDK for Go Cloud Shell Quick Start on page 5313.
- **Oracle Linux Cloud Developer image:** The SDK for Go is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

**Requirements**

To use the SDK for Go, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies, you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Configure the SDK.
- Go versions 1.14, 1.15, or 1.16.

**Services Supported**

- AI Anomaly Detection
- AI Language
- Analytics Cloud
- Announcements
- API Gateway
- Application Migration
- Application Performance Monitoring
- Audit
- Autoscaling (Compute)
- Bastion
- Big Data
- Blockchain Platform

**Installing with Resource Manager**

You can use Resource Manager to install the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes the SDK for Go, along with other Oracle development tools.

**Installing with yum**

If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Go. GoLang 1.16.3 will also be installed.

For Oracle Linux 7:

```
sudo yum-config-manager --enable ol7_developer
sudo yum install go-oci-sdk
```

For Oracle Linux 8:

```
sudo yum-config-manager --enable ol8_developer
sudo yum install go-oci-sdk
```

The OCI Go SDK will be located in `/usr/share/gocode/src/github.com/oracle/oci-go-sdk`.

Golang 1.16.3 enables the go module by default, even when no `go.mod` is present. You need to turn the go module off to ensure that the OCI Go SDK can be referenced from the filesystem where yum installed the Go SDK. To do so, set the following environment variables:

```
export GOPATH=/usr/share/gocode
export GO111MODULE=off
```

SDK for Ruby

The Oracle Cloud Infrastructure SDK for Ruby enables you to write code to manage Oracle Cloud Infrastructure resources.

Note:
The Oracle Cloud Infrastructure SDK for Ruby currently supports Ruby versions 2.6 and 2.7.

Note:
This project is no longer being actively developed by Oracle. We will continue to address security vulnerabilities for the foreseeable future, and will respond to questions on github, but have no plans to introduce any new functionality, and may not be able to address any non-security related issues. We encourage developers to migrate to other OCI SDKs, and developers may fork the project and enhance it as they desire.

This SDK and sample are dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The SDK for Ruby is available on GitHub or RubyGems.

Documentation: SDK for Ruby documentation.

Tip:
The SDK for Ruby is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Installing with yum
If you're using Oracle Linux 7 or 8, you can use yum to install the OCI SDK for Ruby.

The following example shows how to use yum to install the OCI SDK for Ruby 2.6 on Oracle Linux 7:

```bash
sudo yum-config-manager --enable ol7_developer
sudo yum install -y oci-ruby-sdk
source /opt/rh/rh-ruby26/enable
export GEM_PATH="/usr/share/gems:`gem env gempath`"
```

The following example shows how to use yum to install the OCI SDK for Ruby 2.6 on Oracle Linux 8:

```bash
sudo yum-config-manager --enable ol8_developer
sudo yum install -y oci-ruby-sdk
source /opt/rh/rh-ruby26/enable
export GEM_PATH="/usr/share/gems:`gem env gempath`"
```

PL/SQL SDK
The Oracle Cloud Infrastructure SDK for PL/SQL enables you to write PL/SQL code to manage Oracle Cloud Infrastructure resources.

The latest version of the SDK is pre-installed by Oracle for all Autonomous Databases using shared Exadata infrastructure.

Requirements
To use the PL/SQL SDK, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key.

Examples

This section contains examples of how to use the PL/SQL SDK.

Working with Object Storage Buckets

The following example shows examples of how to use the PL/SQL SDK to create and delete buckets using the OCI Object Storage service:

```sql
-- ##################################################################
-- # Create bucket #
-- ##################################################################
set serveroutput on
declare
  response_body  dbms_cloud_oci_object_storage_bucket_t;
  response       dbms_cloud_oci_obs_object_storage_create_bucket_response_t;
  bucket_details dbms_cloud_oci_object_storage_create_bucket_details_t;
  json_obj       json_object_t;
  l_keys         json_key_list;
begin
  bucket_details := dbms_cloud_oci_object_storage_create_bucket_details_t();
  bucket_details.name := 'bucketname';
  bucket_details.compartment_id := 'compartment_OCID';
  response := dbms_cloud_oci_obs_object_storage.create_bucket(
    namespace_name => 'namespace-string',
    opc_client_request_id => 'random-request-id',
    create_bucket_details => bucket_details,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');
  response_body := response.response_body;
  -- Response Headers
  dbms_output.put_line('Headers: ' || CHR(10) || '------------');
  json_obj := response.headers;
  l_keys := json_obj.get_keys;
  for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||
      json_obj.get(l_keys(i)).to_string);
  end loop;
  -- Response status code
  dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
  dbms_output.put_line(CHR(10));
  -- Response body
  dbms_output.put_line(response_body.namespace);
  dbms_output.put_line(response_body.name);
  dbms_output.put_line(response_body.compartment_id);
  dbms_output.put_line(response_body.metadata.to_string());
  dbms_output.put_line(response_body.created_by);
  dbms_output.put_line(response_body.time_created);
  dbms_output.put_line(response_body.approximate_count);
  dbms_output.put_line(response_body.approximate_size);
  dbms_output.put_line(response_body.etag);
  dbms_output.put_line(response_body.public_access_type);
  dbms_output.put_line(response_body.storage_tier);
  dbms_output.put_line(response_body.freeform_tags.to_string());
  dbms_output.put_line(response_body.defined_tags.to_string());
  dbms_output.put_line(response_body.kms_key_id);
  dbms_output.put_line(response_body.object_lifecycle_policy_etag);
```
dbms_output.put_line(response_body.id);
end;
/

-- ####################
-- ## Delete bucket ##
-- ####################
set serveroutput on
declare
  response       dbms_cloud_oci_obs_object_storage_delete_bucket_response_t;
  json_obj       json_object_t;
  l_keys         json_key_list;
begin
  response := dbms_cloud_oci_obs_object_storage.delete_bucket(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

  -- Response Headers
  dbms_output.put_line('Headers: ' || CHR(10) || '------------');
  json_obj := response.headers;
  l_keys := json_obj.get_keys;
  for i IN 1..l_keys.count loop
    dbms_output.put_line(l_keys(i)||':'||json_obj.get(l_keys(i)).to_string);
  end loop;

  -- Response status code
  dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
    CHR(10) || response.status_code);
  dbms_output.put_line(CHR(10));
end;
/

Working with Object Storage Objects

The following example shows how to use the PL/SQL SDK to store and retrieve objects using the OCI Object Storage service:

-- ##################
-- ## Put Object   ##
-- ##################
declare
  my_blob_data   blob;
  response       dbms_cloud_oci_obs_object_storage_put_object_response_t;
  json_obj       json_object_t;
  l_keys         json_key_list;
begin
  /* Some processing producing BLOB data and populating my_blob_data */
  response := dbms_cloud_oci_obs_object_storage.put_object(
    namespace_name => 'namespace-string',
    bucket_name => 'bucketname',
    object_name => 'objectname',
    put_object_body => my_blob_data,
    credential_name => 'OCI_KEY_CRED',
    region => 'region-identifier');

  -- Response Headers
Listing Compartments

The following example shows how to list compartments using the PL/SQL SDK:

```
-- ListCompartments
set serveroutput on
declare
    response_body dbms_cloud_oci_identity_list_compartments_response_t;
    json_obj      json_object_t;
    l_keys        json_key_list;
begin

    response := dbms_cloud_oci_id_identity_list_compartments_response_t;
    response_body := response.response_body;

    -- Response Headers
    dbms_output.put_line('Headers: ' || CHR(10) || '------------');
    json_obj := response.headers;
    l_keys := json_obj.get_keys;
    for i in 1..l_keys.count loop
        dbms_output.put_line(l_keys(i)||':'||
            json_obj.get(l_keys(i)).to_string);
    end loop;

    -- Response status code
    dbms_output.put_line('Status Code: ' || CHR(10) || '------------' ||
        CHR(10) || response.status_code);
    dbms_output.put_line(CHR(10));

    -- Response body
    dbms_output.put_line('Contents: ' ||
        UTL_RAW.cast_to_varchar2(response_body));
end;
/
```
limit => 2, credential_name => 'OCI_KEY_CRED', region => 'region-identifier'); response_body :=
response.response_body; -- Response Headers dbms_output.put_line('Headers: ' || CHR(10) ||'----------'); json_obj :=
response.headers; l_keys := json_obj.get_keys; for i IN 1..l_keys.count loop dbms_output.put_line(l_keys(i)||' '||
json_obj.get(l_keys(i)).to_string); end loop; -- Response status code dbms_output.put_line('Status Code: ' || CHR(10) || '----------' || CHR(10) || response.status_code); for i in 1 .. response_body.count loop dbms_output.put_line(response.body(i)); dbms_output.put_line(response.body(i).id); dbms_output.put_line(response.body(i).compartment_id); dbms_output.put_line(response.body(i).name); dbms_output.put_line(response.body(i).description); dbms_output.put_line(response.body(i).time_created); dbms_output.put_line(response.body(i).lifecycle_state); dbms_output.put_line(response.body(i).inactive_status); dbms_output.put_line(response.body(i).is_accessible);
end loop; for i in 1 .. response_body.private_endpoint_settings.nsg_ids.count loop dbms_output.put_line(response.body.private_endpoint_settings.nsg_ids(i)); end loop; end; /

Working With Streams

The following example shows how to create and delete stream pools using the PL/SQL SDK:

```sql
-- #########################
-- ## Create stream pool  ##
-- #########################
set serveroutput on
declare
    response_body       dbms_cloud_oci_streaming_stream_pool_t;
    response
        dbms_cloud_oci_st_stream_admin_create_stream_pool_response_t;
    stream_pool_details
        dbms_cloud_oci_streaming_create_stream_pool_details_t;
    json_obj            json_object_t;
    l_keys              json_key_list;
begin
    stream_pool_details :=
        dbms_cloud_oci_streaming_create_stream_pool_details_t();
    stream_pool_details.name := 'streampoolname';
    stream_pool_details.compartment_id := 'compartment_OCID';
    response := dbms_cloud_oci_st_stream_admin.create_stream_pool(
        create_stream_pool_details => stream_pool_details,
        opc_request_id => 'random-request-id',
        credential_name => 'OCI_KEY_CRED',
        region => 'region-identifier');
    response_body := response.response_body;
-- Response Headers
    dbms_output.put_line('Headers: ' || CHR(10) || '----------');
    json_obj := response.headers;
    l_keys := json_obj.get_keys;
    for i IN 1..l_keys.count loop
        dbms_output.put_line(l_keys(i)||' '||
            json_obj.get(l_keys(i)).to_string);
    end loop;
-- Response status code
    dbms_output.put_line('Status Code: ' || CHR(10) || '----------' || CHR(10) ||
        response.status_code);
    for i in 1 .. response_body.count loop
        dbms_output.put_line(response.body(i));
        dbms_output.put_line(response.body(i).id);
        dbms_output.put_line(response.body(i).compartment_id);
        dbms_output.put_line(response.body(i).name);
        dbms_output.put_line(response.body(i).description);
        dbms_output.put_line(response.body(i).time_created);
        dbms_output.put_line(response.body(i).lifecycle_state);
        dbms_output.put_line(response.body(i).inactive_status);
        dbms_output.put_line(response.body(i).is_accessible);
        dbms_output.put_line(response.body.private_endpoint_settings.nsg_ids(i));
    end loop;
end; /
```
```sql
dbms_output.put_line(response_body.private_endpoint_settings.nsg_ids(i));
end loop;
end;
/

-- #########################
-- ## Delete stream pool  ##
-- #########################
set serveroutput on
declare
response
dbms_cloud_oci_st_stream_admin_delete_stream_pool_response_t;
json_obj    json_object_t;
l_keys     json_key_list;
beginn
response := dbms_cloud_oci_st_stream_admin.delete_stream_pool(
  stream_pool_id => 'stream-pool-ocid',
  credential_name => 'OCI_KEY_CRED',
  region => 'region-identifier');

-- Response Headers
dbms_output.put_line('Headers: ' || CHR(10) ||'------------');
json_obj := response.headers;
l_keys := json_obj.get_keys;
for i IN 1..l_keys.count loop
dbms_output.put_line(l_keys(i)||':||
  json_obj.get(l_keys(i)).to_string);
end loop;
end;
/
```

**DevOps Tools and Plug-ins**

Oracle Cloud Infrastructure provides a number of DevOps tools and plug-ins for working with Oracle Cloud Infrastructure services. These can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery.

**Terraform Provider** - Manage "infrastructure as code" with this component that connects Terraform to a given Oracle Cloud Infrastructure service.

- **Documentation**: Terraform Provider on page 5412
- **Download**: GitHub

**OCI Modules for PowerShell** - A set of cmdlet modules that can be used with PowerShell Core to manage Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.

- **Documentation**: OCI Modules for PowerShell on page 5469
- **Download**: GitHub or PowerShell Gallery

**Ansible Collection** - Automate provisioning and configuring of Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.

- **Documentation**: Ansible Collection on page 5485
- **Download**: GitHub

**Compute Jenkins Plug-in** - Bring up and down services or nodes as required to serve Jenkins Build Jobs and dynamically allocate Oracle Cloud Infrastructure resources for continuous integration tasks.

- **Documentation**: Compute Jenkins Plug-in on page 5502
- **Download**: GitHub
**OCI DevOps Plug-in for Jenkins** - Upload artifacts, and run deployments on Oracle Cloud Infrastructure from Jenkins. A Jenkins master instance with the DevOps plug-in can upload artifacts to the Artifacts Registry repository, and trigger the deployment pipeline for deploying those artifacts.

- **Documentation**: OCI DevOps Plug-in for Jenkins
- **Download**: GitHub

**Chef Knife Plug-in** - Manage Oracle Cloud Infrastructure resources with Chef Knife, a command line tool that provides an interface between a local chef-repo and the Chef server.

- **Documentation**: Chef Knife Plug-in on page 5502
- **Download**: GitHub

**Grafana Plug-in** - Visualize metrics from the Monitoring service in your Grafana instance.

- **Documentation**: Grafana Plug-in on page 5503
- **Download**: GitHub

**Terraform Kubernetes Installer** - Provision and configure the resources needed to run a highly available and configurable Kubernetes cluster.

- **Download**: GitHub

**Kubernetes Volume Provisioner** - Enable dynamic provisioning of storage resources when running Kubernetes on Oracle Cloud Infrastructure.

- **Download**: GitHub

**DevOps Integrations**

- **Jenkins X Integration**: Create a new Kubernetes cluster on Oracle Cloud Infrastructure Container Engine for Kubernetes.
- **Packer Integration**: Create reusable custom images.

**Other Services and Features for DevOps**

Oracle Cloud Infrastructure provides other services and features relevant to DevOps professionals.

- **Container Engine for Kubernetes (OKE)** Reliably build, deploy, and manage cloud-native containerized applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing tenancy.
- **Oracle Cloud Infrastructure Registry** Store, share, and manage development artifacts like Docker images. As Oracle Cloud Infrastructure Registry is managed by Oracle, your applications are deployed reliably and you don't have to deal with operational issues.

**Terraform Provider**

Terraform is an open source tool that allows you to programmatically manage, version, and persist infrastructure through the "infrastructure-as-code" model. Terraform configurations codify your infrastructure in declarative files that contain the steps required to provision your infrastructure and maintain its state. You can share these files among team members, treat them as code, edit, review, and version them.

Terraform uses providers to interface between the Terraform engine and the supported cloud platform. The Oracle Cloud Infrastructure (OCI) Terraform provider is a component that connects Terraform to the OCI services that you want to manage.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Storing Sensitive Data on page 5446 for more information.</td>
</tr>
</tbody>
</table>
You can use the OCI Terraform provider to manage OCI resources wherever you use a Terraform distribution, including Terraform Cloud and the OCI Resource Manager. Oracle Public Cloud has its own Terraform provider.

Resource Manager is an Oracle Cloud Infrastructure service that uses Terraform to automate the process of provisioning your Oracle Cloud Infrastructure.

**Tip:**
You can migrate existing Terraform state files to Resource Manager using an Import State job.

See Getting Started to begin using the Terraform provider to manage your OCI resources.

**Licensing:** This provider and samples are licensed under the Mozilla Public License 2.0; third-party content is separately licensed as described in the code.

**Availability**
The Oracle Cloud Infrastructure Terraform provider is region agnostic. You can use the Terraform provider to work with supported services in all Oracle Cloud Infrastructure regions in which they are available. Government Cloud customers should use the FIPS-compatible OCI Terraform provider.

See Regions and Availability Domains on page 208 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

**Contributions**
Got a fix for a bug, or a new feature you’d like to contribute? The Terraform provider is open source and accepting pull requests on GitHub.

**Notifications**
To be notified when a new version of the OCI Terraform provider is released, subscribe to the Atom feed.

**Questions or Feedback**
Refer to Troubleshooting Basics and a list of common issues to see if your question has an answer.

You can also use GitHub to file bugs and submit feature requests.

**What’s New**
Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules all have the ability to introduce changes or add new functionality.

**Terraform Updates**
Major Terraform releases might include changes in behavior you should consider when upgrading.

**Terraform v0.14**
The Oracle Cloud Infrastructure (OCI) Terraform provider now supports Terraform v0.14.

Terraform v0.14 changes the output of the `terraform plan` command and introduces a dependency lock file you can use to track the version of the (OCI) Terraform provider used to interact with your OCI resources.

Refer to the official Terraform v0.14 upgrade guide for more information.

**Concise Terraform plan output**
To reduce the verbosity of `terraform plan` output, Terraform output now omits any attribute that has not changed, except for some attributes whose values often contain human-recognizable identifying information.

You can temporarily re-enable verbose output by setting the environment variable `TF_X_CONCISE_DIFF=0` when you run Terraform.

**Sensitive values in Terraform plan output**
Because Terraform v0.14 tracks expressions whose result is derived from a sensitive input variable or sensitive output value, you might find that more values are obscured in the `terraform plan` output than would have been in earlier versions.
If a different module uses a value in its output that was derived from a sensitive variable or value, you must set
\texttt{sensitive = true} in the output of the second module.

Provider dependency lock file

In Terraform v0.13 and earlier, the \texttt{terraform init} command would always install the newest version of any
provider in the configuration that would meet the configured version constraints. To keep the behavior of an already
tested configuration as stable as possible unless intentionally changed by the user, Terraform v0.14 introduces a new
dependency lock file.

Terraform generates this file automatically after running \texttt{terraform init} in the same directory as the
configuration's root module. The dependency lock file includes the specific version numbers selected for each
provider, including the OCI Terraform provider. After running \texttt{terraform init} for the first time after upgrading
to Terraform v0.14, you will find a new file \texttt{.terraform.lock.hcl} in your root module directory. Future
initializations of Terraform automatically read and respect the entries in that file.

Because of this new feature, manually placing extra plugins into the local cache directory \texttt{.terraform/plugins}
is no longer effective.

Terraform v0.12

If upgrading to Terraform v0.12, the Oracle Cloud Infrastructure (OCI) Terraform provider and some existing
configurations might need to be updated as well.

See Upgrading Configurations to Terraform v0.12 on page 5435 for detailed information.

\textit{Tutorials}

For step-by-step instructions and examples of using Terraform and Oracle Cloud Infrastructure, see the following
tutorials:

- Set Up the OCI Terraform Provider
- Create a Compartment
- Create a Compute Instance
- Create a Virtual Cloud Network
- Set Up a Simple Infrastructure
- Create a Kubernetes Cluster
- Set Up Resource Discovery
- Create Scripts and State Files with Resource Discovery
- HashiCorp Learn: Get Started with Oracle Cloud Infrastructure

\textit{For More Information}

For more information, see the following resources:

- Blog: Getting Started Using Terraform with OCI

\textit{Examples, Templates, and Solutions}

The Oracle Cloud Infrastructure (OCI) Terraform provider uses Terraform configuration files to manage your OCI
infrastructure.

Referring to existing example configurations, sample solutions, and templates can help you understand HashiCorp
Configuration Language format (HCL) and see how it is used to define OCI resources.

You can also modify examples or entire solution sets to meet your needs.

Example Configurations

We provide many example Terraform configuration files that show you how to create specific OCI resources. These
examples are intended to be as simple as possible. In most cases, they contain only the specific resource and any
dependencies required for it to run.

Examples are are grouped by service, including Compute, Database, Networking, Load Balancing, and several others.
These do not represent production configurations or real world scenarios, but they can serve as a starting point and be modified and combined as necessary.

Templates

Oracle also provides templates for Resource Manager. Resource Manager uses Terraform to automate deployment and operations for OCI resources.

Templates can help those new to infrastructure-as-code and those who are updating production configurations. Use templates to try out Resource Manager and inspect the underlying oracle-terraform-modules to familiarize yourself with Terraform configuration files.

Architecture Center

The Oracle Architecture Center contains reference architectures, solution playbooks, and best practices. You can filter the content to see Terraform-specific information that you can use with the OCI Terraform provider or Resource Manager.

Guides

This section describes how to configure the Oracle Cloud Infrastructure (OCI) Terraform provider for specific use cases and write Terraform configuration files that manage specific OCI resources.

See the following topics for additional information:

- Authoring Configurations on page 5415
- Specifying Versions on page 5421
- Enabling FIPS Compatibility on page 5423
- Managing Volumes on page 5428
- Migrating an Exadata DB System to the New Resource Model on page 5431
- Targeting Multiple Regions on page 5433
- Upgrading Configurations to Terraform v0.12 on page 5435
- Using Object Storage for State Files on page 5438

Authoring Configurations

Using Terraform, you can describe your Oracle Cloud Infrastructure using the HashiCorp Configuration Language format (HCL) in Terraform configuration files (see Configuration Syntax). Terraform configuration files can use either of two formats: Terraform domain-specific language (HashiCorp Configuration Language format [HCL]), which is the recommended approach, or JSON format if the files need to be machine-readable. Configuration files that use the HCL format end with the .tf file extension; those using JSON format end with the .tf.json file extension. The Terraform format is human-readable, while the JSON format is machine readable.

Use Terraform configurations to define your Oracle Cloud Infrastructure (OCI) resources, variable definitions, data sources, and a great deal more. Terraform, then, converts your OCI configurations into a set of API calls against OCI API endpoints. The key to writing Terraform configuration is understanding how to abstract the wanted infrastructure conceptually into Terraform configuration syntax.

Important:

While the Oracle Cloud Infrastructure API uses camelCase extensively, Terraform does not support camelCase in configuration files. For this reason, in the configurations you see underscores rather than capitalization as separators. For example, where the API uses availabilityDomain, the Terraform configuration uses availability_domain.

Configuration File Requirements

Terraform configuration (.tf) files have specific requirements, depending on the components that are defined in the file. For example, you might have your Terraform provider defined in one file (provider.tf), your variables defined in another (variables.tf), your data sources defined in yet another.
Provider Definitions

The following example using Terraform syntax illustrates the requirements for an OCI Terraform provider definition, and also shows associated variable definitions. The provider definition relies on variables so that the configuration file itself does not contain sensitive data. Including sensitive data creates a security risk when exchanging or sharing configuration files.

```terraform
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

provider "oci" {
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
  region = "${var.region}"
}
```

The region attribute specifies the geographical region in which your provider resources are created. To target multiple regions in a single configuration, you simply create a provider definition for each region and then differentiate by using a provider alias, as shown in the following example. Notice that only one provider, named "oci" is defined, and yet the oci provider definition is entered twice, once for the us-phoenix-1 region (with the alias "phx"), and once for the region us-ashburn-1 (with the alias "iad").

```terraform
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "compartment_ocid" {}

provider "oci" {
  region = "us-phoenix-1"
  alias = "phx"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}
provider "oci" {
  region = "us-ashburn-1"
  alias = "iad"
  tenancy_ocid = "${var.tenancy_ocid}"
  user_ocid = "${var.user_ocid}"
  fingerprint = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}
```

For more information, see Provider Configuration.

Variable Definitions

Variables in Terraform represent parameters for Terraform modules. In variable definitions, each block configures a single input variable, and each definition can take any or all of three optional arguments:
• **type** (optional): Defines the variable type as one of three allowed values: *string*, *list*, and *map*. If this argument is not used, the variable type is inferred based on **default**. If no **default** is provided, the type is assumed to be *string*.
• **default** (optional): Sets the default value for the variable. If no default value is provided, the caller must provide a value or Terraform throws an error.
• **description** (optional): A human-readable description of the variable.

Following are examples of several variable definitions. Some definitions include optional parameters.

```plaintext
variable "tenancy_ocid" {}  
variable "user_ocid" {}  
variable "fingerprint" {}  
variable "private_key_path" {}  
variable "region" {}

variable "AD" {  
default     = "1"  
description = "Availability Domain"  
}

variable "CPUCoreCount" {  
default = "2"  
type    = "string"  
}
```

For more information, see [Input Variable Configuration](#). See also [Input Variables](#).

**Output Configuration**

Output variables provide a means to support Terraform end-user queries. This allows users to extract meaningful data from among the potentially massive amount of data associated with a complex infrastructure. For example, you might be interested only in a handful of key values at any given time and defining output variables allows you to extract exactly the information that you need.

Following is a simple example in which only a few output variables (instance IP addresses and boot volume IDs) are defined:

```plaintext
# Output the private and public IPs of the instance  
output "InstancePrivate IPs" {  
value = ["${oci_core_instance.TFInstance.*.private_ip}"]  
}

# Output the public IPs of the instance  
output "InstancePublic IPs" {  
value = ["${oci_core_instance.TFInstance.*.public_ip}"]  
}

# Output the boot volume IDs of the instance  
output "BootVolume IDs" {  
value = ["${oci_core_instance.TFInstance.*.boot_volume_id}"]  
}
```

For more information, see [Output Variables](#). See also [Output Configuration](#).

**Resources**

Resources are components of your Oracle Cloud Infrastructure. These resources include everything from low-level components such as physical and virtual servers, to higher-level components such as email and database providers, your DNS record.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at [docs.oracle.com](https://docs.oracle.com) and HashiCorp.

Data sources and resources are grouped by service within the reference.
Caution:

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Sensitive Data in State for more information.

Declaring Resources

Following is a simple example of a resource definition that illustrates their basic structure.

```shell
resource "oci_core_virtual_network" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = "${var.compartment_ocid}"
  display_name = "vcn1"
}
```

The resource declaration on the first line of the example uses the keyword "resource" and takes two parameters, resource type and resource name ("oci_core_virtual_network" and "vcn1" in the example). Inside the code block, then, is the resource configuration.

For more information, see Resource Configuration.

Resource Dependencies

When a resource references another resource within its resource block, Terraform automatically infers the primary resource's dependency on the referenced resource. A resource might also depend on resources that are not explicitly referenced within its block. For example, you might need to create policies for a resource before creating the resource itself.

To define hidden dependencies that Terraform cannot automatically infer, you can use the depends_on meta-argument in the resource block.

The following example creates an oci_datascience_notebook_session resource and an oci_identity_policy resource for related policies. Adding the depends_on meta-argument to the oci_datascience_notebook_session resource ensures that the policies are created first:

```shell
resource "oci_datascience_notebook_session" "ods-notebook-session" {
  count = var.enable_ods ? var.ods_number_of_notebooks : 0
  #Required
  compartment_id = var.compartment_ocid
  notebook_session_configuration_details {
    #Required
    shape = var.ods_compute_shape
    subnet_id = local.private_subnet_id
    #Optional
    block_storage_size_in_gbs = var.ods_storage_size
  }
  project_id = oci_datascience_project.ods-project[0].id
  display_name = "${var.ods_notebook_name}-${count.index}"
  depends_on = ["oci_identity_policy.ods-policy"]
}

resource "oci_identity_policy" "ods-policy" {
  provider = oci.home
  compartment_id = var.compartment_ocid
  description = "Data Science Policies"
}
```
Referencing Resources in Another Stack

You can reference resources that exist in other stacks. The Terraform `remote_state` data source allows you to read output variables from state files.

For example, when writing a Terraform configuration for a new web application, you can make the web application use the subnet previously created from your network stack, as long as the required subnet values were output in the network stack state file. In the Terraform configuration for your new web application, do the following:

- Pull the state file of the existing network stack into the context of your current Terraform configuration.
- Load the pulled state file to a data source for remote state files.
- Populate the subnet data source in your current configuration with values from the relevant output variables of the referenced state file.
- Optionally print the identifying information for the populated data source to confirm expected values.

**Note:** In addition to permissions required for Resource Manager operations, you’ll need appropriate permissions for resource types you’re referencing, in the compartment that you’re referencing them. In this example, you need read permissions for network resources in the compartment where they’re located.

The following Terraform configuration excerpt references a subnet in another stack:

```terraform
# The following example assumes that the source stack (defined by `stack_id`) has output a value named `subnet_id`
# Terraform v0.12 is assumed
variable "stack_id" {
  # Pull the state file of the existing Resource Manager stack (the network stack) into this context
  data "oci_resourcemanager_stack_tf_state" "stack1_tf_state" {
    stack_id = "${var.stack_id}"
    local_path = "stack1.tfstate"
  }

  # Load the pulled state file into a remote state data source
  data "terraform_remote_state" "external_stack_remote_state" {
    backend = "local"
    config = {
      path = "${data.oci_resourcemanager_stack_tf_state.stack1_tf_state.local_path}"
    }
  }

  # Populate a data source in this configuration using a value from the remote state data source
  data "oci_core_subnet" "subnet1" {
    subnet_id = "${data.terraform_remote_state.external_stack_remote_state.outputs.subnet_id}"
  }

  # Print the values of the populated data source
  output "print-subnet1" {
    value = "${data.oci_core_subnet.subnet1}"
  }
}
```
Data Sources

Data sources represent read-only views of existing infrastructure intended for semantic use in Terraform configurations. Following is a simple example of a data source configuration to illustrate its basic structure:

```hcl
# Gets a list of Availability Domains
data "oci_identity_availability_domains" "ADs" {
  compartment_id = "${var.tenancy_ocid}"
}

# Get DB node list
data "oci_database_db_nodes" "DBNodeList" {
  compartment_id = "${var.compartment_ocid}"
  db_system_id = "${oci_database_db_system.TFDBNode.id}"
}

# Get DB node details
data "oci_database_db_node" "DBNodeDetails" {
  db_node_id = "${lookup(data.oci_database_db_nodes.DBNodeList.db_nodes[0], "id")}"}

# Gets the OCID of the first (default) vNIC
data "oci_core_vnic" "DBNodeVnic" {
  vnic_id = "${data.oci_database_db_node.DBNodeDetails.vnic_id}"}
```

For more information, see Data Source Configuration.

Filtering Data Sources

Data sources that return lists of resources support filtering semantics. To use a filter, include this block in your data source definition:

```hcl
filter {
  name = ""
  values = ["""
}
```

The `name` value corresponds to the qualified property name to filter with and the `values` lists can contain one or more values filter with.

Nested properties and map elements can be addressed by qualifying the property name with parent property name. Example `r1` will give all the instances which have `source_type` image. Example `r2` will give all the instances which contain a defined tag with value "42" for key `CostCenter` in the namespace `Operations`.

```hcl
data "oci_core_instances" "r1" {
  ...
  filter {
    name = "source_details.source_type"
    values = ["image"]
  }
}

data "oci_core_instances" "r2" {
  ...
  filter {
    name = "defined_tags.Operations.CostCenter"
    values = ["42"]
  }
```
Multiple values work as an OR type filter. In the shape example below, the resulting data source would contain both VM shapes Standard 1.1 and Standard 1.2:

```hcl
data "oci_core_shape" "t" {
  filter {
    name = "name"
    values = ["VM.Standard1.1", "VM.Standard1.2"]
  }
}
```

Multiple filters blocks can be composed to form AND type comparisons. The example below will return a data source containing running instances in the first AD of a region:

```hcl
data "oci_core_instances" "s" {
  filter {
    name = "availability_domain"
    values = ["\w*-AD-1"]
    regex = true
  }

  filter {
    name = "state"
    values = ["RUNNING"]
  }
}
```

As shown above, filters can also employ regular expressions. By setting regex = true, each item in the values list will be treated as a regular expression. Backslashes in strings for regular expression special characters need to be escaped with another slash, shown above as the first \ before \w in "\w*-AD-1".

**Note:**
Drilling into lists of structured objects is not currently supported. If these properties are targeted no results will be returned from the datasource.

Functions

Terraform offers a number of built-in functions that you can use in your configuration files. These functions allow you to modify strings, perform calculations against numeric values, manage collections, and much more.

For more information, see Functions.

For More Information

- Creating Terraform Modules
- Terraform Configurations
- Terraform Configuration Syntax

Specifying Versions

Terraform, the Oracle Cloud Infrastructure (OCI) Terraform provider, and Terraform modules you call in your configuration files all introduce changes or add new functionality from time to time. As these changes are made, new versions are released.

In order to ensure that your configurations are applied consistently to OCI resources, you can explicitly set the version of these components in Terraform configuration files.

Terraform CLI Version
If your Terraform configuration requires that you use a particular version of the Terraform CLI, you can specify that within the `terraform` block using the `required_version` setting. For example:

```terraform
terraform {
  required_version = ">= 0.12.16"
}
```

For more information, see [Specifying a Required Terraform Version](#).

### Note:

<Resource Manager> manages the Terraform version based on the stack version. Any CLI version specified is ignored by Resource Manager.

**Provider Version**

You can control the version of the OCI Terraform provider that Terraform uses when interacting with OCI resources. This ability is especially helpful when your configuration relies on features introduced with a particular version of the provider or it has only been tested with a particular version of the provider.

You can use the `>=` or `=` operators to specify the version, depending on your use case.

For more information, see [Specifying Provider Requirements](#).

#### Using Terraform v0.12 or earlier

Terraform v0.12 or earlier allowed you to specify `version` within the `provider` block. For example:

```terraform
provider "oci" {
  version          = ">= 3.27.0"
  region           = "${var.region}"
  ...}
```

#### Using Terraform v0.13

Terraform v0.13 deprecated `version` within `provider` blocks. Instead, versions should be specified within a `required_providers` block. For example:

```terraform
terraform {
  required_providers {
    oci = {
      source = "hashicorp/oci"
      version = ">= 4.0.0"
    }
    ...}
```

### Module Version

In addition to specifying the version of the Terraform CLI and the OCI Terraform provider, you can also specify the version of Terraform modules.

If a module has been upgraded to use a newer version of Terraform core, but you still use an earlier version of Terraform, you can specify a compatible version of the module. If your configurations have only been tested with a specific version of the module, you can specify that version to ensure compatibility.

Modules accept the `version` argument. For example:

```terraform
module "oke" {
  source = "oracle-terraform-modules/oke/oci"
  version = "1.0.0"
}
Enabling FIPS Compatibility

You can use Terraform and a special FIPS compatible version of the Oracle Cloud Infrastructure (OCI) Terraform provider, as long as a few specific requirements and best practices are employed. This topic provides guidance on these requirements and practices.

**FIPS encryption**

To ensure the highest security standards, traffic from Terraform to OCI endpoints should transit over a TLS connection established with an HTTP client using FIPS certified encryption.

The standard OCI Terraform provider is implemented in Go. Go’s native cryptography implementations, while fully capable of establishing secure TLS connections with OCI endpoints, have not been FIPS certified.

For Terraform traffic to transit to OCI endpoints over FIPS-compliant connections, you must use a special version of the Terraform provider that uses FIPS certified cryptography. This version of the OCI Terraform provider uses the FIPS 140-2 certified Oracle Cloud Infrastructure Cryptographic Library for Kubernetes instead of Go’s native cryptography implementation. Read more about the Oracle Cloud Infrastructure Cryptographic Library for Kubernetes here.

Installing the FIPS-Compliant Terraform Provider

The FIPS-compliant OCI Terraform provider is only available for Oracle Linux. You can install the provider using yum.

**Tip:**

Before installing the OCI Terraform provider, download and install Terraform from HashiCorp, or install Terraform using yum.

If any existing OCI Terraform provider packages are already installed on the Oracle Linux machine, remove them first:

```
yum remove terraform-provider-oci
```

Install the FIPS-compatible OCI Terraform provider by running the following yum command from an Oracle Linux machine:

```
yum install terraform-provider-oci-fips
```

Configuring the Terraform Provider

1. Add an environment variable to set the target region for Terraform:

   ```bash
echo "export TF_VAR_region='<your_region>'" >> ${HOME}/.bash_profile
```

2. Add an environment variable to disable interprocess traffic encryption between Terraform and the OCI Terraform provider:

   ```bash
echo "export TF_DISABLE_PLUGIN_TLS=1" >> ${HOME}/.bash_profile
```

3. Add an environment variable to prevent Terraform from accessing the HashiCorp Checkpoint service:

   ```bash
echo "export CHECKPOINT_DISABLE=1" >> ${HOME}/.bash_profile
```

4. Configure the authentication method for the Terraform provider. See Authentication for more information.

Operating Terraform in a Single Region
To ensure that traffic between Terraform and OCI services does not transit over public internet infrastructure, we recommend that you run Terraform and the OCI Terraform provider from a Compute instance that is hosted in the same region as the resources they create and manage.

Creating a Compute Instance

After Terraform and the OCI Terraform provider are installed on an Oracle Linux machine, you can use Terraform and the following sample Terraform configuration file to:

- Create a designated Compute instance you can use to provision additional infrastructure within the same region.
- Install Terraform and the latest FIPS compliant OCI Terraform provider on the new instance.
- Restrict communication with the instance to OCI endpoints and HTTPS using a service gateway.
- Enable instance principal authentication.

See Authoring Configurations on page 5415 for more information.

To create the compute instance:

1. Copy the `main.tf` file to your Oracle Linux machine.
2. Gather the information required to populate the Terraform configuration file's variables.
3. Refer to Platform Images on page 943 to locate the Oracle Linux image OCID value for your region. Modify the `oel-image` value in the Terraform configuration file.
4. Initialize Terraform in the directory that contains the Terraform configuration file:
   ```
   terraform init
   ```
5. Apply the Terraform configuration:
   ```
   terraform plan
terraform apply
   ```

   **Important:**
   The `instance-ip` output variable provides the IP address you will need to use to sign in to the new Compute instance.

```
main.tf

variable "tenancy_ocid" {
}
variable "user_ocid" {
}
variable "fingerprint" {
}
variable "private_key_path" {
}
variable "region" {
}
variable "compartment_ocid" {
}
variable "ssh_public_key" {
}
variable "ssh_private_key" {
}
```
locals {
  prefix    = "terraform"
  oel-image = "<Oracle_Linux_image_OCID>"
  vm-shape  = "VM.Standard2.1"
}

user-data = <<EOF
#!/bin/bash -x
echo "export TF_VAR_auth='InstancePrincipal'" >> ~/.bash_profile
echo "export TF_VAR_region='${var.region}'" >> ~/.bash_profile
yum install -y terraform terraform-provider-oci-fips
EOF
EOF

provider "oci" {
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
  region           = var.region
}

  compartment_id = var.tenancy_ocid
  name           = "${local.prefix}DynamicGroup"
  description    = "Dynamic Group for executing Terraform with Instance Principal authentication"
  matching_rule  = "ANY {instance.compartment.id = '${var.compartment_ocid}'}"
}

resource "oci_identity_policy" "instance-principal-policy1" {
  compartment_id = var.compartment_ocid
  name           = "${local.prefix}Policy"
  description    = "Policy to allow Instance Principal Terraform execution"
statements = [
"ALLOW dynamic-group ${oci_identity_dynamic_group.dynamic-group1.name} to manage all-resources IN compartment ${data.oci_identity_compartment.compartment1.name}"
]

data "oci_identity_availability_domain" "ad" {
    compartment_id = var.tenancy_ocid
    ad_number = 1
}

resource "oci_core_instance" "instance1" {
    availability_domain = data.oci_identity_availability_domain.ad.name
    compartment_id = var.compartment_ocid
    display_name = "${local.prefix}Instance"
    shape = local.vm-shape
    source_details {
        source_type = "image"
        source_id = local.oel-image
    }
    metadata = {
        ssh_authorized_keys = var.ssh_public_key
        user_data = base64encode(local.user-data)
        tenancy_ocid = var.tenancy_ocid
    }
    create_vnic_details {
        subnet_id = oci_core_subnet.subnet1.id
        assign_public_ip = true
    }
}

output "instance-ip" {
    value = [oci_core_instance.instance1.public_ip]
}

Signing in to the Instance

Use the following SSH command to access the instance:

```
$ ssh -i <private_key_path> <username>@<instance_ip_address>
```

`<private_key_path>` is the full path and name of the file that contains the private key associated with the instance you want to access.

`<username>` is the default username for the instance. For Oracle Linux images, the default username is opc.

`<instance_ip_address>` is the instance IP address that was the output of the Terraform commands.

Installing and Configuring Terraform on the Instance

1. Use yum to install Terraform and the FIPS compatible OCI Terraform provider on the instance:

```
yum install -y terraform terraform-provider-oci-fips
```

2. Add an environment variable to enable `instance principal authentication` to the bash profile:

```
echo "export TF_VAR_auth='InstancePrincipal'" >> $(HOME)/.bash_profile
```

3. Add an environment variable to set the target region for Terraform:

```
echo "export TF_VAR_region='<your_region>'" >> $(HOME)/.bash_profile
```
4. Add an environment variable to disable interprocess traffic encryption between Terraform and the OCI Terraform provider:

```bash
echo "export TF_DISABLE_PLUGIN_TLS=1" >> ${HOME}/.bash_profile
```

5. Add an environment variable to prevent Terraform from accessing the HashiCorp Checkpoint service:

```bash
echo "export CHECKPOINT_DISABLE=1" >> ${HOME}/.bash_profile
```

6. Exit the instance:

```bash
exit
```

### Implementing Security Rules

Before using the new instance to run Terraform, you should update the security rules to prevent egress traffic to any third-party endpoints other than OCI services. You can do this by removing the following egress rule from the Terraform configuration file's `security-list1` resource and running `terraform apply` from the Oracle Linux machine:

```text
// outbound tcp traffic on all ports
// remove this rule or comment it out to prevent egress traffic to third-party endpoints
#egress_security_rules {
 #  destination = "0.0.0.0/0"
 #  protocol    = "6"
 #}
```

**Tip:**

You can also use the OCI Console to [update your security rules](https://docs.cloud.oracle.com/iaas/Content/Networking/Tasks/securityrule.htm) on the new instance.

### Running Terraform from the Instance

After creating the instance, installing and configuring Terraform on the instance, and updating the security rules, you can use Terraform to provision additional OCI infrastructure within the same region. Copy any additional Terraform configuration files to your instance, sign in to the instance, and run your Terraform commands like any other Terraform provider:

```bash
ssh -i <private_key_path> opc@<instance_ip_address>
terraform init
terraform apply
```

### Managing Volumes

This guide details the following scenarios:

1. Preserving boot volumes when performing Compute instance scaling
2. Boot volume troubleshooting and repair
3. Replicating volumes to another availability domain

To read more about boot volumes, see [Boot Volumes](https://docs.cloud.oracle.com/iaas/Content/Computing/Concepts/boottovolumes.htm).

### Preserving Boot Volumes

You may want to change Compute instance shape while using the same boot volume. When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. This approach is useful for scenarios where instance shape cannot be changed while resizing instances.

To achieve this, you need to detach the boot volume from the running instance. This can be performed by either terminating the instance while preserving the boot volume or by stopping the instance and detaching the boot volume,
All Terraform resources of type `oci_core_instance` have the parameter `preserve_boot_volume` set as `true` by default. This parameter ensures that upon termination of the instance, the attached boot volume is not terminated.

```terraform
resource "oci_core_instance" "TFInstance" {  
  ...  
  state = "STOPPED"  // set this state to stop the instance  
  preserve_boot_volume = true  
}  

output "bootVolumeFromInstance" {  
  value = [oci_core_instance.TFInstance.boot_volume_id]  
}
```

Once the boot volume is detached, the OCID of the boot volume can be referred as the source of the new instance, as illustrated below:

```terraform
resource "oci_core_instance" "TFScaleInstance" {  
  ...  
  source_details {  
    source_type = "bootVolume"  
    // reference the original boot volume id here  
    source_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"  
  }  
}
```

**Detaching Boot Volumes for Troubleshooting and Repair**

If you think a boot volume issue is causing a Compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Once the boot volume has been detached, the OCID of the boot volume can be referred as the block volume parameter for another instance.

```terraform
resource "oci_core_volume_attachment" "TFBlockAttach" {  
  ...  
  attachment_type = "iscsi"  
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"  
  // new instance  
  instance_id = "ocid1.instance.oc1.phx.exampleuniqueID"  
  // attach the boot volume as a block volume  
  volume_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"  
}
```

Once you have resolved the issue, detach this volume from the second instance and attach it as a boot volume to the original instance.

```terraform
resource "oci_core_instance" "TFScaleInstance" {  
  ...  
  source_details {  
    source_type = "bootVolume"  
    // attach back as boot volume  
    // reference the volume id here  
    source_id = "ocid1.bootvolume.oc1.phx.exampleuniqueID"  
  }  
}
```
Replicate a Volume to an Availability Domain within the Region

You can use Terraform to replicate existing Compute instance boot and block volumes to another availability domain within the same region.

To replicate a volume:

1. Create a data source for the volume using `oci_core_boot_volume` or `oci_core_volume`.
2. Use the `oci_core_boot_volume_backup` or `oci_core_volume_backup` resource to create a backup of the source volume.
3. Define the target volume resource to be created from the backup.

The following example Terraform configuration replicates both a boot volume and a block volume:

```terraform
provider "oci" {
  region = "us-ashburn-1"
}

locals {
  compartment_id = "ocid1.compartment.oc1..exampleuniqueID"
  target_ad = "ilMx:US-ASHBURN-AD-2"
  source_boot_id = "ocid1.bootvolume.oc1.iad.exampleuniqueID"
  source_volume_id = "ocid1.volume.oc1.iad.exampleuniqueID"
}

# Boot Volume Clone
data "oci_core_boot_volume" "source" {
  boot_volume_id = local.source_boot_id
}
resource "oci_core_boot_volume_backup" "backup" {
  boot_volume_id = data.oci_core_boot_volume.source.id
  type = "FULL"
}
resource "oci_core_boot_volume" "target" {
  availability_domain = local.target_ad
  compartment_id = local.compartment_id
  source_details {
    id = oci_core_boot_volume_backup.backup.id
    type = "bootVolumeBackup"
  }
  display_name = "Test Cloned Boot Volume"
}

# Block Volume Clone
data "oci_core_volume" "source" {
  volume_id = local.source_volume_id
}
resource "oci_core_volume_backup" "backup" {
  volume_id = data.oci_core_volume.source.id
  type = "FULL"
}
resource "oci_core_volume" "target" {
  availability_domain = local.target_ad
  compartment_id = local.compartment_id
  source_details {
    id = oci_core_volume_backup.backup.id
    type = "volumeBackup"
  }
  display_name = "Test Cloned Block Volume"
}
```
You can use these steps to move an instance to the second availability domain or to create a disaster recovery deployment in the second availability domain.

If this method is used for a pure retargeting scenario where the source volumes (and the backups) will be removed after the duplication, then the Terraform configuration must be refactored after the source volumes are removed to avoid destroying the target instances on the next apply.

If using this scenario for disaster recovery cold standby, you can regularly use the Terraform `taint` command to mark the volume for destruction and recreation on the next application of the configuration.

Migrating an Exadata DB System to the New Resource Model

The X8M generation of Exadata hardware introduces a new resource model that replaces the Exadata DB system. The new resource model uses new APIs to provision and manage its resources. The existing DB system APIs for Exadata will be deprecated by Oracle Cloud Infrastructure for all users following written notification and a transition period allowing you to switch to the new API and Console interfaces.

If you have existing Exadata DB systems in Oracle Cloud Infrastructure, you can use Terraform to switch them to the new resource model and APIs.

**Caution:**

Switching an Exadata DB system to the new resource model and APIs cannot be reversed. If you have automation for your system that utilizes the DB system APIs, you may need to update your applications prior to switching.

Switching to the new resource model:

- Does not impact the DB system's existing Exadata databases or client connections
- Does not change the underlying hardware or shape family of your Exadata Cloud Service instance
- Will not affect bare metal and virtual DB systems

After converting your DB system, you will have two new resources in place of the DB system resource: a cloud Exadata infrastructure resource, and a cloud VM cluster resource.

What to expect after switching:

- Your new cloud Exadata infrastructure resource and cloud VM cluster are created in the same compartment as the DB system they replace
- Your new cloud Exadata infrastructure resource and cloud VM cluster use the same networking configuration as the DB system they replace
- After the switch, you cannot perform operations on the old Exadata DB system resource
- Switching is permanent, and the change cannot be undone
- X6, X7, X8 and Exadata base systems retain their fixed shapes after the switch, and cannot be expanded

See [Exadata Cloud Service](#) for more information.

To Migrate an Exadata DB System

These migration steps use the following example, which shows an existing Exadata Cloud Service instance using the old DB system resource model:

```terraform
resource "oci_database_db_system" "test_db_system" {
  availability_domain = data.oci_identity_availability_domain.ad.name
  compartment_id      = var.compartment_ocid
  cpu_core_count      = var.cpu_core_count
  database_edition    = var.db_edition
  time_zone           = var.time_zone

  db_home {
    database {
      admin_password = var.db_admin_password
    }
  }
}
```
To migrate the system to the new resource model, first create the `oci_database_migration` resource:

```bash
resource "oci_database_migration" "test_migration" {
  #Required
  db_system_id = "${oci_database_db_system.test_db_system.id}"
}
```
Provisioning the `oci_database_migration` resource creates two new resources: `oci_database_cloud_exadata_infrastructure` and `oci_database_cloud_vm_cluster`.

You can get OCIDs of these two resources from the `oci_database_migration` resource:

```terraform
output "cloud_exadata_infrastructure_id" {
    value =
    oci_database_migration.test_migration.cloud_exadata_infrastructure_id
}
output "cloud_vm_cluster_id" {
    value =
    oci_database_migration.test_migration.cloud_vm_cluster_id
}
```

Create a Terraform configuration for the two new resources:

```terraform
resource "oci_database_cloud_exadata_infrastructure" "test_cloud_exadata_infrastructure"{}
resource "oci_database_cloud_vm_cluster" "test_cloud_vm_cluster" {}
```

Then run the Terraform import command:

```
terraform import
oci_database_cloud_exadata_infrastructure.test_cloud_exadata_infrastructure <cloud_exadata_infrastructure_id>
terraform import
oci_database_cloud_vm_cluster.test_cloud_vm_cluster <cloud_vm_cluster_id>
```

Terraform now manages the two new resources. After switching to the new Exadata resource model, remove the old `oci_database_db_system` config.

**Tip:**
After the migration, you can use `resource discovery` to create a full configuration and state file for importing these two new resources.

**Targeting Multiple Regions**

You can use a single Terraform configuration to create Oracle Cloud Infrastructure (OCI) resources in multiple regions.

**Create a Provider for Each Region**

A Terraform configuration may have only a single OCI Terraform provider block, but to apply configurations to multiple regions, you need to create multiple provider blocks.

A typical OCI Terraform provider block might look like the following:

```terraform
provider "oci" {
    region = var.region
    tenancy_ocid = var.tenancy_ocid
    user_ocid = var.user_ocid
    fingerprint = var.fingerprint
    private_key_path = var.private_key_path
}
```

**Tip:**
All parameters should be set using variables.
If you want to use more than one region within a single Terraform config, multiple providers are required. Each provider must be given an alias. For example:

```terraform
provider "oci" {
  alias            = "home"
  region           = var.region
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}

provider "oci" {
  alias            = "region2"
  region           = var.region2
  tenancy_ocid     = var.tenancy_ocid
  user_ocid        = var.user_ocid
  fingerprint      = var.fingerprint
  private_key_path = var.private_key_path
}
```

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region, which is your home region. The home region has special properties. For example, IAM resources can only be created in your home region. For that reason, you should designate that region with an appropriate alias, like home. Use simple aliases for other regions so that users can easily map configurations to the regions that they want (for example, region2).

**Note:** Specific regions (us-phoenix-1, us-ashburn-1, and so on) are not hardcoded into either the region or alias fields.

Finding Your Home Region

When deploying to multiple OCI regions, you might want to look up your home region dynamically, so you don't have to explicitly pass the home region as a configuration variable.

One typical use case might require provisioning resources to a specific region using a Terraform configuration that also creates a compartment. Since the compartment must be created in your home region, you could use code like the following to automatically look up the home region:

```terraform
provider oci {}

provider oci {
  alias = "home"
  region = lookup(local.region_map,
                   data.oci_identity_tenancy.tenancy.home_region_key)
}

variable tenancy_id {}

data oci_identity_regions regions {}

data oci_identity_tenancy tenancy {
  tenancy_id = var.tenancy_id
}

locals {
  region_map = { for r in data.oci_identity_regions.regions.regions : r.key => r.name }
}

output home_region {
  value = lookup(local.region_map,
                  data.oci_identity_tenancy.tenancy.home_region_key)
}
```
Provision a Resource

To provision a resource in a region, specify the aliased provider name in the resource.

For example:

```terraform
resource "oci_core_instance" "test_instance" {
  provider = oci.home
  ...
}
```

Modules and Multiple Regions

Typically, a module should use only a single region. If more regions are needed, you should use separate modules.

If the config contains multiple providers, the module should specify the provider to use by using the following format:

```terraform
module "compartments" {
  source       = "./compartments"
  providers = {
    oci = "oci.home"
  }
}
```

Upgrading Configurations to Terraform v0.12

With the release of Terraform v0.12, Oracle Cloud Infrastructure Terraform providers need to be upgraded and some existing configurations may need to be updated as well.

Upgrading the Terraform Provider

Oracle Cloud Infrastructure (OCI) Terraform provider versions 3.26.0 and below are not compatible with Terraform v0.12. OCI Terraform provider version 3.27.0 is the earliest version that supports Terraform v0.12.

**Note:**

All OCI Terraform provider versions remain compatible with Terraform v0.11 and v0.10.

The simplest way to begin using the latest v0.12-compatible provider from the HashiCorp provider registry is to place an explicit version requirement in your provider configuration block, as shown here:

```terraform
provider "oci" {
  version          = ">= 3.27.0"
  region           = "${var.region}"
  tenancy_ocid     = "${var.tenancy_ocid}"
  user_ocid        = "${var.user_ocid}"
  fingerprint      = "${var.fingerprint}"
  private_key_path = "${var.private_key_path}"
}
```

For guidance using additional version configuration options, see Provider Versions.

Upgrading Terraform Configurations

Some users may find that no changes are needed to run existing Terraform configurations with v0.12.

For configurations that do need to be upgraded, see Upgrading Terraform configuration.
Upgrading configurations while preserving v0.11 compatibility

As recommended in Upgrading Terraform configuration, the simplest way to upgrade your configurations is to use the `terraform 0.12upgrade` command. Using the `terraform 0.12upgrade` command to upgrade your configurations, however, renders them incompatible with Terraform v0.11 and earlier.

**Caution:**

Prior to making configuration changes, it is strongly recommended that configuration and state files are backed up using version control or another preferred mechanism.

It may be possible to manually upgrade configurations to work with v0.12 while preserving compatibility with v0.11. Not all possible configurations can be made compatible with both v0.11 and v0.12. This method should only be used as a best-effort to preserve compatibility with v0.11.

The following cases detail where it is possible to convert existing v0.11 usage to be compatible with both v0.11 and v0.12.

Attributes vs. Blocks

In v0.11, it was possible to treat attributes and nested blocks interchangeably. Note how the attribute `metadata` and the nested block `source_details` are both assigned using only braces.

```terraform
// v0.11 compatible representation
resource "oci_core_instance" "my_instance" { 
  metadata = { 
    ssh Authorized_keys = "${var.ssh_public_key}" 
  } 
  source_details = { 
    source_type = "image" 
    source_id = "${var.instance_image_ocid[var.region]}" 
    kms_key_id = "${oci_kms_key.test_key.id}" 
  } 
}
```

In v0.12, attributes need to be assigned using the `=` operator while blocks need to be assigned using only braces. Note how the attribute `metadata` is now assigned with `=`, This usage is still compatible with v0.11.

```terraform
// v0.12 and v0.11 compatible representation
resource "oci_core_instance" "my_instance" { 
  metadata = { 
    ssh Authorized_keys = "${var.ssh_public_key}" 
  } 
  source_details = { 
    source_type = "image" 
    source_id = "${var.instance_image_ocid[var.region]}" 
    kms_key_id = "${oci_kms_key.test_key.id}" 
  } 
}
```

Nested blocks with multiple elements

In v0.11, it was possible to wrap lists of nested blocks inside `[]` like this example.

```terraform
// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" { 
  public_prefixes = [ 
    { 
      cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block}" 
    }, 
  ] 
}
```
In v0.12, it is required to specify each nested block individually without wrapping it in[]. This usage is still compatible with v0.11.

// v0.11 compatible representation
resource "oci_core_virtual_circuit" "virtual_circuit_public" {
  public_prefixes {
    cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block2}"
  }
  public_prefixes {
    cidr_block = "${var.virtual_circuit_public_prefixes_cidr_block3}"
  }
}

Quotes around attribute names
In v0.11, it was possible to put quotation marks"around attribute names. Note how the min and max attributes have quotation marks around them.

// v0.11 compatible representation
resource "oci_core_security_list" "bastion" {
  egress_security_rules {
    destination = "${var.vcn_cidr}"
    protocol   = "${local.tcp_protocol}"  
    tcp_options {
      "min" = 22
      "max" = 22
    }
  }
}

In v0.12, quotation marks"around attribute names are no longer allowed.

// v0.11 and v0.12 compatible representation
resource "oci_core_security_list" "bastion" {
  egress_security_rules {
    destination = "${var.vcn_cidr}"
    protocol   = "${local.tcp_protocol}"  
    tcp_options {
      min = 22
      max = 22
    }
  }
}
Variable names starting with non-alphabetical characters

In v0.11, it was possible to specify variable names that begin with non-alphabetical characters.

```java
// v0.11 compatible representation
variable "2TB" {
    default = "2048"
}
```

In v0.12, variable names must begin with alphabetical characters.

```java
// v0.11 and v0.12 compatible representation
variable "Size2TB" {
    default = "2048"
}
```

Computing list index values

In v0.11, division operations often resulted in integer values that could be used as a valid index in a list.

```java
// v0.11 compatible representation
instance_id = "${oci_core_instance.TFInstance.*.id[count.index / var.NumParavirtualizedVolumesPerInstance]"
```

In v0.12, division operations can result in floating point values that may no longer be valid. To avoid this situation, use the `floor` interpolation to convert floating point values to an index.

```java
// v0.11 and v0.12 compatible representation
instance_id = "${oci_core_instance.TFInstance.*.id[floor(count.index / var.NumParavirtualizedVolumesPerInstance)]"
```

Using Object Storage for State Files

You can store Terraform state files in Oracle Cloud Infrastructure (OCI) Object Storage. Doing so requires that you configure a backend using one of the Terraform backend types.

Terraform supports various backend types to allow flexibility in how state files are loaded into Terraform. (For more information, see Terraform Backend Types.) For our purposes, we address two of these approaches:

- Using an HTTP remote state backend
- Using an S3-compatible remote state backend

**Note:**

Terraform backend types are defined in the `terraform` block. The `terraform` block does not accept variables or locals. All backend configuration values must be hardcoded.

Using an HTTP Backend

Using the HTTP backend type allows you to store state using a simple REST client. With the HTTP backend type, you can easily fetch, update, and purge state using the HTTP GET, POST, and DELETE methods.

To configure the HTTP backend to store your OCI Terraform state files, do the following:
Create a Pre-Authenticated Request

Creating a pre-authenticated request in Oracle Object Storage enables accessing a bucket or object in the OCI without needing to provide credentials. To do so, you must create a pre-authenticated request that has read/write permissions to the object store where you intend to save the Terraform state file. You can do so in any of three ways: by using the Console UI, by using the command line interface (CLI), or by using the REST APIs.

Note:

A state file must exist in the bucket before you create the pre-authenticated request. This file can be an existing state file, or an empty file for the initial state.

For guidance, see Using Pre-Authenticated Requests on page 4387.

Upload Existing State

If you have an existing state file, you can upload it using Curl to make an HTTP PUT request to the object store URL, as shown here:

```bash
curl -X PUT -H "Content-Type: text/plain" --data-binary "@path/to/local/tfstate" http://<prefix>/<my-access-uri>
```

Configure HTTP as a Terraform Backend

The HTTP backend type stores state using a simple REST client and allows you to easily fetch, update, and purge state using the HTTP GET, POST, and DELETE methods.

The access URI for addressing OCI Terraform configurations must be of the form: https://objectstorage.us-phoenix-1.oraclecloud.com/my-access-uri (where region and access URI are specific to you).

For more example configuration and state files that reference code, and a summary of configuration variables, see Standard Backends: HTTP.

Following is an example Terraform configuration. The region in the URL can be something other than the Phoenix region.

```terraform
terraform {
    backend "http" {
        address = "https://objectstorage.us-phoenix-1.oraclecloud.com/<my-access-uri>"
        update_method = "PUT"
    }
}
```

Reinitialize Terraform

Finally, you must reinitialize Terraform and then run the apply command:

```bash
terraform init
terraform apply
```

After completing these steps, you are able to use Oracle Cloud Infrastructure as the backend for storing Terraform state files.

Using an S3-Compatible Backend

Configuring the S3-compatible backend requires that the account be enabled with S3 authentication keys, which are set on a per-user basis.

2. Set the location for the credentials file. The default location is `~/.aws/credentials`. You can set an alternate location by using the S3 backend `shared_credentials_file` option.

   **Caution:**
   Never set the `access_key` and the `secret_key` attributes in the same Terraform backend configuration, since this creates a security risk.

3. Configure the `[default]` entry in the credentials file with the appropriate Object Storage credentials. The file can contain any number of credential profiles. If you provide a different profile name, you must also update the backend `profile` option in your Terraform configuration file.

   Following is an example of Object Storage credentials:

   ```
   [default]
   aws_access_key_id=ocid1.credential.oc1..exampleuniqueID
   aws_secret_access_key=mSTdaWhlbWj3ty4JZX1m0NUZV52x1ImWjayJLJ6OH9A=
   ```

   Where `aws_access_key_id` and `aws_secret_access_key` are user-specific values provided from the Console. The key values provided in the example are not valid and provided as examples only.

4. Set the object storage endpoint value in the following format:

   ```
   https://<namespace>.compat.objectstorage.<region>.oraclecloud.com
   ```

5. Reinitialize Terraform and then run the `apply` command:

   ```
   terraform init
   terraform apply
   ```

   Following is a full example of an Object Storage backend configuration:

   ```
   terraform {
     backend "s3" {
       bucket   = "terraform-states"
       key      = "networking/terraform.tfstate"
       region   = "us-phoenix-1"
       endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"
       shared_credentials_file = "../terraform-states_bucket_credentials"
       skip_region_validation = true
       skip_credential_validation = true
       skip_metadata_api_check = true
       force_path_style = true
     }
   }
   ```

   **Caution:**
   If the same bucket is used across multiple Terraform configurations, the key must be unique to avoid overwriting the state file. This example uses a single bucket (`terraform-states`) to store all Terraform state files, but uses a unique prefix for the object name based on the resource (`networking`).

   Once you have configured the backend, you must run `terraform init` to finish the setup. If you already have an existing `terraform.tfstate` file, then Terraform prompts you to confirm that the current state file is the one to upload to the remote state.

   **Note:**
   The S3 backend configuration can also be used for the `terraform_remote_state` data source to enable sharing state across
Developer Tools

Terraform projects. See Accessing Remote States on page 5441 for more information.

Accessing Remote States

You can use the `terraform_remote_state` data source to access properties of objects in one Terraform configuration from another configuration.

For example, you might use one configuration to define compartments and another to define VCNs. If your resources were in the same Terraform configuration folder, you could refer to a compartment OCID from the VCN configuration by using something like this: `module.iam_compartment_SANDBOX.compartment_id`.

But assume that our definitions do not share a state file and we have a file structure similar to the following:

```
### governance
#   ### compartments.tf
#   ### outputs.tf
#   ### remote-backend.tf
#   ### variables.tf
### networking
#   ### outputs.tf
#   ### remote-backend.tf
#   ### remote-state-data_governance.tf
#   ### variables.tf
#   ### vcns.tf
### terraform-states_bucket_credentials
```

Both `governance` and `networking` configurations store their respective state files on an OCI Object Storage bucket using the `remote-backend.tf` and `terraform-states_bucket_credentials` files.

In this example, the `compartments.tf` file creates a compartment at the root level using the `iam-compartment` module from the Terraform Registry as follows:

```terraform
module "iam_compartment_SANDBOX" {
  source = "oracle-terraform-modules/iam/oci//modules/iam-compartment"
  version = "2.0.0"
  tenancy_ocid = var.tenancy_ocid
  compartment_id = var.tenancy_ocid # define the parent compartment.
  Creation at tenancy root if omitted
  compartment_name = "SANDBOX"
  compartment_description = "Test and evaluate OCI features here"
  compartment_create = true # if false, a data source with a matching name is created instead
  enable_delete = true # if false, on `terraform destroy`, compartment is deleted from the terraform state but not from oci
}
```

Defining Outputs

The `terraform_remote_state` data source can access output values from another Terraform configuration using the latest state file with a remote backend. For your `networking` configuration to access the `governance` configuration and dynamically retrieve Terraform resources properties, you must define outputs for the `governance` Terraform configuration. Without a defined output, the values cannot be used from outside of its configuration.

Your `governance/outputs.tf` file would look like the following:

```terraform
output "iam_compartment_SANDBOX" {
  description = "compartment ocid, parent ocid, name, description"
  value = {
    id = module.iam_compartment_SANDBOX.compartment_id
  }
}
```
**Referring to a Remote State**

In this example, we are using the `vcn` module from Terraform Registry to define a new VCN. The `networking` configuration refers to the `governance` configuration to define the VCN's compartment OCID:

```terraform
module "vcn_hub1iad" {
  source = "oracle-terraform-modules/vcn/oci"
  version = "2.2.0"

  # general oci parameters
  compartment_id =
  data.terraform_remote_state.governance.outputs.iam_compartment_SANDBOX["id"]
  tags = var.tags

  # vcn parameters
  create_drg = false
  internet_gateway_enabled = true
  lockdown_default_seclist = true
  nat_gateway_enabled = false
  service_gateway_enabled = false
  vcn_cidr = "10.0.0.0/16"
  vcn_dns_label = "hub1iad"
  vcn_name = "hub1"
}
```

But, for the `compartment_id =
data.terraform_remote_state.governance.outputs.iam_compartment_SANDBOX["id"]` line to be correctly interpreted, you must define a `data.terraform_remote_state` object.

**Defining the Remote State Data Source**

After the following `terraform_remote_state` data source is added to the `networking` configuration, you can access the `governance` Terraform outputs from configurations within the `networking` folder:

```terraform
data "terraform_remote_state" "governance" {
  backend = "s3"
  config = {
    bucket = "terraform-states"
    key = "governance/terraform.tfstate"
    region = "us-phoenix-1"
    endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"
    shared_credentials_file = "../terraform-states_bucket_credentials"
    skip_region_validation = true
    skip_credentials_validation = true
    skip_metadata_api_check = true
    force_path_style = true
  }
}
```

If you define your remote state data source in a separate file, such as `remote-state-data_governance.tf`, you can copy and paste the file as needed. Each new configuration can then refer to your compartment in the same way.

For More Information
Best Practices

This section documents some best practices that you can apply when you use the Oracle Cloud Infrastructure (OCI) Terraform provider to manage OCI resources.

See the following topics for more information:

- Managing Default VCN Resources on page 5443
- Referencing Availability Domains on page 5444
- Referencing Images on page 5446
- Storing Sensitive Data on page 5446
- Tagging Resources on page 5446

Managing Default VCN Resources

When you create an `oci_core_vcn` resource, it will also create the following associated resources by default:

- `oci_core_security_list`
- `oci_core_dhcp_options`
- `oci_core_route_table`

These default resources will be implicitly created even if they are not specified in the Terraform configuration. Their OCIDs are returned by the following attributes under the `oci_core_vcn` resource:

- `default_security_list_id`
- `default_dhcp_options_id`
- `default_route_table_id`

Default resources must be configured in Terraform using a separate resource type. Here are the mappings between the resource and the new resource type to use for configuring default resources:

- `oci_core_security_list` => `oci_core_default_security_list`
- `oci_core_dhcp_options` => `oci_core_default_dhcp_options`
- `oci_core_route_table` => `oci_core_default_route_table`

Default resources types are configured in the same way as their non-default counterparts. The only difference is specifying the ID of the default resource using the `manage_default_resource_id` argument.

Consequently, the `vcn_id` is no longer necessary for default resources.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

The following example modifies a VCN's default DHCP options:

```terraform
resource "oci_core_vcn" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = var.compartment_ocid
  display_name = "vcn1"
}

resource "oci_core_default_dhcp_options" "default-dhcp-options" {
  manage_default_resource_id = oci_core_vcn.vcn1.default_dhcp_options_id

  // required
  options {
```

Oracle Cloud Infrastructure User Guide 5443
Developer Tools

```java
    type = "DomainNameServer"
    server_type = "VcnLocalPlusInternet"

} // optional

options {
    type = "SearchDomain"
    search_domain_names = [ "abc.com" ]
}
```

Limitations

Default resources can only be removed when the associated `oci_core_vcn` resource is removed. When attempting a targeted removal of a default resource, the resource will be removed from the Terraform state file but the resource may still exist in OCI with empty settings.

Examples of targeted removal include:

- Removing a default resource from a Terraform configuration that was previously applied
- Running a `terraform destroy -target=<default resource>` command
- Changing the `manage_default_resource_id` for a default resource that was previously applied

Referencing Availability Domains

With respect to availability domains, we caution against a common pattern, as shown here:

```java
// Get all availability domains for the region
data "oci_identity_availability_domains" "ads" {
    compartment_id = "${var.tenancy_ocid}"
}

// Then either use it to get a single AD name based on the index:
resource "oci_core_instance" "nat" {
    availability_domain = "${lookup(data.oci_identity_availability_domains.ads.availability_domains[var.nat_instance_ad], "name")}"
    ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
    count = "${length(data.oci_identity_availability_domains.ads.availability_domains)}"
    availability_domain = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")}"
    ...
}
```

The recommendation, then, is to explicitly list the availability domain names for the regions in your configuration. To do so, use a variable that you have defined as follows:

```java
variable "ad_list" {
    type = "list"
}
```

You can then use the variable as shown here:

```java
// Index:
resource "oci_core_instance" "nat" {
    availability_domain = "${var.ad_list[var.nat_instance_ad_index]}"
    ...
}
```
// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(var.ad_list)}"
  availability_domain = "${var.ad_list[count.index]}"
  ...}

You can then set the ad_list variable directly by using the availability domain names for your tenant and region, as shown here:

variable "ad_list" {
  type = "list"
  default = ["kIdk:PHX-AD-1","kIdk:PHX-AD-2","kIdk:PHX-AD-3"]
}

The advantage of using this method is that it gives you control over your availability domain usage and prevents unexpected changes over time. However, this approach is problematic when configurations are shared between tenancies and regions, since availability domain names are tenancy- and region-specific.

A convenient alternative is to instead set the ad_list value by using the oci_identity_availability_domains data source. You should do this in the configuration, then pass them into the modules. This effectively centralizes the list of ADs, making it easy to switch to an explicit list later, should that become necessary: Note that the modules themselves should not use the oci_identity_availability_domains data source.

data "oci_identity_availability_domains" "ad" {
  compartment_id = "${var.tenancy_ocid}"}
data "template_file" "ad_names" {
  count = "${length(data.oci_identity_availability_domains.ad.availability_domains)}"
  template = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index], "name")}"
}

module "ssm_network" {
  ad_list = "${data.template_file.ad_names.*.rendered}"
  ...
}

Regions with a Single Availability Domain

Some Oracle Cloud Infrastructure regions have a single availability domain. When writing configurations that use plural data sources, like oci_identity_availability_domains, ensure that you account for a single domain if required by your region.

The following example uses the oci_identity_availability_domains data source when listing fault domains in a single-availability domain region. The availability_domains index must be 0. Any other index value is invalid in this region:

data "oci_identity_availability_domains" "AvailabilityDomains" {
  compartment_id = var.tenancy_ocid}
data "oci_identity_fault_domains" "FaultDomains" {
  availability_domain =
    data.oci_identity_availability_domains.AvailabilityDomains.availability_domains[0]["name"]
  compartment_id = "${var.compartment_ocid}"
The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Referencing Images

When launching Compute instances, your Terraform configuration should use the same image every time you run a Terraform apply job.

To ensure this, specify the image OCID directly, rather than locating it using the `oci_core_image` data source. This is because the `oci_core_image` data source calls into the `ListImages` API, whose return values can change over time because over time images are added and older ones deleted. For a list of Oracle-provided images and their OCIDs, see Oracle-Provided Images. For more information, see Results of `oci_core_images` will change over time for Oracle-provided images.

We recommend the following pattern for specifying an image for a given region:

```hcl
variable "image_id" {  
type = "map"  
default = {  
  // See https://docs.cloud.oracle.com/iaas/images/  
  // Oracle-provided image "Oracle-Linux-7.4-2018.02.21-1"  
  us-phoenix-1 = "ocid1.image.oc1.phx..<unique_ID>"  
  us-ashburn-1 = "ocid1.image.oc1.iad..<unique_ID>"  
  eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-1..<unique_ID>"  
  uk-london-1 = "ocid1.image.oc1.uk-london-1..<unique_ID>"  
  }  
}  
```

A Compute instance can use this in the following way:

```hcl
resource "oci_core_instance" "TFInstance" {  
  image = "${var.image_id[var.region]}"

  ...
}
```

Storing Sensitive Data

Caution:

Terraform configuration files and state files may contain sensitive data.

When configuring your Oracle Cloud Infrastructure (OCI) Terraform provider, you should use variables to define your provider instead of including sensitive information within the file.

Terraform state files contain all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state itself as sensitive data. Please refer to Sensitive Data in State for more details.

Tagging Resources

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate them, report on them, or take bulk actions on them. Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

There are two types of tags:

Defined tags are set up in your tenancy by an administrator. Only users granted permission to work with the defined tags can apply them to resources. Defined tags provide a key/value map and are organized by combining the tag namespaces with tag keys using dot notation. For example, a tag namespace called HumanResources could have a key named CostCenter. You then associate the namespace and key `HumanResource.CostCenter` and then assign the tag.
**Free-form tags** can be applied by any user with permissions on the resource. Freeform tags are simple key/value maps.

- Refer to the `oci_identity_tag_namespace` reference for guidance on managing the lifecycle of tag namespaces.
- Refer to the `oci_identity_tag` reference for guidance on managing tags.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

For more detailed information about tags and their features, see Tagging Overview.

**Propagation of Tagging on Resources**

OCI services propagate all of a primary resource's freeform tags and defined tags to secondary resources when both resources support the type of tags. For example, if your Terraform configuration has a Compute instance as a primary resource and a VNIC as a nested secondary resource, any tags on the Compute instance are propagated to the VNIC.

This propagation could cause a drift in the Terraform state resulting in a diff after apply. To avoid potential drift, explicitly add all the primary resource's freeform tags and defined tags on the secondary resources as part of the configuration.

The same behavior can be seen while using the Tag Default or Required Tags feature. Avoid drift by applying the Tag Default or Required Tags on all resources (primary and secondary, if any) in the tenancy where Tag Default or Required Tags exist.

**Resource Discovery**

You can use the Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature to search for deployed resources in your compartment and export them to Terraform configuration and state files.

Resource discovery simplifies the move from manually managed infrastructure to Terraform-managed infrastructure. With a single command, you can generate a file that captures your existing compartment's baseline configuration and state.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource discovery is not a migration tool. When cloning or migrating resources, configurations generated by resource discovery are a starting point. They may require changes.</td>
</tr>
</tbody>
</table>

Common uses cases for your new Terraform configuration and state files include:

- Learn how Terraform uses HashiCorp Configuration Language (HCL) syntax to represent Oracle Cloud Infrastructure resources.
- Duplication or rebuild of your existing infrastructure architecture in a new tenancy or region.
- Detection of state drift. Run reports to see if the state of your Terraform-managed resources has changed and differs from your base configuration.

<table>
<thead>
<tr>

Using Resource Discovery

The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery feature uses HashiCorp's `terraform-exec` to import the discovered OCI resources into Terraform configuration and state files.

Prerequisites

Terraform-exec requires the Terraform CLI to be present on your system. See Download and Install Terraform for installation details.

**Note:**

If you are using Terraform version v0.11, this tool cannot generate a state file. Only configurations are supported in v0.11. By default the configurations are generated in v0.12.

If you use v0.13.* of the Terraform CLI, make sure that the version is compatible with v0.12 syntax.
Additionally, you must have the OCI Terraform provider downloaded and installed. See Download and Install the Provider for download instructions.

**Adding the Tools to Your Path**

To run the OCI Terraform provider as an executable and use resource discovery, you can:

- Add `terraform-provider-oci` to your system path.
- Run the provider from the directory where it is located.
- Specify the full path to the provider when you run resource discovery commands.

Because resource discovery commands use `terraform-exec` to call Terraform on your behalf, your system must specify the location of the Terraform CLI using either of the following methods:

- Provide the full path including name for the Terraform CLI using the `terraform_bin_path` environment variable. See Environment Variables for more information on setting variables.
- Add the Terraform CLI to your system path.

**Authentication**

To discover resources in your compartment, the OCI Terraform provider needs authentication information about the user, tenancy, and region with which to discover the resources. It is recommended that you specify a user that has access to inspect and read the resources to discover.

You can use API Key Authentication and Environment Variables or Instance Principal Authorization to provide the required information.

**Exporting Resources**

After you have specified the location of the Terraform CLI and authentication settings, either of the following commands can be used to export a compartment's resources:

```
terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```
```
terraform-provider-oci -command=export -compartment_id=<compartment_OCID> -output_path=<output_path>
```

These commands discover all supported resources within the compartment and generate Terraform configuration files in the given `output_path`. The generated `.tf` files contain the Terraform configuration with the resources that the command has discovered.

**Note:**
The `compartment_id` parameter is required if using Instance Principal Authorization.

Common parameter combinations below export the resources described:

- `compartment_id=<empty_or_tenancy_OCID> services=<empty_or_not_specified>` - All tenancy and compartment scope resources.
- `compartment_id=<empty_or_tenancy_OCID> services=<comma_seperated_list>` - Tenancy and compartment scope resources for the services specified.
- `compartment_id=<non-root_OCID> services=<empty_or_not_specified>` - All compartment scope resources.
- `compartment_id=<non-root_OCID> services=<comma_seperated_list>` - Compartment scope resources for the services specified. Tenancy scope resources will not be discovered even if services with such resources are specified.
## Parameters

You can use the following parameters to control the behavior of the resource discovery tool.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>The command to run. Supported commands include:</td>
</tr>
<tr>
<td></td>
<td>• export - discovers OCI resources within your compartment and generates Terraform configuration files for them</td>
</tr>
<tr>
<td></td>
<td>• list_export_resources - lists the Terraform OCI resource types that are discovered by the export command</td>
</tr>
<tr>
<td></td>
<td>• list_export_services - lists the allowed values for services arguments along with scope in JSON format</td>
</tr>
<tr>
<td>compartment_id</td>
<td>The OCID of the compartment to export. If compartment_id or compartment_name is not specified, the root compartment is used. Required if using Instance Principal Authorization.</td>
</tr>
<tr>
<td>compartment_name</td>
<td>The name of a compartment to export. If compartment_id or compartment_name is not specified, the root compartment is used.</td>
</tr>
<tr>
<td>generate_state</td>
<td>Provide this flag to import the discovered resources into a state file in addition to the Terraform configuration files.</td>
</tr>
<tr>
<td>ids</td>
<td>A comma-separated list of resource IDs to export. The ID could either be an OCID or a Terraform import ID. By default, all resources are exported.</td>
</tr>
<tr>
<td>list_export_services_path</td>
<td>The full path, including the filename, to use as the output for list of supported services, in JSON format.</td>
</tr>
<tr>
<td>output_path</td>
<td>The absolute path to output the generated configurations and state files of the exported compartment.</td>
</tr>
<tr>
<td>parallelism</td>
<td>The number of threads that will be used to discover resources in parallel. The default value is 1.</td>
</tr>
<tr>
<td>services</td>
<td>A comma-separated list of service resources to export. If not specified, all resources within the given compartment (excluding IAM resources) are exported.</td>
</tr>
<tr>
<td></td>
<td>See Supported Services on page 5447 for accepted values and Exporting Identity Resources on page 5457 for related information.</td>
</tr>
</tbody>
</table>
### Parameter Details

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Details</th>
</tr>
</thead>
</table>
| tf_version | The version of Terraform syntax to use when generating configuration files. The default is v0.12. The allowed values are:  
  - 0.11  
  - 0.12  
  If you specify 0.11 as the syntax version, you should use v0.11 of the Terraform CLI to discover resources.  
  If you use Terraform CLI v0.13 and above to discover resources, make sure the version is compatible with v0.12 syntax.  
  State files are generated in Terraform syntax matching the version of the Terraform CLI used to discover resources. The tf_version parameter does not apply to state files. |

### Verbose Logging

To get verbose console output when the provider is running, precede your resource discovery command with the `TF_LOG` or `OCI_TF_LOG` flags. For example:

```bash
TF_LOG=DEBUG terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```

```bash
OCI_TF_LOG=DEBUG terraform-provider-oci -command=export -compartment_name=<compartment_name> -output_path=<output_path>
```

The `TF_LOG` level and `OCI_TF_LOG` flags can also be set as environment variables.  
To redirect verbose console output to a log file, set the `OCI_TF_LOG_PATH` environment variable and provide the path.

### Exit Status

If there is any error related to the OCI APIs or service unavailability while discovering resources, the tool moves on to find next resource. All errors encountered are displayed after the discovery is complete.

- Exit code 0 - Success.
- Exit code 1 - Failure because of errors such as incorrect environment variables, arguments, or configuration.
- Exit code 64 - Partial success. Resource discovery was not able to find all the resources because of service failures.

### Exporting Identity Resources

Some resources, such as identity resources, exist only at the tenancy level and cannot be discovered within a specific compartment. To discover such resources, use the following command, which omits any compartment parameter:

```bash
terraform-provider-oci -command=export -output_path=<output_path> -services=identity
```

**Note:**

When exporting identity resources, the `compartment_id` value, if provided, is ignored.

### Exporting Resources to Another Compartment
Once you have reviewed the generated Terraform configuration files and made any necessary changes, the configuration can be used with Terraform. One such use case is the re-deploying of those resources in a new compartment or tenancy, using Terraform.

To do so, specify the following environment variables:

```
export TF_VAR_tenancy_ocid=<target_tenancy_OCID>
export TF_VAR_compartment_ocid=<target_compartment_OCID>
```

Then run the following command:

```
terraform apply
```

Generating a Terraform State File

Caution:
The state file contains all resource attributes that are specified as part of configuration files. If you manage any sensitive data with Terraform, like database or user passwords or instance private keys, you should treat the state file itself as sensitive data. See Storing Sensitive Data on page 5446 for more information.

It is also possible to generate a Terraform state file to manage the discovered resources. To do so, run the following command, which includes the `-generate_state` flag:

```
terraform-provider-oci -command=export -compartment_id=<compartment_OCID> -output_path=<output_path> -generate_state
```

The results of this command are both the `.tf` files representing the Terraform configuration and a `terraform.tfstate` file representing the state. See State for more information.

Note:
The Terraform state file generated by this command is only compatible with Terraform v0.12.4 and above.

Output File Contents

The Oracle Cloud Infrastructure (OCI) Terraform provider's resource discovery `export` command discovers resources that are in an active or usable state. Resources that have been terminated or otherwise made inactive are generally excluded from the generated configuration.

By default, the Terraform names of the discovered resources share the same name as the display name for that resource, if one exists.

The attributes of the resources are populated with the values that are returned by the OCI services.

In some cases, a required or optional attribute may not be discoverable from the OCI services and may be omitted from the generated Terraform configuration. This omission may be expected behavior from the service, which may prevent discovery of certain sensitive attributes or secrets. In such cases, a placeholder value is set along with a comment like this:

```
admin_password = "" #Required attribute not found in discovery, placeholder value set to avoid plan failure
```

The missing required attributes are also added to lifecycle `ignore_changes`. This addition is done to avoid Terraform plan failure when moving manually-managed infrastructure to Terraform-managed infrastructure. Any changes made to such fields are not reflected in the Terraform plan. If you want to update these fields, remove them from `ignore_changes`. 
Resources that are dependent on availability domains will be generated under `availability_domain.tf` file. These include:

- `oci_core_boot_volume`
- `oci_file_storage_file_system`
- `oci_file_storage_mount_target`
- `oci_file_storage_snapshot`

**Services Reference**

This topic provides a reference of the Oracle Cloud Infrastructure (OCI) services that the Terraform provider supports.

**Full Reference Documentation**

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

**Supported Services**

The following table lists the services supported by the OCI Terraform provider and the services supported by the `resource discovery` feature. This list also includes the values accepted by resource discovery's `services` parameter.

### Deprecated Resources

This topic covers the list of resources and data sources that have been marked deprecated by the Oracle Cloud Infrastructure (OCI) Terraform provider and their respective suggested replacements, if any.

Resources and data sources marked for deprecation will trigger warnings during Terraform plan and apply operations. For example:

The 'oci_autonomous_data_warehouse' resource has been deprecated. Please use 'oci_autonomous_database' instead.

Resources on path to deprecation may stop working in future, use the respective guide, if available, on how to migrate using the new replacements.

### Deprecated Resources and Data Sources

Resources that have a migration path have deprecation guides available on how to rename and migrate them to their new replacements. Data sources do not have deprecation guide as you can directly replace them in their Terraform configuration and refresh the state.

### Caution:

Before executing any deprecation guide, ensure that you have backed up your Terraform state file to avoid any data loss.

<table>

## Deprecation Fields

Deprecation notices for fields can be found in any of the previously released CHANGELOG. Deprecated fields are also shown as deprecated during Terraform Plan and Apply operations. For example:

The `size_in_mbs` field has been deprecated. Please use `size_in_gbs` instead.

When troubleshooting or getting support for the Oracle Cloud Infrastructure (OCI) Terraform provider, it is often useful to first check the status of the OCI services, the version of Terraform and the provider, and enable and collect verbose logging.
Tip:
Checking service status and verbose log output can help you determine whether an issue is related to the Terraform provider or the OCI service the provider is using.

Refer to the list of common issues after you start with the basics.

Checking OCI Service Status and Outages
To check on the latest status and whether there are any outages in OCI, see OCI Status.

Checking the Terraform and OCI Terraform Provider Versions
To verify the version of Terraform and the OCI Terraform provider, initialize Terraform from a directory with your configurations and then run the `version` command. For example:

```
terraform init

terraform -version
```

The versions are displayed:

```
Terraform v0.12.20
+ provider registry.terraform.io/hashicorp/oci v3.95.0
```

Tip:
Newer versions of the OCI Terraform provider include the version of the provider in error messages.

The OCI Terraform provider documentation reflects the latest version. You can view documentation for earlier provider versions by visiting the HashiCorp reference and selecting a specific version. You can also download and install a specific version of the provider.

Verbose Logging for OCI Terraform Provider
To get verbose console output when the provider is running, precede your Terraform command with the `TF_LOG` and `OCI_GO_SDK_DEBUG` flags. For example:

```
TF_LOG=DEBUG OCI_GO_SDK_DEBUG=v terraform plan
```

The `TF_LOG` level and `OCI_GO_SDK_DEBUG` flags can also be set as environment variables.

Automatic Retries
While applying, refreshing, or destroying a plan, Terraform may encounter some intermittent OCI errors (such as 429 or 500 errors) that could succeed on retry. By default, the OCI Terraform provider automatically retries such operations for up to 10 minutes. The following fields can be specified in the `provider` block to further configure the retry behavior:

- `disable_auto_retries` - Disable automatic retries for retriable errors.
- `retry_duration_seconds` - The minimum duration (in seconds) to retry a resource operation in response to HTTP 429 and HTTP 500 errors. The actual retry duration may be slightly longer due to jittering of retry operations. This value is ignored if the `disable_auto_retries` field is set to true.

Concurrency Control Using Retry Backoff and Jitter
To alleviate contention between parallel operations against OCI services, the OCI Terraform provider schedules retry attempts using quadratic backoff and full jitter. Quadratic backoff increases the maximum interval between subsequent retry attempts, while full jitter randomly selects a retry interval within the backoff range.
For example, the wait time between the first and second retry attempts is chosen randomly between 1 and 8 seconds. The wait time between the second and third retry attempts is chosen randomly between 1 and 18 seconds. Regardless of the number of retry attempts, the retry interval time is capped after the 12th attempt at 288 seconds.

Note that the retry_duration_seconds field only affects retry duration in response to HTTP 429 and 500 errors; as these errors are more likely to result in success after a long retry duration. Other HTTP errors (such as 400, 401, 403, 404, and 409) are unlikely to succeed on retry. The retry_duration_seconds field does not affect the retry behavior for such errors.

Common Issues

**Note:**

See Terraform state drift with tag defaults and tags for secondary resources for a known issue with tags related to Terraform.

Resources Are Destroyed When Applying Changes

Existing OCI resources might be destroyed and re-created when Terraform configurations attempt to update a resource property that is not updatable. Terraform warns you when changes will destroy a resource. Always run terraform plan before applying changes to see what resources will be affected. See Destructive Changes for more information.

Resource Cannot Be Destroyed or Updated

You can prevent an OCI resource from being destroyed by including the lifecycle and prevent_destroy = true meta-arguments in the resource block of your Terraform configuration file. The following configuration, for example, results in an Object Storage bucket that cannot be destroyed:

```terraform
resource "oci_objectstorage_bucket" "test_bucket" {
  #Required
  compartment_id = var.tenancy
  name = "test"
  namespace = "exampleNamespace"

  lifecycle {
    prevent_destroy = true
  }
}
```

This meta-argument prevents the use of terraform destroy. Because certain configuration updates require resources to be destroyed before they can be applied, this setting can make some updates impossible to apply as well. In this example, name is a property that cannot be updated without destroying and re-creating the resource. Therefore, you cannot update the name of the bucket without removing or changing the lifecycle meta-argument.

See The lifecycle Meta-Argument for more information.

Resource Argument Cannot Be Unset

Many Oracle Cloud Infrastructure resources managed by the OCI Terraform provider accept configuration arguments that are optional. Once set, whether during resource creation or a subsequent update, these arguments cannot be unset by passing an empty string or removing the argument from the configuration. Attempts to unset these arguments are ignored by Terraform.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

"Operation Timeout" Error

If the Terraform CLI returns an error message like the following:

```
Error: Operation Timeout
```
Then the specified OCI service is indicating that the resource has not yet reached the expected state after polling for some time.

You may need to increase the operation timeout for your resource to continue polling for longer. See Operation Timeouts for details on how to do this.

"Unexpected LifeCycle state" Error

If the Terraform CLI returns an error message like the following:

Error: Unexpected LifeCycle state
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: During deletion, Terraform expected the resource to reach state: TERMINATED, but the service reported unexpected state: RUNNING.
Resource OCID: exampleuniqueID
Suggestion: Please retry or contact support for help with service: <service>

Then the specified OCI service encountered an unknown error. Retry, or contact support regarding that service.

Terraform CLI Issues

This section contains information dealing with the installation and configuration of the Terraform CLI.

"No such file" Error After Upgrading the OCI Terraform Provider

If the Terraform CLI returns an error message like the following:

Error asking for user input: 1 error(s) occurred:
* provider.oci: dial unix /var/folders/6r/8fk5dmbj4_z3s10mc_y_fhjw0000gn/T/plugin811254328|netrpc: connect: no such file or directory

You are likely using a version of the OCI Terraform provider that is not compatible with the Terraform binary you have installed. For OCI Provider versions v3.x.x and above, a minimum Terraform version of v.0.10.1 is required.

"TCP...i/o timeout" Message When Connecting Via Proxy

If the Terraform CLI returns an error message like the following:

* provider.oci: ... dial tcp 134.70.16.0:443: i/o timeout

Then you may not have properly configured your proxy settings. The OCI Terraform provider supports http_proxy, https_proxy and no_proxy variables where the inclusion or exclusion lists can be defined as follows:

export http_proxy=http://www.your-proxy.com:80/
export https_proxy=http://www.your-proxy.com:80/
export no_proxy=localhost,127.0.0.1

"x509: certificate signed by unknown authority" Error Message

If the Terraform CLI returns an error message like the following:

Error: Get https://iaas.<region>.oraclecloud.com/20160918/services: x509: certificate signed by unknown authority
Ensure that Terraform is using trusted TLS certificates and the certificate chain is valid. See Terraform runs failing with "x509: certificate signed by unknown authority" error for more information. If using MacOS Catalina, refer to the MacOS section of the document for more specifics on resolving certificate issues.

"Outdated GPG key...unable to verify new provider releases" Error Message

If the Terraform CLI returns an error message like the following:

```
Warning: registry.terraform.io:
This version of Terraform has an outdated GPG key and is unable to verify new provider releases.
Please upgrade Terraform to at least <version> to receive new provider updates.
For details see: https://discuss.hashicorp.com/t/hcsec-2021-12-codecov-security-event-and-hashicorp-gpg-key-exposure/23512
```

This message means that the Terraform registry is omitting the Terraform provider versions signed by a new GPG key. The Terraform CLI will install the last version of the OCI Terraform provider that it can successfully verify, which might not be the latest version.

To remove this message and ensure you can use the latest version of the OCI Terraform provider, upgrade the Terraform CLI to the latest maintenance release available for the major Terraform version you are using. For example, if you are using Terraform v0.12.21, upgrade to the latest available version of v0.12.

Terraform Provider Issues

This section contains information related to the installation and configuration of the OCI Terraform provider.

"NotAuthenticated" Error When Using Terraform

If the Terraform CLI returns an error message like the following:

```
Error: 401-NotAuthenticated
Provider version: <provider_version>, released on <release_date>. This provider is <n> updates behind to current.
Service: <service>
Error Message: The required information to complete authentication was not provided or was incorrect.
OPC request ID: exampleuniqueID
Suggestion: Please retry or contact support for help with service: <service>
```

- Verify you have properly set `user_ocid`, `tenancy_ocid`, `fingerprint` and `private_key_path`.
- Verify your `private_key_path` is pointing to your private key and not the corresponding public key.
- Verify you have added the corresponding public key to the user account you have specified with `user_ocid`.
- Verify the public/private key pairs you are using are of the correct format. See Required Keys for details on the correct format and how to generate keys.
- Verify the user account is part of a group with the appropriate permissions to perform the actions in the plan you are executing.
- Verify your Tenancy has been subscribed to the Region you are targeting in your plan.

"Can not create client, bad configuration: did not find a proper configuration for tenancy" Message When Using Aliases

If the Terraform CLI returns a message like this, it might indicate an issue with your environment:

```
Error: can not create client, bad configuration: did not find a proper configuration for tenancy
```

If your provider configuration includes an alias, your resources should explicitly specify the provider alias using `provider = "oci.alias_name"`. If a resource does not use the alias to specify the provider, Terraform creates a default provider to use with such resources. The default provider loads configuration values from environment
variables or the ~/.oci/config file. These values may differ from those used by your aliased provider and cause the configuration error.

Either remove the alias in your provider configuration, or ensure that every resource specifies the provider by the proper alias. Read more about using alias in the official Terraform documentation, and see Configuring the Provider for more information about how Terraform uses environment variables and the OCI config file.

"Field cannot be set" Error Message

If the Terraform CLI returns an error message like the following:

* Error: "field_name": this field cannot be set

You are likely using an older version of the OCI Terraform provider and the field you are trying to set was released in a later version. Use the following command to check your Terraform provider version.

terraform -version

The OCI Terraform provider documentation reflects the latest version.

"Could not get info about the first DbHome in the dbSystem" Error Message When Importing db_home

If the oci_database_db_system being imported is missing a primary db_home, an empty placeholder for db_home is set in the Terraform state file. To keep configurations consistent with the imported state, add an empty placeholder for db_home to your configuration. For example:

# Add this placeholder into your oci_database_db_system configuration to indicate that the primary db home is empty.

db_home {
  database {
    admin_password = ""
  }
}

The full reference of the OCI Terraform provider’s supported resources and data sources contains usage, argument, and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

"Failed to query available provider packages" Error Message When Running Resource Discovery

If the Terraform CLI returns an error message like the following when using resource discovery:

Failed to query available provider packages

Could not retrieve the list of available versions for provider hashicorp/oci:
the previously-selected version is no longer available

Then you can ensure that Terraform uses an existing local provider binary by specifying its location using the provider_bin_path environment variable. For example:

export provider_bin_path=/Users/user/go/bin/

Terraform attempts to download the latest version of the OCI Terraform provider when you use resource discovery.

Service API Errors

Because the Terraform provider interacts with OCI services on your behalf, many error messages surfaced by the Terraform provider come directly from OCI services. The API Errors on page 5532 reference lists common errors returned by all services.

Service error messages returned by the OCI Terraform provider include the following information:
• **Error** - the HTTP status and API error codes
• **Provider version** - the version of the OCI Terraform provider used to make the request
• **Service** - the OCI service responding with the error
• **Error message** - details regarding the error returned by the service
• **OPC request ID** - the request ID
• **Suggestion** - suggested next steps

For example:

```
Error: <http_code>-<api_error_code>
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
Error Message: <error_message>
OPC request ID: exampleuniqueID
Suggestion: <next_steps>
```

This section details a few of the more commonly returned service errors.

"400-InvalidParameter" Error

If the Terraform CLI returns an error message like the following:

```
Error: 400-InvalidParameter
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
Error Message: <error_message>
OPC request ID: exampleuniqueID
Suggestion: Please update the parameter(s) in the Terraform config as per
error message: <error_message>
```

Update the parameter specified in the error message in the Terraform configuration for the resource.

The full reference of the OCI Terraform provider's supported resources and data sources contains usage, argument,
and attribute details. The full reference is available at docs.oracle.com and HashiCorp.

Data sources and resources are grouped by service within the reference.

"400-LimitExceeded" Error

While using Terraform, you might encounter errors indicating that you have reached or exceeded the service limits
for a resource. For example:

```
Error: 400-LimitExceeded
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
Error Message: Fulfilling this request exceeds the Oracle-defined limit for
this tenancy for this resource type.
OPC request ID: exampleuniqueID
Suggestion: Request a service limit increase for this resource <service>
```

To understand more about your OCI service limits and how to request a limit increase, see Service Limits.

"404-NotAuthorized" Error

If the Terraform CLI returns an error message like the following:

```
Error: 404-NotAuthorizedOrNotFound
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
```

Error Message: Authorization failed or requested resource not found.
OPC request ID: exampleuniqueID
Suggestion: Either the resource has been deleted or service <service> need
policy to access this resource. Policy reference: <link>

Verify the user account is part of a group with the appropriate permissions to perform the actions in the plan you are
executing. Refer to the Policy Reference for your service for more information.

"500-InternalError" Error

If the Terraform CLI returns an error message like the following:

Error: 500-InternalError
Provider version: <provider_version>, released on <release_date>. This
provider is <n> updates behind to current.
Service: <service>
Error Message: Internal error occurred
OPC request ID: exampleuniqueID
Suggestion: The service for this resource encountered an error. Please
contact support for help with service <service>

The service responded to the request from the Terraform provider with an internal error. If you contact support for
this issue, reference the information in the message.

OCI Modules for PowerShell

The Oracle Cloud Infrastructure Modules for PowerShell is a set of cmdlet modules that can be used with PowerShell
Core to manage Oracle Cloud Infrastructure resources. You can invoke these cmdlets from the PowerShell command-
line and with the associated PowerShell scripting language.

Requirements

To use the OCI Modules for PowerShell, you must have the following:

• An Oracle Cloud Infrastructure account.
• A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for
yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group,
compartment, and policy, see Adding Users. For a list of typical policies you may want to use, see Common
Policies on page 2806.
• A configuration file and key pair used for signing API requests, with the public key uploaded to Oracle Cloud
using Oracle Cloud Infrastructure Console. Only the user calling the API should possess the private key.
• A supported version of PowerShell installed on Windows, Linux, or macOS operating systems.

Note:
For installation instructions, see Installing PowerShell.

Supported PowerShell Versions

To use the OCI Modules for PowerShell, you must have the following:

• PowerShell Core version 6.0 or 7.1.

Note:
For more information, see Installing PowerShell.

Services Supported

• AI Anomaly Detection
• AI Language
• Analytics Cloud
• Announcements
• API Gateway
• Application Migration
• Application Performance Monitoring
• Audit
• Autoscaling (Compute)
• Bastion
• Big Data
• Blockchain Platform
• Budgets
• Compute Instance Agent (Oracle Cloud Agent)
• Container Engine for Kubernetes
• Content Management
• Core Services (Networking, Compute, Block Volume)
• Cloud Guard
• Data Catalog
• Data Flow
• Data Integration
• Data Safe
• Data Science
• Data Transfer
• Database
• Database Management
• Database Migration
• DevOps
• Digital Assistant
• DNS
• Email Delivery
• Events
• File Storage
• Functions
• Generic Artifacts
• GoldenGate
• Health Checks
• IAM
• Integration
• Java Management
• Key Management (for the Vault service)
• Limits
• Load Balancing
• Logging
• Logging Analytics
• Logging Search
• Logging Ingestion
• Management Agent Cloud
• Management Dashboard
• Marketplace
• Monitoring
• Network Load Balancing
• Networking Topology
• Object Storage
• OCI Registry
• Operations Insights
• Operator Access Control
• Optimizer
• Organizations
• OS Management
• Quotas
• Resource Manager
• Roving Edge Infrastructure
• Search
• Secret Management (for the Vault)
• Service Catalog
• Service Connector Hub
• Streaming
• Support Management
• Usage
• VMWare Solution
• Vulnerability Scanning
• Web Application Acceleration and Security
• Work Requests (Compute, Database)

Getting Started
This topic describes how to install and configure the OCI Modules for PowerShell.

Prerequisites
Be sure to satisfy all the requirements listed here.

Installing Modules
1. Start a PowerShell session:
   a. On Windows, launch PowerShell from the Start Menu.
   b. On Linux or MacOS, run `pwsh` from a shell prompt:

```
$ pwsh

PowerShell 7.1.0
Copyright (c) Microsoft Corporation. All rights reserved.
https://aka.ms/powershell
```
2. To install all OCI modules, install the base module:

```
Install-Module OCI.PSMODULES
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uninstalling the OCI.PSMODULES module will not uninstall other OCI modules. To uninstall a specific OCI module installed by this module, the OCI.PSMODULES module will have to be uninstalled first.</td>
</tr>
</tbody>
</table>

3. You can install just the modules for an individual service. Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual Powershell module named OCI.PSMODULES.<ServiceName>.

4. Continue to either Installing from PowerShell Gallery or Installing from GitHub on page 5472.

Installing from PowerShell Gallery

1. By default, PowerShell Gallery (“PS Gallery”) is configured as a PSRepository. This can be verified by running the Get-PSRepository command:

```
PS /> Get-PSRepository
Name                      InstallationPolicy   SourceLocation
----                      ------------------   --------------
PSGallery                 Untrusted            https://www.powershellgallery.com/api/v2
```

2. You can set PS Gallery as a trusted repository to avoid prompts every time you attempt to install a module from PS Gallery:

```
PS /> Set-PSRepository -Name PSGallery -InstallationPolicy Trusted
```

3. PowerShell modules that correspond to a supported OCI service are called service modules. To install a service module run the Install-Module command. This example installs the service module for the OCI Identity service:

```
PS /> Install-Module -Name OCI.PSMODULES.Identity
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each service module depends on the OCI.PSMODULES.Common (Common Module), which offers functionality common to all service modules. Installing a service module will also install the corresponding version of OCI.PSMODULES.Common for that service module.</td>
</tr>
</tbody>
</table>

4. Installed modules can be found in the path specified by the $Env:PSModulePath environment variable, or by running the Get-Module command with the ListAvailable parameter.

```
PS /> Get-Module -ListAvailable
```

Installing from GitHub

To install the OCI PowerShell modules from GitHub:

1. Download the latest OCI Modules artifacts and extract them into a local directory.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmdlets corresponding to each OCI service supported by OCI Modules for PowerShell are packaged into an individual Powershell module named OCI.PSMODULES.&lt;ServiceName&gt;.</td>
</tr>
</tbody>
</table>
Setup

Oracle Cloud Infrastructure User Guide
Follow these installation steps if you haven't installed the required modules.

Before invoking cmdlets in OCI Modules, you need to set up the configuration file, and then optionally import the required modules into a PowerShell session.

Configuration File

A configuration file provides essential configuration information, like user credentials and tenancy OCID. This configuration information is used by the OCI Modules for PowerShell to authenticate and interact with Oracle Cloud services. You can create this file using a setup cmdlet, or manually using a text editor.

Set-OCIClientConfig

The Set-OCIClientConfig cmdlet included in the Common module will walk you through setting up a configuration file. This cmdlet prompts you for information required by the configuration file, including the key pair used to sign API requests.

For more information about how to find the required information, see:

- Where to Get the Tenancy's OCID and User's OCID
- Regions and Availability Domains

Manual Setup

If you want to set up the API signing key pair manually and write your own configuration file, see SDK and Tool Configuration and Required Keys.

Note:

Use the New-OCIClientKeys cmdlet to generate a API signing key pair to include in the configuration file.

Importing Modules

PowerShell will automatically import the module (and its dependencies) into your session the first time you run any command from the installed module. To explicitly import a module, run the Import-Module command.

For example, to import the version 1.0.0 of the Identity service module:

```
PS /> Import-Module OCI.PSMODULES.Identity -RequiredVersion 1.0.0 -Verbose
```

To find all imported modules in your current PowerShell Session, run the Get-Module command:

```
PS /> Get-Module

ModuleType Name                                      ExportedCommands
---------- ----                                      ----------------
Binary    OCI.PSMODULES.Common                      {Clear-OCICmdletHistory, Get-
OCIClientSession], Get-OCICmdletHisto...
Binary    OCI.PSMODULES.Identity                     {Add-OCIIdentityUserToGroup,
Enable-OCIIIdentityMfaTotpDevice...

Note:

Each service module depends on the OCI.PSMODULES.Common (Common Module), which offers functionalities common to all service modules. Installing a service module will also install the corresponding version of OCI.PSMODULES.Common for that service module.

Updating Modules

New versions of the OCI PowerShell modules release weekly. To update the installed OCI PowerShell modules to the latest version, run the Update-Module command.
Note:
Before updating any OCI module, you should first uninstall the module. To avoid dependency conflicts when importing modules into PowerShell session, update all installed OCI Modules to the same version.

PS /> Update-Module -Name "OCI.PSMODULES.*" -Verbose

Uninstalling Modules

To remove any installed module, you can either use the Uninstall-Module cmdlet or delete the module folder located in the path in the $Env:PSModulePath environment variable.

For example:

PS /> Uninstall-Module -Name OCI.PSMODULES.Identity

Next Steps

Now that you’ve taken care of installation and setup, you can proceed directly to Working with Cmdlets, or continue to Advanced Concepts on page 5479.

Working with Cmdlets

The OCI Modules for PowerShell cmdlets are built on the Oracle Cloud Infrastructure SDK for .NET. These cmdlets make calls to Oracle Cloud Infrastructure REST APIs with the passed cmdlet parameter values.

Note:
Cmdlet parameters are named corresponding to the respective REST API parameters as listed in the API reference.

The OCI REST APIs use HTTPS requests and responses. For more information, see About the API.

Cmdlet Discovery

OCI Cmdlets are named using a verb-noun pair pattern, where verb is the operation performed on the resource denoted by the noun, which usually includes the service name followed by the name of the resource in that service.

For example, the following command returns all cmdlets available to work with a compute instance resource in the Compute service, which is part of the OCI Core PowerShell module:

PS /> Get-Command -Module OCI.PSMODULES.Core -Noun "*ComputeInstance*"

<table>
<thead>
<tr>
<th>CommandType</th>

</table>

**Note:**
The standard **Get-Command** can be used to find cmdlets present in any module.

#### Sample Cmdlet

This example shows how to invoke a simple OCI cmdlet that calls the **GetNamespace** operation of the **OCI Object Storage service**. This operation returns the name of the Object Storage namespace for the user making the request.

**Note:**
Install and import the ObjectStorage service before trying out this example. For more information, see **Installation**.

```powershell
PS /> Get-OCIObjectStorageNamespace
us-phx-test-namespace
```

#### Cmdlet Help

To get help information for a cmdlet, use the **Get-Help** cmdlet, passing in the name of the cmdlet as a parameter.

**Note:**
For more detailed help information, use the `-Full` parameter.

This example shows help output for the **Get-OCIObjectStorageNamespace** cmdlet:

```powershell
PS /> Get-Help Get-OCIObjectStorageNamespace
NAME
Get-OCIObjectStorageNamespace
SYNOPSIS
Invokes ObjectStorage service - GetNamespace operation.

SYNTAX

DESCRIPTION
Each Oracle Cloud Infrastructure tenant is assigned one unique and uneditable Object Storage namespace. The namespace is a system-generated string assigned during account creation. For some older tenancies, the namespace string may be the tenancy name in all lower-case letters. You cannot edit a namespace. **GetNamespace** returns the name of the Object Storage namespace for the user making the request. If an optional compartmentId query parameter
is provided, GetNamespace returns the namespace name of the corresponding tenancy, provided the user has access to it.

REMARKS
To see the examples, type: "Get-Help Get-OCIOBJECTSTORAGENAMESPACE -Examples"
For more information, type: "Get-Help Get-OCIOBJECTSTORAGENAMESPACE -Detailed"
For technical information, type: "Get-Help Get-OCIOBJECTSTORAGENAMESPACE -Full"
For online help, type: "Get-Help Get-OCIOBJECTSTORAGENAMESPACE -Online"

Common Parameters
This section describes the optional global cmdlet parameters common to all cmdlets present in any OCI PowerShell service module.

**ConfigFile**
The path to the configuration file that supplies credentials for the Oracle Cloud.

**Endpoint**
Indicates the service endpoint to use for OCI API calls, including any required API version path. For example, https://audit.us-ashburn-1.oraclecloud.com

**FullResponse**
By default, OCI Cmdlets output the response body of the REST API operation. Including the FullResponse switch parameter indicates that the cmdlet should output the complete response returned by the API operation wrapped in its associated .NET type (an object containing API response headers in-addition to an optional response body).

**NoRetry**
A switch parameter to disable default retry logic for calls to services.
By default, OCI Modules for PowerShell retry failed API calls that return status codes 400, 401, 404, 409, 429 and 500. Retry attempts use an exponential backoff algorithm with a maximum of 5 attempts over a maximum time span of 10 minutes. Include this switch parameter in the cmdlet invocation to disable the default retry logic.

**Profile**
Specifies which profile to load from the configuration file. This parameter expects a case-sensitive profile name existing in the configuration file.

**Region**
Specifies the Region-ID of the region to make calls against. For example: us-phoenix-1 or ap-singapore-1.

**TimeOutInMillis**
Specifies the maximum wait time in milliseconds for the API request to complete. The default value is 100,000 milliseconds (100 seconds).
**AuthType**

Defines the type of authentication to use for making API requests. By default the API Key in your config file is used. Valid values are ApiKey or InstancePrincipal.

**Cmdlet Input and Output**

This section describes how the OCI Cmdlets process input and output.

**Cmdlet Input**

OCI Cmdlets currently accept inputs from command line parameters or through pipeline by property names. To see an example on passing inputs through pipeline by property name refer this sample.

**Cmdlet Output**

By default, OCI Cmdlets return only the API response body encapsulated in an associated .NET type. For use cases that require the users to inspect the complete API response including the response headers, use the **FullResponse** switch parameter in the cmdlet invocation.

In the following example, the GetConfiguration operation in the **OCI Audit service** returns a **Configuration** resource in the response body.

**Note:**

To run the following example, import **OCI.PSMODULES.Audit**.

```
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId | gm
```

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>---------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>&lt;Equals&gt;</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>&lt;GetHashCode&gt;</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>&lt;GetType&gt;</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>&lt;ToString&gt;</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>&lt;RetentionPeriodDays&gt;</td>
<td>Property</td>
<td>System.Nullable[int] RetentionPeriodDays</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{get;set;}</td>
</tr>
</tbody>
</table>

In the example output above, the default invocation only returns the .NET object that encapsulates the API response body.

To get an output object that includes the complete API response include the **-FullResponse** parameter in the cmdlet invocation. For example:

```
PS /> Get-OCIAuditConfiguration -CompartmentId $env:CompartmentId -FullResponse | gm
```

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>---------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>&lt;Equals&gt;</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>&lt;GetHashCode&gt;</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>&lt;GetType&gt;</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>&lt;ToString&gt;</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{get;set;}</td>
</tr>
</tbody>
</table>
Asynchronous Calls

For Oracle Cloud APIs that return an asynchronous work request response, with `opc-work-request-id` in the response header and no response body, OCI PowerShell Cmdlets return a `Oci.PSModules.Common.Cmdlets.WorkRequest` object containing the `OpcWorkRequestId` property.

For example:

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Method</td>
<td>bool Equals(System.Object obj)</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Method</td>
<td>int GetHashCode()</td>
</tr>
<tr>
<td>GetType</td>
<td>Method</td>
<td>type GetType()</td>
</tr>
<tr>
<td>ToString</td>
<td>Method</td>
<td>string ToString()</td>
</tr>
<tr>
<td>OpcWorkRequestId</td>
<td>Property</td>
<td>string OpcWorkRequestId {get;set;}</td>
</tr>
</tbody>
</table>

Error Handling

If an error occurs when running an OCI Cmdlet, the cmdlet throws a terminating error with an error record containing the exception and an error message about the underlying cause.

Advanced Concepts

This section covers PowerShell SDK concepts.

Managing Session Preferences

The OCI Modules for PowerShell support the use of environment variables in a PowerShell session to specify values some optional common parameters. These environment variables can be configured directly in the PowerShell session or by using the `Set-OCIClientSession` cmdlet. Values assigned to these environment variables are used for making API calls only in the PowerShell session in which they are set.

Set Environment Variables Directly from PowerShell

The following environment variables can be used to specify values for some parameters used by the OCI Modules for PowerShell:

<table>
<thead>
<tr>
<th>Cmdlet Parameter</th>
<th>Environment Variable Name</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>OCI_PS_REGION</td>
<td>If a value is not specified, region value from the user preferred profile is used.</td>
</tr>
<tr>
<td>Profile</td>
<td>OCI_PS_PROFILE</td>
<td>If a value is not specified, the DEFAULT profile is used.</td>
</tr>
<tr>
<td>ConfigFile</td>
<td>OCI_PS_CONFIG</td>
<td>If a value is not specified, config file at <code>~/.oci/config</code> will be used.</td>
</tr>
<tr>
<td>NoRetry</td>
<td>OCI_PS_NORETRY</td>
<td>If a value is not specified, default retry strategy is used to attempt retries.</td>
</tr>
<tr>
<td>TimeOutInMillis</td>
<td>OCI_PS_TIMEOUT</td>
<td>If a value is not specified, the default value of 100,000 milliseconds (100 seconds) is used.</td>
</tr>
<tr>
<td>AuthType</td>
<td>OCI_PS_AUTH</td>
<td>If a value is not specified, the API key defined in the config file is used.</td>
</tr>
</tbody>
</table>

For example, to set the region:

PS /> $Env:OCI_PS_REGION="us-phoenix-1"
Set Environment Variables using Cmdlets

You can use the Set-OCIClientSession and Get-OCIClientSession cmdlets to set and retrieve the session preference environment variables.

Set-OCIClientSession

This cmdlet sets the Region, Profile and Config file preferences for the PowerShell session through the environment variables shown above.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import OCI.PSMODULES.Common before running the following example.</td>
</tr>
</tbody>
</table>

```bash
PS > Set-OCIClientSession -RegionId "us-ashburn-1" -Profile "Test" -Config "~/oci/testconfig"
```

<table>
<thead>
<tr>
<th>RegionId</th>
<th>Profile</th>
<th>Config</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-ashburn-1</td>
<td>Test</td>
<td>~/.oci/testconfig</td>
</tr>
</tbody>
</table>

To remove a session preference environment variable, run the Clear-OCIClientSession cmdlet with the appropriate parameters.

Get-OCIClientSession

The Get-OCIClientSession cmdlet in the common module is used to retrieve the session preference values set for the common parameters from the current PowerShell session.

```bash
PS > Get-OCIClientSession
```

<table>
<thead>
<tr>
<th>RegionId</th>
<th>Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-ashburn-1</td>
<td>Test</td>
</tr>
</tbody>
</table>

Parameter Precedence

When evaluating parameters, the OCI Modules for PowerShell follows this order of precedence:

1. The value specified in the cmdlet parameter.
2. The value specified in the session preferences.
3. The value specified in the user-selected profile of the OCI configuration file located at ~/.oci/config.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The OCI Modules for PowerShell use the DEFAULT profile as a fall back profile. Any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile.</td>
</tr>
</tbody>
</table>

History Store

By default, OCI Cmdlets output the response body of the underlying REST API operation. The history store provides users with a PowerShell variable that can be used to look into OCI Cmdlet invocations and their complete API responses from OCI services.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each PowerShell session gets its own history store.</td>
</tr>
</tbody>
</table>

You can use the history store to:

- Use the previous Cmdlet’s response object values in the next Cmdlet
• Inspect the complete API response, including the response headers - for example, the use of e-tags for optimistic concurrency, or the OpcNextPage header for pagination
• Examine cmdlet invocation sequences for diagnostic purposes

The history store is encapsulated as an
PowerShell variable named $OCICmdletHistory.

For more information. see the History Store example on GitHub.

History Store Properties

This section explains the properties contained in the history store object stored in $OCICmdletHistory.

<table>
<thead>
<tr>
<th>Name</th>
<th>MemberType</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>LastResponse</td>
<td>Property</td>
<td>psobject LastResponse {get;}</td>
</tr>
<tr>
<td>Size</td>
<td>Property</td>
<td>int Size {get;}</td>
</tr>
</tbody>
</table>

Size

Indicates the maximum number of commands that can be saved in the history store. The default value is 20. Valid values are from 1 and 100000 (inclusive). To modify the size of history store, use Set-OCICmdletHistory.

Note:
We recommend keeping the history size to a minimum to limit memory usage.

Entries

The Oci.PSModules.Common.Cmdlets.CmdletHistory.OCICmdletHistory object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartTime</td>
<td>System.DateTime</td>
<td>Start time of cmdlet execution.</td>
</tr>
<tr>
<td>EndTime</td>
<td>System.DateTime</td>
<td>End time of cmdlet execution.</td>
</tr>
<tr>
<td>Command</td>
<td>System.Management.Automation.InvocationInfo</td>
<td>Describes how and where this command was invoked.</td>
</tr>
</tbody>
</table>

LastResponse

History Store Cmdlets

Oci.PSModules.Common module provides the following cmdlets for working with the History Store. See the GitHub example.
Get-OCICmdletHistory
Gets the cmdlet history stored in the current PowerShell session.

Set-OCICmdletHistory
Sets properties of the history store.

Clear-OCICmdletHistory
Deletes the cmdlet history stored in the current PowerShell session.

Pagination

OCI Cmdlets that invokes list API operations have the ability to paginate results, allowing you to retrieve the available results in batches (automatically following pagination tokens) until no more records are available.

Note:
Examples in this topic call the ListImages operation in the Compute service. Be sure to import OCI.PSMODULES.Core before trying out the examples in this section.

Get First Page Results
The default behavior of a cmdlet that supports pagination is to get only the first page of results when invoked without the -Page parameter specified.

For example, to get the first page of compute images available invoke the Get-OCIComputeImagesList with your compartment ID:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId | Measure-Object
Count             : 100
```

The above example implicitly sets the -Page parameter to NULL.

Note:
The maximum number of results per page is defined by the service and can be found in the service API reference.

Limit Results
The -Limit parameter specifies the maximum number of results returned per page.

This example sets the maximum number of results returned per page to 5:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 5 | Measure-Object
Count             : 5
```

Get Next Page Results
The -Page parameter is used to get the next page of results by passing the pagination token from the `opc-next-page` response header contained in the previous cmdlet response.

Note:
You can use the history store to get the previous cmdlet response.
This example shows how to retrieve the results remaining from a previous paginated call by passing the $OCICmdletHistory.LastResponse.OpcNextPage property from the history store as the argument to the -Page parameter:

```powershell
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Page $OCICmdletHistory.LastResponse.OpcNextPage | Measure-Object
Count             : 100
```

### Get All Results

OCI Cmdlets that support pagination can auto paginate and fetch results from all available pages. Let the cmdlet do the pagination by passing -All switch parameter when running the cmdlet.

```powershell
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -All | Measure-Object
Count             : 293
```

### Waiters and Asynchronous Calls

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your command to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action. You can poll a resource to determine its state.

OCI Modules for PowerShell offer waiter parameters that allow your cmdlet to wait until a resource reaches a desired state. A cmdlet with waiter parameters can be invoked in a blocking manner to wait until either one of the desired states is reached or a timeout is exceeded. Waiters abstract the polling logic that you would otherwise have to add before taking further actions on a resource or a workrequest.

For example, when you call LaunchInstance in the Compute service, the response header contains a work-request-id. The OCI Modules for PowerShell uses this ID when you specify the -WaitForStatus parameter, which causes your script to wait until the work request succeeds before proceeding.

For example:

```powershell
#Create a new compute instance and wait for the instance work request to succeed or fail,
#polling every 60 seconds and attempting 20 times max
$ComputeInstance = New-OCIComputeInstance -LaunchInstanceDetails $LaunchDetails -WaitForStatus Succeeded,Failed -MaxWaitAttempts 20 -WaitIntervalSeconds 60
```

### Waiter parameters

This section describes the parameters used for asynchronous calls.

#### WaitForStatus

Specify this parameter to perform the action and then wait until the resource reaches the desired lifecycle state. Multiple states can be specified, returning when the resource reaches one of the desired states.

#### WaitIntervalSeconds

Check every WaitIntervalSeconds to see whether the resource has reached one of the desired states. Default value for this parameter is 30 seconds.

#### MaxWaitAttempts

Maximum number of attempts to be made until the resource reaches one of the desired states. Default value for this parameter is 3 attempts.
Note:
Currently, OCI Cmdlets do not accept maximum wait time for cmdlets that support waiters. You can work around this limitation by controlling the values of MaxWaitAttempts and/or WaitIntervalSeconds.

On successful completion, the cmdlet returns the original response object received. In case of an error like the resource failing to reach the desired state within the given limits, an exception containing the error message would be thrown.

Stream Inputs and Outputs
Some OCI Cmdlets interact with APIs that accept or return stream type objects (for example, the `InvokeFunctions` operation in the Functions service). These OCI cmdlets accept parameters that can take a file path and implicitly convert files to streams and back.

Note:
You can either pass a stream parameter or the equivalent file parameter, but not both.

The file input parameter is named after the corresponding stream input parameter and file output parameter is named as `OutputFile`.

Note:
For an example, see the help text for the `Invoke-OCIFunctionsInvokeFunction` cmdlet in `OCI.PSMODULES.Functions`.

This sample on GitHub shows how to work with streams.

Logging
To facilitate troubleshooting, OCI Modules for PowerShell supports logging debug- and verbose-level messages on the console in addition to error messages. This feature has been integrated with the standard PowerShell `Debug` and `Verbose` parameters.

Pass the `-Debug` or `-Verbose` parameters in the cmdlet invocation to see log messages on the console.

For example:

```
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Verbose
#More Verbose
PS /> Get-OCIComputeImagesList -CompartmentId $Env:CompartmentId -Limit 1 -Debug
```

Authenticating with Instance Principals

 Instance principals is an IAM service feature that enables instances to be authorized actors (or principals) that can perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

Note:
For more information on instance principals, see Calling Services from an Instance.

To enable instance principal authentication from OCI Cmdlets, call authorize the instance and set the AuthType parameter. For example:

```
PS /> Get-OCIIdentityRegionsList -AuthType InstancePrincipal
```
Examples

Examples of OCI PowerShell Cmdlet usage can be found on GitHub, including:

- Creating an instance using waiters
- Accessing OCI cmdlet history store
- Using OCI cmdlet common parameters
- Downloading an object from Object Storage
- Setting preferred region and profile per session
- List all available Compute Images
- Searching resources using polymorphic objects

If you'd like to see another example not already covered, file a GitHub issue.

Running Examples

1. Clone the OCI PowerShell Modules project from GitHub.
   ```
   PS /> git clone https://github.com/oracle/oci-powershell-modules.git
   ```
2. Navigate to the examples folder inside the cloned repository.
   ```
   PS /> cd ./oci-powershell-modules/Examples
   ```
3. Install the required modules. Find additional details about setting up and running examples from the README page.
4. Run the example scripts after setting the required environment variables.
   ```
   PS /oci-powershell-modules/Examples> ./Waiter_Core.ps1
   ```

Ansible Collection

This topic provides information about the Oracle Cloud Infrastructure (OCI) Ansible collection.

Collections are Ansible's recommended method of packaging and releasing modules, roles, playbooks, and documentation. See Getting Started on page 5486 to begin using our Ansible collection.

OCI supports the use of Ansible modules to automate cloud infrastructure provisioning and configuration, orchestration of complex operational processes, and deployment and update of your software assets.

Ansible tracks your resources using inventory lists. The inventory can be a simple static .ini file or dynamically created, where a plugin assembles an up-to-date infrastructure inventory. For more information, see Working with Ansible Inventory on page 5489.

Ansible playbooks automate configuration, deployment, and orchestration tasks. Ansible playbooks use a declarative language (YAML) that allows you to describe infrastructure configuration, deployment policy, and the orchestration of complex process steps. OCI provides a set of Example Playbooks for your review.

The OCI Ansible collection supports Ansible Tower and AWX. For more information on how to set up the collection with Ansible Tower, refer to the Using Oracle Cloud Infrastructure with Ansible Tower and AWX blog post. To install the free version of Ansible Tower (AWX) on an OCI Compute instance, you can use our solution on GitHub.

- Services supported: Refer to the list of currently supported services for details.
- Licensing: Copyright © 2020, Oracle and/or its affiliates. This software is made available to you under the terms of the GPL 3.0 license or the Apache 2.0 license. See LICENSE.txt for details.
- Documentation: Additional OCI Ansible collection documentation is available on readthedocs.io and GitHub.
- Download: To download our Ansible collection, follow the steps in Getting Started on page 5486.
Tip:
The OCI Ansible collection is pre-installed on the Oracle Linux Cloud Developer platform image. For more information, see Oracle Linux Cloud Developer.

Notifications
To be notified when new versions of our Ansible collection are released, subscribe to the Oracle Cloud Infrastructure Ansible collection Atom feed.

Questions or Feedback
Ways to get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Use the oci-ansible and oracle-cloud-infrastructure tags in your post.
- Developer Tools section of the Oracle Cloud forums.

Getting Started
This topic discusses how to get started using the Oracle Cloud Infrastructure (OCI) Ansible collection. The OCI Ansible collection replaces our legacy Ansible modules.

Note:
If you currently use our legacy Ansible modules and would like to start using collections, refer to our migration guide.

To start using Ansible with OCI, ensure that you meet the prerequisites, then install the Ansible collection using yum or manually.

Tip:
You can use Resource Manager to preinstall the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud Development Kit includes Ansible, the OCI Ansible collection and its dependencies, and preconfigures the required authorization. Both Ansible and our Ansible collection also come preinstalled and preauthenticated on Cloud Shell.

Prerequisites for Using Ansible with Oracle Cloud Infrastructure

- You must have an Oracle Cloud Infrastructure account.
- You must have a user in that account in a security group with a policy that grants necessary permissions for working with resources in the account compartments. For guidance, see How Policies Work on page 2800.
- You must have the necessary credentials and OCID information.

Installing the Ansible Collection with Yum

If you're running Oracle Linux 7 or Oracle Linux 8, you can use yum to install the Oracle Cloud Infrastructure Ansible collection RPM.

The Ansible collection RPM installs the OCI Ansible collection and its required dependencies: the OCI SDK for Python and Ansible.

Note:
This installation uses Python version 3.6 and Ansible version 2.9 or later.

Use one of the following commands to enable the Oracle Linux developer repository and install the Ansible collection RPM, depending on your Oracle Linux version.
Oracle Linux 7:
```
yum install -y oci-ansible-collection --enablerepo ol7_developer --enablerepo ol7_developer_EPEL
```

Oracle Linux 8:
```
yum install -y oci-ansible-collection --enablerepo ol8_developer --enablerepo ol8_developer_EPEL
```

After installing the RPM, you must configure the SDK and CLI configuration file as explained in Configuring Authentication on page 5488.

**Test the Installation**

To test the installation of the RPM and configuration of the SDK, you can run a sample Ansible playbook.

If you're using Oracle Linux 7, use the following command to test your installation:

```
ansible-3 localhost -m oracle.oci.oci_object_storage_namespace_facts
```

If you're using Oracle Linux 8, use the following command to test your installation:

```
anible localhost -m oracle.oci.oci_object_storage_namespace_facts
```

**Manual Installation**

**Installing the Oracle Cloud Infrastructure SDK for Python**

1. Download and install the SDK for Python by following instructions in the topic, SDK for Python. For additional guidance, see Downloading and Installing the SDK.
2. After installing the SDK for Python, you must configure it using instructions in the topic Configuring the SDK.

**Installing and Configuring Ansible**

- To install Ansible, follow the instructions provided in the Ansible Installation Guide.
- For guidance configuring Ansible, see Configuring Ansible.

**Note:**
The OCI Ansible collection requires Ansible version 2.9 or later. If you are using an earlier version of Ansible, refer to the documentation for our legacy modules.

**Installing the Oracle Cloud Infrastructure Ansible Collection**

Install the OCI Ansible collection from Ansible Galaxy by using the following command:

```
$ ansible-galaxy collection install oracle.oci
```

If you've already installed the collection, you can update its modules to the latest version by adding the `--force` flag to the command. For example:

```
$ ansible-galaxy collection install --force oracle.oci
```

**Sample Playbooks**

Sample playbooks are available in the Oracle Cloud Infrastructure Ansible collection GitHub project. The samples library is updated regularly with the addition of new samples. See Example Ansible Playbooks on page 5496 for more information.

**Writing a Sample Playbook**
After your installation is complete, or if you’re using the Cloud Shell, you can write a sample playbook that uses Ansible modules. Following is an example playbook (named list_buckets.yml) that uses the `oci_object_storage_bucket_facts` module to fetch facts pertaining to the buckets in your compartment.

---
- name : List summary of existing buckets in OCI object storage
  collections:
    - oracle.oci
  connection: local
  hosts: localhost
  tasks:
    - name: List bucket facts
      oci_object_storage_bucket_facts:
        namespace_name: '<yournamespace>'
        compartment_id: '<yourcompartmentocid>'
        register: result
    - name: Dump result
      debug:
        msg: '{{result}}'

 Executing the Playbook

 Execute the Ansible playbook using Python by invoking this command:

```
$ ansible-playbook list_buckets.yml
```

How to Obtain Module Documentation

Detailed information about using our Ansible modules is available on readthedocs.io.

To obtain access to detailed information about using Ansible modules in the CLI, use the `ansible-doc` command on the module's name. For example, to get the documentation for the `oci_object_storage_bucket_facts` module, execute the following command:

```
$ ansible-doc oracle.oci.oci_object_storage_bucket_facts
```

Configuring Authentication

When creating and configuring Oracle Cloud Infrastructure resources, Ansible modules use authentication information that is outlined in the SDK and CLI Configuration File on page 5308.

**Caution:**

[User Credentials](#) on page 3056 that are referenced in Oracle Cloud Infrastructure SDK configuration files grant access to Oracle Cloud Infrastructure resources. Therefore, it is important to secure the credentials to prevent unauthorized access to these resources. To secure the credentials on the controller node where your Ansible playbooks run, follow guidelines outlined in the document [Securing IAM](#) on page 4686 (see section entitled "IAM Credentials").

Ansible modules permit you to override authentication information specified in the SDK configuration file by using module options and environment variables. Documentation for authentication overrides is provided internally, as described in [How to Obtain Module Documentation](#). However, using environment variables and Ansible module options to override authentication information must be avoided in production scenarios.

We recommend using Oracle Cloud Infrastructure SDK configuration files to specify authentication information. To support multiple users, use the "profiles" feature in the SDK configuration file. When distributing roles that use Ansible modules, ensure that no IAM credentials are included with the roles.

For More Information

- Using collections
**Working with Ansible Inventory**

Ansible tracks configuration resources by preserving lists, called inventory lists, as simple files (also sometimes called a *hostfile*). These inventory lists can be static or dynamic. Dynamic lists can automatically update when inventory resources are added, deleted, or moved.

Because many Oracle Cloud Infrastructure (OCI) resources are added and deleted over time, static inventory lists can easily become obsolete. Tools such as Terraform or the OCI SDKs also may affect your resources.

Oracle Cloud Infrastructure provides a dynamic inventory plugin for maintaining accurate Ansible inventory.

For more information about Ansible inventory files, see Working with Inventory and Working with Dynamic Inventory.

### Enabling the Inventory Plugin

The OCI inventory plugin, like most inventory plugins shipped with Ansible, is disabled by default. Plugins must be enabled in your `ansible.cfg` file to function.

Enable the OCI inventory plugin by adding it to your `ansible.cfg` file. For example:

```
[inventory]
enable_plugins = oracle.oci.oci
```

If you still use our legacy Ansible modules, your `ansible.cfg` file should contain the following entry instead:

```
[inventory]
enable_plugins = oci
```

### Configuring the Inventory Plugin

The only requirement for using the OCI inventory plugin after it is enabled is to provide an inventory source you have permissions to parse. Inventory sources are defined in a YAML configuration file. See User Permissions on page 5495 for more information.

To start using the inventory plugin with a YAML configuration source, create a file with with one of the following accepted filenames:

- `<filename>.oci.yml`
- `<filename>.oci.yaml`

Add `plugin: oracle.oci.oci` to the YAML configuration file.

The minimum inventory source file needed to run the OCI inventory plugin looks like this, for example:

```
# demo.oci.yml
plugin: oracle.oci.oci

# Optional fields to specify oci connection config:
config_file: ~/.oci/config
config_profile: DEFAULT
```

This example uses the `config_file` and `config_profile` parameters so the plugin can use authentication information that is outlined in the SDK and CLI Configuration File on page 5308. Some parameters can also be provided as environment variables.

For a complete list of parameters and environment variables that the plugin supports, see OCI Inventory Plugin. The inventory scenarios include many of the available parameters.

---

**Important:**

By default, the OCI inventory plugin discovers and lists only Compute instances that have a public IP address. See Hostname Format Preferences on page 5491 for more information.

---

Oracle Cloud Infrastructure User Guide 5489
**Order of Precedence**

The inventory plugin uses the following order of precedence when an option is provided in more than one location:

1. YAML file settings.
2. Environment variables.
3. Configuration settings in the selected profile in your OCI configuration file.

**Fetching Database Hosts**

By default, the OCI inventory plugin discovers and lists only Compute instances. Database nodes are servers running database software. Database nodes are fetched by setting the option `fetch_db_hosts` to `true`. For example:

```yaml
# demo.oci.yml
# DB Hosts
plugin: oracle.oci.oci
fetch_db_hosts: true
```

**Using the Inventory Plugin**

Ansible inventory plugins allow you to define the data sources used to compile an inventory of hosts that Ansible uses to target tasks. These data sources are accessed by using either the `-i /path/to/file` or the `-i 'host1, host2'` command line parameters, or from other configuration sources.

You can run the inventory with this command, for example:

```
ansible-inventory -i <filename>.oci.yml --graph
```

This produces output similar to the following:

```
@all:
  |--@oci:
  |    |--compute_instance1
  |    |--compute_instance2
  |--@ungrouped:
```

**Important:**

By default, the inventory is generated for all the compartments in the tenancy. You must have COMPARTMENT_INSPECT permission on the root compartment for this script to be able to access all compartments. However, when `compartment_ocid` is specified, the inventory is generated for only the specific compartment, so you only need COMPARTMENT_INSPECT permission on the specified compartment. For more information, see *How Policies Work* on page 2800.

To fetch all instance details, you must also have permission to list and read instances and VNICs, and read VCNs and subnets. See *User Permissions* on page 5495 for more information.

You can add inventory plugins to your plugin path and set the default inventory path to simplify your commands. Add the default inventory path to the `[defaults]` section of your `ansible.cfg` file, or use the `ANSIBLE_INVENTORY` environment variable to point your inventory sources. You can then run the following command to yield the same output as when you pass your YAML configuration sources directly:

```
ansible-inventory --graph
```

Inventory plugins normally only execute at the start of a run, before playbooks, plays, and roles are loaded. You can ‘re-execute’ a plugin by using the `meta: refresh_inventory` task, which clears out the existing inventory and rebuilds it.
Inventory Output

The inventory list that is generated by the inventory plugin is grouped using the following attributes:

- The region in which the Compute instance resides
- The name of the compartment the Compute instance belongs to
- The Availability Domain the Compute instance is in
- The `vcn_id` of the VCN the compute instance is in
- The `subnet_id` of the subnet the Compute instance is in
- The `security_list_ids` of the subnet the Compute instance is in
- The `image_id` of the image used to launch the Compute instance
- Shape of the Compute instance
- The Compute instance's free-form tags, with the group name set to `tag_<tag_name>=<tag_value>`
- The Compute instance's defined tags, with the group name set to `<tag_namespace>#<tag_name>=<tag_value>`
- OCI Compute instance metadata (key-value pairs), with the group name set to `<metadata-key>=<metadata-value>`
- OCI Compute instance extended metadata (key-value pairs), with the group name set to `<metadata-key>=<metadata-value>`

Hostname Format Preferences

The inventory generated by the OCI inventory plugin contains only instances that have a public IP address by default. This is useful in cases where the Ansible controller node is outside of the VCN, since Ansible can only reach instances that have public IP addresses.

You can configure the `inventory_hostname` to `private_ip` or any custom hostname by passing Jinja2 expressions as a list to the `hostname_format_preferences` option. The `hostname_format_preferences` option takes a list of Jinja2 expressions in order of precedence to compose `inventory_hostname`. The inventory plugin ignores expressions if the result is an empty string or "None" value. The instance is ignored if none of the `hostname_format_preferences` expressions result in a non-empty value.

The following example sets the `inventory_hostname` to either "display_name+'.oci.com'" or "private_ip":

```yaml
hostname_format_preferences:
  - "display_name+'.oci.com'"
  - "private_ip"
```

Expressions are evaluated on `host_vars` of every instance. Evaluation respects the order of precedence in your configuration to compose `inventory_hostname`. In the preceding example, "display_name+'.oci.com'" is evaluated before "private_ip".

Filtering Hosts

The OCI inventory plugin comes with various filtering options to filter the hosts returned by the plugin.

Exclude Hosts from Inventory

You can pass a list of Jinja2 conditional expressions to the `exclude_host_filters` parameter. Each expression in the list is evaluated for each host. When the expression is true, the host is excluded from the inventory. The `exclude_host_filters` parameter takes priority over the `include_host_filters` and `filters` options.

The following example excludes hosts that are not in the region 'iad' from the inventory:

```yaml
exclude_host_filters:
  - "region not in ['iad']"
```
Include Hosts in Inventory

You can pass a list of Jinja2 conditional expressions to the `include_host_filters` parameter. Each expression in the list is evaluated for each host. When the expression is true, the host is included in the inventory.

The following example includes only the hosts that have a `display_name` ending with `.oci.com` in the inventory:

```yaml
include_host_filters:
  - "display_name is match('.*oci.com')"
```

**Note:**
The `include_host_filters` and `filters` options cannot be used together.

Enabling Caching

Caching can be enabled to speed lookups. You can set caching options for an individual YAML configuration source or for multiple inventory sources using environment variables or Ansible configuration files. If you enable caching for an inventory plugin without providing inventory-specific caching options, the inventory plugin uses fact-caching options.

Here is an example of enabling caching for an individual YAML configuration file:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci_inventory
cache_prefix: oci
```

Using Dynamic Groups

You can create dynamic groups using host variables with the constructed `keyed_groups` option. The option groups can also be used to create groups and create and modify host variables.

For example:

```yaml
# demo.oci.yml
plugin: oracle.oci.oci
regions:  
  - us-phoenix-1
  - us-ashburn-1
keyed_groups:  
  # add hosts to tag_Name_value groups for each oci host's tags.Name variable  
  - key: tags.Name
    prefix: tag_Name_
  groups:  
    # add hosts to the group development if any of the dictionary's keys or values is the word 'devel'
    development: "'devel' in (tags|list)"
```

This example produces output similar to the following:

```yaml
@all:  
  --@oci:  
    |--compute_instance1  
    |--compute_instance2  
    --...
  --@development:  
    |--compute_instance1
```

Oracle Cloud Infrastructure User Guide 5492
Developer Tools

| |--compute_instance2
| |--@tag_Name_Dev_Instance:
| |--compute_instance1
| |--@tag_Name_Test_Server:
| |--compute_instance2
|--ungrouped

If a host does not have the variables specified in the configuration (such as tags.Name, tags, private_ip_address), the host is not added to groups other than those that the inventory plugin creates and the ansible_host host variable is not modified.

Inventory Scenarios

The following sections include configuration examples that cover common inventory scenarios.

Fetch All Compute Hosts

To fetch all hosts, your configuration can be as simple as the following example:

```yaml
plugin: oracle.oci.oci
```

Fetch Only DB Hosts

To fetch all nodes hosting database software while excluding Compute hosts, your configuration would look like the following example:

```yaml
plugin: oracle.oci.oci
# fetch database hosts
fetch_db_hosts: true
# don't fetch Compute hosts
fetch_compute_hosts: False
```

Fetch Hosts from Specific Regions

To fetch hosts only in specified regions, your configuration would look similar to the following example:

```yaml
plugin: oracle.oci.oci
# Fetch only the hosts in the regions us-ashburn-1, us-phoenix-1
regions:
  - us-ashburn-1
  - us-phoenix-1
```

Set Inventory Hostname

To set the format of the inventory hostname used in the inventory, your configuration would include a section similar to the following example:

```yaml
plugin: oracle.oci.oci
# Sets the inventory_hostname to either "display_name+.oci.com" or "id"
# "display_name+.oci.com" has more preference than "id".
hostname_format_preferences:
  - "display_name+.oci.com"
  - "id"
```

See Hostname Format Preferences on page 5491 for more information.

Exclude Hosts from Inventory
To use a Jinja2 conditional expression to exclude hosts from the inventory, your configuration would include a section similar to the following example:

```yaml
plugin: oracle.oci.oci

# Excludes hosts that are not in the region 'iad' from the inventory
exclude_host_filters:
  - "region not in ['iad']"
```

See Filtering Hosts on page 5491 for more information.

**Include Hosts in Inventory**

To use a Jinja2 conditional expression to include hosts in inventory, your configuration would include a section similar to the following example:

```yaml
plugin: oracle.oci.oci

# Includes only the hosts that have a display_name ending with '.oci.com' in the inventory
include_host_filters:
  - "display_name is match('.*.oci.com')"
```

See Filtering Hosts on page 5491 for more information.

**Note:**
The `include_host_filters` and `filters` options cannot be used together.

**Fetch Hosts from Specific Compartments**

The following example shows how to fetch all hosts from the specified compartments:

```yaml
# Fetch all hosts
plugin: oracle.oci.oci

# Select compartment by OCID or name
compartments:
  - compartment_ocid: <ocid1.compartment.oc1..exampleuniqueID>
    fetch_hosts_from_subcompartments: false
  - compartment_name: "<compartment_name>"
    parent_compartment_ocid: <ocid1.tenancy.oc1..exampleuniqueID>
```

**Other Options**

The following example configuration combines the preceding scenarios with more configuration options:

```yaml
# Fetch all hosts
plugin: oracle.oci.oci

# Optional fields:
config_file: ~/.oci/config
config_profile: DEFAULT

# Example select regions
regions:
  - us-ashburn-1
  - us-phoenix-1

# Enable threads to speedup lookup
enable_parallel_processing: yes
```
# Select compartment by ocid or name
compartments:
  - compartment_ocid: `<ocid1.compartment.oc1..exampleuniqueID>`
    fetch_hosts_from_subcompartments: false
  - compartment_name: `<compartment_name>`
    parent_compartment_ocid: `<ocid1.tenancy.oc1..exampleuniqueID>`

# Sets the inventory_hostname. Each item is a Jinja2 expression and it gets evaluated on host_vars.
hostname_format_preferences:
  - "display_name+'.oci.com'"
  - "id"

# Excludes a host from the inventory when any of the Jinja2 expression evaluates to true.
exclude_host_filters:
  - "region not in ['iad']"

# Includes a host in the inventory when any of the Jinja2 expression evaluates to true.
include_host_filters:
  - "display_name is match('.*.oci.com')"

# Example group results by key
keyed_groups:
  - key: availability_domain

# Example to create and modify a host variable
compose:
  ansible_host: display_name+'.oracle.com'

# Example flag to turn on debug mode
dbg: true

dbg: true

dbg: true

# Enable Cache
cache: yes
cache_plugin: jsonfile
cache_timeout: 7200
cache_connection: /tmp/oci-cache
cache_prefix: oci_

# DB Hosts
fetch_db_hosts: True

# Compute Hosts (bool type)
fetch_compute_hosts: True

# Process only the primary vnic of a compute instance
primary_vnic_only: True

Troubleshooting the Inventory Plugin

If the inventory list generated by the OCI inventory plugin does not include every Compute instance in your tenancy, review the following information.

User Permissions

Ensure that the user has the policy permissions to list the Compute instances. The user OCID is specified using either the OCI_USER environment variable, or the profile section in your SDK and CLI configuration file.

To see a list of permissions for API operations, see Details for the Core Services.

The inventory plugin makes API calls for the following operations:
• ListCompartments
• GetCompartment
• ListVNICAttachments
• GetVNIC
• GetSubnet
• GetVLAN
• GetVCN
• ListInstances
• GetInstance
• ListDBNodes
• ListDBSystems
• ListRegionSubscriptions

For More Information

Detailed information about using the OCI inventory plugin is available on readthedocs.io.

You can also use the following command to see the plugin documentation:

```
ansible-doc -t inventory oracle.oci.oci
```

Refer to the [the official Ansible documentation](https://docs.ansible.com/ansible/latest/glossary.html#inventory-plugin) for more information about inventory plugins.

**Example Ansible Playbooks**

This topic provides a catalog of sample Ansible playbooks for Oracle Cloud Infrastructure (OCI) that illustrate how to carry out common infrastructure provisioning and configuration tasks using our Ansible collection.

These samples and solutions are organized in sections associated with OCI services. You can find a brief description of each playbook along with links to each sample on the [Oracle GitHub repository](https://github.com/oracle/oci-ansible-collection). Be sure to review the `Readme.md` file that is included in each playbook's root directory for additional instructions.

See [Getting Started](#) on page 5486 to begin using our Ansible collection.

**Samples**

**Block Volume**

**Attaching a block volume to a Compute instance**

This sample playbook shows how to attach a block volume to a Compute instance using the iSCSI volume attachment type, and then connect it to the Compute instance using `iscsiadm`. The sample shows how to do the following:

• Generate a temporary, host-specific SSH key pair.
• Specify the public key from the key pair for connecting to the instance, and then launch the instance.
• Create a new Block Volume for the instance, attach the volume to the instance, and specify iSCSI as the volume attachment type.
• Connect to and then mount the volume from the Compute instance by executing `iscsiadm` commands over SSH using an Ansible module.

[Go to the sample on Oracle GitHub.](https://github.com/oracle/oci-ansible-collection)

**Compute**

**Launching an Always Free Compute instance**

This sample shows how to [launch](https://docs.oracle.com/en_us/oci/doc/instances.html) and [access](https://docs.oracle.com/en_us/oci/doc/instances.html) an Always Free Compute instance from the internet using SSH using OCI Ansible collections.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Connect to the newly launched instance using SSH.

Go to the sample for Always Free on Oracle GitHub.

Launching a Compute instance using App Catalog
This sample shows how a public Compute instance can be launched using app_catalog and accessed from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Fetch app_catalog and its versions and create a subscription for it.
• Launch the instance using app_catalog and connect to it using SSH.

Go to the sample on Oracle GitHub.

Creating an instance pool
This sample shows how to manage your Compute instances using resources such as instance configurations and instance pools that are provided using OCI Ansible collections. Instance pools help you create and provision multiple Compute instances within the same region based on a single instance configuration.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from that key-pair to connect to the instance during instance launch.
• Create an instance configuration that defines settings for creating a Compute instance as part of the instance pool. The configuration provides details such as base image, shape, and metadata.
• Use the instance pool to launch Compute instances based on the instance configuration.
• Connect to one of the Compute instances using SSH.

Go to the sample on Oracle GitHub.

Creating instance Console connections and capturing Console history
This sample shows how a serial and VNC console connection can be created for a Compute instance, and how the serial console data can be captured and fetched from a Compute instance using OCI Ansible collections. For more information about Console connections, see Troubleshooting Instances Using Instance Console Connections.

This sample shows how to do the following:
• Generate a temporary SSH key pair for the serial Console connection.
• Create an instance Console connection for a Compute instance.
• Capture serial Console data for a Compute instance, and then save the data to a local machine so you can troubleshoot and debug issues.

Go to the sample on Oracle GitHub.

Launching a Compute instance
This sample shows how to launch and access a public Compute instance from the internet using SSH with OCI Ansible collections.

This sample shows how to do the following:
• Generate a temporary, host-specific SSH key pair.
• Specify the public key from the key pair for connecting to the instance, and then launch the instance.
• Connect to the newly launched instance using SSH.

Go to the sample on Oracle GitHub.

Enabling internet access from a Compute instance using the OCI NAT Gateway

This sample shows how you can use OCI Ansible collections to enable internet access from Compute instances in a private subnet using a NAT Gateway in a public subnet. For more information about NAT gateways, see NAT Gateway on page 4119 and Access Resources on the Public Internet Through an Oracle Cloud Infrastructure NAT Gateway.

This sample shows how to do the following:
• Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, and the necessary security lists and route rules.
• Provision a bastion instance in the public subnet and a private instance in the private subnet.

Once set up, the private instance will have outbound Internet access through the NAT gateway, and will be accessible using SSH from the bastion instance.

Go to the sample on Oracle GitHub.

Enabling internet access from a Compute instance using an OCI NAT Instance

This sample shows how you can use OCI Ansible collections to enable internet access from Compute instances in a private subnet using a NAT instance in a public subnet as discussed here and in the whitepaper here.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>An NAT gateway is available as a reliable and highly available solution in the OCI Networking service. Please refer to the sample for more details.</td>
</tr>
</tbody>
</table>

This sample shows how to do the following:
• Set up the topology described in the whitepaper by creating the VCN, the internet gateway, the public and private subnets, and the necessary security lists and route rules. A NAT instance is provisioned in the public subnet and a private instance is provisioned in the private subnet.
• After the setup, the private instance has outbound internet access through the NAT instance in the public subnet.

Go to the sample on Oracle GitHub.

Accessing Object Storage from a private instance using a service gateway

This sample playbook shows how you can use OCI Ansible collections to enable private access to an Object Storage from a Compute instance using a service gateway. For more information about service gateways, see Access to Oracle Services: Service Gateway on page 4127. To read a blog post discussing how to connect Compute instances using the service gateway, see Connect Private Instances with Oracle Services Through an Oracle Cloud Infrastructure Service Gateway.

This sample shows how to do the following:
• Set up a user, group, and the policies required for managing buckets.
• Create and upload the required API keys to the user.
• Set up the VCN, the NAT gateway, the internet gateway, the public and private subnets, as well as the required security lists and route tables. A bastion instance is provisioned in the public subnet, and a private instance is provisioned in the private subnet.
• Provision a Compute instance in the private subnet,
• Install the OCI command line interface (CLI) and configure the CLI using the cloud init script.
• Disable the NAT gateway to restrict public access to the private instance.
• Create a bucket from the private instance using the OCI CLI, then verify that the bucket is created.

Following this setup, the private instance has private access to Object Storage.
Go to the sample on Oracle GitHub.

**Container Engine for Kubernetes**

**Creating a cluster using Container Engine for Kubernetes**

This sample creates a cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes (OKE) using OCI Ansible collections.

This sample shows how to do the following:

- Create and configure a VCN and related resources required for setting up an OKE cluster.
- Create a cluster.
- Create a node pool.
- Download the kubeconfig file for the cluster.

Go to the sample on Oracle GitHub.

**Database**

**Creating an Always Free Autonomous Database**

This sample shows how you can use the OCI Ansible collection to create an Always Free Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. See [Overview of Autonomous Databases](#) on page 1671 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
- Stop and start an Autonomous Database.
- Delete an Autonomous Database.

Go to the sample on Oracle GitHub.

**Setting up an Autonomous Database**

This sample shows how you can use the OCI Ansible collection to create an Autonomous Database with Autonomous Transaction Processing and manage its lifecycle. Refer to the [Overview of Autonomous Databases](#) on page 1671 for more information.

This sample shows how to do the following:

- Set up an Autonomous Database with Autonomous Transaction Processing.
- List all of the Autonomous Transaction Processing instances available in a compartment, filtered by display name.
- Get the "facts" for a specified database.
- Stop and start an Autonomous Database.
- Delete an Autonomous Database.

Go to the sample on Oracle GitHub.

**Creating a Bare Metal and Virtual Machine DB system**

This sample shows how you can use the OCI Ansible collection to [create Bare Metal and Virtual DB systems](#). For more information about OCI co-managed DB Systems, see [Bare Metal and Virtual Machine DB Systems](#) on page 1874.

This sample shows how to do the following:

- Set up a Virtual Machine DB System.
- Get facts of a specific DB System and list available DB Homes.
Developer Tools

- List all the databases available in specified DB Home and get facts of specific database.
- Collect DB Node's VNIC information of a specified DB system.
- Extract Public and Private IPs of the DB Node from VNIC.
- Create a backup from initial database.
- Restore a database from latest backup.
- Create a new database from backup.
- Update database fields.

Go to the sample on Oracle GitHub.

File Storage

**Creating and mounting a file system**

This sample shows how you can use the OCI Ansible collection to create and access a File Storage file system through compute instances.

This sample shows how to do the following:

- Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
- Generate the certificates required by instances.
- Create File Storage components such as mount target, file system, export, and snapshot.
- Mount the file system through a Compute instance and access the contents through another Compute instance.

Go to the sample on Oracle GitHub.

**Exporting multiple file systems and mount targets**

This sample shows how you can use the OCI Ansible collection to export one file system using two different export paths on two different mount targets. It also demonstrates how a single mount target can export paths from two different file systems.

This sample shows how to do the following:

- Generate all network related dependencies (e.g. VCN, subnets) and security lists with the configuration required by File Storage.
- Generate the certificates required by instances.
- Create File Storage components such as mount target, file system, export, and snapshot.
- Export one file system to two different mount targets.
- Export paths from a single mount target to two different file systems.
- Mount the file system through a compute instance.

Go to the sample on Oracle GitHub.

Identity

**Adding a user and group**

This sample shows how you can use the OCI Ansible collection to perform basic Oracle Cloud Infrastructure Identity and Access Management (IAM) tasks. The sample assumes the default user configured in the OCI configuration is in the Administrator group or has the required access for managing users, groups, policies.

This sample shows how to do the following:

- Create a new group.
- Create a policy.
- Create a user then add it to the group and policy.
- Create user password.
- Generate SSH keys and assign them to the user.
Go to the sample on Oracle GitHub.

Load Balancing

Creating a load balancer
This sample shows how you can use the OCI Ansible collection to create a public load balancer.
This sample shows how to do the following:
• Generate all network-related dependencies, like a VCN and subnets.
• Generate the certificates required by the load balancer.
• Create a public load balancer.

Go to the sample on Oracle GitHub.

Networking

Provisioning a VCN with private subnets
This sample shows how you can use the OCI Ansible collection to provision a virtual cloud network (VCN) with two private subnets in different availability domains and a Site-to-Site VPN. The Site-to-Site VPN uses a dynamic routing gateway (DRG), customer-premises equipment (CPE), and an IPSec connection. The provisioned resources are illustrated in this networking scenario.
This sample shows how to provision the following resources:
• A VCN
• Two private subnets
• A dynamic routing gateway
• Customer-premises equipment
• An IPSec connection between DRG & CPE
Finally, it retrieves IPSec connection configuration information and status.

Go to the sample on Oracle GitHub.

Object Storage

Getting a namespace
This sample playbook shows how to use the OCI Ansible collection to get the tenancy namespace in Object Storage.

Go to the sample on Oracle GitHub.

Listing objects and buckets
This sample playbook shows how to use the OCI Ansible collection to list all Object Storage objects from all buckets in a namespace.

Go to the sample on Oracle GitHub.

Deleting objects
This sample playbook shows how to use the OCI Ansible collection to delete objects created within a specified range of days from all buckets in a namespace. You can modify the sample so that it deletes objects older than a specified number of days, which helps you prune old or unwanted objects stored in the Object Storage service.

Go to the sample on Oracle GitHub.

Solutions

MuShop
MuShop is a showcase of several Oracle Cloud Infrastructure (OCI) services in a unified reference application. The sample application implements an e-commerce platform built as a set of microservices. The accompanying content can be used to get started with cloud native application development on OCI.

MuShop can be deployed in different ways to explore OCI based on your subscription. OCI offers Always Free tier with resources that can be used indefinitely.

This project is an example of how you can build OCI infrastructure using the OCI Ansible collection.

Grafana Plug-in

This topic provides instructions for installing, configuring, and using the Oracle Cloud Infrastructure Data Source for Grafana, otherwise referenced as the Grafana Plug-in.

Grafana Plug-in Overview

Grafana is an open-source visualization and alerting tool that you can use for analytics and monitoring of time-series data (metrics). While metrics from Oracle Cloud Infrastructure Monitoring are visible in metrics charts through the Console, you can use Oracle Cloud Infrastructure Data Source for Grafana ("the Grafana Plug-in") to view metrics from resources across providers on a single Grafana dashboard.

Prerequisites for Using the Grafana Plug-in

- An Oracle Cloud Infrastructure account.
- A user in that account, in a security group with an IAM policy that grants necessary permissions for working with resources in the account compartments. The policy must give you access to the metric namespaces emitting metrics (such as Compute) as well as the related resources (such as a set of Compute instances). If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. Administrators: For common policies that give groups access to metrics, see Let users access monitoring metrics in a compartment on page 2820 and Restrict user access to a specific metric namespace on page 2820. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group through its matching rules, and then create a policy that allows that dynamic group access to metrics. To allow access across compartments, create the policy in the tenancy. Because of the concept of policy inheritance, instances in the indicated dynamic group can then access metrics in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy. See Let instances make API calls to access monitoring metrics in the tenancy on page 2821.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 1154.
- Required keys and Oracle Cloud Infrastructure IDs (OCIDs). For guidance, see “Required Keys and OCIDs” in the Oracle Cloud Infrastructure User Guide.

Download and Install the Grafana Plug-in

Note:

Grafana must be installed before you can install the Grafana Plug-in. Version 3.0 or later required.

Authentication for metric access depends on where Grafana is running. If you are running Grafana on a local machine outside Oracle Cloud Infrastructure, you must call the Monitoring API using the Command Line Interface (CLI). If you are running Grafana on an Oracle Cloud Infrastructure Compute instance that you created, then you can add the instance to a dynamic group by configuring a matching rule. In all scenarios, you have the option of calling the API using the CLI.

For instructions on installing the Grafana Plug-in (Oracle Cloud Infrastructure Data Source for Grafana), see https://github.com/oracle/oci-grafana-plugin.

Configure the Grafana Plug-in

This section describes how to add the Grafana Plug-in and set up a dashboard.

To configure the Grafana Plug-in

Note:

When installed locally, the Grafana plug-in accesses metrics using calls to the Monitoring API.
1. Set up the CLI for accessing Oracle Cloud Infrastructure APIs.
   You'll need to access the Monitoring API for authentication.
2. Navigate to the Grafana homepage at the following URL.
   http://localhost:3000
3. Add the Grafana Plug-In (Oracle Cloud Infrastructure Data Source for Grafana).
   In addition to the steps below, see the Grafana instructions for adding data sources at https://grafana.com/docs/grafana/latest/getting-started/getting-started/.
   a. In Grafana, on the Home Dashboard, click the gear icon on the left.
   b. Click Add data source.
   c. In the Filter text box, type: oracle-oci-datasource
   d. In the filtered list, select oracle-oci-datasource.
   e. In the Settings page, fill in your Tenancy OCID, Default Region, and Environment. For Environment choose local.
4. Set up a dashboard of the type "Graph."
5. (Optional) To confirm access to metrics from Oracle Cloud Infrastructure, update your dashboard query ("Metrics") with a specific region, compartment, namespace, metric. You can also add one or more dimensions.
   Congratulations. You can now view your Oracle Cloud Infrastructure metrics in Grafana!

Environment options

local is for Grafana deployments outside Oracle Cloud Infrastructure.

OCI Instance is for Grafana deployments on Oracle Cloud Infrastructure resources.

The data source is now added, enabling you to set up a dashboard showing metrics from Oracle Cloud Infrastructure.

Troubleshoot the Plug-In

If the dashboard query ("Metrics") fails to populate with options, or if you have other issues accessing metrics, then the IAM policy used to access metrics may be malformed, or it may not include all required matching rules for your dynamic group (for running Grafana on an Oracle Cloud Infrastructure Compute instance that you created).

To resolve this issue, do the following.

• Review your IAM policy to ensure that it matches prerequisites.
• If you updated your IAM policy, then restart the Grafana server and refresh the Grafana homepage.

Other Tools

Tools and Plug-ins for SDKs and CLI

Oracle Cloud Infrastructure provides additional developer tools for automating processes and facilitating development.

WebKit for Eclipse - The toolkit is an open source plug-in for the Eclipse Integrated Development Environment (IDE) that enables Java developers to code and deploy applications more quickly and efficiently.

• Documentation: Toolkit for Eclipse on page 5523
• Download: To build and install the Toolkit, clone the GitHub repository then follow instructions in Getting Started with Toolkit for Eclipse.

Oracle Developer Tools for Visual Studio -The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can use the tools to view and manage your Oracle Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

• Documentation: Oracle Developer Tools for Visual Studio on page 5525
• **Download**: Refer to the documentation.

**HDFS Connector for Object Storage** - Read and write data with your Apache Hadoop application to and from the Oracle Cloud Infrastructure Object Storage service. Building the connector relies on Maven artifacts that are provided by the SDK for Java.

• **Documentation**: [HDFS Connector for Object Storage](#) on page 5505

• **Download**: GitHub

**Toolkit for Data Science** - The Oracle Accelerated Data Science (ADS) SDK is a Python library that is included as part of the Oracle Cloud Infrastructure Data Science service. ADS offers a friendly user interface that covers all the steps involved in the life-cycle of machine learning models, from connecting to different sources to using AutoML for model training to model evaluation and explanation. ADS also provides a simple interface to access the Oracle Cloud Infrastructure Data Science service model catalog and other Oracle Cloud Infrastructure services, including Object Storage.

• **Documentation**: [Oracle Accelerated Data Science (ADS) Python Library](#)

• **Download**: Oracle ADS Python library is pre-installed in the Oracle Cloud Infrastructure Data Science notebook session resource environment. It is not publicly available.

**HDFS Connector for Object Storage**

The Hadoop Distributed File System (HDFS) connector lets your Apache Hadoop application read and write data to and from the Oracle Cloud Infrastructure Object Storage service.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

• **Services supported**: Object Storage

• **Download**: GitHub or Maven

• **API Documentation**: [HDFS Connector API Reference](#)

**Requirements**

To use the HDFS connector, you must have:

• An Oracle Cloud Infrastructure account.

• A user created in that account, in a group with a policy that grants the desired permissions for any bucket you want to use. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a basic Object Storage policy, see Let Object Storage admins manage buckets and objects on page 2813.

• Java 8

• A TTL value of 60. For more information, see Configuring JVM TTL for DNS Name Lookups on page 5505.

**Credentials and Passwords**

If you use an encrypted PEM file for credentials, the passphrase will be read from configuration using the `getPassword` Hadoop Configuration method. The `getPassword` option checks for a password in a registered security provider. If the security provider doesn't contain the requested key, it will fallback to reading the plaintext passphrase directly from the configuration file.

**Configuring JVM TTL for DNS Name Lookups**

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called `time-to-live` (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the `networkaddress.cache.ttl` property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, −1, indicates that the lookup should be cached forever.
Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

  ```
  networkaddress.cache.ttl=60
  ```

- To set TTL only for your application, set the following in your application's initialization code:

  ```
  java.security.Security.setProperty("networkaddress.cache.ttl", "60");
  ```

**Installation**

Copy the bundled jars from lib and third-party/lib the to each node of the Hadoop cluster so that they are included in Hadoop’s CLASSPATH.

**SDK for Java and Maven Artifacts**

Building an HDFS connector relies on Maven artifacts that are provided by the Oracle Cloud Infrastructure SDK for Java. To obtain the artifacts, you must [download the SDK for Java](https://oracle.com) and build it locally. You can then build the HDFS connector.

**Important:**

The SDK for Java file version that you download from the Oracle Releases page must match the HDFS connector version, which you can find in the `hdfs-connector/pom.xml` file in the dependency tag block that has the `groupId` attribute.

**HDFS Connector and Maven Artifacts**

The HDFS connector is available on Maven Central and JCenter.

To use the HDFS connector in your project, import the following project dependency. For example:

```
<dependency>
  <groupId>com.oracle.oci.sdk</groupId>
  <artifactId>oci-hdfs-connector</artifactId>
  <!-- Replace the version below with your required version -->
  <version>2.9.2.0</version>
</dependency>
```

**Properties**

You can set the following HDFS connector properties in the `core-site.xml` file. The [BmcProperties](https://oracle.com) page lists additional properties that you can configure for a connection to Object Storage.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs.oci.client.hostname</code></td>
<td>The URL of the host endpoint. For example, <code>https://www.example.com</code>.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Type</td>
<td>Required</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------</td>
<td>----------</td>
</tr>
<tr>
<td>fs.oci.client.auth.tenantId</td>
<td>The OCID of your tenancy. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td>fs.oci.client.auth.userId</td>
<td>The OCID of the user calling the API. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes</td>
</tr>
<tr>
<td>fs.oci.client.auth.fingerprint</td>
<td>The fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
<tr>
<td>fs.oci.client.auth.pemfilepath</td>
<td>The full path and file name of the private key used for authentication. The file should be on the local file system.</td>
<td>String</td>
<td>Yes, unless you provide a custom authenticator.</td>
</tr>
<tr>
<td>fs.oci.client.auth.passphrase</td>
<td>The passphrase used for the key, if it is encrypted.</td>
<td>String</td>
<td>Only if your key is encrypted.</td>
</tr>
</tbody>
</table>
### Setting the Region Endpoint

There are several methods you can use to set the region endpoint for the HDFS Connector:

- Specifying the hostname property in `core-site.xml`
- Specifying the region code or region identifier property in `core-site.xml`
- Allowing the ObjectStorage client to pick up the endpoint via the instance metadata service

#### Configuring Properties with `core-site.xml`

This example shows how properties can be configured in a `core-site.xml` file (the OCIDs are shortened for brevity):

```xml
<configuration>
  ...
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-ashburn-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.hostname.myBucket.myNamespace</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value><!-- Use Phoenix for myBucket@myNamespace -->
  </property>
  <property>
    <name>fs.oci.client.auth.tenantId</name>
    <value>ocid1.tenancy.oc1..exampleuniqueID</value>
  </property>
  <property>
    <name>fs.oci.client.auth.userId</name>
    <value>ocid1.user.oc1..exampleuniqueID</value>
  </property>
  <property>
    <name>fs.oci.client.auth.fingerprint</name>
  </property>
  <property>
    <name>fs.oci.client.auth.pemfilepath</name>
    <value>~/.oci/oci_api_key.pem</value>
  </property>
  ...
</configuration>
```
Using Instance Principals for Authentication

Oracle provides instance principals so that you no longer need to configure user credentials or provide PEM files on services running on instances. Each of these instances has its own identity and authenticates by using certificates added to the instance by instance principals.

To use instance principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator`.

Because using instance principals provides your instance with a custom authenticator, it is no longer necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
- `fs.oci.client.auth.passphrase`

The following example code illustrates using instance principals for authentication with the HDFS connector:

```xml
<?xml version="1.0"?>
<configuration>
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.custom.authenticator</name>
    <value>com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator</value>
  </property>
</configuration>
```

For more information about instance principals, see Announcing Instance Principals for Identity and Access Management.

Using Resource Principals for Authentication

Similar to instance principals, Oracle provides resource principals to authenticate the resources which are not instances (such as a jupyter notebook). Each resource has its own identity, and authenticates using the certificates that are added to it.

To use resource principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.ResourcePrincipalsCustomAuthenticator`.

Because using instance principals provides your instance with a custom authenticator, it is no long necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
- `fs.oci.client.auth.passphrase`

The following example code illustrates using resource principals for authentication with the HDFS connector:

```xml
<?xml version="1.0"?>
<configuration>
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
</configuration>
```
For more information about instance principals, see Using Resource Principals in the Data Science Service.

Using the Jersey Default HttpUrlConnectorProvider

Starting with version 3.3.0.7.0.0, the HDFS supports using the Apache client by default to make OCI service calls. This is because the HDFS Connector relies on the SDK for Java to send requests to the server. The SDK for Java supports using the Jersey ApacheConnectorProvider by default instead of the Jersey HttpUrlConnectorProvider to allow the Apache HttpClient to make OCI service calls.

To switch back to the old Jersey default client, set the property `fs.oci.client.jersey.default.connector.enabled` in the `core-site.xml` file to `true`. By default, this value is set to `false`.

Performance optimization with the Apache Connector for HDFS

When using `ApacheConnectionClosingStrategy.GracefulClosingStrategy`, streams returned from a response are read until the end of the stream when closing the stream. This can introduce additional time when closing the stream with a partial read, depending on how large the remaining stream is. To avoid this delay, consider using `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` for large files with partial reads. With `ApacheConnectionClosingStrategy.ImmediateClosingStrategy`, streams are not read until the end when closing the stream, which can improve performance. Note that `ApacheConnectionClosingStrategy.ImmediateClosingStrategy` takes longer when using partial read for smaller stream size (streams smaller than 1MB).

Setting the connection closing strategy

Set the connection closing strategy by setting `fs.oci.client.apache.connection.closing.strategy` property in the `core-site.xml` file:

- To use `ApacheConnectionClosingStrategy.ImmediateClosingStrategy`, set the `fs.oci.client.apache.connection.closing.strategy` to `immediate`.

Note:

These closing strategies only work with the Apache Connector for HDFS and are ignored when using the Jersey default connector.

Switching back to the Jersey default connector

The Jersey default connector reads streams to the end and then reuses the stream, which can lead to better performance than the Apache Connector for HDFS in some scenarios. If these Apache Connection closing strategies do not give you optimal results for your use cases, you can switch back to Jersey Default 'HttpUrlConnectorProvider'. You can switch back to the old Jersey default client by setting the `fs.oci.client.jersey.default.connector.enabled` property in the `core-site.xml` file to `true`. By default, this value is set to `false`.

For more information, see: https://github.com/oracle/oci-java-sdk/blob/master/ApacheConnector-README.md.
**Connection Pooling in HDFS**

You can set the maximum number of connections in the HDFS Connector connection pool.

To do this, change the property `fs.oci.client.apache.max.connection.pool.size` in the `core-site.xml` file to a positive integer that specifies how many connections to pool.

*Note:*

This property is only supported when using the ApacheConnector for HDFS; otherwise it is ignored.

**Configuring a HTTP Proxy**

You can set the following optional properties in the `core-site.xml` file to configure a HTTP proxy:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs.oci.client.proxy.uri</code></td>
<td>The URI of the proxy endpoint. For example, <code>http://proxy.mydomain.com:80</code>.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.proxy.username</code></td>
<td>Username to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.proxy.password</code></td>
<td>Password to authenticate with the proxy.</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.allowed</code></td>
<td>Enables the upload manager to support multipart uploads.</td>
<td>Boolean</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.minobjectsize.mb</code></td>
<td>Specifies the minimum object size in mebibytes in order to use the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
<tr>
<td><code>fs.oci.client.multipart.partsize.mb</code></td>
<td>Specifies the part size in mebibytes for the upload manager.</td>
<td>Integer</td>
<td>No</td>
</tr>
</tbody>
</table>

*Note:*

Configuring a proxy enables use of the ApacheConnectorProvider when making connections to Object Storage. It buffers requests into memory and can impact memory utilization when uploading large objects. It is recommended to enable multipart uploads and adjust the multipart properties to manage memory consumption.

**Large Object Uploads**

Large objects are uploaded to Object Storage using multipart uploads. The file is split into smaller parts that are uploaded in parallel, which reduces upload times. This also enables the HDFS connector to retry uploads of failed parts instead of failing the entire upload. However, uploads may transiently fail, and the connector will attempt to abort partially uploaded files. Because these files accumulate (and you will be charged for storage), list the uploads periodically and then after a certain number of days abort them manually using the SDK for Java.
Information about using the Object Storage API for managing multipart uploads can be found in Using Multipart Uploads on page 4382.

The following sections contain best practices to optimize usage and performance.

**Directory Names**

There are no actual directories in Object Storage. Directory grouping is a function of naming convention, where objects use / delimiters in their names. For example, an object named a/example.json implies there is a directory named a. However, if that object is deleted, the a directory is also deleted implicitly. To preserve filesystem semantics where the directory can exist without the presence of any files, the HDFS connector creates an actual object whose name ends in / with a path that represents the directory, (that is, create an object named a/). Now, deleting a/example.json doesn't affect the existence of the a directory, because the a/ object maintains its presence. However, it's entirely possible that somebody could delete that a/ object without deleting the files/directories beneath it. The HDFS connector will only delete the folder object if there are no objects beneath that path. The folder object itself is zero bytes.

**Inconsistent Filesystem**

Deleting a directory means deleting all objects that start with the prefix representing that directory. HDFS allows you to query for the file status of a file or a directory. The file status of a directory is implemented by verifying that the folder object for that directory exists. However, it's possible that the folder object has been deleted, but some of the objects with that prefix still exist. For example, in a situation with these objects:

- a/b/example.json
- a/b/file.json
- a/b/

HDFS would know that directory /a/b/ exists and is a directory, and scanning it would result in example.json and file.json. However, if object a/b/ was deleted, the filesystem would appear to be in an inconsistent state. You could query it for all files in directory /a/b/ and find the two entries, but querying for the status of the actual /a/b/ directory would result in an exception because the directory doesn't exist. The HDFS connector does not attempt to repair the state of the filesystem.

**File Creation**

Object Storage supports objects that can be many gigabytes in size. Creating files will normally be done by writing to a temp file and then uploading the contents of the file when the stream is closed. The temp space must be large enough to handle multiple uploads. The temp directory used is controlled by the hadoop.tmp.dir configuration property.

**Read/Seek Support**

When in-memory buffers are enabled (fs.oci.io.read.inmemory), seek is fully supported because the entire file is buffered into a byte array. When in-memory buffer is not enabled (likely because object sizes are large), seek is implemented by closing the stream and making a new range request starting at the specified offset.

**Directory Listing**

Listing a directory is essentially a List bucket operation with a prefix and delimiter specified. To create an HDFS FileStatus instance for each key, the connector performs an additional HEAD request to get ObjectMetadata for each individual key. This will be required until Object Storage supports richer list operation data.
**URI Format for Filesystems and Files**

HDFS filesystems and files are referenced through URIs. The scheme specifies the type of filesystem, and the remaining part of the URI is largely free for the filesystem implementation to interpret as it wants.

Because Object Storage is an object store, its ability to name objects as if they were files in a filesystem is used to mimic an actual filesystem.

**Root**

The root of Object Storage filesystem is denoted by a path where the authority component includes the bucket name and the namespace name, as shown:

```
oci://MyBucket@MyNamespace/
```

This is always the root of the filesystem. The reason for using authority for both bucket and namespace is that HDFS only allows the authority portion to determine where the filesystem is; the path portion denotes just the path to the resource (so `oci//MyNamespace/MyBucket` won't work, for example). Note that the `@` character is not a valid character for buckets or namespaces, and should allow the authority to be parsed correctly.

**Sub-directories**

Sub-directories do not actually exist, but can be mimicked by creating objects with `/` characters. For example, two files named `a/b/c/example.json` and `a/b/d/path.json` would appear as if they were in a common directory `a/b`. This would be achieved by using the Object Storage prefix- and delimiter-based querying. In the given example, referencing a sub-directory as a URI would be:

```
oci://MyBucket@MyNamespace/a/b/
```

**Objects/Files**

An object named `a/b/c/example.json` is referenced as:

```
oci://MyBucket@MyNamespace/a/b/c/example.json
```

**Logging**

Logging in the connector is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see, the SLF4J manual.

The following example shows how to enable basic logging to standard output.

1. Download the SLF4J Simple binding jar: [SLF4J Simple Binding](#)
2. Add the jar to your classpath
3. Add the following VM arg to enable debug level logging (by default, info level is used): 
   ```
   -Dorg.slf4j.simpleLogger.defaultLogLevel=debug
   ```

You can configure more advanced logging options by using the log4j binding.
package com.oracle.oci.hadoop.example;

import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;
import org.apache.commons.io.IOUtils;

        for (final IntWritable val : values) {
            sum += val.get();
        }
        this.result.set(sum);
        context.write(key, this.result);
    }
}

Troubleshooting
This section contains troubleshooting information for the HDFS connector.

Troubleshooting Service Errors
Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the HDFS connector. For information about common service errors returned by OCI, see API Errors.

Java Encryption Key Size Errors
The HDFS connector can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256. Use one of the following workarounds to fix this issue:

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Contributions
Got a fix for a bug, or a new feature you’d like to contribute? The SDK is open source and accepting pull requests on GitHub.
Notifications
If you wish to be notified when a new version of the HDFS connector is released, subscribe to the Atom feed.

Using the HDFS Connector with Spark

Introduction
This article provides a walkthrough that illustrates using the Hadoop Distributed File System (HDFS) connector with the Spark application framework. For the walkthrough, we use the Oracle Linux 7.4 operating system, and we run Spark as a standalone on a single computer.

Prerequisites
Following are prerequisites for completing the walkthrough:
- You must have permission to create a Compute instance. For guidance, see Creating an Instance on page 1023.
- You must be able to connect to the service instance that you've launched. For guidance, see Connecting to an Instance on page 1083.
- You must have the appropriate OCID, fingerprint, and private key for the Identity and Access Management (IAM) user that you will use to interact with an Object Storage. For guidance, see Setup and Prerequisites on page 5303.
- You must have an Object Storage bucket that you can connect to.
- The IAM user must be able to read and write to that bucket using the Console.

Using Spark

Install Spark and Dependencies

Note:
For the purpose of this example, install Spark into the current user’s home directory. Note that for production scenarios, you would not do this.

Note:
Versions 2.7.7.0 and later no longer install all of the required third party dependencies. Required third party dependencies are bundled under the third-party/lib folder in the zip archive and should be installed manually.

1. Create an instance of your Compute service. For guidance, see Creating an Instance on page 1023.
2. Ensure that your service instance has a public IP address so that you can connect using a Secure Shell (SSH) connection. For guidance, see Connecting to an Instance on page 1083.
3. Connect to your service instance using an SSH connection.
4. Install Spark and its dependencies, Java and Scala, by using the code examples that follow.

```bash
# We'll use wget to download some of the artifacts that need to be installed
sudo yum install wget

# First install Java
sudo yum install java-1.8.0-openjdk.x86_64
```
export JAVA_HOME=/usr/lib/jvm/jre-1.8.0-openjdk
# Should be something like: OpenJDK Runtime Environment (build 1.8.0_161-
b14)
java -version

# Then install Scala
sudo yum install scala-2.12.4.rpm
# Should be something like: Scala code runner version 2.12.4 -- Copyright 2002-2017, LAMP/EPFL and Lightbend, Inc.
scala -version

# Then download Spark
wget https://archive.apache.org/dist/spark/spark-2.2.1/spark-2.2.1-bin-
hadoop2.7.tgz
tar xvf spark-2.2.1-bin-hadoop2.7.tgz
export SPARK_HOME=$HOME/spark-2.2.1-bin-hadoop2.7
export PATH=$PATH:$SPARK_HOME/bin

# Start a Spark master
cd $SPARK_HOME
./sbin/start-master.sh

---

**Download the HDFS Connector and Create Configuration Files**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For the purposes of this example, place the JAR and key files in the current user's home directory. For production scenarios you would instead put these files in a common place that enforces the appropriate permissions (that is, readable by the user under which Spark and Hive are running).</td>
</tr>
</tbody>
</table>

Download the HDFS Connector to the service instance and add the relevant configuration files by using the following code example. For additional information, see HDFS Connector for Object Storage on page 5505.

```bash
wget https://github.com/oracle/oci-hdfs-connector/releases/download/v2.9.2.1/oci-hdfs.zip
unzip oci-hdfs.zip -d oci-hdfs

cd $HOME
mkdir .oci
# Create or copy your API key into the $HOME/.oci directory

cd $SPARK_HOME/conf
# Create a core-site.xml (e.g. by transferring one you have, using vi etc.). Consult
# https://docs.oracle.com/iaas/Content/API/SDKDocs/hdfsconnector.htm#Properties
# for what this should look like

# Create a spark-defaults.conf file from the template
cp spark-defaults.conf.template spark-defaults.conf
```

In the `spark-defaults.conf` file, add the following at the bottom:

```
spark.sql.hive.metastore.sharedPrefixes= shaded.oracle,com.oracle.bmc
```

---

**Prepare Data**

For testing data, we will use the MovieLens data set.

2. Unzip the download file.

3. Upload the movies.csv file to your Object Storage bucket.

Test Using the Spark Shell

With the data ready, we can now launch the Spark shell and test it using a sample command:

```
cd $SPARK_HOME
./bin/spark-shell
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
java.io.IOException: No FileSystem for scheme: oci
```

You receive an error at this point because the oci:// file system schema is not available. We need to reference the JAR file before starting the Spark shell. Here's an example for doing so:

```
./bin/spark-shell --jars $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar --
driver-class-path $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar
```

```
scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
res0: org.apache.spark.rdd.RDD[(String, String)] = oci://
PipedUploadTest@sampletenancy/ MapPartitionsRDD[1] at wholeTextFiles at <console>:25
```

```
scala> sc.textFile("oci://PipedUploadTest@sampletenancy/
movies.csv").take(20).foreach(println)
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
10,GoldenEye (1995),Action|Adventure|Thriller
11,"American President, The (1995)",Comedy|Drama|Romance
12,Dracula: Dead and Loving It (1995),Comedy|Horror
13,Balto (1995),Adventure|Animation|Children
14,Nixon (1995),Drama
15,Cutthroat Island (1995),Action|Adventure|Romance
16,Casino (1995),Crime|Drama
17,Sense and Sensibility (1995),Drama|Romance
18,Four Rooms (1995),Comedy
19,Ace Ventura: When Nature Calls (1995),Comedy
```

The command is successful so we are able to connect to Object Storage. Note that if you do not wish to pass the --jars argument each time the command executes, you can instead copy the oci-hdfs-full JAR file into the $SPARK_HOME/jars directory.

Start the Spark Thrift Server

Start the Spark Thrift Server on port 10015 and use the Beeline command line tool to establish a JDBC connection and then run a basic query, as shown here:

```
cd $SPARK_HOME
./sbin/start-thriftserver.sh --hiveconf hive.server2.thrift.port=10015
```
Once the Spark server is running, we can launch Beeline, as shown here:

```
cd $SPARK_HOME
./bin/beeline
```

Beeline version 1.2.1.spark2 by Apache Hive

```
beeline>
```

Next, connect to the server, as shown here:

```
beeline> !connect jdbc:hive2://localhost:10015 testuser testpass
```

Note:

For the purposes of this example, we have not configured any security, so any user name and password will be accepted. For production scenarios you would not do this.

```
beeline> !connect jdbc:hive2://localhost:10015 testuser testpass
Connecting to jdbc:hive2://localhost:10015
log4j:WARN No appenders could be found for logger
  (org.apache.hive.jdbc.Utils).
log4j:WARN Please initialize the log4j system properly.
log4j:WARN See http://logging.apache.org/log4j/1.2/faq.html#noconfig for
  more info.
Connected to: Spark SQL (version 2.2.1)
Driver: Hive JDBC (version 1.2.1.spark2)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

If we now check to see what tables exist, we see the following:

```
0: jdbc:hive2://localhost:10015> show tables;
+-----------+------------+--------------+--+
| database  | tableName  | isTemporary  |
+-----------+------------+--------------+--+
+-----------+------------+--------------+--+
No rows selected (0.724 seconds)
```

None exist presently; however, we can create a table and link it to the `movies.csv` file that we downloaded and placed in the Object Storage bucket, as shown here:

```
0: jdbc:hive2://localhost:10015> create table test_table (movieId integer, title string, genres string) using csv options (path "oci://myBucket@myTenant/movies.csv", header "true", delimiter ",");
0: jdbc:hive2://localhost:10015> describe formatted test_table;
+-------------------------------+------------------------------------------------------------+----------+--+
|           col_name            |                         data_type | comment  |
+-------------------------------+------------------------------------------------------------+----------+--+
| movieId                       | int                         |
| title                         | string                      |
| genres                        | string                      |
|                               |                            |
|                               | # Detailed Table Information|          |
| Database                      | default                     |
```
Note that the table stores its data externally in Object Storage and the data can be accessed using the HDFS Connector (the `oci://` file system scheme). Now that we have a table, we can query it:

```sql
0: jdbc:hive2://localhost:10015> select * from test_table limit 10;
+----------+-------------------------------------+------------------+
<table>
<thead>
<tr>
<th>movieId</th>
<th>title</th>
<th>genres</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Toy Story (1995)</td>
<td>Adventure</td>
</tr>
<tr>
<td>2</td>
<td>Jumanji (1995)</td>
<td>Adventure</td>
</tr>
<tr>
<td>3</td>
<td>Grumpier Old Men (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>4</td>
<td>Waiting to Exhale (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>5</td>
<td>Father of the Bride Part II (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>7</td>
<td>Sabrina (1995)</td>
<td>Comedy</td>
</tr>
<tr>
<td>8</td>
<td>Tom and Huck (1995)</td>
<td>Adventure</td>
</tr>
<tr>
<td>9</td>
<td>Sudden Death (1995)</td>
<td>Action</td>
</tr>
</tbody>
</table>
+----------+-------------------------------------+------------------+
```

Toolkit for Eclipse

The Oracle Cloud Infrastructure Toolkit for Eclipse is an open source plug-in for the Eclipse Integrated Development Environment (IDE). The toolkit provides a set of features that help developers connect to Oracle Cloud Infrastructure from within Eclipse. For example, you can use the toolkit to deploy an application to a VM in the cloud by using the Oracle Container Engine for Kubernetes, or upload multiple files to Object Storage with one click. The Compute feature enables you to start a compute instance or restart it if needed. You can also switch between multiple accounts and regions from the Eclipse IDE.

**Download**: To install the Toolkit, download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub, then follow the instructions in Getting Started with Toolkit for Eclipse on page 5523.

**Requirements**

To use the Oracle Cloud Infrastructure Toolkit for Eclipse, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users on page 81. For a list of typical policies you may want to use, see Common Policies on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs on page 5303.
- SDK for Java on page 5351
- Eclipse IDE for Java Developers 4.3 or later

**Services Supported**

- Compute
- Object Storage
- Autonomous Database
- Container Engine for Kubernetes

**Contact Us**

**Contributions**

Got a fix for a bug or a new feature you’d like to contribute? The plug-in is open source and accepting pull requests on GitHub.

**Notifications**

To be notified when a new version of the toolkit is released, subscribe to the Atom feed.

**Questions or Feedback**

- My Oracle Support

Getting Started with Toolkit for Eclipse

**Downloading the Toolkit**

You can download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub.

Installing the Toolkit

After downloading the toolkit, launch the Eclipse IDE.
1. From the top navigation bar, select Help > Install New Software...
2. In the Install dialog, click Add...
3. In the Add Repository dialog, click Archive...
4. In the right pane of the Repository Archive window, select the zip file containing the toolkit. Click Open.
5. In the Add Repository dialog click Add.
6. In the Available Software dialog, select Oracle Cloud Infrastructure Toolkit for Eclipse, then click Next.
7. In the Install Details dialog, click Finish.

Configuring the Toolkit

Oracle Cloud Infrastructure Preferences
Before you can use the toolkit, you must configure the Oracle Cloud Infrastructure Preferences in the Eclipse IDE. This process will provide the necessary identifiers and credentials so the toolkit can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs on page 5303.

1. From the top navigation bar, select Preferences > Oracle Cloud Infrastructure Preferences.
2. For Profile Name, provide a short descriptive name.
3. From the Region dropdown, select your region.
4. Enter your User OCID and Tenancy OCID. For information on how to locate this information, see Where to Get the Tenancy's OCID and User's OCID on page 5308.
5. For Key File, click Browse and select the appropriate file. For more information, see How to Generate an API Signing Key on page 5304.
6. Enter the Fingerprint for the Key File. For more information, see How to Get the Key's Fingerprint on page 5307.
7. Enter the Passphrase, if you created one for the key pair. If not, leave this field blank.
8. Click Save Profile.
9. Click Apply and Close.

Proxy Settings
If you are on a network that uses a proxy to connect to the internet, you must configure Eclipse proxy settings. For more information, see Network Connections in the Eclipse IDE Documentation.

Uninstalling the Toolkit
Launch the Eclipse IDE.

1. From the top navigation bar, select Help > About Eclipse IDE
2. Click Installation Details.
3. In the Installation Details window, select the Installed Software tab.
4. Select Oracle Cloud Infrastructure Toolkit for Eclipse and click Uninstall...
5. In the Uninstall dialog, confirm the items to be uninstalled then click Finish.
6. Click Restart.

Using Toolkit for Eclipse
After configuring the Oracle Cloud Infrastructure Preferences on page 5524, you can connect to your tenancy via Eclipse and use the Oracle Cloud Infrastructure Explorer to view and update your resources. You can also switch between different accounts saved in the profile.

To change the region, click the region icon in the Explorer navigation bar and select from the dropdown.

To change the compartment, click the compartment icon and select from the dropdown.

Using the Toolkit for Eclipse with Compute Instances
In the Oracle Cloud Infrastructure Explorer, double-click Compute to view available resources.

Double-click Instances to display a list of instances. You can right-click each one in the list to start, stop, or reboot it.
You can also double-click **Block Volumes** to view a list of block volumes.

Using the Toolkit for Eclipse with Object Storage

In the Oracle Cloud Infrastructure Explorer, double-click Object Storage to view available resources.

**Working with Buckets**

To create a bucket, right-click **Object Storage** and select **Create New Bucket**.

To view content and details, double-click or right-click the bucket and select **Open Bucket**.

To delete a bucket, view the bucket's details and click **Delete Bucket**.

**Working with Objects**

To upload an object, select the destination bucket and view its details. Right-click the Object list and select **Upload Object**. You can also drag one or more files to the Object list to upload.

To download one or more objects, right-click and select **Download Object**.

To delete one or more objects, right-click and select **Delete Object**.

Deploy Applications using Oracle Container Engine for Kubernetes

**Prerequisites**

1. Install **Docker Desktop v2.2.0.0** or higher.
2. Verify that Docker desktop is running, and that the Docker CLI client and Kubernetes CLI client (kubectl) are available in the command line.
3. Install the **Oracle Cloud Infrastructure command line client (OCI CLI)**.
4. Verify that OCI CLI works by typing "oci" on command prompt. This should return a list of all the services supported by OCI CLI.

**Deploy an Application to Container Engine for Kubernetes**

1. In the Oracle Cloud Infrastructure Explorer, double-click **Container Engine for Kubernetes**.
2. Double-click **Container Cluster (OKE)** to display a list of available clusters. A cluster should be created prior to this step in the console.
3. Right click on the cluster name and select **Deploy Docker Image to OKE**.
4. Follow the deployment wizard steps to to deploy the application.

**Oracle Developer Tools for Visual Studio**

The Oracle Developer Tools for Visual Studio provide a set of features that helps developers connect to Oracle Cloud Infrastructure from within the Microsoft Visual Studio IDE. You can use the tools to view and manage your Oracle Databases and Oracle Autonomous Databases in Oracle Cloud Infrastructure and quickly and easily deploy a web application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

**Requirements**

To use the Oracle Developer Tools for Visual Studio, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see **Adding Users** on page 81. For a list of typical policies you may want to use, see **Common Policies** on page 2806.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see **Required Keys and OCIDs** on page 5303.
- The Oracle Cloud Infrastructure **Command Line Interface (CLI)** on page 5316 installed and configured.
- Microsoft Visual Studio 2019 or later
• Docker Desktop v2.2.0.0 or higher

Questions or Feedback
For questions or to provide feedback, please use one of the following resources:
• The Developer Tools section of the Oracle Cloud forums
• My Oracle Support

Getting Started with Oracle Developer Tools for Visual Studio

Installing the Extension
The Oracle Developer Tools for Visual Studio is available in the Visual Studio Marketplace.
1. From the Visual Studio menu, select Extensions->Manage Extensions
2. From the list on the left side of the dialog, select Online and then Visual Studio Marketplace
4. Click on the Download button next to the extension.
5. A browser window opens with instructions to download the installer.

Configuring the Toolkit

Oracle Developer Tools for Visual Studio Preferences
Before you can use the developer tools, you must configure the Oracle Cloud Infrastructure Preferences. This
process will provide the necessary identifiers and credentials so the developer tools can connect to your Oracle Cloud
Infrastructure account. For more information, see Required Keys and OCIDs on page 5303.
1. The deployment wizard requires an Oracle Cloud Infrastructure user credentials configuration file. For more
information, see SDK and CLI Configuration File on page 5308.
2. Run the "docker desktop" app, and ensure it has the Linux Containers option selected.
3. If behind a proxy, set the proxy values http_proxy and https_proxy in the environment variables for Windows and
in the Docker Desktop settings (see the Resources->Proxies menu).

Uninstalling the Toolkit
1. From the Visual Studio menu, select Extensions, then Manage Extensions.
2. From the list on the left side of the dialog, select Installed.
3. Select "Oracle Developer Tools for Visual Studio 2019" from the middle menu and click on the Uninstall button
that appears next to it.

Note:
The uninstall completes when you exit Visual Studio.

Using the Oracle Developer Tools for Visual Studio
This topic shows how to use the Oracle Developer Tools for Visual Studio's Deployment wizard to deploy a web
application to Oracle Cloud Infrastructure Container Engine for Kubernetes.

Note:
The Oracle Developer Tools for Visual Studio has additional functionality
that is not covered in this document. For more information, see Oracle

Prerequisites
This topic assumes a working knowledge of OCI Container Engine for Kubernetes. The tutorials below will help
understand some of the technologies and backend framework used by the wizard for deployment.
• Pushing an Image to Oracle Cloud Infrastructure Registry
• Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes
• Deploying an Application to OKE

Overview

Using the Oracle Developer Tools for Visual Studio assumes you've already created a docker image for your application. This workflow generally looks like this:

• Build your web application.
• Build a docker image for your application locally. For more information, see the Docker documentation.
• Push the docker image of the web application to the Oracle Cloud Infrastructure Registry. For more information on pushing a docker image to OCIR, see Push an Image to Oracle Cloud Infrastructure Registry.
• Create a cluster in Oracle Cloud using Oracle Container Engine Service for Kubernetes. See Create a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes and download the resulting kubeconfig file.
• Create a named secret containing OCI credentials to be used for Kubernetes deployment. For more information, see Pull an Image from Oracle Cloud Infrastructure Registry when Deploying a Load-Balanced Application to a Cluster.

Deploy an Application Using the Oracle Deployment Wizard

1. From the Visual Studio Extensions menu, select Oracle Cloud App Deployment -> Deploy to Oracle Cloud. The Oracle Deployment Wizard displays.
2. Click Next.
3. Select an Authentication Profile (make sure that this profile matches the OCI CLI profile) and click Next.
4. Select a deployment option:
   a. Redeploy using an existing deployment configuration: This deployment choice should be used for re-deployment of a web application when there are no deployment configuration changes. If the developer needs to make changes only to his/her web application and then re-deploy, they can do so using this option. This option allows developers to do quick deployment in a few clicks with no new information asked for.
   b. Redeploy with a different deployment configuration: This deployment choice should be used for re-deployment of a web application when there are deployment configuration changes. Scenarios where this is an appropriate choice include deploying on a different cluster, using a different Docker image, or a change in the Kubernetes configuration.

   Note:

   If selecting a different cluster during re-deployment, delete the Kubernetes resources for your previous deployment using the "kubectl delete" command.

   c. Create a new deployment: Use this option when deploying your web application for the first time using this wizard. The name for this deployment should be unique, must be no longer than 63 characters, must start and end with a lowercase letter or number, and may contain lowercase letters, numbers, and hyphens.
5. On the Select A Cluster panel, select an existing Kubernetes cluster from any of the compartments in your tenancy (the wizard does not support creating a cluster, so you should create a cluster using the console first). Click Next.
6. On the Specify Deployment Details panel, you can modify existing deployment details.

   Note:

   The deployment file created by the wizard can be modified in any editor and used for re-deployments using the wizard.

   a. Select a Docker image from the drop-down list.
   b. Select a Kubernetes Secret Name from the drop-down list.
7. Click Next.
8. Verify your deployment details, and then click **Deploy**. The window will actively update with the deployment status as it progresses. You can dismiss this dialog and check the deployment status later by selecting **Oracle Cloud App Deployment -> Check Deployment Status** from the Visual Studio menu.

Deleting A Deployment

The wizard doesn't support deleting a deployment using the Visual Studio IDE. To delete a deployment:

1. Delete the deployment from the OKE cluster using the following command: `kubectl delete -f <path-to-deployment-file> --kubeconfig <path-to-kubeconfig-file>` If the deployment file is not present, you can use the following command: `kubectl delete deploy/<deployment_name> svc/<service_name>`

2. Delete the folder in `~/.oci/visualstudiowebapps/<your-application-deployment-name>` from the client machine.

**API Reference and Appendices**

This section covers general SDK concepts and references.

- [REST APIs](#) on page 5528
- [Client-Side Encryption](#) on page 5557 - Discusses how client-side encryption works for the Oracle Cloud Infrastructure SDK for Python and the SDK for Java.

**REST APIs**

The Oracle Cloud Infrastructure APIs are typical REST APIs that use HTTPS requests and responses. This topic describes basic information about using the APIs.

**API Reference and Endpoints**

For links to the Oracle Cloud Infrastructure API reference and a list of the regional API endpoints, see **API Reference and Endpoints**.

**API Version**

The base path of the endpoint includes the desired API version (for example, 20160918). Here's an example for a POST request to create a new VCN in the Ashburn region:

```
POST https://iaas.us-ashburn-1.oraclecloud.com/20160918/vcns
```

**Request Signing Required**

All Oracle Cloud Infrastructure API requests must be signed for authentication purposes. For information about the required credentials and how to sign the requests, see **Request Signatures** on page 5546.

**HTTPS and TLS 1.2 Required**

All Oracle Cloud Infrastructure API requests must support HTTPS and SSL protocol TLS 1.2.

**Maximum Allowed Client Clock Skew**

HTTP status code 401 (NotAuthenticated) is returned if the client's clock is skewed more than 5 minutes from the server's. To determine the server's clock time, use this curl command with the API endpoint:

```
curl -s --head <endpoint> | grep Date
```

For example:

```
curl -s --head https://iaas.us-phoenix-1.oraclecloud.com | grep Date
```
**Request and Response Format**

The Oracle Cloud Infrastructure APIs use standard HTTP requests and responses. Each may contain Oracle-specific headers for pagination, entity tags (ETags), and so on as described elsewhere in this topic and in the API documentation.

Each response includes a unique Oracle-assigned request ID (for example, bb3f3275-f356-462a-93c4-bf40fb82bb02) in the opc-request-id response header. If you need to contact Oracle about a particular request, please provide this request ID.

Many of the API operations require JSON in the request body or return JSON in the response body. The specific contents of the JSON are described in the API documentation for the individual operation. Notice that the JSON is not wrapped or labeled according to the operation's name or the object's name or type.

**Note:**

Make sure to set the `Content-Type` header to `application/json` in your POST and PUT requests that contain JSON in the body.

**Example CreateVcn Request**

```plaintext
POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/vcns
host: iaas.us-phoenix-1.oraclecloud.com
opc-retry-token: 239787fs987
Content-Type: application/json
HTTP headers required for authentication
Other HTTP request headers per the HTTP spec

{
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq",
    "displayName": "Apex Virtual Cloud Network",
    "cidrBlock": "172.16.0.0/16"
}
```

**Example CreateVcn Response**

```plaintext
200 OK
opc-request-id: 6c4d01a6-f764-4325-a3f8-720c8b5cae7b

{
    "id": "ocid1.vcn.oc1.phx.aaaaaaaa4ex5pqjtkjhdb4h4gcnk07vx5uto5puj5noa5awznsqpwjt3pqyq",
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq",
    "displayName": "Apex Virtual Cloud Network",
    "cidrBlock": "172.16.0.0/16"
    "defaultRouteTableId": "ocid1.routebletable.oc1.phx.aaaaaaaaaa3pv6wkcr4jqa5f44n2b2m2yt2j6rx32uzr4h25vqstlfdsq",
    "defaultSecurityListId": "ocid1.securitylist.oc1.phx.aaaaaaaaac6h4ckr3ncbxmvwinfzxjbr7owu5hfzbvutu33kfe7hgsc5fe",
    "defaultDhcpOptionsId": "ocid1.dhcpoptions.oc1.phx.aaaaaaaaawg1zon7s5sgyfzn125a4vxgu76c2hrgvzc3psn6vcx331zmu2xao",
    "state": "PROVISIONING",
    "timeCreated": "2016-07-22T17:43:01.389+0000"
}
```
**Error Format**

If a request results in an error, the response contains a standard HTTP response code with 4xx for client errors and 5xx for server errors. The body also includes JSON with an error code and a description of the error. For example:

```json
{
    "code": "InvalidParameter",
    "message": "Description may not be empty; description size must be between 1 and 400"
}
```

For a list of common errors across all services, see API Errors.

**Request Throttling**

Oracle Cloud Infrastructure applies throttling to many API requests to prevent accidental or abusive use of resources. If you make too many requests too quickly, you might see some succeed and others fail. Oracle recommends that you implement an exponential back-off, starting from a few seconds to a maximum of 60 seconds. When a request fails due to throttling, the system returns response code 429 and the following error code and description:

```json
{
    "code": "TooManyRequests",
    "message": "User-rate limit exceeded."
}
```

**Polling for Resource Status**

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your code to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action.

You can poll a resource to determine its state. For example, when you call GetInstance, the response body contains an instance resource that includes the lifecycleState attribute. You might want your code to wait until the instance's lifecycleState is RUNNING before proceeding.

Different resources take different amounts of time to transition between states. Therefore, the optimal frequency and duration parameters for a polling strategy can vary among resources. The Oracle Cloud Infrastructure SDK waiters use the following default strategy:

- Use an exponential back-off, starting from a few seconds to a maximum of 30 seconds between poll attempts.
- Poll up to 20 minutes, and then stop.

Or more information on waiters, see:

- SDK for Java waiters documentation
- SDK for Ruby waiters documentation

**Where to Find Your Tenancy's OCID**

If you use the API, you'll need your tenancy's OCID in order to sign the requests (see Request Signatures on page 5546). You'll also need it for some of the IAM API operations. An OCID is an Oracle Cloud ID (see Resource Identifiers).

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu and click Tenancy: `<your_tenancy_name>`.
2. The tenancy OCID is shown under **Tenancy Information**. Click **Copy** to copy it to your clipboard.

![Tenancy Information](image)

The tenancy OCID looks something like this (notice the word "tenancy" in it):

```
ocid1.tenancy.oc1..<unique_ID>
```

**List Pagination**

Most List operations paginate results. For example, results are paginated for the **ListInstances** operation in the Core Services API. When you call a paginated List operation, the response indicates more pages of results by including the **opc-next-page** header.

**Note:**

A page can be empty even when more results remain. Anytime the **opc-next-page** header appears, there are more list items to get. For more information about resource list control, see **Overview of Search** on page 4620.

List pagination for Object Storage **ListObjects** works differently because the pagination controls are also used for object name filtering. **ListObjects** returns **nextStartWith** instead of **opc-next-page** in the response body. To paginate through more objects, use the returned **nextStartWith** value with the **start** parameter. To filter which objects **ListObjects** returns, use the **start** and **end** parameters.

To get the next page of results

Make a new GET request against the same URL, modified by setting the page query parameter to the value from the **opc-next-page** header. Repeat this process until you get a response without an **opc-next-page** header. The absence of this header indicates that you have reached the last page of the list.

**Note:**

For an alternative to writing pagination code, see the functions in the **pagination module** provided with the SDK for Python.

To get the previous page of results

(Available with some APIs.) Make a new GET request against the same URL, modified by setting the page query parameter to the value from the **opc-prev-page** header. Repeat this process until you get a response without an **opc-prev-page** header. The absence of this header indicates that you have reached the first page of the list.

**Note:**

For an alternative to writing pagination code, see the functions in the **pagination module** provided with the SDK for Python.

To change the maximum number of results per page
In the GET request, set the limit to the number of items you want returned in the response.

**Note:**
The service will return no more than the number specified as limit, but might not return that exact number.

**Retry Token**
For some operations you can provide a unique retry token (opc-retry-token) so the request can be retried in case of a timeout or server error without the risk of executing that same action again. The token expires after 24 hours, but can be invalidated before then due to conflicting operations (for example, if a resource has been deleted and purged from the system, then a retry of the original creation request may be rejected).

**ETags for Optimistic Concurrency Control**
The API supports etags for the purposes of optimistic concurrency control. The GET and POST calls return an etag response header with a value you should store. When you later want to update or delete the resource, set the if-match header to the ETag you received for the resource. The resource will then be updated or deleted only if the ETag you provide matches the current value of that resource's ETag.

**Null vs. Empty Strings for Optional Parameters**
If you send an empty string ("") as the value of an optional parameter, the API validates the value as normal (for example, checks against minimum and maximum allowed length, and so on). Often the minimum allowed length is 1, so an error would be returned. If you don't set the value (it's null), the API performs no validation, and some other action may occur. For example: if you don't set a value for the displayName when creating a new VCN object, the service will auto-generate a value.

**API Errors**

### Common Errors Returned by All Services
The following table lists the common errors returned by all the services for Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
<th>Retry</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>CannotParseRequest</td>
<td>The request is incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>InvalidParameter</td>
<td>A parameter is invalid or incorrectly formatted.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>LimitExceeded</td>
<td>Fulfilling this request exceeds the Oracle-defined limit for this tenancy for this resource type.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>MissingParameter</td>
<td>A required parameter is missing.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>QuotaExceeded</td>
<td>Fulfilling this request exceeds the administrator-defined quota for this compartment for this resource.</td>
<td>No.</td>
</tr>
<tr>
<td>400</td>
<td>RelatedResourceNotAuthorizedOrNotFound</td>
<td>A resource specified in the body of the request was not found, or you do not have authorization to access that resource.</td>
<td>No.</td>
</tr>
<tr>
<td>401</td>
<td>NotAuthenticated</td>
<td>The required authentication information was not provided or was incorrect. There are other reasons why this error code is generated. For more information, see HTML Status Code 401.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>NotAllowed</td>
<td>This operation must be directed at the home region.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>NotAuthorized</td>
<td>You do not have authorization to update one or more of the fields included in this request.</td>
<td>No.</td>
</tr>
<tr>
<td>403</td>
<td>SignUpRequired</td>
<td>This operation requires opt-in before it may be called.</td>
<td>No.</td>
</tr>
<tr>
<td>HTTP Status Code</td>
<td>Error Code</td>
<td>Description</td>
<td>Retry</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>404</td>
<td>InvalidParameter</td>
<td>A dynamic path component is invalid or is syntactically valid but is not allowed.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>NotAuthorizedOrNotFound</td>
<td>The resource specified via the URI (path or query parameters) of the request was not found, or you do not have authorization to access that resource. For more information, see HTML Status Code 404.</td>
<td>No.</td>
</tr>
<tr>
<td>404</td>
<td>NotFound</td>
<td>There is no operation supported at the URI path and HTTP method you specified in the request.</td>
<td>No.</td>
</tr>
<tr>
<td>405</td>
<td>MethodNotAllowed</td>
<td>The target resource does not support the HTTP method.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>Conflict</td>
<td>The requested state for the resource conflicts with its current state. This state is not transient.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>IncorrectState</td>
<td>The requested state for the resource conflicts with its current state but given some amount of time it will be in the correct state.</td>
<td>Yes, with backoff. Refer to the error description for any required actions before you retry.</td>
</tr>
<tr>
<td>409</td>
<td>InvalidatedRetryToken</td>
<td>The provided retry token was used in an earlier request that resulted in a system update, but a subsequent operation invalidated the token. This can happen, for example, in cases where an entity created with the same token has since been deleted. If the system state change that is associated with this request should be performed again, retry it using a different token.</td>
<td>No.</td>
</tr>
<tr>
<td>409</td>
<td>NotAuthorizedOrResourceAlreadyExists</td>
<td>You do not have authorization to perform this request, or the resource you are attempting to create already exists. This error code is returned only from create operations, where it is returned instead of the more general NotAuthorizedOrNotFound error code.</td>
<td>No.</td>
</tr>
<tr>
<td>412</td>
<td>NoEtagMatch</td>
<td>The ETag specified in the request does not match the ETag for the resource.</td>
<td>No.</td>
</tr>
<tr>
<td>413</td>
<td>PayloadTooLarge</td>
<td>The request entity is larger than limits defined by server.</td>
<td>No.</td>
</tr>
<tr>
<td>422</td>
<td>UnprocessableEntity</td>
<td>Payload is syntactically correct but semantically invalid.</td>
<td>No.</td>
</tr>
<tr>
<td>429</td>
<td>TooManyRequests</td>
<td>You have issued too many requests to the Oracle Cloud Infrastructure APIs in too short of an amount of time.</td>
<td>Yes, with backoff.</td>
</tr>
<tr>
<td>431</td>
<td>RequestHeaderFieldsTooLarge</td>
<td>The request's HTTP headers are too long. The request may be resubmitted after reducing the size of the request headers.</td>
<td>No.</td>
</tr>
<tr>
<td>500</td>
<td>InternalServerError</td>
<td>An internal server error occurred.</td>
<td>Yes, with backoff.</td>
</tr>
</tbody>
</table>
### HTTP Status Code Reference

<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
<th>Retry</th>
</tr>
</thead>
<tbody>
<tr>
<td>501</td>
<td>MethodNotImplemented</td>
<td>The HTTP request target does not recognize the HTTP method.</td>
<td>No</td>
</tr>
<tr>
<td>503</td>
<td>ServiceUnavailable</td>
<td>The service is currently unavailable.</td>
<td>Yes, with backoff</td>
</tr>
</tbody>
</table>

#### Error Details and Troubleshooting

**HTTP status code: 401**

- **Missing or incorrect authentication information.** Verify that all the required information (tenant OCID, user OCID, fingerprint, and private key) is provided and accurate. Verify that the public key corresponding to the fingerprint has been uploaded for the user. For more information, see Required Keys and OCIDs on page 5303.

- **Clock skew.** This status code is returned if the client's clock is skewed more than five (5) minutes from the server's clock. For more information, see Maximum Allowed Client Clock Skew on page 5528.

- **API request signature error.** This status code is returned if a required header is missing from a signing string. For more information, see Request Signatures on page 5546.

**Error Codes:** NotAuthorizedOrNotFound, RelatedResourceNotAuthorizedOrNotFound, NotAuthorizedOrResourceAlreadyExists

- **Authorization error.** Verify that the user is in a group that has the permissions to work with resources in a compartment.

- **Compartment or resource not found.** Verify that the compartment or resource exist and is referenced correctly. For example, this status code is returned for either of the following errors:
  - CompartmentNotFound if a compartment doesn't exist
  - VolumeNotFound if a volume doesn't exist

**Asynchronous Work Requests**

This topic describes asynchronous work requests for long-running operations against Oracle Cloud Infrastructure services. It also provides guidance on obtaining request status, and for inspecting the request response to enable filtering for affected resources.

#### Overview

API calls to Oracle Cloud Infrastructure services can launch long-running operations that do not complete the client's request before a response is returned. In these cases, the service spawns an asynchronous work request that allows for visibility into the progress of long-running, asynchronous operations. The response to the REST API call contains a work request ID in the opc-work-request-id header, which allows you to monitor its progress and status. The work request itself remains in a queue until the operation has completed.

You can monitor the status of the work request at any time by calling GetWorkRequest and passing in the work request ID.

---

**Note:**

Some services, such as Compute and Database, support work requests using Work Requests API, which contains the GetWorkRequest operation.

Some Oracle Cloud Infrastructure services offer work requests supported by the service API rather than the Work Requests API discussed in this topic. These service APIs each include operations that work in a similar manner to the GetWorkRequest operation used by the Work Requests API.

**Services with their own work request APIs**
Two features of the request response are of particular interest: the status of the work request, and a list of the resources that are affected by the work request. The status is important because asynchronous work requests must know when an operation has completed, is still running, or whether it has failed altogether.

To retrieve information about work request failures or errors, each service provides APIs for fetching information about errors, and logs. For links to API reference documentation for each of the service, see the section For More Information on page 5546.

Also important in cases where a work request operation affects several resources is having a list of the resources that a work request affects, along with each one's entityType and actionType attributes.

Work Request Status

Asynchronous work requests allow you to monitor their progress by providing a status attribute on the WorkRequest object. Each of the supported services provides its own API for obtaining status, as listed in the following sections.

<table>
<thead>
<tr>
<th>Service</th>
<th>Status Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Migration</td>
<td>• ACCEPTED</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS</td>
</tr>
<tr>
<td></td>
<td>• SUCCEEDED</td>
</tr>
<tr>
<td></td>
<td>• FAILED</td>
</tr>
<tr>
<td></td>
<td>• CANCELING</td>
</tr>
<tr>
<td></td>
<td>• CANCELED</td>
</tr>
</tbody>
</table>

Note:

There is a ContainerEngineWaiters class that allows you to create a callback using the forWorkRequest method. Use this API to forward a notification when an operation's status changes, for example, from IN_PROGRESS to COMPLETED.

The following table lists status attributes that are supported by the WorkRequest object on the respective services.
<table>
<thead>
<tr>
<th>Service</th>
<th>Status Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Performance Monitoring</td>
<td>• ACCEPTED</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS</td>

Filtering the Request Response

You sometimes need to know which resources are affected by a given asynchronous work request. In cases where the request response includes just one or two affected resources, the body of the request response is probably sufficient. However, in cases where a request response affects a great many resources, you must filter the response to identify the resources that you're interested in.

Filtering of resources listed in a work request response relies on two attributes of the `WorkRequestResource` type: `entityType` and `actionType`.

- **entityType**: Represents the resource type which the work request affects. This is an optional attribute, but each resource can have only one `entityType`.
- **actionType**: Represents how the specified resource is affected by the operation associated with the work request. Each service specifies a fixed list of allowable `actionType` values (shown in the sections following).

To obtain resource information on a work request, call `GetWorkRequest` and pass in the work request ID. The call returns a response in JSON format. Following is an example from calling `GetWorkRequest` on the Object Storage service.

```json
{
    operationType: "COPY_OBJECT",
    status: "IN_PROGRESS",
    id: "f5452?d6-029b-4221-9046-a811b7686202",
    resources: [
        {
            entityType: "object",
            actionType: "READ",
            entityUri: "/n/mynamespace/b/backups/o/myobject",
        },
        {
            entityType: "object",
            actionType: "WRITTEN",
            entityUri: "/n/mynamespace/b/backups/o/copyofmyobject"
        },
    ],
    timeAccepted: 2017-10-13T17:23:46.000Z,
    timeStarted: 2017-10-13T17:23:52.198Z,
    percentComplete: 10.0
}
```
The following table lists the entity types and action types that are supported by Oracle Cloud Infrastructure services.

#### Request/Response Sample

Following is a sequence of REST API calls to create a cluster, which is a common long-running operation. The caller retrieves the work request ID from the response to the initial POST call and then periodically polls the WorkRequest to determine the status of the operation. The request/response sequence that follows depicts this workflow:

1. The user issues a CreateCluster API call.
2. The service responds with status code 202, indicating that the request has been accepted and returns a work request ID in the Opc-Work-Request-Id header.
3. Next, the user issues a GET call on the work request ID to obtain the status of the work request.
4. The service responds with status code 200, indicating in the response body that the CLUSTER_CREATE operation has the status ACCEPTED.
5. With continued polling, we see another GET call for the work request.
6. The service responds with status code 200. The response body reports that the operation SUCCEEDED.

**Step 1. Initial API call to initiate a CLUSTER_CREATE operation.**

```bash
POST https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/clusters
Accept: application/json
authorization: <Redacted>
content-length: 480
Content-Type: application/json
date: Mon, 02 Jul 2018 18:20:03 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: D7A390ED909C47038C438BA3629FB612
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)

"name":"JavaSDK.CRUD",
"compartmentId":"ocid1.compartment.oc1..<unique_ID>",
"vcnId":"ocid1.vcn.oc1.eu-frankfurt-1.<unique_ID>",
"kubernetesVersion":"v1.10.3",
"options":{"serviceLbSubnetIds":["ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>",
"ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>"],
"managementAgent":null,"managementAgentOptions":null}"
```

Oracle Cloud Infrastructure User Guide  5543
**Step 2.** The response to the initial API call, which contains the work request ID in the `Opc-Work-Request-Id` header.

```plaintext
202
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 0
Date: Mon, 02 Jul 2018 18:20:04 GMT
Opc-Request-Id: 
Opc-Work-Request-Id: ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID
Uri: /20180222/clusters
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:53077
```

**Step 3.** Because this is a long-running operation, the user periodically polls the work request using a GET call to determine its status.

```plaintext
GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:20:04 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: E8F20DAC443346B3B0E9594F367EE294
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM) 64-Bit Server VM/25.172-b11)
```

**Step 4.** The GET call returns the following response, which indicates in the response body that the `CLUSTER_CREATE` operation has a status of ACCEPTED.

```plaintext
200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 717
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:20:05 GMT
Etag: 56a41efaf33d81a54933495ee910c24d7bce7a83ad1f8810f95e07b2d2055805
Opc-Request-Id: 
Opc-Work-Request-Id: ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID

Request Signatures

This topic describes how to sign Oracle Cloud Infrastructure API requests. Signing samples are included for the following:

- Java on page 5550
- Python on page 5552
- TypeScript on page 5552
- JavaScript on page 5553
- Ruby on page 5554
- Go on page 5554
- Bash on page 5556
- C# on page 5556

Signature Version 1

The signature described here is version 1 of the Oracle Cloud Infrastructure API signature. In the future, if Oracle modifies the method for signing requests, the version number will be incremented and your company will be notified.

Required Credentials and OCIDs

You need an API signing key in the correct format. See Required Keys and OCIDs on page 5303.
Caution:

Client Clock Skew

If the client's clock is skewed more than 5 minutes, a 401 (NotAuthenticated) HTTP status code is returned. This will affect your API requests. For more information, see Maximum Allowed Client Clock Skew.

You also need the OCIDs for your tenancy and user. See Where to Get the Tenancy's OCID and User's OCID on page 5308.

Summary of Signing Steps

In general, these are the steps required to sign a request:

1. Form the HTTPS request (SSL protocol TLS 1.2 is required).
2. Create the signing string, which is based on parts of the request.
3. Create the signature from the signing string, using your private key and the RSA-SHA256 algorithm.
4. Add the resulting signature and other required information to the Authorization header in the request.

See the remaining sections in this topic for details about these steps.

Specification You Need to Be Familiar With

To learn how to perform steps 2-4 in the process above, refer to draft-cavage-http-signatures-08. It's a draft specification that forms the basis for how Oracle handles request signatures. It describes generally how to form the signing string, how to create the signature, and how to add the signature and required information to the request. The remaining sections in this topic assume you're familiar with it. Important details of the Oracle Cloud Infrastructure implementation of the reference are listed in the next section.

Special Implementation Details

The following sections describe important items to note about the Oracle Cloud Infrastructure implementation of the spec.

Authorization Header

The Oracle Cloud Infrastructure signature uses the "Signature" Authentication scheme (with an Authorization header), and not the Signature HTTP header.

Required Headers

This section describes the headers that must be included in the signing string.

Note:

Error if Required Header is Missing
If a required header is missing, your client will receive a 401 "Unauthorized" response.

For GET and DELETE requests (when there's no content in the request body), the signing string must include at least these headers:

- (request-target) (as described in draft-cavage-http-signatures-08)
- host
- date or x-date (if both are included, Oracle uses x-date)

For PUT and POST requests (when there's content in the request body), the signing string must include at least these headers:

- (request-target)
- host
- date or x-date (if both are included, Oracle uses x-date)
For PUT and POST requests, your client must compute the x-content-sha256 and include it in the request and signing string, even if the body is an empty string. Also, the content-length is always required in the request and signing string, even if the body is empty. Some HTTP clients will not send the content-length if the body is empty, so you must explicitly ensure your client sends it. If date and x-date are both included, Oracle uses x-date. The x-date is used to protect against the reuse of the signed portion of the request (replay attacks).

The one exception is for Object Storage PUT requests on objects (see the next section).

Special Instructions for Object Storage PUT

For Object Storage PutObject and UploadPart PUT requests, the signing string must include at least these headers:

• (request-target)
• host
• date or x-date (if both are included, Oracle uses x-date)

If the request also includes any of the other headers that are normally required for PUT requests (see the list above), then those headers must also be included in the signing string.

Case and Order of Headers

The headers must be all lowercase in the signing string.

The order of the headers in the signing string does not matter. Just make sure to specify the order in the headers parameter in the Authorization header, as described in the draft-cavage-http-signatures-05.

URL Encoding of Path and Query String

When forming the signing string, you must URL encode all parameters in the path and query string (but not the headers) according to RFC 3986.

Key Identifier

You must set keyId="<TENANCY OCID>/<USER OCID>/<KEY FINGERPRINT>" in the Authorization header that you add to the request. To get those values, see Where to Get the Tenancy's OCID and User's OCID on page 5308. An example keyId looks like this (wrapped to better fit the page):

ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/key_fingerprint

Signing Algorithm

The signing algorithm must be RSA-SHA256, and you must set algorithm="rsa-sha256" in the Authorization header (notice the quotation marks).
Signature Version

You should include `version="1"` in the Authorization header (notice the quotation marks). If you do not, it's assumed that you're using whatever the current version is (which is version 1 at this time).

Example Header

Here's an example of the general syntax of the Authorization header (for a request with content in the body):

```
Authorization: Signature
version="1",keyId="[tenancy_ocid]/[user_ocid]/[key_fingerprint]",algorithm="rsa-sha256",headers="(request-target) date x-content-sha256 content-type content-length",signature="Base64(RSA-SHA256([signing_string]))"
```

Test Values

Here's an example key pair, two example requests, and the resulting Authorization header for each.

**Caution:** The example signatures use the RSA 2048-bit keys below. Use these keys only for testing your signing code, not for sending production requests.

```
-----BEGIN PUBLIC KEY-----
MIGfMA0GCQgIBAAKBgQDCFENGw33yGihy92pDjZQh10C36rPj+j+CvfSC8+q28hxA161QFNud13wuCTUcqQd2qsBe/2hFyc2DCJjg0h1L78+6Z4UM7E0cpfdeU9EFf3m+hs+FUR45uBJeDk1HSFH8bH6k6v8FPGfJotc+2xjJw

7UlyQXnTAEFYM50yRJ1upOb1V4cScGd365t1SMSxV0vTA==
-----END RSA PRIVATE KEY-----
```

The public key is stored under keyId:

```
ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/<key_fingerprint>
```

For the following GET request (line breaks inserted between query parameters for easier reading; also notice the URL encoding as mentioned earlier):

```
GET https://iaas.us-phoenix-1.oraclecloud.com/20160918/instances
?availabilityDomain=PWf%3A%20PHX-AD-1
&compartmentId=ocid1.compartment.oc1...<unique_ID>
&displayName=TeamInstances
&volumeId=ocid1.volume.oc1.phx.<unique_ID>
```

Date: Thu, 05 Jan 2014 21:31:40 GMT
The signing string would be (line breaks inserted into the (request-target) header for easier reading):

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): get /20160918/instances?availabilityDomain=Pjwf%3A%20PH
X-AD-1&compartmentId=ocid1.compartment.oc1..aaaaaaaam3we6vgherjq5q2i
dncodf1vjsnog7mlr6rtdb25q1chfeyjxa&displayName=TeamXInstances&
volumeId=ocid1.volume.oc1.phx.abyhqljrgvtttn1x73nmrwaux7kcvzfs3s66izvxf2h
41gyvynsdsn0iwr5q
host: iaas.us-phoenix-1.oraclecloud.com

The Authorization header would be:
Signature version="1",headers="date (request-target) host",keyId="ocid1.tenancy.oc1..<unique_ID>/ocid1.user.oc1..<unique_ID>/
<key_fingerprint>,algorithm="rsa-sha256",
signature="<your_signature>"

For the following POST request:

POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/volumeAttachments
Date: Thu, 05 Jan 2014 21:31:40 GMT

{ 
   "compartmentId": "ocid1.compartment.oc1..<unique_id>",
   "instanceId": "ocid1.instance.oc1.phx.<unique_id>",
   "volumeId": "ocid1.volume.oc1.phx.<unique_id>"
}

The signing string would be:

date: Thu, 05 Jan 2014 21:31:40 GMT
(request-target): post /20160918/volumeAttachments
host: iaas.us-phoenix-1.oraclecloud.com
content-length: 316
content-type: application/json
x-content-sha256: V9Z20UJTvkvpJ50f1BzKE32+6m2zJjweHpDMX/U4Uy0=

The Authorization header would be:

Signature version="1",headers="date (request-target) host content-length c
ontent-type x-content-sha256",
keyId="ocid1.tenancy.oc1..<unique_id>/ocid1.user.oc1.<unique_id>/
<your_fingerprint>",
algorithm="rsa-sha256",signature="<your_signature>"

Sample Code

This section shows the basic code for signing API requests.

Go

The following example shows how to create a default signer.

Note:
The SDK for Go exposes a stand-alone signer that you can use to sign custom requests. You can find related code at http_signer.go.

Client-Side Encryption
The Oracle Cloud Infrastructure SDK for Python and SDK for Java support Client Side Encryption, which encrypts
your data on the client side before storing it locally or using it with other Oracle Cloud Infrastructure services.
By default, the SDK generates a unique data key for each data object that it encrypts. Data is encrypted using a
secure, authenticated, symmetric AES/GCM key algorithm with a 256-bit key length.
To use client-side encryption, you must create a master encryption key (MEK) using the Key Management Service.
This can be done using the CreateKey or ImportKey operations.
The MEK is used to generate a Data Encryption Key (DEK) to encrypt each payload. A encrypted copy of this DEK
(encrypted under the MEK) and other pieces of metadata are included in the encrypted payload returned by the SDKs
so that they can be used for decryption.
Java Prerequisites
The unlimited policy files for earlier releases are required only for JDK 8, 7, and 6 updates earlier than 8u161, 7u171,
and 6u16. For those versions and later the policy files are included but not enabled by default.
Current versions of the JDK do not require these policy files. They are provided here for use with older versions of
the JDK. JDK 9 and later ship with the unlimited policy files and use them by default.
Examples
The following code example show how to encrypt a string:
Java

// String encryption example
final byte[] plainText = "Hello World".getBytes();
String masterKeyId = "OCID....";
Map<String, String> context = Collections.singletonMap("Example", "value");
OciCrypto ociCrypto = new OciCrypto();

KmsMasterKey kmsMasterKey = new KmsMasterKey(authenticationProvider, 
    Region.US_ASHBURN_1.getRegionId(), vaultId, masterKeyId); 
KmsMasterKeyProvider kmsMasterKeyProvider = new 
    KmsMasterKeyProvider(kmsMasterKey); 
OciCryptoInputStream encryptingStream = 
    ociCrypto.createEncryptingStream(kmsMasterKeyProvider, in);

// Write the encrypted data to file 
FileOutputStream out = new FileOutputStream(srcFile + ".encrypted");
IOUtils.copy(encryptingStream, out); 
encryptingStream.close();
out.close();

// For decryption, no need to pass key info
KmsMasterKeyProvider kmsMasterKeyProvider = new
    KmsMasterKeyProvider(authenticationProvider);
// Create the Decryption file stream.
in = new FileInputStream(srcFile + ".encrypted");
OciCryptoInputStream decryptingStream =
    ociCrypto.createDecryptingStream(kmsMasterKeyProvider, in);

// Return the plaintext data
out = new FileOutputStream(srcFile + ".decrypted");
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
out.close();

Python

import oci

        stream_to_decrypt,
        kms_master_key_provider
    ) as decryption_stream:
        shutil.copyfileobj(decryption_stream, output_stream)
Glossary

A

AD-specific subnet

A subnet that is specific to a particular availability domain (AD). Historically, all subnets were AD-specific. Now, subnets can be either AD-specific or regional.

alarm

The trigger rule and query to evaluate, plus related configuration, such as the notification details to use when the trigger is breached. Alarms passively monitor your cloud resources by using metrics in the Monitoring service.

API key

A credential for securing requests to the Oracle Cloud Infrastructure REST API.

application (Application Migration)

A combination of the artifacts and configuration deployed on one or more service instances running in the source environment.

attach (Block Volume)

To link a volume and instance together. Attaching lets an instance connect to and mount the volume as a hard drive.

attribute

The combination of a name and data type used to describe a data item, for example, a column in a table or a field in a file.

auth token

A token generated by Oracle Cloud Infrastructure that you use to authenticate with third-party APIs, such as a Swift client.

availability domain

One or more isolated, fault-tolerant Oracle data centers that host cloud resources such as instances, volumes, and subnets. A region contains one or more availability domains.

B

backend set

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy.

bare metal instance

A compute instance that uses hosted, dedicated physical hardware, unlike virtual machines. Bare metal instances ensure a high level of security and performance.

block storage volume

A virtual disk that provides persistent storage space for instances in the cloud.

bucket

A logical container for storing objects.
C

category
A grouping of logically related business terms in a glossary. You nest categories as needed to group terms.

Challenge-Handshake Authentication Protocol (CHAP)
A security protocol used by iSCSI for authentication between a volume and an instance.

Block Volume
A service that allows you to add block storage volumes to an instance to expand the available storage on that resource.

cloud network
A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

cluster network
A pool of high performance computing (HPC) instances that are connected with a high-bandwidth, ultra low-latency network.

compartment
A collection of related resources that can be accessed only by groups that have been given permission by an administrator in your organization.

Compute service
A service that lets you provision and manage compute hosts, known as instances.

connect
To make an attached volume usable by an instance's guest OS.

CPE (customer-premises equipment)
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when you set up Site-to-Site VPN (an IPSec connection) between Oracle and your on-premises network.

CPE Configuration Helper
A feature of the Oracle Console that generates information that a network engineer can use to configure the customer-premises equipment (CPE) at their end of a Site-to-Site VPN IPSec connection.

cross-connect
The physical cable that connects your existing network to Oracle in a FastConnect location. A cross-connect is used with FastConnect if you're using a third-party provider or are colocated with Oracle in a FastConnect location.

cross-connect group
A link aggregation group (LAG) that contains at least one cross-connect. A cross-connect group is used with FastConnect if you're using a third-party provider or are colocated with Oracle in a FastConnect location.

customer-premises equipment (CPE)
The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when you set up Site-to-Site VPN (an IPSec connection) between Oracle and your on-premises network.
D

data asset (Data Catalog and Data Integration)

Represents a data source, such as a database, an object store, a file or document store, a message queue, or an application.

tag (Data Catalog)

Free-form labels or keywords that you create to logically identify data objects. Tags help in metadata classification and discovery. You create tags for data assets, data entities, and attributes. Using tags, you can search for all data objects with a specific tag name.

data entity (Data Catalog and Data Integration)

A collection of data, such as a database table or view, or a single logical file. A data entity normally has many attributes that describe its data.

data point (Monitoring)

A timestamp-value pair for a specified metric—for example, 2018-05-10T22:19:00Z, 10.4.

DB system

A dedicated bare metal instance running Oracle Linux, optimized for running one or more Oracle databases. A DB system is a Database service resource.

DHCP options

Configuration information that is automatically provided to the instances when they start up.

dimension (Monitoring)

A qualifier provided in a metric definition—for example, a resource identifier (resourceId) provided in the definitions of oci_computeagent metrics.

display name

A friendly name or description that helps you easily identify the resource.

DRG (dynamic routing gateway)

An optional virtual router that you can add to a virtual cloud network (VCN) to provide a path for private network traffic between the VCN and an on-premises network.

DRG attachment object

The result of attaching a dynamic routing gateway (DRG) to a virtual cloud network (VCN). To detach the DRG from the VCN, you delete the attachment object.

drift (Resource Manager)

The difference between the actual state of your infrastructure and the stack's last executed configuration.

dynamic group

A special type of Identity and Access Management (IAM) group that contains instances that match rules that you define. As a result, membership in the groups changes dynamically as matching instances are terminated or launched. These instances act as "principal" actors and can make API calls to Oracle Cloud Infrastructure services according to IAM policies that you write for the dynamic group.

dynamic routing gateway (DRG)

An optional virtual router that you can add to a virtual cloud network (VCN) to provide a path for private network traffic between the VCN and an on-premises network.
E

ephemeral public IP address
A temporary public IP address (and related properties) that exists for the life of the instance that it's assigned to. It can be assigned only to the primary private IP address on a VNIC.

export (File Storage)
Controls how file systems are accessed by NFS clients when they connect to a mount target.

export options (File Storage)
A set of parameters that specify the level of access granted to NFS clients when they connect to a mount target.

F

FastConnect
A dedicated, private connection between your data center or existing network and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options and a more reliable and consistent networking experience compared to internet-based connections.

FastConnect location
A specific data center from which you can connect to Oracle Cloud Infrastructure by using FastConnect.

fault domain
A logical grouping of hardware and infrastructure within an availability domain. Fault domains isolate resources during hardware failure or unexpected software changes.

file system
An organized system of directories and folders in which data is stored.

frequency (Monitoring)
The time period between each posted raw data point for a given metric. (Raw data points are posted by the metric namespace to the Monitoring service.)

G
glossary
A collection of business concepts in your company. A glossary contains categories and business terms.

group
A collection of users who all need a particular type of access to a set of resources or compartment.

guest operating system
An operating system installed on a cloud instance.

guest OS
An operating system installed on a cloud instance.

H

harvest
A process that extracts technical metadata from your connected data sources into your Data Catalog repository.
**Glossary**

**health check**
A test that confirms the availability of backend servers.

**IaaS**
A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

**IAM (Identity and Access Management)**
The Oracle Cloud Infrastructure service that controls the authentication and authorization of users who need to use your cloud resources.

**Identity and Access Management (IAM)**
The Oracle Cloud Infrastructure service that controls the authentication and authorization of users who need to use your cloud resources.

**identity provider (Idp)**
A service that provides identifying credentials and authentication for federated users.

**IdP (identity provider)**
A service that provides identifying credentials and authentication for federated users.

**image**
A template of a virtual hard drive that determines the operating system and other software for an instance.

**Infrastructure-as-a-Service**
A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

**instance (Compute)**
A bare metal or virtual machine compute host. The image used to create an instance determines its operating system and other software. The shape specified during the creation process determines the number of CPUs and memory allocated to the instance.

**instance wallet (Autonomous Database)**
A file that contains credentials and keys for only a single database instance.

**internet gateway**
An optional virtual router that you can add to a virtual cloud network (VCN). It provides a path for network traffic between the VCN and the internet.

**interval (Monitoring)**
The time window used to convert a given set of raw data points—for example, 5 minutes.

**IPSec connection**
The secure connection between a dynamic routing gateway (DRG) and customer-premises equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components that form a site-to-site VPN between a virtual cloud network (VCN) and your on-premises network.

**IPv6**
An object that contains an IPv6 address and related properties. IPv6 addressing is supported for all commercial and government regions. Only instances in IPv6-enabled virtual cloud networks (VCNs) and IPv6-enabled subnets can have IPv6 addresses.
IQN (iSCSI qualified name)
A unique ID assigned to an iSCSI device. You use an IQN when you connect a volume to an instance.

iSCSI
A TCP/IP-based standard used for communication between a volume and attached instance.

iSCSI qualified name (IQN)
A unique ID assigned to an iSCSI device. You use an IQN when you connect a volume to an instance.

K
key pair
A security mechanism that consists of a public key and a private key. A key pair is required, for example, for Secure Shell (SSH) access to an instance.

L
listener
An entity that checks for incoming traffic on a load balancer's public floating IP address.

local peering gateway (LPG)
A component on a virtual cloud network (VCN) that routes traffic to a locally peered VCN. "Local" peering means that the two VCNs are in the same region.

local VCN peering
The process of connecting two virtual cloud networks (VCNs) in the same region so that their resources can communicate without routing the traffic over the internet or through your on-premises network.

LPG (local peering gateway)
A component on a virtual cloud network (VCN) that routes traffic to a locally peered VCN. "Local" peering means that the two VCNs are in the same region.

M
message (Notifications and Monitoring)
An alert published to all subscriptions in the specified topic. Each message is delivered at least once per subscription.

metric (Monitoring)
A measurement related to the health, capacity, or performance of a given resource. For example, CPU Utilization (CpuUtilization) measures the activity level from CPU, expressed as a percentage of total time.

metric definition (Monitoring)
A set of references, qualifiers, and other information provided by a metric namespace for a given metric.

metric namespace (Monitoring)
Indicates the resource, service, or application that emits a metric. The namespace is provided in the metric definition. For example, the CpuUtilization metric definition emitted by the Oracle Cloud Agent software on Compute instances lists the oci_computeagent metric namespace as the source of the metric.

metric stream (Monitoring)
An individual set of aggregated data for a metric, typically specific to a resource.
**migration (Application Migration)**

The end-to-end workflow of moving an application from a source environment to Oracle Cloud Infrastructure.

**Monitoring Query Language (MQL) (Monitoring)**

The syntax used for metric and alarm queries. In the Console, the MQL syntax of queries is displayed in Advanced Mode.

**mount point (File Storage)**

A directory from which a client may access a remote file system.

**mount target (File Storage)**

A network file system (NFS) endpoint that allows a file system to be accessed by clients.

**MQL (Monitoring Query Language) (Monitoring)**

The syntax used for metric and alarm queries. In the Console, the MQL syntax of queries is displayed in Advanced Mode.

**N**

**NAT gateway**

An optional virtual router that you can add to your virtual cloud network (VCN) to perform Network Address Translation (NAT). A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

**network security group (NSG)**

One method for implementing security rules in a virtual cloud network (VCN). A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources.

**network source**

A group of IP addresses that can be used in policies to restrict access.

**notification destination (Monitoring)**

Protocol and other details for sending messages when the alarm transitions to another state, such as from OK to FIRING.

**NSG (network security group)**

One method for implementing security rules in a virtual cloud network (VCN). A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources.

**O**

**object**

Data stored in Object Storage. Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

**OCID (Oracle Cloud Identifier)**

An Oracle-assigned unique ID for a cloud resource. This ID is included as part of the resource’s information in both the Console and API.

**one-time password (OTP)**

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.
**Oracle Cloud Identifier (OCID)**

An Oracle-assigned unique ID for a cloud resource. This ID is included as part of the resource's information in both the Console and API.

**OTP (one-time password)**

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.

**policy (IAM)**

An Identity and Access Management (IAM) document that specifies who has what type of access to your resources. *Policy* can refer to several types of documents: an individual statement written in the policy language, a collection of statements in a single named "policy" document, and the overall body of policies that your organization uses to control access to resources.

**policy statement (IAM)**

An individual statement written in the policy language. Policies can contain one or more statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

**primary IP**

The private IP address that is automatically created and assigned to a VNIC when an instance is created.

**primary VNIC**

The VNIC that is automatically created and attached to an instance when it is created.

**private IP**

An object that contains a private IPv4 address and related properties, such as a hostname for DNS. Each instance automatically has a primary private IP address, and you can add secondary ones.

**private peering**

One of the ways to use FastConnect. Private peering lets you extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud). Communication across the connection is with IPv4 private addresses (typically those specified in RFC 1918).

**private subnet**

A subnet in which instances are not allowed to have public IP addresses.

**private virtual circuit**

A FastConnect virtual circuit that supports private peering.

**public IP**

An object that contains a public IP address and related properties. You control whether each private IP address on an instance has an assigned public IP address. The two types of public IP addresses are reserved and ephemeral.

**public peering**

One of the ways to use FastConnect. Public peering lets your on-premises network access public services in Oracle Cloud Infrastructure—for example, Object Storage, the Console and APIs, or public load balancers in your VCN—without using the internet. Communication across the connection is with IPv4 public IP addresses.

**public subnet**

A subnet in which instances are allowed to have public IP addresses. When you launch an instance in a public subnet, you specify whether the instance should have a public IP address.
public virtual circuit
A FastConnect virtual circuit that supports public peering.

Q
query (Monitoring)
The expression to evaluate for returning aggregated data. A valid query includes a metric, statistic, and interval. In the Console, you can view a query in Basic Mode or Advanced Mode. The latter displays the Monitoring Query Language (MQL) syntax.

R
realm
A logical collection of regions. Realms are isolated from each other and don’t share any data. Your tenancy exists in a single realm and can access the regions in that realm.
region
A collection of availability domains located in a single geographic location.
regional subnet
A subnet that spans all the availability domains in the region. Oracle recommends using regional subnets because they are more flexible and make it easier to implement failover across availability domains.
regional wallet (Autonomous Database)
A file that contains the credentials and keys for all Autonomous Databases in a specified region.
remote peering connection (RPC)
A component on a dynamic routing gateway that routes traffic to a remotely peered virtual cloud network (VCN). "Remote" peering means that the two VCNs are in different regions.
remote VCN peering
The process of connecting two virtual cloud networks (VCNs) in different regions so that their resources can communicate without routing their traffic over the internet or through your on-premises network.
reserved public IP address
A public IP address (and related properties) that you create in your tenancy and assign to your instances in a given region as needed. A reserved public IP address persists in your tenancy until you delete it. It can be assigned to any private IP on a given VNIC, not just the primary private IP.
resolution (Monitoring)
The period between time windows, or the regularity at which time windows shift—for example, 1 minute.
resource
The cloud objects that you create and use when interacting with Oracle Cloud Infrastructure.
route table
A virtual route table for your virtual cloud network (VCN) that maps the traffic from subnets through gateways to external destinations.
RPC (remote peering connection)
A component on a dynamic routing gateway that routes traffic to a remotely peered virtual cloud network (VCN). "Remote" peering means that the two VCNs are in different regions.
**S**

**secondary IP address**  
An additional private IP address that you add to a VNIC on an instance. Each VNIC automatically comes with a primary private IP address that can't be removed.

**secondary VNIC**  
An additional virtual network interface card (VNIC) that you add to an instance. Each instance automatically comes with a primary VNIC that can't be removed.

**security list**  
A method for implementing security in a virtual cloud network (VCN). A security list consists of security rules that apply to all resources in any subnet that uses the security list.

**security rule**  
Virtual firewall rules for your virtual cloud network (VCN). Each security rule specifies a type of ingress or egress traffic allowed in or out of a resource or VNIC.

**service gateway**  
An optional virtual router that you can add to your virtual cloud network (VCN). The gateway enables on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

**shape**  
A template that determines the number of CPUs, amount of memory, and other resources that are allocated to a compute instance.

**source (Application Migration)**  
The environment from which the application is being migrated.

**statement**  
The part of a policy that gives a group a certain type of access to certain resources in a particular compartment.

**statistic (Monitoring)**  
The aggregation function applied to the given set of raw data points—for example, SUM.

**subnet**  
A subdivision of your virtual cloud network (VCN). Subnets separate your network into multiple smaller and distinct networks.

**subscription (Notifications)**  
An endpoint for a topic, typically a URL or email address. Published messages are sent to each subscription for a topic.

**suppression (Monitoring)**  
A configuration to avoid publishing messages during the specified time range. Suppression is useful for suspending alarm notifications during system maintenance.

**Swift password**  
Deprecated. Use an auth token to authenticate with your Swift client in Object Storage.
tenancy
A secure and isolated partition within Oracle Cloud Infrastructure (OCI) where you can create, organize, and administer your cloud resources. When you sign up for OCI, a tenancy is created for your company. Tenancy also refers to the root compartment that contains all of your organization's compartments and other OCI resources.

tenant
The name assigned to a particular company's or organization's overall environment. Users provide their tenant when signing in to the Console.

term (Data Catalog)
The definition of a business concept as agreed on by different stakeholders in your company. You use terms to organize your data entities and attributes.

topic (Notifications)
A communication channel for sending messages to the subscriptions in a topic.

transit routing
A network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with a FastConnect private virtual circuit or VPN Connect. Then you configure the VCN routing so that traffic transits through the VCN to its destination beyond the VCN.

trigger rule (Monitoring)
The condition that must be met for an alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

user
An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources.

VCN (virtual cloud network)
A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual circuit
An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure. Virtual circuits are used with Oracle Cloud Infrastructure FastConnect.

virtual cloud network (VCN)
A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual machine (VM)
A software-based emulation of a full computer that runs within a physical host computer.

virtual network interface card (VNIC)
Enables an instance to connect to a virtual cloud network (VCN) and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and
you can add secondary ones. Other types of cloud resources, such as load balancers and DB systems, also automatically get a VNIC when they are created.

**VM (virtual machine)**

A software-based emulation of a full computer that runs within a physical host computer.

**VNIC (virtual network interface card)**

Enables an instance to connect to a virtual cloud network (VCN) and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources, such as load balancers and DB systems, also automatically get a VNIC when they are created.

**volume**

A detachable block storage device that lets you dynamically expand the storage capacity of an instance.

**work request**

An object that reports on the current state of an asynchronous service request.
Release Notes

You can find the Oracle Cloud Infrastructure Release Notes online.
